PURPOSE

Coronary artery calcium (CAC) is a robust predictor of cardiovascular events (CVE) in asymptomatic individuals. Several guidelines

recommend reporting of CAC scores in ungated chest CT exams. In addition, chest CT can be used to quantify thoracic aorta calcification (TAC) and cardiac valve calcification (CVC), which may further improve prediction of CVE. This study evaluates the performance of an automatic method for scoring of CAC, TAC and CVC on routine chest CT exams.

CONCLUSION

Fully automatic scoring of coronary, aortic and cardiac valve calcifications highly correlates with manual scoring, even in ungated routine chest CT.

CLINICAL RELEVANCE/APPLICATION

Automatic calcium scoring in routinely acquired ungated chest CT enables identification of subjects at elevated cardiovascular risk without additional reading time.

SSG13-09 Automated Contrast Timing Classification with Deep Convolutional Neural Networks

PURPOSE

To investigate whether a machine learning technique known as deep learning, e.g., Deep Convolutional Neural Networks (CNNs), which selects image pixel data directly (rather than utilizing human-designed features) in the extraction of image descriptors, has potential to explore and discover latent imaging features that are difficult to categorize by the human visual system and thus be used in a development of novel imaging biomarkers. We aim to evaluate if machine learning can achieve a classification of the contrast enhancement timing without any human annotation.

METHOD AND MATERIALS

700 CTs acquired at the portal venous phase had their contrast timing determined by a consensus reading between experienced radiologists. Patients were divided between optimal-timing (n=443) vs non-optimal timing (early or late, n=257). These timing data were used as the reference standard for the automated timing classification system. The whole 3D voxel images (normalized to 512*512*150) were used directly as input to a deep learning method (CNNs) to maximally explore the potential imaging features. The proposed network consisted of 5 convolutional layers and LeakyReLU activations, followed by average pooling layers and three dense layers. The outputs were equivalent to the classes: optimal and non-optimal. To train and evaluate the CNN we used a dataset of 700 CTs, within which 600 (396:204) were used as training and validation. The remaining 100 (57:43) were not included in the training set and were thus totally blind to the computer when used for testing. Five-fold cross validation was used to assess performance.

RESULTS

The classification performances were 89.3% (SE:0.01) in the training set and 93.2% (SE:0.01) in the validation set, which demonstrated the potential of CNNs in automatically analyzing contrast enhancement timing classification in CT scans.

CONCLUSION

There is great potential for the application of deep learning methods as an aid to radiologists in the analysis of medical images. Larger datasets with a wider spectrum of timing will be needed to refine performance and the learned imaging features needed to be examined.

CLINICAL RELEVANCE/APPLICATION

An immediate, unbiased appraisal of contrast timing can reduce medical error because certain pathologies are invisible outside of the appropriate contrast phase.

ABSTRACT

X-ray Imaging of the breast in 3D Prospective clinical trials, retrospective multi-reader studies and observational studies from clinical practices have shown the benefits of digital breast tomosynthesis (DBT), a limited-angle tomographic technique, in breast cancer screening. These include reduced callback rates, particularly reduction in false-positive callbacks, and increased cancer detection rates, particularly for invasive cancers. While DBT continues to be rapidly adopted in clinical practices, studies on further optimization and improvements to DBT continue. In this session, knowledge-gaps in terms of reducing breast compression, system-specific optimization of angular range and angular sampling, model-based iterative reconstruction techniques, methods to monitor system performance using phantoms, and developing a framework for conducting virtual clinical trials to evaluate the potential performance improvements are addressed. Dedicated breast CT is an emerging modality with tremendous potential to be the future of breast imaging addressing numerous clinical needs from screening to surgical planning and monitoring therapy response. It eliminates the need for multiple views with breast compression, as a single scan provides volumetric data with near isotropic spatial resolution that allows viewing the breast in any orientation. It is inherently quantitative and allows for risk estimation by quantifying fibroglandular tissue volume, discriminating malignant and benign lesions by analyzing the enhancement from administered contrast media and quantifying treatment response by monitoring temporal changes in tumor volume.

SSG14-02 Optimized Technique for Reducing Breast Compression in Digital Breast Tomosynthesis

PURPOSE

Digital breast tomosynthesis (DBT) provides tissue separation superior to mammography, and thus may obviate the need for breast compression, used to reduce breast thickness and consequently improve image quality and reduce mean glandular dose (MGD). Previous attempts to reduce breast compression have either resulted in poorer image quality or increased MGD. We optimized and evaluated an imaging technique for DBT with minimal breast compression without compromising image quality or MGD.

METHOD AND MATERIALS

Imaging technique for a Siemens MAMMOMAT Inspiration DBT system using reduced breast compression (<4 daN) was optimized using a signal-difference-to-noise ratio (SDNR) model accounting for the increase in scattered radiation due to increased breast thickness. Optimal tube potential (kVp) was determined by limiting MGD increase to <10% without decreasing SDNR. The optimized technique was evaluated in an IRB-approved, HIPAA-compliant prospective clinical study, where 21 patients with abnormal mammograms underwent DBT scans using full compression (FC) and minimal compression (MC). Skin markers were affixed to either side of the breast for motion assessment. Two breast radiologists scored lesion conspicuity in the two sets of images using a five-

point scale (-2: full compression much better, to +2: minimal compression much better).

RESULTS

Increasing the tube potential by 2-3 kVp over the FC technique causes no significant change in MGD or image quality. Conspicuity of 26 masses and 6 microcalcification clusters in 21 patients were compared. MGD for FC and MC were not significantly different; patient motion was shown to be comparable. Mass conspicuity was equivalent for FC and MC (mean score = -0.15, bootstrapped 95% CI: -0.38, 0.08); microcalcification conspicuity for MC was noninferior to FC (mean score = -0.17, 95% CI: -0.5, 0). All patients reported MC to be more comfortable than FC.

CONCLUSION

By optimizing imaging technique, breast compression can be reduced to less than half in DBT without sacrificing image quality or increasing MGD. The resulting increase in patient comfort may improve compliance with recommended screening practices.

CLINICAL RELEVANCE/APPLICATION

Breast compression in DBT may be reduced to <4 daN without compromising image quality or dose by optimizing imaging technique, potentially improving patient compliance with screening protocols.

SSG14-03 Design and Application of a Phantom for Testing Tomosynthesis Systems with Particular Emphasis on Automatic Cloud-Based Monitoring

Tuesday, Nov. 28 10:50AM - 11:00AM Room: S405AB

Participants
David J. Goodenough, PhD, Myersville, MD (*Presenter*) Consultant, The Phantom Laboratory

goodenou@gwu.edu

PURPOSE

To investigate the possibility of using a newly developed Tomosynthesis Phantom specifically developed for remote monitoring of DBT sites

METHOD AND MATERIALS

A newly developed Tomosynthesis QA Phantom has been developed for testing DBT systems. The phantom is also designed to allow remote analysis via web or cloud. The phantom includes: phantom positioning and alignment (important for remote analysis); scan geometry (x and y); chest wall offset; scan slice width and SSP(z) slice geometry (slice width); scan slice incrementation (z); Z axis geometry bead; low contrast from low contrast spheres; Point Spread Function (PSF); Image uniformity and Contrast to Noise Ratio (CNR). This study shows the success of remotely monitoring this phantom via cloud based uploads of Dicom data to a central processing system.

RESULTS

Results are shown for monitoring each of the parameters as listed in Methods and Materials. Data is shown for all known commercial Tomosynthesis systems. System reproducibility and performance over time, and long term trend analysis are shown. The results show robust and reproducible results. Results are shown for monitoring each of the parameters as listed in Methods and Materials. Data is shown for all known commercial Tomosynthesis systems. System reproducibility and performance over time, and long term trend analysis are shown. The results show robust and reproducible results. The ability to measure phantom position and alignment including roll, yaw, and pitch are found to be important but easily handled by the current software. Data on SSP and in plane resolution (MTF) are found to vary greatly among systems, depending on the DBT design, but amenable to remote monitoring and performance tracking.

CONCLUSION

It is possible to design and utilize phantoms for remote monitoring and performance tracking of Tomosynthesis DBT systems. Slice widths (SSP), and in plane resolution PSF and corresponding MTF although vary greatly among systems depending on the DBT design, are amenable to remote monitoring.

CLINICAL RELEVANCE/APPLICATION

A DBT phantom that is robust in performance measurements, and amenable to remote monitoring, offers clinicians, physicists, and administrators a tool to track the performance of the system.

SSG14-04 Impact of Tomosynthesis Angular Range on Mass Conspicuity in Patients with Dense Breasts

PURPOSE

Recent studies have suggested that cancer detection rates for digital breast tomosynthesis (DBT) are poor for patients with heterogeneously to extremely dense breasts. These studies have been predominantly limited to narrow-angle DBT. Increasing angular range (AR) reduces breast structural noise and increases image contrast for masses, potentially improving mass detection in dense breasts. We investigate the effect of AR on mass detectability using a previously validated cascaded linear system model (CLSM) for DBT, and compare theoretical results with clinical findings in an IRB-approved pilot study.

METHOD AND MATERIALS

Mass conspicuity in DBT reconstructions was modeled as a function of AR using a normalized detectability index *d'*, incorporating breast structural noise and image contrast. Under IRB-guidance, DBT images for 6 patients with heterogeneously or extremely dense breasts were compared using both the Hologic Selenia Dimensions DBT system (AR = 15°) and the Siemens MAMMOMAT Inspiration DBT system (AR = 50°). Two breast radiologists were presented with both sets of images for each patient and compared lesion conspicuity on a five-point scale (-2: lesion much more conspicuous on narrow-angle DBT, to +2: lesion much more conspicuous on wide-angle DBT).

RESULTS

Mass detectability was predicted to increase with increasing AR due to reduced structural noise and increased contrast in the reconstructed image slices. Increasing AR from 15° to 50° was predicted to increase detectability of 2, 5 and 10 mm masses by 85.3%, 87.5% and 87.9%, respectively. Clinical findings corroborated simulation results, with mass conspicuity shown to be equivalent or superior for wider-angle DBT, with a mean score of 0.89 (95% CI: 0.44, 1.44). Importantly, masses found in areas with high masking risk (defined as high local density as characterized by the radiologist) were more conspicuous on wider-angle DBT.

CONCLUSION

Using a normalized detectability index *d'*, mass conspicuity was shown to increase with increasing AR. These results were corroborated by a pilot reader study, and motivate a larger clinical study comparing mass conspicuity for differing DBT acquisition geometries.

CLINICAL RELEVANCE/APPLICATION

Tomosynthesis with wider angular ranges may provide mass conspicuity superior to tomosynthesis with narrow-angular range for patients with heterogeneously to extremely dense breasts.

SSG14-05 Reduced Anatomical Noise in Digital Breast Tomosynthesis with Model Based Iterative Reconstruction

Tuesday, Nov. 28 11:10AM - 11:20AM Room: S405AB

jwgarrett@wisc.edu

PURPOSE

The anatomical background of the breast strongly influences mass detection performance in breast imaging. Anatomical noise has previously been quantified using a parameter, ß, which is strongly correlated with mass detection. Reported values of ß in clinical modalities are approximately 3.3 for mammography, 3.2 for digital breast tomosynthesis (DBT), and 2.0 for breast CT. The purpose of this work was to determine whether the anatomical clutter in DBT reconstructions can be reduced using MBIR.

METHOD AND MATERIALS

The anatomical noise power spectrum (NPS) was measured for 105 clinical DBT exams acquired using Hologic Selenia Dimensions systems. A power-law model (NPSa=af-ß) fitting of the anatomical NPS was performed. The exponent, ß, was used as a surrogate for the anatomical noise background and compared between the commercial reconstruction (FBP) and an in-house MBIR method. ß was measured as a function of position within the breast (central 25 slices) and averaged for each breast. The mean measured ß values were compared using a two-tailed t-test (H0:ßComm=ßMBIR) to determine if the difference was statistically significant. The reconstructed images were also assessed subjectively.

RESULTS

The measured ß for the commercial reconstruction method was 3.27±0.40, consistent with previously published values. For the MBIR method, the measured ß value was 2.30±0.55. The reduction in anatomical noise was significant using the MBIR method compared with the commercial method ($p<<0.001$). The variation in ß at different slice locations was negligible in both reconstruction methods. The appearance of anatomical clutter was reduced substantially in reconstructed images as well.

CONCLUSION

MBIR significantly reduced the anatomical noise in DBT reconstructions as quantified using a power-law fitting of the anatomical NPS. The reduction of ß from 3.3 to approximately 2.3 indicates that with MBIR the anatomical noise in DBT is more similar to breast CT than mammography.

CLINICAL RELEVANCE/APPLICATION

Reducing anatomical noise in DBT images with MBIR may improve mass detection for DBT images. This has the potential to improve the sensitivity of treatable cancers for breast screening

SSG14-06 Digital Breast Tomosynthesis as a Replacement of Full-Field Digital Mammography for the Detection of Breast Cancer: An Open-Source, In-Silico Clinical Trial

Tuesday, Nov. 28 11:20AM - 11:30AM Room: S405AB

aldo.badano@fda.hhs.gov

PURPOSE

To determine the comparative performance of digital breast tomosynthesis (DBT) as a replacement to full-field digital mammography (FFDM) using entirely in silico open-source methods and to compare results to previously reported clinical trials. Secondary objectives include measurements of the differential performance in subpopulations and across lesion types.

METHOD AND MATERIALS

Analytic breast phantoms modeling anatomical structures were generated in large numbers corresponding to 4 size and apparent density combinations (from 3.5 to 6 cm compressed thickness and 4 BIRADS density categories) and were compressed using finite-element modeling prior to imaging. Lesions were inserted representing microcalcification clusters and spiculated masses. Phantoms were imaged using a detailed Monte Carlo simulation approach with the GPU-accelerated, freely available MC-GPU code with improved focal spot and tube motion models and thick-layer detector description including fluorescence, anti-scatter grid, and electronic noise. 50-micron voxelized models were simulated using a binary tree geometry and delta-scattering transport. The detection algorithm uses a location-known-exactly paradigm with a channelized Hotelling Observer and spatial frequency filtering for irregular morphology. A small set of readers were trained with distinct training sets of normals and cancers and tested on independent sets. Uncertainty was estimated using a fully-paired multiple-reader, multiple-case analysis. The study was sized to achieve uncertainties lower than those seen in human trials for the differential performance in terms of area-under-the-ROC curve (AUC).

RESULTS

The performance AUC for FFDM during the prepilot stage ranged between 0.87 and 0.96. Sizing of the pivotal trial indicates that 30 computational readers trained on subsets of 100 pairs of cancer and normal regions-of-interest achieve the target uncertainty of approximately 0.01.

CONCLUSION

The findings indicate that the performance seen in in silico trials for FFDM is comparable, under reasonable assumptions, to results obtained in trials using patients and clinicians.

CLINICAL RELEVANCE/APPLICATION

This report describes the first imaging clinical trial performed exclusively using open-source computational methods. Our findings stimulate discussion around increasing the use of computational modeling in the assessment of imaging systems for regulatory evaluation.

SSG14-07 Initial Experimental Results from the First X-Ray Dark Field Breast Tomosynthesis Prototype System

PURPOSE

X-ray digital breast tomosynthesis imaging systems have been successfully introduced in current clinical practice. However, the image contrast is limited as it depends on a single contrast mechanism: x-ray absorption. In this work, the first prototype breast tomosynthesis imaging system with both absorption contrast and a new contrast mechanism: dark-field contrast, was constructed and initial experimental results to assess imaging performance are presented.

METHOD AND MATERIALS

The prototype dark field tomosynthesis imaging system was based on a full field digital mammography system (Senographe 2000D,

The prototype dark field tomosynthesis imaging system was based on a full field digital mammography system (Senographe 2000D, GE Healthcare) with a dual-track rotating anode (Rh/Mo) tube and a CsI-based plat panel detector with 100 µm pixel size. Three x-ray gratings were integrated into the mammography system. The dark field tomosynthesis image acquisition was performed using the Grossman geometry, in which the gantry (including both the x-ray tube and detector) rotate around a fixed image object over an arc of 28° (2° interval). The system was operated at 36 kVp/180 mAs with the Rh anode and Rh filter. From a single tomosynthesis acquisition, both dark field and conventional absorption contrast tomosynthesis images were reconstructed using the shift-and-add algorithm; the images have an in-plane pixel size of 70 µm and a slice thickness of 0.5 mm. Two test objects, an overlay of microcalcifications on top of microbubbles and a mouse lung specimen, were used to perform the initial evaluation of the prototype system.

RESULTS

In addition to the conventional absorption contrast tomosynthesis imaging, x-ray dark field tomosynthesis imaging provided complementary image information for detailed structures in the two specimens. The contrast-to-noise ratio of the low-attenuating microbubbles was boosted from 5.9 in absorption tomosynthesis images to 21.0 in dark field tomosynthesis images.

CONCLUSION

A clinically compatible x-ray dark field breast tomosynthesis prototype system was developed. Based on the promising initial results using both phantom and biological specimen studies, this system will be used to evaluate the potential clinical utility of x-ray dark field tomosynthesis imaging.

CLINICAL RELEVANCE/APPLICATION

This is the very first report of a prototype x-ray dark field tomosynthesis system that will enable future clinical evaluation of the x-ray dark field breast tomosynthesis imaging method.

SSG14-08 A Novel Automatic Segmentation Algorithm for Tissue Classification of Dedicated Breast CT Images

Tuesday, Nov. 28 11:40AM - 11:50AM Room: S405AB

marco.caballo@radboudumc.nl

PURPOSE

To develop and validate a fully automatic classification algorithm to identify voxels containing skin, adipose, fibroglandular and vasculature in dedicated breast CT (BCT) images.

METHOD AND MATERIALS

The developed algorithm involves the following steps: i) an intensity and region-based segmentation method for skin detection; ii) a combination of unsupervised neural networks and energy minimizing splines for fibroglandular tissue segmentation and iii) an unsupervised data mining approach to classify the remaining tissue into fat and vasculature. To evaluate the accuracy of the algorithm, one slice each from five different patient BCT images were manually segmented under the supervision of an experienced breast radiologist and considered the gold standard. To evaluate the robustness of the algorithm to image noise, Gaussian, Poisson and speckle noise were separately added to another five patient BCT slices. Finally, to evaluate the classification of the vasculature, three different pre- and post-contrast injection patient BCT images were classified and compared. Dice Similarity Coefficients (DSCs) were calculated for all comparisons.

RESULTS

The DSCs between the manually and automatically segmented slices were (mean ± 1 std.dev): skin: 0.949 ± 0.005; fibroglandular: 0.955 ± 0.009; adipose: 0.986 ± 0.016; vasculature: 0.879 ± 0.052. The DSCs between the original segmentation result and the ones corrupted by noise were 0.887 ± 0.07 for Gaussian, 0.920 ± 0.06 for speckle and 0.912 ± 0.03 for Poisson noise. Finally, the vasculature DSCs for the three patient cases between the pre- and post-contrast injection images were 0.974, 0.952 and 0.891.

CONCLUSION

The algorithm results in accurate and robust breast tissue classification with no prior training and with the ability to detect blood vessels even in non-enhanced images. Potential applications include breast density quantification and tissue pattern characterization, both biomarkers of cancer development. Further possibilities include automatic identification of breast skin thickening, related to cancer development, and development of patient image-based phantoms which could be used for breast imaging research.

CLINICAL RELEVANCE/APPLICATION

Classification of breast CT images can provide quantitative assessments of breast tissue composition, density and distribution, all biomarkers of breast cancer development.

SSG14-09 Patient-Based 4D Digital Phantom for Dynamic Contrast-Enhanced Breast CT Imaging

marco.caballo@radboudumc.nl

PURPOSE

To develop a realistic patient-based 4D digital breast phantom including time-varying contrast enhancement for dedicated breast CT perfusion imaging.

METHOD AND MATERIALS

A phantom was created by first segmenting a breast CT scan from a healthy patient into skin, fibroglandular tissue, adipose tissue and vasculature using an automated classification algorithm developed in our laboratory. A tumor model (a sphere with a radius of 10 voxels, equivalent to 2.6 mm) was inserted within the segmented fibroglandular tissue. Average values for blood volume and wash-in and wash-out rates were defined for each tissue type and for the tumor based on results from contrast enhanced dynamic breast MRI. Given these parameters, the proposed algorithm automatically calculates input functions for each tissue type, including the tumor. Then, blood flow (BF) and mean transit time (MTT) are computed for each voxel, taking into account the Hounsfield unit values from the original patient image. Finally, time attenuation curves are calculated for each voxel by convolving the inputs with an exponential function that depends on the BF and MTT values associated with that voxel.

RESULTS

The first 4D voxel phantom constructed in the present study has dimensions of 1008x1008x198x560 (x, y, z, t) with a sampling time of 1 s. Results show the expected enhancement of tissues according to the given input parameters. Moreover, the tumor presents a higher and much faster enhancement compared to the other healthy tissues, as expected. Additional phantoms from other patient cases can be generated at will.

CONCLUSION

The proposed digital phantom can model the behaviour of contrast in the breast during 4D breast CT image acquisition, displaying the different enhancement dynamics that may be found in a patient breast. These phantoms will be used to optimize the development of dynamic contrast enhanced dedicated breast CT imaging to obtain the highest possible image quality with the minimum possible dose. Future work includes the evaluation of the enhancement of different tumor types, 4D breast CT simulations and estimation of radiation dose.

CLINICAL RELEVANCE/APPLICATION

The proposed phantom can be used for optimizing 4D breast CT imaging, which has the potential to aid in the staging and characterization of breast tumors and in the monitoring of treatment.

PURPOSE

To develop a framework and software tool for efficient optimization of CT protocols using a channelized Hotelling observer (CHO) and associated task-based image quality metrics.

METHOD AND MATERIALS

The lack of efficient tools for CT image quality assessment and protocol optimization has been one of the main reasons for a large variation of radiation dose among CT practices. In this work, we developed a quantitative framework for protocol optimization and a software tool to address this issue. A phantom containing 21 objects of various contrast levels and sizes was 3D-printed and inserted into anthropomorphic phantoms of 3 sizes to mimic different adult attenuation levels. The software tool consists of two major components: (1) automated CHO calculation and (2) protocol optimization. The first component performs automated CT image quality assessment after loading the phantom images, which includes calculation of contrast-dependent spatial resolution, 2D and 3D noise power spectrum, index of detectability (d'), and area under the ROC curve (AUC) for a low-contrast detection task. The AUC and d' were based on a previously validated CHO model, with Gabor channels optimized to improve the statistical performance. The second component of the software tool automates the process of protocol optimization by using a predefined target AUC value or an AUC value associated with a reference protocol. As an example, the tool was tested on a 128-slice scanner to determine the dose reduction potential of iterative reconstruction (IR) in a routine abdomen/pelvis protocol.

RESULTS

CHO can be efficiently calculated using the developed tools with the number of Gabor channels reduced to 12 and the required number of repeated scans reduced to 15-20 without sacrificing the CHO accuracy. In the example of protocol optimization for IR, when the predefined target AUC was 0.9, acceptable dose reduction was between 20% and 30%, depending on the phantom sizes.

CONCLUSION

The developed framework for protocol optimization and software tool allows for efficient and objective determination of task-based image quality, which can be used for quantitative protocol optimization in CT.

CLINICAL RELEVANCE/APPLICATION

CT protocols can be efficiently and objectively optimized using the proposed quantitative method based on model observers, which may lead to reduced dose variation across CT practice.

SSG15-02 Task-based Parameter Optimization for Low Signal Correction in Low-Dose CT

Tuesday, Nov. 28 10:40AM - 10:50AM Room: S503AB

gomezcardona@wisc.edu

PURPOSE

Low signal correction (LSC) techniques applied to raw projection data in CT are an effective means to reduce noise streaks and noise amplitude in CT, enabling high quality CT images at reduced dose levels. Current empirical parameter selection in LSC requires many trial-and-error experiments, and often leads to variable performance for different imaging tasks. The purpose of this work is to present a task-based parameter optimization framework for LSC methods in low dose CT.

METHOD AND MATERIALS

Since LSC methods reduce noise in the raw data locally, noise and spatial resolution may not be uniform across the field of view (FOV). In the proposed framework, noise and spatial resolution were measured through repeated scans at a given dose level and incorporated into a mathematical observer model to calculate detectability. The detectability index was then used as figure of merit to optimize parameter selection for a given LSC method. Detectability maps obtained for a given LSC parameter space were incorporated into the following parameter selection criteria: a) maximize detectability for a given imaging task and given spatial location, b) maximize global detectability across imaging tasks for a given location, c) maximize detectability for a given imaging task across spatial locations, or d) maximize global detectability across imaging tasks and across locations.

RESULTS

Noise and spatial resolution properties were found to vary considerably across the FOV. Once these metrics were incorporated into the detectability index, the imaging performance for a given operating point in the parameter space was found to have a strong dependence on spatial location and imaging task. The proposed parameter selection criteria addressed the selection of the optimal filter parameters for LSC.

CONCLUSION

A task-based detectability framework was developed to optimize the selection of parameters for LSC. This framework is generalizable to any LSC methods that can be parameterized.

CLINICAL RELEVANCE/APPLICATION

LSC methods play an essential role in low dose CT technologies. An imaging task-based parameter selection framework can provide a means to achieve radiation dose reduction while to maintain diagnostic performance in low dose CT exams.

SSG15-03 CT Number Bias in Low Dose MDCT with Model Based Iterative Reconstruction (MBIR)

Tuesday, Nov. 28 10:50AM - 11:00AM Room: S503AB

gomezcardona@wisc.edu

PURPOSE

New technologies have been developed and deployed in the field to enable radiation dose reduction. Although clinical benefits seem to be apparent, the potential challenges associated with radiation dose reduction have not been fully investigated. In this work, systematic studies were performed to investigate the change of CT number bias from reference with the decrease of radiation exposure levels and to compare the potential difference between CT number bias in conventional FBP reconstruction and model based iterative reconstruction (MBIR).

METHOD AND MATERIALS

To extract CT number bias, multiple repeated scans were performed on a quality assurance phantom and a clinical MDCT system equipped with both FBP and MBIR reconstruction methods. The CT number of 7 inserts with different attenuation levels was measured from a combined set of 10 exposure levels and 3 tube potentials, with each parameter set repeated 50 times. These measurements were finally compared to a reference consisting of the average of an ensemble of 50 scans obtained at a reference dose level at each kV. CT number bias was defined as the difference between the ensemble average CT number measured at a given exposure level and the ensemble average CT number measured at a reference exposure level for a given kV.

RESULTS

There are three important findings from this work: (1) CT number bias increases with decreasing radiation dose levels for both FBP and MBIR; (2) For a given material insert, the CT number biases in FBP and MBIR are completely inverted, i.e., for FBP a positive bias was obtained as the exposure level decreased; in stark contrast, for MBIR the bias becomes negative at low exposure levels; (3) CT number bias was found to be proportional to its own CT number level for both FBP and MBIR.

CONCLUSION

CT number bias increases with radiation dose reduction in both FBP and MBIR and a peculiar CT number bias inversion with respect to FBP, was experimentally observed for MBIR as exposure level was reduced.

CLINICAL RELEVANCE/APPLICATION

The discovery of increased CT number bias in low dose CT sets a new lower bound for radiation dose reduction to maintain diagnostic accuracy in low dose CT clinical exams.

SSG15-04 CT Iterative Reconstruction Kernels: Noise Characteristics and Their Differences

Tuesday, Nov. 28 11:00AM - 11:10AM Room: S503AB

Participants
Gary Ge, Lexington, KY (*Presenter*) Nothing to Disclose
Victor Weir, PHD, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose
Jie Zhang, PhD, Lexington, KY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To better understand noise characterization of computed tomography (CT) images reconstructed with iterative reconstruction kernels and demonstrate their differences.

METHOD AND MATERIALS

Unsubtracted and subtracted noise power spectra (NPS) and modulation transfer function (MTF) were measured using CT images acquired from a routine water phantom on Siemens Definition Edge, Force, and GE Revolution, respectively. Series of cutting-edge iterative reconstructions in Sinogram Affirmed Iterative Reconstruction (SAFIRE I31f-I70f), Advanced Modeled Iterative Reconstruction (ADMIRE I31f-I70f, and Br20s-Br70s in dual-source), and Advanced Statistical Iterative Reconstruction-V (ASIR-V Bone, Lung, Detail, Standard) were evaluated and compared at different strength settings (1-5 for Siemens, 20-100 for GE).

RESULTS

Each NPS demonstrates the expected shape of traditional back-projection filters. The peak frequency gradually shifts to lower frequency with the increased strength, corresponding to stronger smoothing effect. Low-frequency structured noise is observed in unsubtracted NPS for all kernels and is successfully removed in subtracted NPS. With the increases in filter sharpness, the NPS shifts to higher frequencies, preserving higher-frequency noise. The series of I kernels in SAFIRE and ADMIRE demonstrate comparable NPS. However, the Br kernels in ADMIRE dual-source shows differences from I kernels. There are notable differences in the NPS between manufacturers. Comparing the NPS of ADMIRE and ASIR-V shows that the GE kernels generally exhibit a larger decrease in peak noise resolution due to increasing kernel strength and a generally wider NPS profile than comparable Siemens kernels. Over-enhancing is observed in all sharp kernels.

CONCLUSION

Analysis of NPS helps characterize image noise associated with various reconstruction kernels and identify their differences to help in their clinical application. A comparison between manufacturers potentially helps standardize protocols across different CT scanners.

CLINICAL RELEVANCE/APPLICATION

Understanding how reconstruction kernels affect noise pattern allows tailoring protocols to task-specific clinical applications.

SSG15-05 Contrast Dose Reduction in Coronary CT Angiography on 16cm Wide-Detector CT with Reduced Injection Time

Tuesday, Nov. 28 11:10AM - 11:20AM Room: S503AB

PURPOSE

To investigate the effect of contrast agent injection time on coronary artery image quality in coronary CT angiography (CCTA) with wide-detector CT.

METHOD AND MATERIALS

A total of 40 patients underwent CCTA on a 16cm wide-detector Revolution CT with 100kVp tube voltage and automatic tube current modulation for noise index of 21HU. The contrast agent iopamidol (370mg/ml) was used at a dose rate of 25mgI/kg/s. The patients were divided into two groups based on the injection time: Group A (n=20 with standard 12s injection time) and Group B (n=20,8s) The CT value and standard deviation in the lumen of the ascending aorta,right coronary artery,left anterior descending branch,proximal lumen of LCX and adjacent tissue were measured to calculate the contrast-to-noise ratio (CNR) and signal-to-noise ratio (SNR) for arteries. Two imaging radiologists with cardiovascular diagnosis experience over 8 years assessed image quality independently for subjective score using a 5-point scoring system (5: best,1: worst,>= 3: diagnosable). Measurements between the two groups were compared using T test or rank sum test.

RESULTS

There was no significant difference in age,heart rate and body mass index between the two groups (P>0.05); The CT number,SNR,CNR,effective dose and subjective score of the two groups were statistically the same (p>0.05). There was a significant difference in contrast dose between group A (54.7±8.3ml) and group B (37.9±6.5ml) (P<0.05),a reduction of about 30%.

CONCLUSION

Reduction of contrast injection time from the conventional 12s to 8s in CCTA with 16cm wide-detector CT effectively reduces contrast dose by 30% while maintaining image quality.

CLINICAL RELEVANCE/APPLICATION

Faster scan time enables the shortening of contrast injection time to save contrast dose by 30% while maintaining image quality in CCTA with 16cm wide-detector.

SSG15-06 Framework for Objective Clinical Image Quality Assessment in Thorax CT: A 3D Model Observer in Combination with A 3D Printed Lung Phantom Containing Nodules

Tuesday, Nov. 28 11:20AM - 11:30AM Room: S503AB

I.Hernandez_Giron@lumc.nl

PURPOSE

To apply a 3D model observer to analyze the detectability of lung nodules in a 3D printed lung phantom in CT images acquired at different dose levels.

METHOD AND MATERIALS

A model of the distribution of the lung vessels, based on published morphometry based human data, was generated using an in-house algorithm developed in MATLAB. The simulated lung vessels had diameters between 8.5 and 0.2mm. The model was printed in a ProJet HD 3000 3D printer using Visijet EX200 as material. A PMMA thorax shaped holder (20x30x3cm3) was created to contain the lung insert. Twenty cork spheres (6mm diameter) were placed at different positions as nodules surrogates. The phantom was scanned with a thorax protocol (Toshiba Aquilion Genesis, 120kV, collimation=0.5x80mm, pitch=0.637, RFOV=400mm, AIDR3D, FC18 kernel, 0.5mm slice thickness and interval, 250-30-5-3mAs)). Twenty acquisitions were performed for each dose level, 10 with lesions and 10 without. Volumes of interest (16x16x8.5mm3), centered on the nodule locations, were selected. Volumes were also cropped in equivalent anatomical positions in the nodule-free images. For the highest dose, ROIs were taken on the bigger vessels and also in the central slice of the nodules to estimate their attenuation. A 3D channelized Hotelling model observer (CHO) , with 20 Gabor channels was used to analyze the samples with and without lesions for each dose level. Half of the images were used for training and half for testing for each condition. Test-statistics were calculated over the distributions of the model observer outcomes and a detectability index was calculated for each dose level.

RESULTS

The phantom vessels had a mean pixel value of (118±5HU) and the nodules (-815±20HU). The detectability of the lesions increased with increasing mAs value, for the 3D model observer. The d' values, from highest to lowest dose level (CTDIvol=10.9-2.6-0.4-0.2mGy) were (13.8±1.1, 11.2±0.8, 8.3±0.6, 7.5±0.5).

CONCLUSION

A 3D model observer was applied to analyze the detectability of nodules in CT images of a 3D printed lung phantom mimicking the human vessel distribution. The detectability of the lesions increased with dose. These results represent a step towards measurement of clinical image quality with 3D model observers in CT.

CLINICAL RELEVANCE/APPLICATION

A 3D model observer can be a useful tool towards measuring clinical image quality in CT, in particular, for lung nodule detection tasks in a 3D printed lung phantom.

SSG15-07 Noise Suppression Dependency on Patient Size and Lesion Size with Adaptive Statistical Iterative Reconstruction in Adult Abdomen CT

Tuesday, Nov. 28 11:30AM - 11:40AM Room: S503AB

Participants
Yifang Zhou, PhD, Los Angeles, CA (*Presenter*) Nothing to Disclose
Jessica L. Nute, PhD, Los Angeles, CA (*Abstract Co-Author*) Nothing to Disclose
Christina M. Lee, BS,ARRT, Los Angeles, CA (*Abstract Co-Author*) Nothing to Disclose
Alexander W. Scott II, PhD, Los Angeles, CA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To demonstrate the noise suppression dependency on patient size, lesion size and dose with adaptive statistical iterative reconstruction (ASIR) in adult abdomen CT.

METHOD AND MATERIALS

Three adult abdomen phantoms simulating the small, medium and large patient were scanned using a GE VCT 64-slice scanner.

Different dose levels were applied (CTDI_vol 2 mGy to 40 mGy). The images were reconstructed with variable ASIR fractions (0 - 100%). The noise images were obtained using subtraction between eight nearest neighbor slices. They were partitioned into matrices of square elements scaled 1.8 mm - 10 mm to match the lesion sizes of interest, and the statistically defined minimum detectable contrast (MDC) were computed to represent the noise suppression. To describe the relative noise suppression over FBP images, the normalized MDC (N_MDC) was defined as the ratio of the MDC with ASIR to the MDC with FBP. N_MDC was obtained at each element size from different ASIR blending fractions at variable dose levels.

RESULTS

N_MDC was found to decrease linearly as the ASIR blending fraction increases. The slope of the N_MDC, however, depends on the lesion size, patient size and dose. The slope was fitted against the lesion size by a power law with more contrast enhancement at smaller lesion size ($R^2 > 0.935$ among all cases). The contrast enhancement or noise suppression was found to be more pronounced as the phantom size increases or as the dose decreases. The difference on noise suppression due to different doses was also observed smaller for the smaller lesion sizes.

CONCLUSION

The suppression using ASIR in adult abdomen CT not only depends on the ASIR blending fraction, but also depends on the lesion size, patient size and dose.

CLINICAL RELEVANCE/APPLICATION

Adult abdomen CT dose optimization

SSG15-08 Impact of Iterative Reconstructions on Image Quality in Clinical CT Images Demonstrated by a Novel Noise Power Spectrum Measurement Tool

PURPOSE

To quantify noise texture and magnitude characteristics of clinical Computed Tomography (CT) images obtained with Iterative Reconstructions (IR) techniques.

METHOD AND MATERIALS

An algorithm was developed to extract noise texture and magnitude metrics from 10 chest and abdomen clinical CT-scans (Discovery CT750 HD; GE Healthcare, Wisconsin) performed for oncology follow-up by measuring a global Noise Power Spectrum (NPS). After subtraction of adjacent slices, a segmentation algorithm was applied to exclude remaining anatomical structures. Noise magnitude (i.e. area under the 1D-NPS curve) and peak frequency (fpeak) were measured, within all the available regions of interest that did not contain edge pixels, and compared for chest and abdomen on image subsets of all CT scans reconstructed using Filtered Back Projection (FBP), Adaptive Statistical Iterative Reconstruction 30 % (ASIR30), 50 % (ASIR50) and Model-Based Iterative Reconstruction (MBIR).

RESULTS

Compared to FBP, ASIR30 and ASIR50, MBIR reduced noise magnitude by 31 %, 17 % and 13 % in chest and by 47 %, 34 % and 29 % in abdomen respectively ($p < 0.01$ each). These noise magnitude reductions were also associated to changes in noise texture: for chest and abdomen, fpeak were significantly lower for MBIR (0.08 and 0.09 mm^{-1} respectively), ASIR50 (0.13 and 0.14 mm^{-1} respectively) and ASIR30 (0,16 and 0.18 mm^{-1} respectively) compared to FBP (0.23 and 0.27 mm^{-1} respectively; $p < 0.01$ each).

CONCLUSION

Assessing NPS of clinical CT examinations can demonstrate the reduction of noise magnitude and the changes of noise texture associated to IR. This method could be used to tailor CT protocols according to radiologists' preferences regarding noise texture and magnitude.

CLINICAL RELEVANCE/APPLICATION

The proposed technique enables automatic quality control monitoring of image noise characteristics in clinical practice.

SSG15-09 Objective Quantification of the Impact of Image Artifacts on Lesion Detectability Using a Channelized Hotelling Model Observer

Tuesday, Nov. 28 11:50AM - 12:00PM Room: S503AB

ferrero.andrea@mayo.edu

PURPOSE

Objective assessment of the impact of image artifacts on the diagnostic quality of a cone-beam CT (CBCT) images is difficult, as conventional image quality metrics are not adequate to assess the influence of non-uniform artifacts. In this work, we investigated the use of a channelized Hotelling observer (CHO) to quantify the impact of artifacts arising from both the test object and external sources on lesion detection in CBCT data.

METHOD AND MATERIALS

A custom phantom insert containing vessels of diameter 2, 4 and 8 mm was filled with diluted iodine contrast medium to produce different image contrast levels (range 0-300 HU) and placed inside an anthropomorphic thoracic phantom. Projection images were acquired at 1.5º/frame over a 200º range using a C-arm. Severe external image artifacts were introduced by placing two metal pins adjacent to the posterior surface of the phantom. Detectability index (d') of a CHO was estimated using 150 background only images and 150 images of the iodine vessels with and without external artifacts. Using a standard CHO implementation, the total contribution of the vessels and artifacts to d' was estimated. The contribution of the artifacts was determined by masking the image area of the iodine vessels prior to channelization. d' of the artifacts was then subtracted from the total d's to estimate d' of the iodine vessels only.

RESULTS

Per expectation, the contribution to d' of artifacts originating from the iodine vessels was proportional to the HU contrast of the iodine vessels whereas that of the external artifacts was independent of iodine concentration. As the severity of the externally produced artifacts was variable across the 2D images, their estimated contribution to d' was also variable with location in the image. After correcting for external artifacts, d' of the iodine vessels with external artifacts present was 4-67% lower than that without external artifacts.

CONCLUSION

This work proposes masking of the test object to directly estimate CHO d' of CBCT image artifacts arising both from the test object and external sources. This method may be used to directly estimate the magnitude of image artifacts and to remove their influence on d' estimates.

CLINICAL RELEVANCE/APPLICATION

Artifacts present in CBCT images can confound CHO performance. A correction method is proposed to eliminate their effect and provide valuable information on their influence on lesion detection in CBCT.

jamie@jcesaretti.com

PURPOSE

The purpose of the abstract was to determine both the acute and long terms consequences of VMAT to 81Gy for prostate cancer in a cohort of 501 men treated between 8/2010 and 12/2015 using a validated measure of urinary function.

METHOD AND MATERIALS

Five hundred and one men were treated with VMAT to 81 Gy from 8/2010 to 12/2015 for low (27.5%), intermediate (47.7% and high risk (24.8%) prostate cancer. In addition to the use of VMAT, patients were treated using gold fiducial markers, a rectal stabilization device and MRI treatment planning. All men were given the International Prostate Symptom Score sheet prior to treatment, at one month following treatment and at one year. IPSS scores were prospectively collected and comparisons of means were made by T-test. The incidence of elevations in IPSS which have been previously described to be bothersome to men and require either medical or surgical intervention are also reported.

RESULTS

The baseline IPSS score prior to therapy was 9.57 for the entire cohort, at one month following completion of radiation the average score was 10.51 ($p=0.003$) and at one year 9.23 ($p=0.17$). 119/501 (23.8%) of patients began treatment with an IPSS score great than or equal to 15 with an average score of 19.65. At one month following treatment the IPSS score was 15.34 ($p<0.01$) and at a year 13.9 ($p<0.01$). For patients with baseline IPSS less than 15, the average score prior to therapy was 6.49, and at one month and one year 9.01 and 7.66 respectively ($p<0.01$). For 171 (34.1%) patients who were initially asymptomatic, IPSS less than or equal to 5, the average IPSS prior to treatment was 2.81, and at one month and one year 7.08 and 6.29 ($p<0.01$). When evaluated individually, 111/501 (22.2%) patients experienced a rise in IPSS of at least 5, 46/501 (9.1%) of 10, 15/501 (3.0%) of 15 and 6/501 (1.2%) of 20 points. No patient required catheterization at any point or use of pads.

CONCLUSION

Patients who were highly symptomatic prior to VMAT therapy experienced improved urinary function prior to baseline measurements at one month following treatment and continued improvement on to one year of treatment. Very few patients experienced a clinically signficant rise in IPSS of greater than 15 and 20 from their pretreatment baseline measurements. No patient experienced catheterization or incontinence.

CLINICAL RELEVANCE/APPLICATION

Prostate cancer treatment to very high doses is associated with minimal urinary toxicity.

SSG16-04 Differences in Prostate Gland Geometry and Dosimetry After Pre-operative and Intra-operative Ultrasound Planning in Patients Undergoing Prostate Seed Brachytherapy: Implications for Current Practice

Tuesday, Nov. 28 11:00AM - 11:10AM Room: S104A

Participants
Brian Lee, PhD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
Zachary Grelewicz, PhD, Chicago, IL (*Presenter*) Nothing to Disclose
George Kalapurakal, BS, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
Irene Helenowksi, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
John A. Kalapurakal, MD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Currently prostate brachytherapy (PB) plans are generated using either pre-operative (POP) (done 2-3 wks before PB) or intra-operative (OR) ultrasound volume studies. This report compared: A) Prostate geometry between POP and OR volume studies; B) Prostate I-125 seed distribution between POP and OR plans; C) Prostate dosimetry after OR planning and POP planning.

METHOD AND MATERIALS

The POP and OR ultrasound volume studies and PB plans of 30 patients were analyzed and compared. PB dose was 144Gy with I-125 seeds. Different prostate gland volumes (cc) receiving a %dose (V100% and V150%) and dose to % prostate volumes (D90%) were estimated and compared using Wilcoxon rank sum test.

RESULTS

A) Mean prostate volume (cc) after POP vs. OR scans respectively and P values (P) was: prostate base 23.4 $\pm$ 3.2 vs. 22.8$\pm$ 3.0 (P 0.35); prostate mid gland 24.0$\pm$ 3.6 vs. 22.6$\pm$ 2.8 (P 0.003); prostate apex 11.4$\pm$3.1 vs. 10.3 $\pm$ 2.5 (P 0.07). B) Median difference in number of I-125 seeds between POP and OR plans were: Base 2.0 $\pm$ 4 (P 0.03); Mid gland 2.0 $\pm$ 9.6 (P 0.4); Apex 2.0 $\pm$ 6.4 (P 0.02). Median number of seeds added or removed for the 2 plans were: +4 and -2 for Base; +4 and -3.5 for Mid gland and +7.5 and -6.5 for Apex. These changes in number of seeds in the apex and base indicates significant difference in prostate geometry between these scans. C) Mean prostate PTV (cc) (V100% dose) between OR vs. POP plans was: Base 22.0$\pm$4 vs. 21.7$\pm$2.9 (P 0.004); Mid gland 23$\pm$4.3 vs. 22.7$\pm$3.2 (P 0.03) and Apex 10.8$\pm$3.3 vs. 10.2$\pm$3.3 (P 0.03). Mean prostate PTV (cc) (V150% dose) between OR vs. POP plans was: Base 10.8$\pm$4.0 vs.10.4$\pm$2.6 (P 0.049); Mid gland 12.2$\pm$4.2 vs.12.0$\pm$2.6 (P 0.3) and Apex 4.9$\pm$1.9 vs. 4.3$\pm$1.8 (P 0.02). Dose to 90% prostate PTV (D90) for OR vs. POP plans was 119$\pm$16% vs. 113$\pm$20% (P 0.04).

CONCLUSION

There were significant differences in prostate geometry and dosimetry between OR and POP scans. Differences in patient positioning (hip flexion) and use of general anesthesia for OR plans were responsible for these observations. The use of POP scans for PB may result in higher relapse rates due to underdosage of at-risk regions in the prostate. Intra-operative ultrasound volume study-based PB treatment planning provides superior prostate dosimetry compared to preoperative planning.

CLINICAL RELEVANCE/APPLICATION

Intra-operative volume study-based PB planning delivers a higher target dose to the prostate gland compared to pre-operative planning.

SSG16-05 Multiparametric MRI for Renal Cell Carcinoma: Assessment of Tumor Response after Stereotactic Ablative Body Radiotherapy

Hayley.Reynolds@petermac.org

PURPOSE

Response assessment of renal cell carcinoma (RCC) after stereotactic ablative body radiotherapy (SABR) using size criteria from CT is challenging, as changes may evolve over months and even years post-therapy. The purpose of this study was to analyze early diffusion and perfusion changes in RCC tumors shown by multiparametric MRI after SABR, and to assess whether any changes are associated with overall treatment response.

METHOD AND MATERIALS

Twelve patients in a prospective Phase Ib clinical trial were analyzed, where patients with RCC tumour size <5cm diameter received a single fraction of 26 Gy and larger lesions received three fractions of 14 Gy. Multiparametric MRI including diffusion weighted (DWI) and dynamic contrast-enhanced (DCE) imaging was acquired at baseline and approximately three weeks and three months after SABR. Apparent diffusion coefficient (ADC) maps were computed from DWI data, heuristic parametric and pharmacokinetic maps using the extended Tofts model were fitted to the DCE data. Tumour volumes were contoured and statistics including histogram metrics extracted. Changes in DWI and DCE MRI characteristics were correlated with change in tumour volume shown by late follow-up CT (average 28 months after baseline CT, range 17-40 months) and with the Response Evaluation Criteria in Solid Tumors (RECIST) criteria.

RESULTS

The ADC mean, median and kurtosis measures increased in most patients at the third MRI scan indicating increased diffusion after

SABR, however there was no clear correlation with the change in tumour volume. DCE analysis showed strong correlations between the change in enhancement curve type and the change in tumor volume. Pharmacokinetic maps showed a positive correlation between tumour volume change and the difference in Ktrans, and a negative correlation with the change in Ve, at the third MRI scan.

CONCLUSION

Voxel-based analysis of tumors using DCE MRI shows promise for early prediction of overall tumour response, and may provide a useful biomarker for guiding patient management which is more reliable than RECIST criteria. DWI analysis did not provide a strong early indicator of treatment response.

CLINICAL RELEVANCE/APPLICATION

DCE MRI after SABR treatment for RCC may provide novel early response biomarkers which are more reliable than conventional CT based geometric RECIST response criteria.

SSG16-06 High Quality Volumetric CT Reduces PTV Margin for Radiotherapy of Prostate Cancer

Tuesday, Nov. 28 11:20AM - 11:30AM Room: S104A

Participants

young-bin.cho@rmp.uhn.on.ca

ABSTRACT

Purpose/Objective(s): To determine whether superior soft tissue contrast provided by high-dose-high-quality volumetric CT (HDVCT) scans can reduce inter-observer variability in prostate gland segmentation which may results in the reduction of PTV margin.Materials/Methods: Ten prostate patients receiving radiotherapy were imaged with conventional CT (CCT, 120kV, 300mAs), HDVCT (120kV, 2300mAs, 80 slices of volumetric scan) and 3T MRI (T2W) all with 2mm thickness. Five radiation oncologists delineated prostate gland on all three image sets, totaling 150 contoured target volumes. Inter-observer variability was measured along base/middle/apex, posterior/anterior, and left/right directions. Degree of target confidence was measured in terms of membership by counting the number of times that each image voxel (0.2mmx0.2mmx2.0mm) were enclosed by contours delineated by five observers. A modal target volume was defined by the voxels with the membership of 50% or more in each imaging modality used. PTV margin was calculated by expanding every 150 contours with a step size of 0.5mm to 10mm that guarantees 95% of the prescription dose to the modal target volume to more than 90% of patient population. When contours to be expanded and the modal target volume to be covered are from the same image modality, the PTV is called intra modal PTV margin, and with different imaging modality, it is called inter modal PTV margin. Intra and inter modal PTV were compared for each image modality. Results: Inter-observer variability was 2.0mm, 2.0mm, and 1.7mm on average and 2.5mm, 2.1mm and 2.0mm with the maximum in apex region for CCT, HDVCT, and MRI, respectively (pConclusion: Inter-observer variability in target delineation is a source of systematic uncertainty. HDVCT CT and MRI imaging demonstrated significant reduction in inter-observer variability and intra PTV margin compared to CCT. Inter modal PTV margin appears minimal with HDVCT (5mm) than CCT or MRI (6mm) although the average volume of HDVCT is smaller than that of CCT. Smaller target volume together with smaller inter/intra PTV margin for HDVCT is promising for radiotherapy planning of prostate cancer.

SSG16-07 Early Urinary and Sexual Toxicity Outcomes for Patients Receiving Proton Radiation for Prostate Cancer

PURPOSE

While proton therapy becomes increasingly available to patients with prostate cancer, only a few centers have published their clinical results to date. We present our 2-year results using proton beam therapy (PBT) to treat patients with prostate cancer.

METHOD AND MATERIALS

82 patients on an IRB approved institutional registry were treated with PBT from 2013-2015. CTCAE v4.0 was used to score toxicity. Univariate and multivariate Cox regression were performed to identify clinical and dosimetric predictors of toxicity.

RESULTS

For the 82 patients treated, 23 had low risk prostate cancer, 42 intermediate risk, and 17 high risk. 95% of patients received >=78 CGE. 25 patients received androgen deprivation therapy (ADT). Median follow up was 2 years. Time to PSA nadir was 1 year, with an average nadir of 0.5 ng/mL for patients treated with radiation alone without androgen deprivation. Two-year grade 2 and 3 GU toxicity were 22.0% and 1.2% respectively. Median time-to-event for G2+ urinary toxicty was 8 months. Univariate analysis showed a significant correlation between grade 2+ urinary toxicity and pretreatment prostate reductive procedures such as TURP

(p=0.009), ADT use (p=0.006), baseline IPSS score (p=0.02) and baseline IPSS bother score (p=0.01). Relative volume of bladder receiving 81 Gy was also significantaly related to G2+ urinary toxicity (p=0.04). On multivariate analysis, ADT use and baseline IPSS bother score correlated significantaly with grade 2+ toxicity (p=0.006 and p=0.01).Two year rates of grade 2 and 3 decline in erectile function were 19.5% and 1.2%, respectively. On univariate analysis, only age was significant for grade 2+ sexual toxicity (p=0.001). There were only two events of grade 2 hip pain.

CONCLUSION

Rates of grade 2+ urinary, sexual, and hip toxicities were acceptable after proton therapy for prostate cancer. The highest risk subgroup for developing urinary toxicity was men on ADT with high baseline IPSS bother scores. Future analysis will include larger patient numbers and longer follow up to better assess late treatment toxicities and PSA trends.

CLINICAL RELEVANCE/APPLICATION

Our preliminary results show acceptable rates of urinary, sexual, and hip toxicity in patients with prostate cancer treated with proton therapy, with adequate PSA response.

SSG16-08 Analysis of 2-Year Gastrointestinal Toxicity in Patients Receiving Proton Radiation Therapy for Prostate Cancer

PURPOSE

Increasing numbers of patients with prostate cancer are being treated with proton therapy. Theoretically, proton beam therapy (PBT) may have dosimetric advantages over photon radiation in treating a smaller region of the rectum. An ongoing randomized trial of proton versus photon therapy for prostate cancer has bowel toxicity as the primary endpoint (PARTIQoL). We present the 2-year bowel toxicity data for patients treated for prostate cancer at our proton center.

METHOD AND MATERIALS

82 patients on an IRB approved registry were treated with PBT from 2013-2015. CTCAE v4.0 was used to score bowel toxicity. Univariate Cox regression was performed to test correlations of baseline patient and dosimetric features with grade 2 or higher bowel toxicity.

RESULTS

For the 82 patients treated, 23 had low risk prostate cancer, 42 intermediate risk, and 17 high risk. Ninety-five percent of patients received >=78 CGE, and 4 patients received pelvic node radiation. 25 patients received androgen deprivation therapy. 33 patients were treated with uniform scanning, and 49 patients were treated with pencil beam scanning. Median follow-up was 2 years. Radiation proctitis with transient rectal bleeding was the predominant bowel toxicity after PT, accounting for 95% of events. Grade 1 toxicity occurred in 15 patients (18%), grade 2 in 20 patients (24%), and grade 3 in 1 patient (1.2%). There were no grade 4 or 5 events. Median time to developing rectal bleeding was 14 months (range 5-33). Univariate analyses showed borderline correlation between grade 2+ toxicity and hyperlipidemia (p=0.05). No other associations to clinical variables, including use of anticoagulation, were observed. Dose-volume histogram parameters did not show a statistically significant correlation with grade 2+ toxicity, but the best correlation was with rectal V70 (p=0.11). No difference in toxicity risk was found between uniform scanning versus pencil beam scanning techniques.

CONCLUSION

We report 2-year bowel toxicity results from our proton center experience treating prostate cancer. A larger patient series with longer follow up is underway to better delineate the risk factors for development of bowel toxicity with proton radiation.

CLINICAL RELEVANCE/APPLICATION

Our preliminary results show acceptable rates of bowel toxicity in patients with prostate cancer treated with proton therapy, our studies are ongoing with larger patient numbers and longer follow up.

SSG16-09 The Impact of Magnetic Resonance Imaging on Clinical Decision-Making in Patients Undergoing Prostate Brachytherapy

ABSTRACT

Purpose/Objective(s): Multiparametric magnetic resonance imaging (MRI) is increasingly being used to manage patients with prostate cancer. For brachytherapy (BT) patients, it can identify frank radiographic extracapsular extension (ECE) or seminal vesicle invasion (SVI) that may not be adequately covered by BT monotherapy. The objectives of our study were to identify predictors of ECE and SVI on MRI and determine how often MRI findings alter management in patients electing BT.Materials/Methods: We performed a retrospective cohort study of prostate cancer patients at our institution electing low dose rate (LDR) or high dose rate (HDR) BT and who underwent MRI prior to treatment. Patients with frank ECE or SVI on MRI were not recommended to undergo BT monotherapy and were offered either combined external beam radiotherapy + BT boost (CMT) or another approach. Clinical records were used to determine changes in physician recommendations due to MRI findings. Chi-Square tests were performed for univariate analysis (UVA) to determine covariates associated with ECE or SVI, including risk group, T-stage, Gleason score and group, prostate-specific antigen (PSA), percent positive cores (ppc; =50% vs. Results: The study cohort included 54 patients evaluated from August 2013 to January 2017 who elected BT (8 low risk, 40 intermediate risk and 6 high risk). 40 patients had cT1c disease, and 14 patients had cT2 disease. Median PSA was 6.51. 12 (22%), 30 (55%), 11 (20%), and 2 (4%) had Gleason group 1, 2, 3, and 5, respectively. 19 patients (35%) had =50% ppc. 13 patients had radiographic ECE (24%) and 2 (4%) had SVI. Only ppc =50% was associated with ECE (p=0.02); 15% of patients with ppc On MVA, ppc =50% continued to be associated with ECE (Odds Ratio 4.36, 95% Confidence Interval 1.17-16.3; p=0.29), but Gleason group did not (p=0.99). No variables predicted for SVI on UVA or MVA.No low risk or high risk patients had a change in recommendation due to MRI findings, but 20% (n=8) of the intermediate risk patients had a change in recommendation. 6 of these patients were switched from monotherapy to CMT due to ECE (and also SVI in 1 patient). One patient had hormonal therapy added to planned CMT. One patient had HDR recommended instead of LDR due to large gland size.Conclusion: MRI should be considered to help determine candidacy for BT monotherapy in intermediate risk prostate cancer patients and those with =50% ppc due to a higher risk of radiographic ECE that may not be adequately covered with monotherapy. Longer follow-up is needed to determine the impact on disease control.

maxime.ronot@aphp.fr

PURPOSE

Vascular arterial complications after orthotopic liver transplantation (OLT) are actively searched for and treated to prevent the development of ischemic cholangiopathy (IC). To date, very few studies have analyzed the long-term outcome of this policy. Therefore the aim of this study was to evaluate the long-term results of a systematic screening and treatment policy of impaired hepatic artery after OLT.

METHOD AND MATERIALS

Between 2003 and 2013, over 1048 liver transplantations, a total of 53 patients (42 men, age 19-69) were diagnosed and treated by endovascular techniques for early or late arterial complications such as stenosis, thrombosis, dissection or kinking of the hepatic artery. Radiological and surgical data were retrospectively analyzed and survivors were recalled to undergo follow-up Magnetic Resonance Cholangiopancreatography (MRCP) and duplex ultrasound (DUS) of the liver to identify vascular anomalies and ischemic cholangiopathy. Factors associated with IC were identified.

RESULTS

Technical success was 94%, and 6 patients experienced serious adverse event. After a median follow-up of 56.7 months (range 15.6-123.6) DUS of the hepatic artery showed normal values (resistive index, time to peak and maximum velocity) in 72% of the patients. Over the same period, 17 patients (32%) developed radiological features of IC with a mortality rate of 13% compare to 10% in patients without IC (p=0.0163). Patients with arterial complication appearing before 3 months have significantly more IC when compared to others (p=0.028). No other factor was associated with the occurrence of IC. Patients with IC had a significantly lower survival (median 77 months (95% IC 53 - 101) vs. not reached in patients without IC, p = 0.0163).

CONCLUSION

Systematic screening and endovascular treatment of arterial complication after OLT appears safe, efficient and is associated with good long-term outcome. Nevertheless, one third of the patients eventually develop IC, especially if arterial complications appear early after OLT.

CLINICAL RELEVANCE/APPLICATION

Systematic screening and endovascular treatment of arterial complication after OLT appears safe, efficient and is associated with good long-term outcome, event though one third of the patients eventually develop IC.

SSG17-02 Volumetric Phase Contrast MR Imaging (4D Flow) of Transjugular Intrahepatic Portosystemic Shunts

Tuesday, Nov. 28 10:40AM - 10:50AM Room: E351

Participants

Joseph W. Owen, MD, Saint Louis, MO (*Presenter*) Nothing to Disclose
Kathryn J. Fowler, MD, Saint Louis, MO (*Abstract Co-Author*) Nothing to Disclose
Nael E. Saad, MBBCh, Saint Louis, MO (*Abstract Co-Author*) Research Consultant, Veran Medical Technologies, Inc; Proctor, Sirtex Medical Ltd
Glenn Foster, RT, St. Louis, MO (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To demonstrate feasibility of interrogating transjugular intrahepatic portosystemic shunts (TIPS) with 4D Flow MR in patients with suspected TIPS dysfunction.

METHOD AND MATERIALS

Adult patients with suspected TIPS dysfunction were eligible for enrollment. A volumetric phase contrast sequence, with VENC 75-225 cm/sec, was used to image TIPS stents. Particle tracing CINE images were used for qualitative assessment of stenosis and stents were segmented to generate quantitative data sets of peak velocity. MR parameters were modified to improve image quality and post processing. Segmentation and quantitative measurement of flow throughout an entire TIPS stent defined technical success. Comparison was made to Doppler US and venogram (reference standards).

RESULTS

4D Flow MRA was performed in 23 encounters, was technically successful in 16/23 encounters, and failed in 7/23 encounters. The 3 cases which demonstrated both focal aliasing and abnormal velocities (>190cm/s or <90cm/s) on 4D Flow had venogram confirmed stenosis. The 4 cases which demonstrated elevated in-stent velocities >190 cm/s without focal aliasing, and the 2 cases with aliasing but normal velocities, did not have stenosis. Suboptimal imaging was due to low signal-to-noise related to FOV (3/5), ascites (1/5), or incorrect VENC selection (1/5). Failure of imaging occurred due to presence of stainless steel stent (2/7), improper FOV (3/7), incorrect VENC (1/7), and data corruption (1/7).

CONCLUSION

4D Flow MRA may be a feasible modality for the evaluation of TIPS stent dysfunction after protocol optimization and with careful patient selection to increase technical success

CLINICAL RELEVANCE/APPLICATION

4D Flow MRA is a promising modality for the evaluation of transjugular intrahepatic portosystemic shunt (TIPS) dysfunction, and could be incorporated into routine Liver MR protocols for improved surveillence of TIPS stents.

SSG17-03 Transhepatic Portomesenteric Stenting Improves Outcomes in Cancer Patients with Extrahepatic Portomesenteric Venous Stenosis/Occlusion

rasheth@mdanderson.org

PURPOSE

To compare serologic and clinical outcomes between conservative management versus stenting in cancer patients with extrahepatic portomesenteric venous stenosis or occlusion.

METHOD AND MATERIALS

A single institution, IRB-approved retrospective review of all patients with extrahepatic portomesenteric venous occlusion or stenosis (PVO) from 2007-2015 was performed. A total of 347 patients were identified, of whom 38 underwent portomesenteric venous stenting (PVS). To reduce selection bias, a propensity score matching algorithm was used in a 2:1 ratio to create a subset of non-stent patients from the remainder of the 309 patients that were matched with the PVS cohort in age, underling malignancy, and extent of PVO. These matched 76 patients comprised the non-stent comparison cohort. Univariate and multivariate analyses of serologic and clinical parameters was performed between the two cohorts.

RESULTS

Of the 114 patients, pancreatic cancer was the most common malignancy (68/114, 60%), followed by cholangiocarcinoma (16/114, 14%). Stenosis or occlusion involved greater than one portomesenteric vein in the majority of patients (93/114, 82%). In the PVS cohort, stent deployment involved greater than one portomesenteric vein in most patients (32/38, 84%). Technical success for PVS was 95% (36/38), with no major or minor complications. In the non-stent cohort, 50% of patients (38/76) were treated with systemic anticoagulation, with 50% of patients unable to be anticoagulated due to history of bleeding and/or thrombocytopenia. While there was a significant decrease in serum albumin ($P < 0.01$) and platelet counts ($P = 0.01$) in the non-stent cohort at 6 months following the diagnosis of PVO, albumin ($P = 0.4$) and platelet levels ($P = 0.8$) were maintained in the PVS cohort after stenting. There was also a significant increase in the proportion of non-stent patients with symptomatic ascites ($P < 0.001$) following PVO diagnosis compared to a significant decrease in the PVS group ($P < 0.01$). There was a significant increase in survival amongst the PVS cohort ($P = 0.02$).

CONCLUSION

In appropriately selected cancer patients with PVO, PVS can reduce the development of ascites, maintain platelet and albumin counts, and possibly increase survival.

CLINICAL RELEVANCE/APPLICATION

PVS is a safe, highly technically feasible intervention that improves clinical and serologic outcomes in cancer patients with PVO.

SSG17-04 Cross-Sectional Imaging (CSI) Findings Predict Clinically Significant Portal Hypertension (pHTN): Correlation with Direct Hepato-Portal Venous Gradient (HPVG) and Portosystemic Gradient (PSG) Manometry

Tuesday, Nov. 28 11:00AM - 11:10AM Room: E351

For information about this presentation, contact:

andrew.renaldo@gmail.com

PURPOSE

To investigate the prognostic value of CSI findings of pHTN through correlation with direct HPVG and PSG manometry values.

METHOD AND MATERIALS

IRB approved HIPAA compliant study of 100 consecutive patients (Mean age 55.4 [20-77] yrs, 44% female, 56% male) with suspected pHTN who underwent transjugular liver biopsies from Nov 2014 to Nov 2016. PSGs (difference between right atrial and wedge pressures) and HPVGs (difference between free hepatic and wedge pressures) were recorded for all cases. CT and MRI were used to record secondary signs of pHTN (i.e., hepatic hydrothorax, ascites, varices, umbilical vein recanalization, venous shunts) and measure liver, spleen, left renal, and main portal vein diameters. Overall liver morphologies were noted. Portal venous flow direction was confirmed with Doppler. Each variable was correlated with PSGs and HPVGs. Pressure gradients >5 mmHg defined pHTN, while >=10 mmHg defined clinically significant pHTN. Characteristic differences between groups were compared using Chi-Square utilizing SPSS software v20.0 (IBM, Armonk, NY). Significance was set at <0.05.

RESULTS

Of the 100 subjects, 90% had pHTN (30% alcohol-related, 19% Hep C, 3% Hep B, 9% NASH, 29% cryptogenic), 10% had normal pressures, and 70% had stage III/ IV fibrosis. Average PSG was 17 mmHg (s=9), while the average HPVG was 13 mmHg (s=8). Variables predicting a PSG >10 mmHg included hepatofugal flow (p=0.000), liver diameter <15 cm (p=0.034), spleen >11 cm (p=0.029), hydrothorax (p=0.004), ascites (p=0.000), esophageal varices (p=0.000), gastric varices (p=0.006), perisplenic varices (p=0.031), omental varices (p=0.001), recanalized umbilical vein (p=0.029), gastrorenal shunt (p=0.000), and an IMV to superior rectal shunt (p=0.023). Variables predicting HPVG >10 included a hepatofugal flow (p=0.000), liver diameter <15 cm (p=0.047), spleen >11 cm (p=0.002), hydrothorax (p=0.018), ascites (p=0.001), esophageal varices (p=0.001), gastric varices (p=0.006), perisplenic varices (p=0.002), omental varices (p=0.000), recanalized umbilical vein (p=0.001), gastrorenal shunt (p=0.001), and an IMV to superior rectal shunt (p=0.017).

CONCLUSION

CSI findings can predict clinically significant pHTN and may thus guide patient prognosis and clinical decision-making for specific associated pathologies.

CLINICAL RELEVANCE/APPLICATION

Specific findings on CSI reliably correspond to PSGs and HPVGs, can predict clinically significant pHTN, and may justify forgoing additional invasive interventions.

SSG17-05 Hepatofugal Flow in the Main Portal Vein Prior to Transjugular Intrahepatic Portosystemic Shunt (TIPS) as a Predictor for Post-TIPS Variceal Embolization in Patients with Gastrointestinal Bleeding

Tuesday, Nov. 28 11:10AM - 11:20AM Room: E351

For information about this presentation, contact:

maureen.kohi@ucsf.edu

PURPOSE

To investigate whether hepatofugal flow (HF) in the main portal vein (MPV) prior to transjugular intrahepatic portosystemic shunt (TIPS) creation can serve as a predictor for post TIPS variceal embolization in patients with gastrointestinal (GI) bleeding.

METHOD AND MATERIALS

A retrospective review of consecutive patients with GI bleeding who underwent TIPS from 1/2007 to 1/2017 was conducted. Pre-

and post-TIPS portosystemic pressure gradients and embolization of varices were reviewed. The directionality of the blood flow in the MPV prior to TIPS creation was determined to be HF or hepatopedal (HP) by a fellowship trained interventional radiologist blinded to the purpose of this study. Variceal embolization data was analyzed using the Fisher's exact test and mean post-TIPS portosystemic pressure gradients was analyzed using the student's T -test. A P value less than 0.05 was considered statistically significant.

RESULTS

40 patients were identified. The predominant causes of cirrhosis were hepatitis C and alcohol abuse. 24 patients demonstrated HP flow and 16 patients had HF flow. Of the 24 patients with HP flow, 6 patients (25%) required coil embolization post TIPS. This is compared to the 10 out of 16 patients (62.5%) with HF flow who underwent post-TIPS embolization, (p = 0.0245). Post TIPS portosystemic pressure gradient in the HP group was 6 mm Hg compared to 8 mm Hg (p = 0.058). Pre-TIPS portosystemic pressure gradient was not significantly different between the two groups.

CONCLUSION

In the setting of GI bleeding, HF blood flow in the MPV prior to TIPS creation may serve as a predictor for requiring post-TIPS variceal embolization.

CLINICAL RELEVANCE/APPLICATION

Pre-TIPS portograms are an essential part of imaging required for measuring the length of the shunt. Our group continues derive as much information from this imaging study, including consistent markers, that can be used best prepare Interventional Radiologists prior to TIPS procedures. In this study, we have demonstrated an association between the presence of HF flow on pre-TIPS portograms and the probable need for coil embolization in-TIPS procedure. Of course, larger scale studies are required to validate the data, including prospective randomized trials. In addition, we have shown a possible trend between HF flow demonstrated on pre-TIPS imaging predicting a post-TIPS pressure gradient of 6 mm Hg or more. Further data is required to validate this trend.

SSG17-06 Large Spontaneous Portosystemic Shunts in Therapy-Refractory Cirrhotic Patients: A Clear Definition of Risks and Tricks of Endovascular Management

Tuesday, Nov. 28 11:20AM - 11:30AM Room: E351

PURPOSE

This study aimed to analyze the efficacy and safety of embolization of large spontaneous portosystemic shunts (SPSS) in cirrhotic patients with recurrent hepatic encephalopathy (HE).

METHOD AND MATERIALS

From February 2002 to January 2017, a prospective study of chronic therapy-refractory HE patients who underwent SPSS embolization was performed. Inclusion criteria: refractory chronic HE (recurrent episodes of HE without known precipitant and >=2 hospital admissions because of HE after the start of standard therapy), exclusion criteria: absence of cirrhosis, surgical shunt or TIPS graft, portal vein thrombosis, preexisting hepatocellular carcinoma, Child-Pugh class C13. Analysis and outcome parameters: baseline characteristics, diagnostic workup, therapeutic method, clinical and radiological outcomes.

RESULTS

Forty consecutive patients were found eligible according to inclusion and exclusion criteria. Mean age at treatment was 62.5±13.9, 55.0% male. Chronic liver damage: alcoholic abuse (36.7%), HCV (23.4%), cryptogenic (20.0%), non-alcoholic steatohepatitis (13.3%), primary biliary cirrhosis (3.3%), autoimmune hepatitis (3.3%). Prior to embolization, five patients had liver transplants. SPPS characterization: Doppler-Color Ultrasound, CT-Angiography, indirect Portography. SPSS types: spleno-renal (68.4%), meso-caval/renal (15.8%), gastro-acygos/renal (10.5%), recanalized para-umbilical veins (5.3%). Approaches: common femoral vein (60.0%), internal jugular vein (30.0%), transhepatic (6.7%), transplenic (3.3%). Materials: coils (28.5%), occlusion devices (25.0%), liquid agents (7.2%), combination (39.3%). Secondary procedures were performed in four patients after identification of revascularized SPSS. Follow-up range: 3-31 months. All patients improved autonomy and decreased severity of the worst HE episode. One patient had transient low cardiac output due to acute shunt-closure. There were no other procedure-related complications, portal hypertensive gastropathy or varices development.

CONCLUSION

SPSS embolization is an effective and safe complementary or curative treatment for HE persistence in cirrhotic patients, even after liver transplantation, improving quality of life by reduction of hospitalizations.

CLINICAL RELEVANCE/APPLICATION

The presence of large SPSS provides an explanation for hepatic encephalopathy persistence in cirrhotic patients and represents a therapeutic target in chronic medically refractory HE patients.

SSG17-07 Non-Invasive Pressure Monitoring After Transjugular Intrahepatic Portosystemic Shunt Implantation with Integrated Stent-Graft

PURPOSE

In vitro and ex vivo testing of a novel stent-graft with integrated pressure sensors capable of wirelessdigital data transmission for non-invasive pressure monitoring after TIPS.

METHOD AND MATERIALS

Ten stent-grafts for TIPS-implantation (100x10 mm) were designed including integrated pressure sensors at both ends within layers of polytetrafluorethylen (PTFE). Digital data conversion could be performed by integrated microcontrollers within the PTFE-membrane providing energy and datatransfer by inductive coupling. The stent-grafts were placed in a silicone liver phantom and in explanted porcine livers via 16F applicators.

RESULTS

First in vitro and ex vivo testing demonstrated a capable TIPS stent-graft design with integrated sensors in a stable PTFE-covering after crimping and application into a liver phantom and 4 porcine livers. In both setups measurements were simultaneously taken from the two sensors with an accuracy of ±1.2 mmHg up to a distance of 10 cm in a liver phantom and a distance of 8 cm in a porcine liver.

CONCLUSION

First in vitro and ex vivo results demonstrate a successful approach for non-invasive pressuremonitoring after TIPS by integrated sensors within a PTFE-cover. Further in vivo tests are required before the potential implementation into a product.

CLINICAL RELEVANCE/APPLICATION

Non-invasive pressure acquisition after TIPS via integrated sensors with the PTFE-membrane provides a suitable and precise way of monitoring patency.

SSG17-08 Clinical Significance of Abnormal findings on Baseline Transjugular Intrahepatic Portosystemic Shunt Doppler Sonography

Tuesday, Nov. 28 11:40AM - 11:50AM Room: E351

Participants
Peiman Habibollahi, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose
Sara Pourhassan Shamchi, MD , Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose
Charles N. Weber, MD, Boston, MA (*Abstract Co-Author*) Nothing to Disclose
Gregory J. Nadolski II, MD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose
Jill E. Langer, MD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose
Anil Chauhan, MD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Doppler Sonography (DS) is frequently performed as a screening and diagnostic modality to evaluate the transjugular intrahepatic portosystemic shunt (TIPS). However, the clinical significance of initial frequently observed abnormalities of flow velocities, gradient and flow direction on baseline DS is less studied.

METHOD AND MATERIALS

A retrospective study was performed at a large referral center between 2002 and 2010 and all patients undergoing TIPS procedure for the management of portal hypertension (PHTN) were initially included. Patients without sufficient medical records or US examinations were excluded. Electronic medical records were reviewed and baseline DS findings as well as clinical data regarding recurrent symptoms of portal hypertension, and findings of TIPS angiography/revision studies were recorded. Abnormal DS indices were defined as peak intra-shunt velocities (PSV) <90 or >190 cm/sec, intra-shunt gradient >50 cm/s and abnormal flow direction in main, right or left portal veins.

RESULTS

195 patients underwent TIPS during the study period. 34 patients were excluded due to lack of clinical or sonographic follow up. Indication for TIPS was uncontrolled ascites in 95 (59%) and bleeding secondary to PHTN in 66 patients (41%). Median follow up was 24.6 months. During follow up period, PHTN symptoms recurred in 37 patients out of which 33 patients underwent TIPS angiography/revision. With regards to baseline US, Low PSVs were present in 54 (33.5%), normal PSVs in 96 (59.6%) and high PSVs in 9 patients (5.6%) while in 2 patients shunts were occluded. There was significantly lower rate of stenosis diagnosed on TIPS angiography/revision in patients with baseline low velocity PSVs (2/10 (20%) in patients with low PSVs compared to 14/21 (66.7%) and 1/2 (50%) in patient with normal and high baseline PSVs, p-value=0.02). There was no significant relationship between presence of abnormal intra-shunt gradient or abnormal flow direction on baseline DS and development of stenosis during follow up (p>0.05).

CONCLUSION

These findings suggest that in the absence of clinical findings of shunt failure, abnormal findings on baseline TIPS DS have low yield

for predicting development stenosis and recurrent PHTN.

CLINICAL RELEVANCE/APPLICATION

In the absence of other indicators of portal hypertension and shunt failure, abnormal findings on TIPS baseline DS may be safely observed without need for immediate invasive procedures.

SSG17-09 Delineation of Hepatic Veins: Comparison of Magnetic Resonance Angiography Using Spatial Labeling with Multiple Inversion Pulses, Perfusion-Weighted Imaging and Computer Tomography Angiography

Tuesday, Nov. 28 11:50AM - 12:00PM Room: E351

zhudi0304@163.com

PURPOSE

To evaluate and compare the visualization of hepatic veins by non-contrast-enhanced magnetic resonance angiography (MRA) using spatial labeling with multiple inversion pulses (SLEEK) with magnetic resonance perfusion-weighted imaging (PWI) and computer tomography angiography (CTA).

METHOD AND MATERIALS

SLEEK-MRA and CTA were performed on 20 patients with liver diseases. For visualization of hepatic veins, one inversion pulse was placed to cover the heart to suppress the signal in the hepatic artery, while the other beneath the bottom edge of liver to suppress the inflow signal of portal system. Subsequently 9 of the patients were examined with PWI. The visualization quality score of hepatic veins was scored on a four-point scale for assessment of left hepatic vein (LHV), middle hepatic vein (MHV) and right hepatic vein (RHV). On the original images of SLEEK-MRA, PWI and CTA, regions of interest were placed in LHV, MHV, RHV and homogenous liver parenchyma to acquire signal intensity and standard deviation. Contrast ratio (CR) of vessels to liver parenchyma, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. The visualization quality was analyzed with Wilcoxon signed-rank test. The CR, SNR and CNR were analyzed with paired t-test. A p value of <0.05 was considered statistically significant.

RESULTS

Compared to CTA, SLEEK-MRA revealed significantly higher visualization quality score, SNR, CNR and CR in MHV (3.2±0.6 vs 2.1±1.0, 37.3±10.2 vs 6.3±1.6, 19.1±9.1 vs 1.5±0.5, 2.1±0.5 vs 1.3±0.1) and RHV (3.0±0.7 vs 2.1±1.0, 36.3±7.5 vs 6.5±1.6, 18.2±5.6 vs 1.7±0.8, 2.0±0.3 vs 1.4±0.2)($p<0.01$), while significantly higher SNR, CNR and CR in LHV (32.1±8.6 vs 6.2±1.8, 12.9±6.7 vs 1.5±0.8, 1.7±0.3 vs 1.3±0.1)($p<0.01$). Compared to PWI, SLEEK-MRA revealed significantly higher CNR and CR in LHV (11.2±4.0 vs 6.0±3.8, 1.6±0.2 vs 1.2±0.2) and MHV (18.3±8.7 vs 7.3±2.6, 2.0±0.4 vs 1.3±0.1)($p<0.01$), as well as in RHV (16.7±6.4 vs 9.3±2.9, 1.9±0.3 vs 1.4±0.2)($p<0.05$). No statistically significant difference was found for visualization quality score and SNR in hepatic veins.

CONCLUSION

SLEEK-MRA visualizes hepatic veins in high quality and better contrast than traditional contrast-enhanced CTA and PWI.

CLINICAL RELEVANCE/APPLICATION

SLEEK-MRA provides a method to selectively delineate hepatic veins with high image quality and contrast to the liver background, while free from exogenous contrast media.

PURPOSE

To assess one-view digital breast tomosynthesis (DBT) and a combination of one-view DBT and one-view digital mammography (DM) compared to two-view DM in population-based screening.

METHOD AND MATERIALS

This is a prospective, one-arm, single-institution, population-based screening trial involving 14,848 women aged 40-74 years randomly invited from the service screening programme in an urban area, Jan 2010-Feb 2015. Women underwent one-view DBT (mediolateral oblique view) with reduced compression force and two-view DM at one screening occasion. Images were read in two separate reading arms (DBT reading arm and DM reading arm) with independent double reading and scoring. The reading sequence in the DBT arm was: 1. one-view DBT; 2. one-view DBT + cranio-caudal view of DM; 3. addition of prior two-view DM if available. McNemar's test with 95 % confidence intervals was used to compare detection and recall rates.

RESULTS

In total, 137 women had screen-detected cancers in the trial (one bilateral case). Eighty-eight of the cases were detected with both DBT and DM, 41 were detected only in the DBT reading arm and eight only in the DM reading arm. The breast cancer detection rate was 8.7/1000 screened women in the DBT reading arm (95% CI: 7.3-10.3) and 6.5/1000 screened women in the DM reading arm (95% CI: 5.2-7.9). The relative increase in cancer detection in the DBT reading arm vs. DM was 34.4% (95% CI: 18.8-52.0, $p<0.001$). All but two cancers in the DBT reading arm were detected in the first reading step, i.e. one-view DBT alone. The recall rate after arbitration in the DBT reading arm was 3.6% (95% CI 3.3-3.9) and for the DM reading arm 2.5% (95% CI 2.2 -2.8), a statistically significant increase, $p<0.001$.

CONCLUSION

Breast cancer screening using one-view DBT with reduced compression increases cancer detection significantly at a reasonable recall rate and seems to be a feasible screening strategy.

CLINICAL RELEVANCE/APPLICATION

It is a well-recognized fact that DM has its limitations as a stand-alone screening modality. DBT represents an advancement of the mammographic technique. The results of the current trial indicate that DBT as a stand-alone screening modality is feasible and the reduced compression force may represent a further benefit potentially encouraging more women to attend screening.

SSJ01-02 Detection of Ductal Carcinoma in Situ in the Experimental Arm of a Trial Comparing Tomosynthesis plus Digital Mammography vs Digital Mammography

PURPOSE

While higher sensitivity for invasive cancers of tomosynthesis (DBT) compared to digital mammography (DM) has been showed in many studies, there are inconsistent results if DBT is more sensitive than DM in detecting ductal carcinoma in situ (DCIS). Here we present the results of detection of DCIS in the preliminary analysis of the RETomo trial by arm and imaging results.

METHOD AND MATERIALS

Women (45-70yo) presenting for a screening mammography in Reggio Emilia, were asked to participate and, if willing, randomized to the experimental arm (DBT+DM), or to the control arm (DM), both with double reading. Results of the DBT alone were recorded separately, but women were managed according to the joined evaluation DBT+DM (NCT02698202). Relative detection rate of DCIS in the experimental arm compared to control arm is reported; DCIS detected in the experimental arm are presented in detail by results of DBT alone and DBT+DM. Images with discordant DBT and DBT+DM reports were submitted to informed review by a third independent radiologist.

RESULTS

From March 2014 to March 2016 approximately 19637 women were recruited, 9854 in the experimental arm. The overall detection rate was 8.2/1000 and 4.5/1000 in the experimental and control arm respectively (relative detection rate 1.83, 95% confidence interval (CI) 1.26-2.64). DCIS were 14 and 5 in the experimental and control arm respectively (relative DCIS detection 2.85, 95%CI 1.03-7.90). Six out of 14 DCIS of the experimental arm were reported as negative by both readings, while were recalled when DM was analysed together with DBT. Among invasive cancers in the experimental arm, only 2 out of 65 were negative to both DBT readings. The post-hoc informed revision showed that DBT-negative DCIS were visible as microcalcifications. Only the comparison of DM with previous screening mammograms led to suspect of malignancy.

CONCLUSION

DBT+DM increases the detection of DCIS compared to DM alone. In a low prevalence setting where low recall rate is pre-fixed target for readers, the identification of DCIS needs careful evaluation of priors to pose the suspect of malignancy.

CLINICAL RELEVANCE/APPLICATION

DBT+DM increases the detection of DCIS compared to DM alone, but, in the evaluation of microcalcifications, to pose the suspect of malignancy 2D images for comparison are needed.

SSJ01-03 Screening Mammography Findings from One Standard Projection Only in Era of Full Field Digital Mammography and Tomosynthesis

Tuesday, Nov. 28 3:20PM - 3:30PM Room: Arie Crown Theater

Participants
Ethan O. Cohen, MD, Houston, TX (*Presenter*) Spouse, Consultant, Medtronic plc; Spouse, Consultant, Novo Nordisk AS; Spouse, Consultant, Eli Lilly and Company; Spouse, Consultant, AstraZeneca PLC
Hilda H. Tso, DO, Houston, TX (*Abstract Co-Author*) Nothing to Disclose
Ray C. Mayo III, MD, Houston, TX (*Abstract Co-Author*) Nothing to Disclose
Kanchan Phalak, MD, Houston, TX (*Abstract Co-Author*) Nothing to Disclose
Jessica W. Leung, MD, Houston, TX (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

ecohen@mdanderson.org

PURPOSE

To compare outcomes of findings seen on one view only from full-field digital screening mammograms (FFDM) and FFDM with tomosynthesis (FFDM-DBT).

METHOD AND MATERIALS

An IRB-approved, HIPAA-compliant retrospective review was performed of 103,070 consecutive screening mammograms obtained from February 2011 through June 2014 at two community-based breast centers. Recalled findings prospectively seen on one view only were analyzed. Pearson's chi-squared test and Fisher's exact test were performed, and 95% CIs were determined.

RESULTS

The study included 71,656 FFDM and 31,414 FFDM-DBT. Overall, 5641 of the 71,656 FFDM (7.9%) and 1914 of the 31,414 FFDM-DBT (6.1%) were recalled, and 2213 of the recalled FFDM and 433 of the recalled FFDM-DBT revealed findings on only one view. 689 FFDM and 92 FFDM-DBT were excluded for insufficient mammographic follow-up(<24 months). Significantly more FFDM than FFDM-DBT had a one-view-only finding (3.1% vs 1.4%; p<0.0001). Summation artifacts accounted for more one-view-only findings from FFDM (1067 of 1592, 67.0%) than FFDM-DBT (190 of 354, 53.7%) (p<0.0001). In the FFDM cohort, 28 one-view-only findings proved malignant (24 invasive ductal carcinoma [IDC], 1 invasive lobular carcinoma [ILC], 3 ductal carcinoma in situ [DCIS]). In the

FFDM-DBT cohort, 14 one-view-only findings proved malignant (11 IDC, 1 ILC, 2 DCIS). The positive predictive value (PPV) of a one-view-only finding was significantly lower for FFDM (1.76%) than FFDM-DBT (3.95%) (p=0.010).

CONCLUSION

One-view-only screening mammography findings that prompt recall are more frequent, are more likely to represent summation artifacts, and have a lower PPV with FFDM than with FFDM-DBT.

CLINICAL RELEVANCE/APPLICATION

One-view-only findings are not uncommonly recalled at screening mammography, and to our knowledge, their outcomes have not been analyzed since the advent of digital imaging. Radiologists should be aware of the differences between one-view-only findings from FFDM versus FFDM-DBT and apply this to clinical practice.

SSJ01-04 Radiation Dose from Tomosynthesis and Digital Mammography versus Quantitative Breast Density

Tuesday, Nov. 28 3:30PM - 3:40PM Room: Arie Crown Theater

Participants
Gisella Gennaro, PhD, Padua, Italy (*Presenter*) Nothing to Disclose
Daniela Bernardi, MD, Trento, Italy (*Abstract Co-Author*) Nothing to Disclose
Nehmat Houssami, MBBS, Sydney, Australia (*Abstract Co-Author*) Nothing to Disclose
Ralph P. Highnam, PhD, Wellington, New Zealand (*Abstract Co-Author*) CEO, Matakina Technology Limited CEO, Volpara Solutions Limited

For information about this presentation, contact:

gisella.gennaro@iov.veneto.it

PURPOSE

To compare radiation dose by digital breast tomosynthesis (DBT) and digital mammography (FFDM) counting for breast density.

METHOD AND MATERIALS

4764 breast paired views (cranio-caudal, CC, and medio-lateral oblique, MLO) were obtained by the same acquisition system with DBT and FFDM, keeping the same breast compression (COMBO mode) and using the automatic exposure mode. Raw images were processed to compute volumetric breast density. Mean glandular dose (MGD) was calculated for both image modalities, according to the model proposed by Dance, using breast density (BD) to adjust the estimated MGD. Quantitative breast density values were groupped in four categories (A, B, C, D) and MGD of DBT and FFDM was compared for each BD class. The dose ratio was determined by dividing MGD DBT by MGD FFDM dose for each pair.

RESULTS

The mean MGDs for the four breast density categories (A, B, C, D) were higher with tomosynthesis than mammography (DBT: 3.062, 2.551, 1.832, 1.430 mGy, DM: 1.900, 1.721, 1.365, 1.121 mGy),. DBT dose correlates differently with FFDM dose, depending on the breast density class. The mean dose ratio (DBT/FFDM) was 1.617 for breast density class A, 1.495 for class B, 1.375 for C, and 1.305 for D, showing that tomosynthesis dose increase compared to mammography is higher for fatty breasts than for dense breasts.

CONCLUSION

Radiation dose per-view is higher with tomosynthesis compared to mammography. Dose increase is higher for fatty breasts and lower for dense breasts.

CLINICAL RELEVANCE/APPLICATION

Digital breast tomosynthesis radiation dose is slighly higher than digital mammography. The increase is lower for dense breasts.

SSJ01-05 Digital Breast Tomosynthesis Cancer Screening versus Full Field Digital Mammography Cancer Screening: Imaging and Pathological Features

Tuesday, Nov. 28 3:40PM - 3:50PM Room: Arie Crown Theater

francesca.caumo@aulss9.veneto.it

PURPOSE

To evaluate imaging characteristics, size, grade, type, node status and biological features of cancers detected by digital breast tomosynthesis plus synthesized 2D images (DBT+synt2D) in a breast cancer screening program, compared with those found with full-field digital mammography (FFDM).

METHOD AND MATERIALS

All consecutive breast cancers diagnosed in 16666 women screened by DBT+synt2D (April 2015 to March 2016; DBT group) and in 14423 women screened by FFDM (April 2014 to March 2015; FFDM group) were retrospectively reviewed. Radiological characteristics, cancer size, grade, type (ductal, lobular, tubular, other), node status and biological features (oestrogen and progesterone receptors, Ki-67, HER2/neu) were compared between the two groups.

RESULTS

Cancer detection rate (CDR) was 9.78/1000 in DBT group versus 5.34/1000 in FFDM group (RR 1.83, 95% CI 1.40-2.40). DBT findings included opacity in 68.1% (versus 58.4% at FFDM) and architectural distortion in 9.2% of cases (versus 2.6% at FFDM) (p=0.029). The CDR for invasive cancers was 8.58/1000 in DBT group versus 4.02/1000 in FFDM group (p=0.01). The size of invasive cancers was significantly smaller in DBT group versus FFDM group (median 13.4 mm vs 16.4 mm, p=0.001). More low-grade invasive cancers were detected in DBT group versus FFDM group: 31.9% versus 11.7%, respectively (p=0.01). No differences were found in cancer type (p=0.224), with a prevalence of invasive ductal carcinoma in both groups (63.8% and 59.7%, respectively). Node status was similar between the two groups (p=0.091). More HER2 negative cancers were detected in DBT group (91.6%) versus FFDM group (79.3%; p=0.01) while no differences were found in oestrogen and progesterone receptors expression and in the Ki67 proliferation index (p>0.05).

CONCLUSION

Breast cancer screening with DBT+synt2D increases overall breast cancers detection, with a preferential increase in the detection of invasive cancers, improving visualization of opacities and architectural distortions. Additional breast cancers found are more likely to be smaller, low-grade, ductal type and HER2 negative, with important prognostic and predictive implications.

CLINICAL RELEVANCE/APPLICATION

The analysis of cancers detected by DBT has prognostic and treatment significance and could be the initial step to address concerns about DBT contributing to overdiagnosis.

SSJ01-06 Comparing Two Visualization Protocols for Tomosynthesis in Screening: Specificity and Sensitivity of Slabs vs Slabs plus Planes

valentina.iotti@asmn.re.it

PURPOSE

There is growing evidence that tomosynthesis (DBT) is more sensitive than digital mammography (DM), but its introduction in screening is limited by longer reading times. Simplified visualization protocols have been designed to reduce reading time. In this study we compared the accuracy of simplified protocol with slab (1 cm thickness, overlapped 0.5 cm) alone vs. a standard protocol of slab plus planes (1 mm thickness, continuous). Both were integrated with synthetic-2D (Sy2D).

METHOD AND MATERIALS

Two expert screening radiologists retrospectively examined 906 randomly selected DBT from the RETomo screening trial experimental arm, where women received DBT+DM. Only women that were positive at the screening reading were assessed for cancer. All the DBT were read by both radiologists with both protocols after 3 months wash-out period. The order of reading was randomly assigned to have half of the sample read before with simplified and half with standard protocol. We present sensitivity, specificity and kappa values for inter-reader agreement.

RESULTS

Among the 906 women, 24 were recalled and 12 had a cancer (including 2 in situ). With the simplified protocol readers correctly classified as positive 15 out of 24 readings of women with cancer: 4 cancers were missed by both readers and one by only one, for a total of 9 false negative readings (sensitivity 63%, 95% confidence interval (CI) 41-81); 20 in the standard protocol (sensitivity 83%, 95%CI 62-95) (p=0.1). Among women who did not have evidence of cancer, the simplified protocol correctly classified as negative 1727 out of 1788 readings (specificity 96.6%, 95%CI 95.6-97.4); the standard protocol correctly classified 1699 readings (specificity 95.0%, 95%CI 93.9-96.0) (p=0.006). Inter-reader agreement was 0.53 and 0.36 with simplified and standard protocol, respectively.

CONCLUSION

A simplified protocol (Sy2D+slabs) increased the specificity and reproducibility of reading in a screening population, but had a negative impact on sensitivity. The study will be completed with the analysis of a DBT set enriched of cases in order to have a more precise estimate of sensitivity.

CLINICAL RELEVANCE/APPLICATION

To overcome the longer reading time for DBT in screening, a simplified protocol (synthetic2D+slabs) increased the specificity and reproducibility of readings, but with negative impact on sensitivity.

PURPOSE

To determine whether a predictive model for contrast-enhanced ultrasound (CEUS) of the breast can improve the precision of breast imaging reporting and data system (BI-RADS) categorization.

METHOD AND MATERIALS

A total of 730 patients with 742 solid breast lesions classified as BI-RADS 4 or 5 on conventional ultrasound and mammography were evaluated. CEUS was performed before core needle biopsy or surgical resection and a revised BI-RADS classification was assigned based on six predictive models for CEUS of malignant and benign breast lesions analyzed on 10 enhancing patterns. Receiver operating characteristic curve analysis was conducted to evaluate the diagnostic performance of CEUS-based BI-RADS assignment with pathological examination as reference criteria.

RESULTS

The CEUS-based BI-RADS evaluation classified 262/742 (35.31%) lesions into category 3, 43 (5.79%), 27 (3.64%), and 47 (6.33%) lesions into categories 4A, 4B and 4C, respectively, and 363 (48.92%) into category 5, compared with 276/742 (37.19%), 199 (26.82%), 93 (12.53%), and 172 (23.18%) in BI-RADS 4A, 4B, 4C, and 5 based on conventional ultrasound and mammography. Selecting CEUS-based BI-RADS category 3 as an appropriate cutoff resulted in accuracy, sensitivity, specificity, and positive and negative predictive values of 80.05%, 98.26%, 64.32%, 70.42%, and 97.71%, respectively, for the diagnosis of malignant disease. The cancer-to-biopsy yield was 64.3% with CEUS-based BI-RADS 3 selected as the biopsy threshold compared with 46.42% otherwise, while the biopsy rate was only 72.2% compared with 100% otherwise. Overall, only 1.74% of invasive cancers were misdiagnosed as BI-RADS 3, the category we use nowadays.

CONCLUSION

In our patient cohort, evaluation of BI-RADS 4 or 5 breast lesions with CEUS results in reduced biopsy rates and increased cancer-to-biopsy yield.

CLINICAL RELEVANCE/APPLICATION

CEUS can improve the BI-RADS with reduced biopsy rates and increased cancer-to-biopsy yield.

SSJ02-02 Correlation of Quantitative and Qualitative US Indexes of Tumor Vascularity with Histologic Vascular Parameters in Breast Masses: Superb Microvascular Imaging (SMI) and Contrast-enhanced US

(CEUS)

PURPOSE

To investigate the correlation between quantitative and qualitative ultrasound (US) indexes of tumor vascularity on Superb Microvascular Imaging (SMI) and contrast-enhanced ultrasound (CEUS) and histologic vascular parameters in breast masses.

METHOD AND MATERIALS

This prospective study was approved by the institutional review board and written informed consent was obtained. Ninety-eight suspicious solid breast masses (57 benign and 41 malignant) were examined by SMI and CEUS prior to biopsy. We used Aplio 500 US equipment (Toshiba Medical Systems Corporation, Japan) and SonoVue contrast agent (Bracco, Italy). Two radiologists analyzed quantitative and qualitative vascularity indexes of SMI (vascular index, vessel morphology, distribution, and penetrating vessel) and CEUS (time intensity curve parameters and enhancement pattern). Histological vascular parameters, including microvessel density and diameter, were measured. Histological parameters according to tumor type, grade, and hormone receptor were compared using t- and Mann-whitney test. Correlations analysis was performed between US indexes and histologic parameters using spearman's correlation and Kruskal-Wallis test with Bonferroni correction.

RESULTS

Microvessel density was significantly higher in malignant masses than benign masses and malignant masses with negative estrogen receptor or high grade had higher microvessel density than those with positive estrogen receptor or low grade ($P<.05$). Microvessel diameter was not different between benign and malignant masses ($P>.05$). Quantitative US indexes including peak intensity ($r=0.546$), slope ($r=0.462$) and area ($r=0.574$) on CEUS and vascular index ($r=0.634$) on SMI were correlated with microvessel density ($P<.01$ for all). Qualitative US indexes including enhancement degree, enhancement order, penetrating vessel, perfusion defect on CEUS and vessel morphology, distribution, penetrating vessel were significantly correlated with microvessel density ($P<.01$ for all).

CONCLUSION

Quantitative and qualitative US indexes of tumor vascularity on SMI and CEUS are significantly correlated with histologic microvessel density in the corresponding tumor region.

CLINICAL RELEVANCE/APPLICATION

US vascularity indexes on SMI and CEUS could be used as surrogate markers representing histologic tumor microvessel density and may be used for predicting tumor angiogenesis in the preintervention period.

SSJ02-03 Optoacoustic Imaging of the Breast: Down-classification and Up-classification of Suspicious Breast Masses

Tuesday, Nov. 28 3:20PM - 3:30PM Room: E450A

PURPOSE

Optoacoustics (OA/US) imaging is a new technology based on laser light excitation. Combined with gray scale ultrasound, it enables simultaneous assessment of functional and anatomical information that may improve distinction between benign and malignant masses of the breast. The aim of this study was to assess OA/US's sensitivity, specificity and its ability to downgrade benign masses and upgrade malignant masses in terms of probability of malignancy (POM) and BI-RADS category.

METHOD AND MATERIALS

In this prospective, multi-center study, compliant with ISO14155 and applicable laws and regulations, we report results of 209 patients with 215 breast masses classified as BI-RADS 4a or 4b by conventional diagnostic ultrasound (CDU). Patients were enrolled

between 2015 and 2016. Institutional review board approval and written informed consent were obtained. All masses were evaluated with OA/US prior to biopsy. For each mass, the radiologist scored 5 OA/US features, and then adjusted the POM and BI-RADS category. OA/US sensitivity, specificity, BI-RADS downgrade and upgrade percentages were assessed with the contribution from an estimator.

RESULTS

OA/US specificity improvement over CDU was 41.1%. OA/US sensitivity was 95.5%. With OA/US, 41.1% of benign masses classified as BI-RADS 4a or 4b were downgraded to BI-RADS 3 or 2 and 49.2% of malignant masses were upgraded in BIRADS category.

CONCLUSION

OA/US improves the distinction between benign and malignant masses compared to CDU alone. Benign masses (particularly those classified as BI-RADS 4a) may be downgraded to BI-RADS 3 or 2 with OA/US, potentially decreasing negative biopsies and short interval follow-up imaging exams.

CLINICAL RELEVANCE/APPLICATION

With OA/US, many benign masses classified as BI-RADS 4a with CDU may be downgraded to BI-RADS 3 or 2, offering the potential to decrease biopsies of benign lesions and short interval follow-up imaging exams.

SSJ02-04 Targeted Axillary Dissection: Challenges with Axillary Lymph Node Clip Placement, Clip Identification, and Clip Retrieval post Neoadjuvant Therapy

PURPOSE

Clinically node-positive breast cancer patients often receive neoadjuvant chemotherapy (NAC) which eradicates nodal disease in 40-70% of patients. Clip placement in biopsy-confirmed metastatic lymph nodes (LNs) allows for selective removal in addition to sentinel node removal after NAC as part of targeted axillary dissection (TAD). We report success rates of clip placement, clip identification, and clip retrieval in metastatic axillary nodes to facilitate TAD.

METHOD AND MATERIALS

A retrospective institutional review board approved study was performed of 2 cohorts of patients: 223 LNs in 222 patients with clip placement from October 1, 2011 to December 30, 2015 [cohort 1]; 100 LNs in 100 patients from January 1, to November 30, 2016 [cohort 2; changes were made to the ultrasound image capture protocol for the documentation of clipped lymph nodes after the first 5 years of performing this procedure that included measurement of distance from clip to skin in transverse and longitudinal planes at the time of placement]. Success rates of clip placement, clip identification, and clip retrieval, were compared with clinico-pathologic features in cohort 1, and also between the 2 cohorts.

RESULTS

Overall, clip placement failure occurred in 14/323 LNs (4.3%) and 9/310 (2.9%) clips were not identified on follow-up ultrasound. Of 223 clipped LNs that underwent radioactive seed placement, the clip and seed were successfully retrieved in the same LN in 215 (96.4%). In cohort 1, failure in clip identification was associated with larger number of abnormal lymph nodes at diagnosis, perinodal clip placement, thinner cortex after neoadjuvant therapy, and greater distance of node from skin. Clip location in the cortex was a significant predictor for clip retrieval. Cohort 2 had a higher rate of successful clip placement (99% vs 94.2%, p=.07) and clip identification (100% vs 90.1%, p=.0004) than cohort 1.

CONCLUSION

Optimal techniques for clip placement, that include location within the cortex and detailed imaging after placement, help to improve the ability to identify and retrieve clipped axillary nodes after NAC.

CLINICAL RELEVANCE/APPLICATION

While there are clinico-pathologic features (clip location in cortex) that impact clip placement, clip identification, and clip retrieval success, appropriate training in clip documentation at diagnosis can mitigate against these challenges.

SSJ02-05 Cancer Detection in Breast Ultrasound Using an Industrial Grade Deep Learning Image Analysis Software

Tuesday, Nov. 28 3:40PM - 3:50PM Room: E450A

PURPOSE

To train a generic deep learning software (DLS) for the diagnosis of breast cancer in ultrasound images and to compare the performance to human readers with variable breast imaging experience.

METHOD AND MATERIALS

In this IRB-approved, HIPAA compliant, retrospective study, all breast ultrasound examinations from one year were reviewed. Patients with scars, initially indeterminate, or malignant lesions with histological diagnoses or 2-year follow-up were included. The DLS was trained with 70% of the images, the remaining 30% were used to validate the performance. Three readers with variable expertise also evaluated the validation set (radiologist, resident, medical student). Diagnostic accuracy was assessed with a receiver operating characteristic (ROC) analysis. Interreader agreement was measured with the concordance correlation coefficient (CCC).

RESULTS

Eighty-two patients with malignant and 550 with benign lesions were included. Time needed for training was 7 minutes (DLS). Evaluation times were 3.7 seconds (DLS) and 28, 22 and 25 minutes for human readers (decreasing experience). ROC analysis revealed non-significant differences in the area under the curve of 0.84 (DLS), 0.88 (experienced and intermediate readers) and 0.79 (inexperienced reader). Interreader agreement was best between the two more experienced readers (0.56, 95% CI 0.45-0.67) and the DLS and the reader with intermediate experience (0.49, 0.38-0.59), respectively.

CONCLUSION

DLS can diagnose cancer in breast ultrasound images with an accuracy comparable to radiologists. DLS learns substantially better and faster than a human reader with no prior experience given the same amount of training data.

CLINICAL RELEVANCE/APPLICATION

Real-time heatmaps embedded in an ultrasound examination could increase the radiologists sensitivity to subtle or atypical cancerous lesions.

SSJ02-06 Quantitative Analysis of Contrast-Enhanced Ultrasound of Lymph Nodes: A Novel Technique to Detect Early Metastasis

Tuesday, Nov. 28 3:50PM - 4:00PM Room: E450A

Kei Takase, MD, PhD, Sendai, Japan (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

naokomori7127@gmail.com

PURPOSE

To evaluate whether quantitative analysis of contrast-enhanced ultrasound (CE-US) can predict early lymph node (LN) metastasis in clinically node-negative breast cancer.

METHOD AND MATERIALS

This prospective study was approved by the institutional review board and informed consent was obtained from participants. In total, 56 patients who had no swelling LN using conventional CT, MR or US imaging underwent CE-US before surgery. Microbubble (Sonazoid; 0.015 mL/kg) was injected as a bolus with a 10-mL saline flush and continuous 75 s DICOM images were obtained. Time intensity-curve analysis was used to quantitatively analyze CE-US images. A region of interest (ROI) was placed within each LN where the highest signal increase was observed on CE-US images to obtain the peak intensity of the maximum enhanced area (PImax). A ROI was placed where the lowest signal increase was observed to obtain peak intensity of the minimum enhanced area (PImin). To evaluate heterogeneity of enhancement in LNs, the PIratio was calculated: PIratio = PImax / PImin. For visual analysis, the presence of a perfusion defect in LNs was evaluated. PI ratios and visual analyses were compared between pathological positive- and negative-metastasis groups in breast cancer patients.

RESULTS

Fifteen patients were diagnosed histologically with positive LN metastases (median 4, range 2.5-12 mm) and the remaining 41 as negative. The PIratio was significantly higher in the positive-metastasis than in the negative-metastasis group ($p = 0.0073$). ROC analysis revealed that the most effective threshold of PIratio was 1.52 and the area under the curve was 0.74. Using this threshold, the sensitivity, specificity, PPV, and NPV were 53%, 93%, 73%, and 84%, respectively. No statistically significant difference was found in visual assessments between negative- and positive-metastasis groups ($p = 0.09$).

CONCLUSION

The PIratio in quantitative analysis of CE-US imaging may be useful for detecting the presence of early LN metastasis in clinically node-negative breast cancer.

CLINICAL RELEVANCE/APPLICATION

Quantitative analysis of CE-US imaging may be useful for detecting the presence of early lymph node metastasis and is recommended in the initial evaluation of lymph node status.

PURPOSE

To characterize adaptive changes in mitral annulus anatomy in patients with mitral valve prolapse as compared to healthy subjects using mitral valve characterization software and multiphase cardiac CT datasets.

METHOD AND MATERIALS

In this retrospective study, 50 patients with known mitral valve prolapse who had previously undergone retrospective ECG-gated cardiac CTA using 1st generation dual-source CT (SOMATOM Definition, Siemens Healthcare) were evaluated. The control group comprised of 50 patients without mitral-valve pathology who underwent retrospective ECG-gated coronary CTA on 2nd generation dual-source CT (SOMATOM Definition Flash, Siemens Healthcare). Thin section, multiphase axial images were loaded into prototype mitral valve characterization software on a dedicated post processing workstation (Syngo.via VA30, Siemens Healthcare). Using 16 seeding points, the program semi-automatically segmented the saddle-shaped mitral valve annulus, generating the following parameters: annulus circumference (AC), surface area (SA), distance between the right and left trigone (TT), distance between the anterior and posterior horn (AP), distance between anterolateral and posteromedial annulus point (ALPM), ratio of AP and ALPM defined as ellipticity (E). Computed parameters were compared between the two groups.

RESULTS

Except E(0.81 [0.67-0.93] vs. 0.82 [0.65-0.92], p = 0.44), all other parameters were significantly different between the prolapsed and non-prolapsed groups (p<.001) with circumference (144 [115-173] vs. 117 [99-144] mm), SA (1533 [935 - 2223] vs. 1005 [717 - 1496] mm2), AP (38.4 [29.6 - 46.7] vs. 31.5 [26.5 - 37.9] mm) and ALPM (47.3 [37.1 - 57.4] vs. 38.5 [32.6 - 49.4] mm) being most prominent. Values over a cardiac cycle were more stable in the non-prolapsed valves, with more variation across the cardiac cycle seen in patients with prolapsing mitral valves.

CONCLUSION

This mitral valve characterization tool can be used to distinguish between prolapsed and non-prolapsed valves by using a set of standardized, quantitative parameters that may have relevance for the design and implementation of catheter-deployed mitral valve prostheses.

CLINICAL RELEVANCE/APPLICATION

Quantitative assessment of the mitral valve will enhance diagnosis of mitral valve prolapse and has the potential to improve procedure planning by allowing patient-specific prosthesis selection.

SSJ03-02 The Association between Morphological and Functional Characteristics of Bicuspid Aortic Valve and Bicuspid Aortopathy

Tuesday, Nov. 28 3:10PM - 3:20PM Room: S502AB

Participants
Sung Min Ko, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Song Soo Kim, MD, PhD, Daejeon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

ksm9723@yahoo.co.kr

PURPOSE

The aims of this study were to determine the association between morphological and functional characteristics of bicuspid aortic valve (BAV) and bicuspid aortopathy and to identify the determinants of aortic dilatation using cardiac computed tomography (CCT).

METHOD AND MATERIALS

This study cohorts included 282 subjects (206 men, age 52±15 years) who underwent both CCT and transthoracic echocardiography. BAVs were classified as anterior-posterior (BAV-AP) or lateral (BAV-LA) and divided according to the presence (raphe+) or absence of a raphe (raphe-) based on CCT findings. The sinuses of Valsalva and proximal ascending aorta were measured by CCT. Factors related to aortic root and ascending aorta diameter were evaluated by multiple linear regression analysis. The determinants of aortic root and proximal ascending aortic dilatation (size index >2.1 cm/m2) were assessed by multiple logistic regression analysis.

RESULTS

BAV-AP was present in 173 patients (61%) and raphe+ in 168 (60%). BAV morphotype and raphe+ or raphe- were not associate with aortic root and ascending aortic diameters. The aortic root diameter were significantly associated with aortic stenosis (AS) severity (estimate -1.87, p=0.02) and sex (estimate -2.77, p<0.01) and the ascending aorta diameter with age (estimate 0.14, p<0.001). Patients with dilated aortic root (n=207) were older (p=0.02) and had a lower prevalence of male sex (p<0.03) and lower body surface area (BSA, p<0.001). Patients with dilated ascending aorta (n=217) were older (p<0.001) and had lower prevalence of male sex (p<0.001), lower BSA (p<0.001), higher prevalence of hypertension (p=0.04), raphe+ (p=0.017), BAV-LA (p=0.04), moderate-to-severe AS (p<0.001) and none or mild aortic regurgitation (p<0.001). BSA was the sole independent determinant of aortic root diameter (p<0.001). Independent determinants of ascending aortic diameter were age (p<0.001), New York Heart Association class (p=0.01), BSA (p<0.001), and AS severity (p=0.003).

CONCLUSION

BAV morphotype and presence or absence of raphe are not associated with aortic root and ascending aortic dilatation and not the determinants of aortic dilatation. Further studies are needed to investigate the discrepancy in the importance of BAV morphotype predicting phenotypes of bicuspid aortopathy.

CLINICAL RELEVANCE/APPLICATION

Morphological characteristics of BAV may not have a direct impact on clinical outcomes and management plan for BAV-associated aortopathy.

SSJ03-03 Aortic Annulus Sizing in Bicuspid and Tricuspid Aortic Valves Using CT: Comparison with Surgically Replaced Prosthetic Valve Size in 667 Patients

PURPOSE

Controversy exists regarding measurement of bicuspid aortic annulus diameter on computed tomography. Although we routinely measure bicuspid aortic annulus size similar to the method for tricuspid aortic valve (AV) prior to aortic valve replacement (AVR) or transcatheter aortic valve implantation (TAVI), there has been no study to validate the method for bicuspid valve.

METHOD AND MATERIALS

Annular measurements (maximal diameter, mean diameter, area-derived diameter, and perimeter-derived diameter) were performed in 667 (362 tricuspid, 166 bicuspid with raphe and 139 bicuspid without raphe) patients who underwent surgical AVR between June 2011 and Mar 2016. The differences between CT measurements and prosthetic AV sizes were evaluated. To find factors to affect the differences between CT diameters and prosthetic AV size, patients with 10% more larger diameter (n=421) on CT from the prosthetic AV size were compared with those within 10% range.

RESULTS

Bicuspid AV parameters were well correlated with prosthetic AV size as well as tricuspid AV parameters. The most representative measurements correspond to prosthetic AV size were area-derived diameter in tricuspid (r=0.69, p<0.001) and bicuspid AV without raphe (r= 0.73, p<0.001), and perimeter-derived diameter in bicuspid AV without raphe (r=0.65, p<0.001). In multivariable linear regression analysis, prosthetic AV size could be suggested using both area-derived diameter and sinus diameter (r2=0.59, p<0.001). The difference between CT-derived diameter and prosthetic AV size is affected by prosthetic valve types (OR 9.5; 95%CI 4.0-22.4; p<0.001), surgeons (OR 2.5; 95%CI 1.1-5.5; p=0.03), sex (OR, 3.5; 95%CI 2.0-6.2; p <0.001) and area-derived diameters (OR, 2.0; 95%CI 1.7-2.3; p<0.001) in multivariate logistic regression analysis. Area-derived diameter and sex were remained after adjusting the effects of prosthetic valve types and surgeon factors (p<0.01). Bicuspid AV did not affect the differences between CT diameters and prosthetic AV sizes.

CONCLUSION

Bicuspid AV diameters measured on CT showed good correlation with prosthetic AV size as well as tricuspid AV parameters. The difference between CT-derived diameter and prosthetic AV size is affected by prosthetic valve types, surgeons, sex, and CT-derived diameters.

CLINICAL RELEVANCE/APPLICATION

CT is useful for AV sizing including bicuspid AV, and this information could be important to select optimal valve size for both surgical AVR and TAVI.

SSJ03-04 Utility of Cardiac CT for Preoperative Evaluation for Mitral Regurgitation: Localization of Mitral Valve Prolapse and Prediction of Repairability

Tuesday, Nov. 28 3:30PM - 3:40PM Room: S502AB

rongzusuh@gmail.com

PURPOSE

We aimed to investigate the diagnostic accuracy of dual-source cardiac computed tomography (CT) for detection of the prolapsed segment in mitral regurgitation (MR) and for prediction of non-repairable mitral valve (MV) with surgical finding as standard reference.

METHOD AND MATERIALS

A total of 85 patients with severe MR who underwent preoperative cardiac CT before MV surgery (MV replacement or repair) were retrospectively enrolled. The prolapsed segment of MV was assessed using Carpentier classification. Non-repairable MV was defined when met one of followings: 1) anterior leaflet prolapse, 2) bi-leaflet prolapse, 3) severe thickening and/or calcification of leaflets. Diagnostic performance of CT for the detection of prolapsed segment was assessed per patient, per leaflet (anterior or posterior) and per segment, with surgical findings as the standard reference. Diagnostic performances of CT for the prediction non-repairable MV was assessed and compared between each criteria for non-repariable MV by area under the curve (AUC) of receiver operating characteristics curve.

RESULTS

On the surgical field, MV prolapse was identified in 73.5%, and the most common segment was P2 (n=23). The sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy for detection of MV prolapse were 98.4% (60/61), 72.7% (16/22), 80.8% (60/66), 81.0% (16/17) and 91.6% (76/83) per patient, 97.2% (69/71), 94.7% (90/95), 93.2% (69/74), 97.8% (90/92) and 95.8% (159/166) per leaflet and 79.6% (74/93), 92.6% (375/405), 71.2% (74/104), 95.2% (375/394) and 90.2% (449/498) per segment. Forty-seven patients met the criteria of non-repairable MV by CT (sensitivity 87.5% and specificity 86.5%). Among criteria for non-repairable MV, criteria 3 (severe thickening and/or calcification of leaflets) showed higher diagnostic performance than other two findings (AUC; 0.569 for criteria 1, vs. 0.540 for criteria 2 vs. 0.819 for criteria 3; P<0.05).

CONCLUSION

Cardiac CT may have high diagnostic performance in detecting the prolapsed segment of MV and predicting non-repairable MV before surgery. Among CT findings, valve morphology such as severe leaflet thickening and/or calcification is the most important predictor for non-repairable MV.

CLINICAL RELEVANCE/APPLICATION

Cardiac CT can be helpful to predict non-repairable MV before surgery, and valve morphology is the most important predictor.

SSJ03-05 Semi-Automatic CT-Angiography Based Evaluation of the Aortic Annulus in Patients Prior to TAVR: Interchangeability with Manual Measurements

Tuesday, Nov. 28 3:40PM - 3:50PM Room: S502AB

PURPOSE

To compare a semi-automatic software tool to full manual measurement to obtain aortic annulus parameters and determine trans-catheter aortic heart valve (THV) size in a large patient cohort prior to TAVR.

METHOD AND MATERIALS

We included 355 consecutive patients (156 male, median age 82 years) in this retrospective study. Two readers independently assessed aortic annulus size by manually determining long and short axis, circumference and area of the aortic valve annulus. A third independent reader performed annulus evaluation using a software tool for automatic detection and measurement of the aortic annulus plane (‚Valve Pilot', ‚CT Cardiac Function' tool, SyngoVia, Siemens Healthcare). Automatically detected annulus plane and contour could be manually changed if necessary. The parameter ‚annulus area' was used to determine optimal size of a hypothetical THV based on an algorithm suggested before (Binder et al. 2013). We calculated the intraclass calculation coefficient (ICC) to compare both manual measurements as well as semi-automatic measurements to the mean of both manual measurements.

RESULTS

There was excellent correlation between both observers in manual measurement of annulus long (ICC 0.89[95% CI 0.87;0.91]) and short axis (0.89[0.86;0.91]), circumference (0.93[0.92;0.95]) and area (0.94[0.93;0.96]). Both readers agreed in 81% (287/355) of patients regarding proposed THV size. During semi-automatic measurements, manual adjustment of the annulus plane and minimal adjustment of the annulus contour without changes in the automatically selected plane were performed in 11% (38/355) and 79% (282/355) of cases, respectively. No change of the suggested annulus segmentation was required in 10% of cases (35/355). Again, there was excellent correlation between semi-automatic measurements and mean of both manual measurements of long (0.89[0.87;0.91]) and short axis (0.86[0.83;0.88]), circumference (0.95[0.93;0.96]) and area (0.95[0.94;0.96]). Semi-automatic measurements resulted in identical THV size selection in 82% (290/355) of patients.

CONCLUSION

Semi-automatic measurements of anatomic parameters of the aortic root show high agreement with manual measurements in CT-angiography prior to TAVR.

CLINICAL RELEVANCE/APPLICATION

Semi-automatic assessment of the aortic root is equal to full manual measurement and can facilitate the complex evaluation of the aortic annulus prior to TAVR.

SSJ03-06 Prognostic Value of Left Ventricular Fibrosis Volume as a Parameter for Long-Term Survival after TAVI

Tuesday, Nov. 28 3:50PM - 4:00PM Room: S502AB

PURPOSE

Patients with severe aotic stenosis develop left ventricular hypertrophy. They suffer from reduced left venricular function. Due to the insufficient vascularization of the hypertrophic left ventricular myocardium the development of left ventricular fibrosis is a common problem in these patients. The transcatheter aortic valve implantation (TAVI) is an upcoming procedure to reduce the workload and improve the left ventricular funtion. The long-term-survival shows huge inter-individual differences. The assesment of NYHA class 30 days afer TAVI has shown to be a strong and independent parameter for long-term-survival. The aim of this study was to assess the value of left ventricular fibrosis volume as a predictive parameter for the clinical outcome after TAVI.

METHOD AND MATERIALS

In the study 35 consecutive patients with TAVI procedure were enrolled. The mean chracteristics were 81±7 years, mean NYHA class 3.2±1.4, EF 48±9.3%. In each patient pre-interventional contrast enhanced cardiac MRI was performed at a Philips Ingenia 3T. The left ventricular fibrosis volume was measured. The functional recovery was assessed using the NYHA class 30 days after the procedure.

RESULTS

NYHA class after TAVI was reduced significantly (1.7±1.3; $p<0.001$). Twenty-two (63%) patients revealed a 2 class reduction. Twelve (34%) patients showed a reduction of 1 class. One Patient remained in the same NYHA class. The left ventricular fibrosis volume was inversely related to the reduction of NYHA class: patients with left ventricular fibrosis volume of 720±232mm3 had a NYHA reduction of 2 or more classes whereas patients with a left ventricular fobrosis volume of 1501±321mm3 had a reduction of less than 2 classes.

CONCLUSION

The left ventricular fibrosis volume seems to have an impact on the reduction of the NYHA class 30 days after successful TAVI implantation.

CLINICAL RELEVANCE/APPLICATION

The quantification of the left ventricular fibrosis volume may be used as a prognostic parameter for long-term survival in TAVI patients.

PURPOSE

ESS is associated with coronary plaque progression and modulates development of high-risk plaque features. However, the relationship between ESS and existing disease toward identifying the plaques at high risk of rupture has not been studied to date. We assessed whether ESS calculated from non-invasive coronary CTA can detect vulnerable plaque as determined by histopathologic examination.

METHOD AND MATERIALS

CTA was performed for 5 donor hearts with coronary artery disease. Histology was obtained every 1mm along the length of the major coronary arteries and coregistered to CTA using surgical knots and anatomic landmarks. Plaques were classified based on histology using the modified American Heart Association scheme: adaptive (AIT) and pathological (PIT) intimal thickening, fibrous (FIB), and, early (EFA), late (LFA) and thin-cap (TCFA) fibroatheroma. Resting-state ESS was calculated from CTA using a previously validated computational fluid dynamics (CFD) approach (non-Newtonian blood, flow proportional to myocardial mass and distributed using Murray's law). ESS was coregistered automatically to CTA, blinded to histology. Mean ESS at 0.5 mm intervals in each major artery was analyzed with one-way analysis of variance (ANOVA) to determine differences in ESS between plaque types. For plaque types associated with significantly different ESS, logistic regression and receiver operating characteristic analyses (ROC) were used to determine diagnostic accuracy of ESS to predict that plaque type.

RESULTS

214 histology sections with plaque were analyzed (31 AIT, 98 PIT, 37 FIB, 29 EFA, 9 LFA, 10 TCFA). Mean ESS differed significantly for TCFA vs all other types (p2.4 Pa to detect TCFA were 80%, 87.3%, and 86.9%, respectively. ESS detected EFA (ROC AUC=0.86, odds ratio=40.6/1Pa drop); sensitivity, specificity and diagnostic accuracy of ESS<1.1Pa to detect EFA were 86%, 75.9%, and 84.6%, respectively.

CONCLUSION

ESS from CTA detects EFA (low ESS2.4Pa). The former finding is in keeping with knowledge suggesting low ESS leads to early fibroatheromas. The latter finding implies a mechanical pathway (when high flow velocities and thus high ESS are present) in fibrous cap thinning and development of TCFAs.

CLINICAL RELEVANCE/APPLICATION

ESS from CTA detects thin-cap fibroatheroma and early fibroatheroma likely to progress to thin-cap. It can thus facilitate timely prevention or intervention, which no other non-invasive imaging offers.

PURPOSE

CT-Fractional Flow Reserve (CT-FFR) is known to underestimate the FFR compared to invasive measurement, leading to considerable false-positive study results especially when the disease prevalence is low. The purpose of the study was to evaluate how an adjustment of CT-FFR's underestimation impacts the estimated clinical outcomes.

METHOD AND MATERIALS

This HIPAA-compliant, IRB-approved prospective study included 44 coronary arteries from 38 patients (67.8±9.6 yrs, ca score=347.7±459.3) who underwent a 1 heart-beat 320 row coronary CTA which showed 30-90% stenosis in at least one segment and also underwent invasive FFR. The CT-FFR was calculated onsite using a commercial software. We assessed the diagnostic accuracy of CT-FFR based on the receiver operating curve (ROC) using invasive FFR<=0.8 as a positive outcome. A hypothetical 1-year cardiac event incidence if revascularization (PCI) was decided based on CT-FFR was estimated, using previous evidences on incidences following invasive FFR (positive test (<=0.8) with PCI=0.03, without PCI=0.05, negative test (>0.8) with PCI=0.03, without PCI=0.01). We repeated the estimation with an adjustment of CT-FFR to minimize the deviation from invasive FFR, and assessed the change in the hypothetical cardiac events under four different disease prevalence (0.2, 1, 5, 10%).

RESULTS

A total of 16 vessels had significant ischemia (invasive FFR<=0.8). A cutoff CT-FFR of 0.8 achieved 94% sensitivity and 75% specificity (AUC of ROC=0.82), but it significantly underestimated the invasive FFR especially when CT-FFR was <0.7; estimated total cardiac events per 100,000 population was 158.7 under the 1% disease prevalence, 84.9 of which were events among patients with false-positive CT-FFR. After the adjustment of CT-FFR using a formula of 0.3X+0.634 for CT-FFR<0.7 to counteract its underestimation, the estimated total cardiac event decreased to N=123.5 at the 0.8 cutoff and was minimized to N=110 (30.5% reduction) at a 0.75 cutoff. When the disease prevalence was 0.2, 5, and 10%, the % reduction of the events was 31.5%, 25.4% and 19.5%.

CONCLUSION

Adjustment of CT-FFR to counteract the underestimation decreased the estimated 1-year cardiac events up to 31.5% depending on the disease prevalence.

CLINICAL RELEVANCE/APPLICATION

When using a CT-FFR to decide revascularization, underestimation should be adjusted to reduce cardiac events attributable to false positive results, especially when the disease prevalence is low

SSJ04-03 Sexual Dimorphism in the Association between Coronary Plaque Burden and Coronary Wall Thickness in Asymptomatic Coronary Artery Disease

PURPOSE

To evaluate the relationship between coronary plaque burden measured by Computerized Tomography Angiography (CTA) and coronary wall thickness (VWT) using Magnetic Resonance Imaging (MRI) in a low/intermediate risk asymptomatic population. The study also is to assess the value of VWT-MRI as a surrogate marker of plaque burden alone or in tandem with traditional atherosclerosis risk factors.

METHOD AND MATERIALS

We prospectively evaluated 124 asymptomatic adults with one or more modifiable cardiovascular risk factors. All subjects signed

informed consent for this IRB approved study and underwent CTA and 3 Tesla (3T) VWT-MRI. Estimated risk for atherosclerotic disease, coronary calcification, and plaque burden scores including segment involvement (SIS), volume (SVS) and stenosis scores (SSS) were obtained for all subjects. Series of univariable and multivariable generalized nonlinear regression modeling with consideration for interactions with gender were performed to investigate the association of traditional atherosclerotic risk factors and VWT with plaque burden scores.

RESULTS

A total of 62 male and 62 age- and BMI-matched female asymptomatic subjects with low/intermediate Framingham score (FrS) <20% were successfully imaged. Age, gender, and VWT, individually, were significant predictors of all coronary plaque burden scores. Additionally, gender remained a significant effect modifier in all plaque burden scores. In women, VWT, while in men, age, were the only common statistically significant predictor of coronary plaque burden scores with a statistically significant interactions between VWT and sex for SIS (ß=0.792, P =0.024) and for SSS (ß=1.292, P =0.009).

CONCLUSION

In asymptomatic subjects with low/intermediate FRS there is evidence of a sex-dimorphic association between VWT and gender as a predictor of coronary plaque burden. MRI-based VWT could supplement traditional risk scores for CAD risk stratification in women. This is in line with the previous studies that demonstrated the suboptimal performance of CAD risk score models for women compared to men.

CLINICAL RELEVANCE/APPLICATION

Coronary wall thickness measured noninvasively by MRI is a surrogate for subclinical atherosclerosis in low and intermediate CAD risk asymptomatic women but not in a similar male population. This sex-specific difference is clinically relevant for CAD risk stratification, life style modification and therapy of CAD in women.

SSJ04-04 Prevalence of Unrecognized Myocardial Infarction Detected By Cardiac Magnetic Resonance and Its Relation to Coronary Artery Calcium Score in Asymptomatic Asian Cohort

holymosquito@hanmail.net

PURPOSE

To investigate the prevalence of unrecognized myocardial infarctions (UMIs) in asymptomatic Asian subjects, assessed with cardiac magnetic resonance (CMR), and to relate the findings to cardiovascular risk prediction scores and coronary artery calcium (CAC) scores.

METHOD AND MATERIALS

Total 519 asymptomatic subjects (male:female, 476:43; age, 54.54 ± 6.41) who underwent both CMR and CAC scoring CT, with their interval less than 1 year, were included. Those with prior hospital-reported cardiovascular event were not included. Framingham risk score (FRS), ACC/AHA risk score and CAC score were assessed based on clinico-laboratory results and imaging data. Comparison of variables between those with and without UMI was performed by use of Student's t-test, Mann-Whitney test, chi-square test and Fisher's exact test. The confidence level and cutoff value of CAC score was analyzed with the receiver operating characteristic (ROC) method.

RESULTS

Late gadolinium enhancement (LGE) indicating UMI was noted in 12 of 519 subjects (2.3%). However, none of them showed pathologic Q-wave or ST-segment change on electrocardiography (ECG). Among clinico-laboratory results and risk prediction scores, only CAC scores differed significantly between those with and without UMIs ($p < .001$). The prevalence of UMI was as follows: 10 of 275 (3.6 %) in subjects with CAC score > 0 and 2 of 244 (0.8 %) in subjects with CAC score = 0. Among those with CAC score > 0, area under the ROC curve of CAC score for predicting UMI was 0.868 (95% CI, 0.823 - 0.906; $p < .001$). A CAC score with cutoff value of 301 demonstrated a sensitivity of 80.0% (95% CI, 44.4%-97.5%), a specificity of 86.0% (95% CI, 81.3%-90.0%), and a negative predictive value of 97.9% (95% CI, 95.0%-99.5%) in predicting UMI.

CONCLUSION

The prevalence of UMI in asymptomatic Asian subjects was 2.3%. CMR was a sensitive tool in depicting UMI and was superior to ECG. Those with CAC score above 301 can be potential candidates of CMR for UMI screening, as high CAC score is predictive of UMI.

CLINICAL RELEVANCE/APPLICATION

Asymptomatic individuals with CAC score above 301 are potential candidates of CMR for UMI screening, as high CAC score is predictive of UMI detected on CMR.

SSJ04-05 Correlation between Haptoglobin Phenotypes and Myocardial Reperfusion Injury in Consecutive ST-Elevation Myocardial Infarction as Detected by Cardiac Magnetic Resonance

PURPOSE

Primary percutaneous coronary intervention (pPCI) has significantly reduced cardiovascular mortality of ST-segment elevation myocardial infarction (STEMI) patients. Cardiac magnetic resonance (CMR) has emerged as the gold standard technique for the measurement of the myocardial salvage index (MSI) and microvascular obstruction (MVO) over the traditional risk stratification. Aim of this study is to evaluate the correlation between variants of haptoglobin and myocardial reperfusion injury as detected by CMR in consecutive STEMI patients who underwent successful pPCI.

METHOD AND MATERIALS

Consecutive STEMI patients reperfused by primary PCI were enrolled. For each patient, the characterization of different phenotypes of haptoglobin was evaluated. Moreover, a CMR was performed by 1 week after STEMI evaluating: left ventricle ejection fraction (LVEF), MSI and prevalence and amount of MVO. The primary endpoint of study was to evaluate the correlation between different phenotypes of haptoglobin and myocardial reperfusion injury as detected by CMR.

CONCLUSION

Different variants of haptoglobin may play a crucial role in cardiac repair responses by reducing oxidative stress, maintaining microvascular integrity and proper scar formation. Further studies should be performed to evaluate if different therapeutic strategies should be developed based on phenotypes of haptoglobin of patients.

CLINICAL RELEVANCE/APPLICATION

haptoglobin may play a crucial role in cardiac repair responses and could represent a theraputic target in order to reduce myocardial reperfusion injury.

SSJ04-06 Coronary to Pulmonary Artery Fistula in the Adult: Natural History and Management Strategies

jijung@catholic.ac.kr

PURPOSE

To evaluate the natural history of coronary-to-pulmonary artery fistula (CPAF) detected on coronary CT angiography (CCTA) and to propose potential treatment strategies.

METHOD AND MATERIALS

The institutional review board approved this retrospective study and informed consent was waived. 12,436 CCTA scans were performed in our institute between March 2009 and June 2016, and 74 patients were diagnosed as CPAF. Among them, patients with a follow-up of at least 2 years were retrospectively reviewed. Demographics, clinical history, prior cardiac testing, and reasons for CCTA were collected by a review of electronic medical records. The morphologic features of CPAF were analyzed, including vessel of origin site and number, size, and the presence of an aneurysmal sac. All patients were examined to what treatment they received after the diagnosis of CPAF. We investigated whether there were major adverse cardiac events (MACE), which was defined as the presence of death, myocardial infarction, and the need for revascularization or percutaneous intervention during the follow-up period.

RESULTS

48 patients had a follow-up period of more than 2 years. The mean age of the study population was 62 years (range 43-84, 39% male), and average follow-up period was 5.1 years. Common causes of CCTA were chest pain, palpitation, asymptomatic in order. Underlying diseases were hypertension, coronary artery disease, hyperlipidemia, and diabetes. The origin of CPAF was the left coronary artery in 22, the right coronary artery in one and both coronary arteries in 23 cases. More than half of the fistula sizes were less than 2 mm (26 cases, 62%). 12 cases were associated with an aneurysm (mean 12±7.5 mm). 4 cases underwent surgical ligation due to continued chest pain or having a larger aneurysm (range 12-19 mm). After the operation, they were free of a symptom. Another 44 patients were observed with optical medical treatments (OMT) and their symptom was controlled well. All

patients treated either surgery or OMT did not experience MACE during the follow-up period.

CONCLUSION

The natural course of CPAF detected by CCTA is usually benign. Optimal medical treatment is sufficient in most of the cases. Continued symptom and aneurysmal size are determinant for surgical ligation.

CLINICAL RELEVANCE/APPLICATION

As a treatment strategy for CPAF, OMT and observation are first and in most cases that are enough.

SSJ05-01 Chest Keynote Speaker: Focal Lung Lesions: The Potential Role of MRI for the Assessment of Malignancy

Tuesday, Nov. 28 3:00PM - 3:10PM Room: S404CD

Participants
Jurgen Biederer, MD, Heidelberg, Germany (*Presenter*) Nothing to Disclose

ABSTRACT

In current practice, magnetic resonance imaging (MRI) of the lung is increasingly recognized as a valuable adjunct or even alternative to computed tomography (CT). Superior soft tissue contrast of morphologic sequences and the functional imaging capacities of MRI open new perspectives for detection and assessment of pulmonary malignancy. In a screening setting, applications range from lung MRI as the first choice screening modality to the role of an ad hoc on site test for the detailed evaluation of positive CT screening results with multi-parametric characterization of lung pathology. Malignant lung lesions, carcinoma, metastases, carcinoid and lymphoma usually show a nonspecific low or intermediate signal intensity on T1-weighted images and high signal intensity on T2-weighted images. Short tau inversion recovery (STIR) sequences achieve a sensitivity of approximately 80 % and a specificity of 60%. Dynamic contrast enhanced (DCE) MRI is based on the evaluation of contrast uptake in the assessed lesion after bolus injection. It achieves specificities of 50-95% and sensitivities of 50-100% with diagnostic accuracies of 75-94%, hence coming close to the accuracies of contrast enhanced MDCT and FDG PET/CT. As in dynamic CT, it can be assumed that DCE MRI of solid pulmonary lesions has a high negative predictive value in cases of very low or missing enhancement after intravenous contrast application. More recently, diffusion weighted imaging (DWI) has been advocated for the assessment of focal lung lesions. DWI yields sensitivities between 70% and 90% and specificities of 60-95% for malignancy. However, DCE and DWI MRI cannot yet be considered robust, highly standardized and simple techniques for clinical use. The applied protocols vary widely and solutions for basic problems such as compensation for respiratory motion and for the non-linearity of blood/tissue-signal with gadolinium-concentration are still subject to research. Further methods to evaluate tumor viability based on multi-parametric MRI are on an early, experimental level. The presentations comprised within this scientific session will contribute valuable insights into the further development, application, performance and diagnostic yield of these emerging techniques.

SSJ05-02 Diagnostic Performance of Diffusion-Weighted Imaging with Multiple Parameters for Assessment and Characterization of Pulmonary Lesions: A Meta-Analysis

Tuesday, Nov. 28 3:10PM - 3:20PM Room: S404CD

Participants
Guohua Shen, MD,PhD, Chengdu, China (*Presenter*) Nothing to Disclose
Anren Kuang, MD, Chengdu, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Regarding DWI application in thoracic disease, several appropriate parameters have been reported, commonly including 5-point rank scale, lesion-to-spinal cord ratio (LSR) and apparent diffusion coefficient (ADC). This study aimed to evaluate the diagnostic performance of diffusion-weighted imaging (DWI) using these three parameters for the characterization of pulmonary lesions.

METHOD AND MATERIALS

After literature search in several databases (the PubMed, EMBASE, Cochrane library and China National Knowledge Infrastructure databases), two investigators independently selected studies, assessed methodological quality, and extracted data. On a per-lesion basis, we pooled and compared three parameters between malignant and benign pulmonary lesions. Then, we determined pooled sensitivity and specificity with individual 95% confidence intervals (CIs). In addition, the summary receiver operation characteristic curves (SROC) for DWI with area under the curve (AUC) and Q* index were constructed.

RESULTS

In total, 31 articles involving 2368 lesions were included. The score of 5-point scale of malignant and benign lesions were 3.83

(3.71-3.96) and 2.36 (2.18-2.54), respectively. The LSR of malignant and benign lesions were 1.15 (1.07-1.24) and 0.71 (0.62-0.79), respectively. The ADC values of malignant lesions and benign lesions were 1.23 (1.21-1.24) and 1.72 (1.68-1.77), respectively. All of three parameters differed significantly between malignant and benign lesions (Figure 1) ($p<0.05$). With a cut-off value of 3, the pooled sensitivity and specificity were 0.88 (0.84-0.91) and 0.75 (0.68-0.80) for 5-point scale. The SROC curve displayed AUC of 0.9107 and Q* index of 0.8429, respectively. For LSR, the pooled sensitivity, specificity, AUC and Q* index were 0.80 (0.75-0.85), 0.85 (0.76-0.92), 0.9159 and 0.8487, respectively. The ADC measurements yielded the pooled sensitivity of 0.84 (0.82-0.86), pooled specificity of 0.84 (0.81-0.87), AUC of 0.9198, and Q* index of 0.8532.

CONCLUSION

DWI can help to distinguish malignant from benign pulmonary lesions based on visual parameter (5-point scale), semiquantitative parameter (LSR) and quantitative parameter (ADC).

CLINICAL RELEVANCE/APPLICATION

In clinical practice, 5-point scale, LSR, and ADC were useful diagnostic parameters for pulmonary lesions, and the diagnostic performances of them did not show any significant differences.

SSJ05-03 Assessment of Intravoxel Incoherent Motion Diffusion-Weighted MR Imaging in Solitary Pulmonary Nodules: Comparison and Correlation with Dynamic Contrast-Enhanced MR Imaging

Tuesday, Nov. 28 3:20PM - 3:30PM Room: S404CD

Participants
Shuchang Zhou, Wuhan, China (*Presenter*) Nothing to Disclose
Liming Xia, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

zhoushuchang@hust.edu.cn

PURPOSE

To compare intravoxel incoherent motion (IVIM) and dynamic contrast-enhanced MR imaging (DCE-MRI) in their ability to discriminate lung cancer(LC) from benign pulmonary lesions.

METHOD AND MATERIALS

57 consecutive patients with solitary pulmonary nodules underwent DW-IVIM (multi-b-factor DWI with b values of 0, 20,50, 100, 150,200, 400, 600, and 1000 s/mm2) and DCE-3.0T MRI. ADCtotal, Tissue diffusivity (D), pseudo-diffusion coefficient (D*), and perfusion fraction (F) were calculated with mono--exponential and IVIM models. MER,Tmax, SLE and washout were calculated with semi-quantitative DCE analysis. Receiver operating characteristic (ROC) curves was constructed to estimate the diagnostic performance of both methods in differentiating diagnosis and the optimal cut-off values were obtained.

RESULTS

ADCtotal and D were significantly higher for benign lesions than for LC ([1.83?±?0.66]?×?10-3 mm2/s vs. [1.30?±?0.40]?×?10-3 mm2/s; P?=?0.005; [1.33?±?0.43]?×?10-3 mm2/s vs. [0.88?±?0.29]?×?10-3 mm2/s; P?=?0.002). D*was found to be significantly higher in LC than benignity ([50.65?±?46.08] ×?10-3 mm2/s vs. [19.68?±?30.54] ×?10-3 mm2/s; P?=?0.005). No difference was observed in F between LC and benignity (P?=?0.06).By DCE-MRI,Tmax were significantly shorter in LC than that of benignity([131.6?±?83.4]?s vs. [309.7?±?126.0]?s; P? **CONCLUSION**

Both IVIM model based on DWI and DCE-MRI were useful for discriminating benign lesions from malignant pulmonary nodules, and can provide quantitative diffusion and perfusion information by multiple parameters. We suggest that a combined DCE and IVIM could provide a more promising way in determination microstructure characteristics of solitary pulmonary nodules.

CLINICAL RELEVANCE/APPLICATION

Combination of DCE and IVIM could provide an alternative noninvasive method for diagnosis of SPN without radiation explosure.

SSJ05-04 How to Apply Computed Diffusion-Weighted Image for Improving Diagnostic Performance of Chest MR Imaging in Patients with Pulmonary Nodules?

PURPOSE

To determine the utility of computed diffusion-weighted image (cDWI) for improving diagnostic performance on chest MR imaging in patients with pulmonary nodules.

METHOD AND MATERIALS

61 consecutive patients (38 men and 23 women; mean age, 69.1±9.7 years) with 82 pulmonary nodules underwent DWIs,

transbronchial or CT-guided biopsies, surgical resection, pathological, microbaclterial and follow-up examinations. All DWI were obtained at a 3T MR system by using fast advanced spin-echo (FASE) sequence with b values at 0 and 1000s/mm2. As well as actual DWI at 1000s/mm2 (aDWI), cDWIs were generated at b value as 400 (cDWI400), 600 (cDWI600), 800 (cDWI800), 1000 (cDWI1000), 1500 (cDWI1500) and 2000 (cDWI2000) s/mm2 by commercially available software. According to results of pathological and follow-up examinations, all nodules were divided into malignant (n=41) and benign (n=41) nodule groups. Then, signal-to-noise ratio (SNR) and contrast ratio (CR) between nodule and thoracic muscles were determined by ROI measurement at each nodule. To compare image quality between aDWI and each cDWI, SNRs were compared by Dunnett multiple comparison test. To determine the utility of cDWI with aDWI, the logistic regression analysis was also performed with aDWI and all cDWIs. To compare diagnostic performance of pulmonary nodule, ROC analyses were performed among aDWI, each DWI and combined aDWI with appropreate cDWI determined by logistic regression analysis. Finally, sensitivity, specificity and accuracy were compared by McNemar's test.

RESULTS

SNRs of cDWI400 (p=0.002) and cDWI600 (p=0.008) were significantly higher than that of aDWI1000, although that of cDWI1500 (p<0.001) and cDWI2000 (p<0.001) were significantly lower than that of aDWI1000. Logistic regression analysis showed aDWI and cDWI600 were significant predictors for diagnosis of malignancy (p<0.05). Accuracy of aDWI with cDWI600 (86.6 [71/82] %) was significantly higher than that of aDWI (81.7 [67/82] %, p<0.05).

CONCLUSION

Computed DWI has a potential to improve diagnostic performance of DWI in patients with pulmonary nodules, when generated at appropriate b value.

CLINICAL RELEVANCE/APPLICATION

Computed DWI has a potential to improve diagnostic performance of DWI in patients with pulmonary nodules, when generated at appropriate b value.

SSJ05-05 The Value of Differential Diagnosis the Invasive Adenocarcinoma of Lung in 3T MRI

PURPOSE

To investigate the value of magnetic resonance imaging (MRI) in differential diagnosis of invasive pulmonary adenocarcinoma (IPA) appearing as ground-glass nodules

METHOD AND MATERIALS

Retrospective analysis was performed on CT and MRI findings in patients with pulmonary ground-glass nodules from December 2014 to December 2016. All patients were undergo the surgery and pathologically proved, they were pre-cancerous lesions or clinical stage 1 of lung adenocarcinoma. The image features of the lesions were analyzed by two readers who did not know the pathological results. Maximum diameter, T2 signal intensity and ADC value were measured. According to the pathology, the lesions were divided into two groups. One included pre-invasive lesion (AAHs and AISs) and MIAs, another included IPAs. Compared the 3 indicators between two groups . All statistical analyses were performed using SPSS 21.0. The measurement data were analyzed by using two independent samples t test,If it was suitable for the normal distribution, otherwise using Mann-Whitney U test. Count data were compared using chi square test. Receiver operating characteristic (ROC) curve analysis were performed to evaluate diagnostic test.

RESULTS

A total of 34 participants (14 male, 57.1±14.7 year-old; 20 female, 54.9±10.1year-old) with 34 nodules were enrolled in the study. There were 15 cases in group A , including 4 AAH, 2 AIS and 9 MIA, and19 cases in group B. There was no significant differences in the age of patient and gender between the two groups. The maximum diameter of lesions in group A was significantly less than that in group B(9.9±2.6mm vs 13.1±2.7mm). The T2 signal intensity of lesions in group A was significantly lower than that in group B(93.0±8.3 vs 113.6±22.9).The ADC value in group A(1.0±0.2*10-3 mm2/s) was also significantly lower than that in group B (1.3±0.3*10-3 mm2/s). The best index to distinguish the two groups is the maximum diameter of lesions The optimal cut-off value for maximum diameter was 11.5mm (sensitivity, 73.7%; specificity, 73.3%).The AUC for maximum diameter was 0.791 (95% confidence interval: 0.640,0.942)

CONCLUSION

The maximum diameter of the nodule, T2 signal intensity and ADC value are helpful for differential diagnosis of invasive lung adenocarcinoma.

CLINICAL RELEVANCE/APPLICATION

The maximum diameter of the nodule, T2 signal intensity and ADC value are helpful for differential diagnosis of invasive lung adenocarcinoma.

SSJ05-06 Primary Tumor Cellularity Assessed on Diffusion Weighted MRI and Metabolism Assessed on PET/CT as Predictive Factors for Lymph Node Involvement in Non-Small Cell Lung Cancer (NSCLC)

PURPOSE

The aim of this study was to prospectively analyze the potential role of primary tumor apparent diffusion coefficient (ADC) derived from whole body MRI (WB-MRI) with diffusion weighted imaging (DWI) and metabolic parameters derived from FDG PET/CT in predicting pathologically assessed lymph node metastasis in non-small cell lung cancer (NSCLC) patients before treatment.

METHOD AND MATERIALS

Ethic committee approval was obtained for this prospective study as well as written informed consent from every patient. The study group comprised 32 consecutive patients (mean age: 67yrs) with histologically proven NSCLC (SCC n= 8 and AC n=24) who underwent 1.5 T WB-MRI with DWI and FDG PET/CT before treatment. Maximum diameter (maxTD) and minimum and mean ADC (ADCmin and ADCmean) of primary tumor were calculated on DWI images (b-values 0-1000). Maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were measured on FDG PET/CT. Presence of lymph node (LN) metastases was pathologically assessed and served as reference standard. Relationships between imaging metrics and LN status were evaluated using the Mann-Whitney U test. The area under the receiver operating characteristic (ROC) curve was used to evaluate accuracy.

RESULTS

Lymph node metastasis were documented in 11 patients (34%). There were significant correlations between primary tumor maxTD, ADCmean, MTV, TLG and presence of LN metastasis (p: 0.05, 0.05, 0.04 and 0.04 respectively). ADCmin and SUVmax were not associated with LN metastasis. On ROC curve analysis, the areas under the curve (AUC) for maxTD, ADCmean, MTV and TLG for were 0.71, 0.70, 0.71 and 0.73 respectively, for predicting LN status.

CONCLUSION

Parameters derived from pre-treatment WB-MRI with DWI (maxTD and ADCmean) and from FDG PET/CT (MTV and TLG) may serve as predictive biomarkers of lymph node metastasis in patients with non small cell lung cancer.

CLINICAL RELEVANCE/APPLICATION

Diffusion weighted MRI and FDG PET/CT functional characteristics of the primary tumor can be used for predicting pathologic lymph-node involvement in NSCLC patients.

PURPOSE

Time-efficient CT imaging in acute stroke is essential for improving patient outcomes. This can be systematically evaluated using imaging timestamps. In this work, we retrospectively analyzed CT imaging speed in acute stroke response and compared performance between different scanners, times of day, and technologists.

METHOD AND MATERIALS

We extracted timestamps related to image acquisition, reconstruction, and availability in PACS from 636 complete acute stroke CT exams at a single institution under IRB approval. Exams were sorted by technologist, scanner location, and time of day. To investigate differences in efficiency by scanner location and exam time, we used Mann-Whitney U tests to compare the time of acquisition and time to PACS for each of the four series in our stroke CT protocol (head without contrast, CTA, perfusion, head with contrast). Non-parametric tests were used to investigate differences in efficiency by scan operator, including a Kruskal-Wallis test and *post hoc* Mann-Whitney U tests.

RESULTS

A significant increase in time from exam start to image availability for interpretation was observed in all series from exams performed on the Emergency Department (ED) back-up scanner in Radiology compared to those performed on the dedicated CT in the ED (p<0.001, median 3-4 min depending on series). This was despite there being no significant difference in image acquisition time. Despite increased acquisition time during overnight shifts, CTA, perfusion, and head with contrast series were available in PACS significantly sooner during the night shift (p<0.01, median 2-3 min). Comparisons between CT technologists indicated significant differences between operators in exam acquisition time and time to image availability in PACS (p<0.05, median time differed by up to 5.5 and 14 min, respectively).

CONCLUSION

There were significant differences in the speed of image acquisition, processing, and availability for interpretation based on scanner location, time of day, and operator. These findings can direct our efforts for improved training and more rapid acute stroke care. This method of quality analysis will be useful for continued monitoring of performance in the future.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates a method for performance monitoring in stroke care using imaging timestamps. The results indicate new areas for quality improvement in our institution's acute stroke workflow.

SSJ06-02 Dual Energy CT Angiogram of the Head: Quantifying Iodine Concentration in Acute Ischemic Stroke

PURPOSE

Non-contrast CT and CTA provides a rapid, accessible and accurate assessment of parenchymal infarction in acute ischemic stroke (AIS). CTA has also been shown to demonstrate areas of low cerebral blood volume in regions of infarction.The advent of dual energy/spectral imaging presents the potential to quantify iodine in the region of infarct. Our study aims to assess whether iodine quantification can reliably differentiate between infarcted and normal brain in patients presenting with AIS.

METHOD AND MATERIALS

A retrospective study on patients that presented to the Emergency Department (ED) at our institution between January and April, 2016, with clinical suspicion of acute MCA territory infarction within the last 4 hours and underwent contrast enhanced DECT angiogram of the head and neck (N = 34). Catheter angiography served as the reference standard.Images were acquired on a third generation dual-source, DECT scanner at 90 kV and Sn150 kV. Iodine Overlay (IO) images were reconstructed and iodine measurements were normalized to that of the precentral gyrus on the unaffected side. ROIs were drawn over the insular cortex , basal ganglia (BG) and white matter (WM) external capsule in the region of the ischemia and contralateral normal parenchyma to measure iodine concentration and calculate percentage uptake. Mean values were compared between normal and ischemic parenchyma.

RESULTS

The mean iodine concentration and percent iodine values for the normal and ischemic brain tissues were as follows: 1.01 ± 0.04 mg/ml and 92.69% ± 2.2 for normal insula and 0.26 mg/ml ± 0.03 and 23.41% ± 2.2 for ischemic insula; 0.35 mg/ml ± 0.03 and 29.75% ± 2.2 for normal WM and 0.13 mg/ml ± 0.02 and 10.48% ± 1.4 for ischemic WM; and 0.7 mg/ml ± 0.05 and 65.12% ± 3.7 for normal BG and 0.28 mg/ml ± 0.04 and 24.68% ± 3.5 for ischemic BG. Infarcted brain GM, WM, and BG exhibited statistically significant less iodine concentration compared to their normal counterparts ($p < 0.0001$).

CONCLUSION

Iodine quantification in DECT reliably differentiated between normal and infarcted brain tissue in our study. Its use in the acute stroke imaging protocol improved detection of acute infarcts on DECTA images of the head.

CLINICAL RELEVANCE/APPLICATION

Iodine quantification in DECTA images may improve detection of acute infarcts in patients presenting with acute stroke symptoms.

SSJ06-03 Impact of Reader Experience and Greyscale Inversion on the Detection of Emergent Large Vessel Occlusion Stroke with CT Angiography

PURPOSE

CT angiography (CTA) is now an essential component of acute stroke imaging protocols to confirm or exclude the presence of emergent large vessel occlusion (ELVO) stroke. ELVO detection must be possible at all levels of training and without sub-specialized training. This study examines sensitivity, specificity, agreement, reading time, time to detection, and self-reported confidence for ELVO detection between neuroradiologists, non-neuroradiologists, and residents using both greyscale inversion (black blood) and normal viewing conditions.

METHOD AND MATERIALS

A random and counterbalanced experimental design was used, where 16 radiologists (10 attendings, 6 residents) read the same patient images with and without greyscale inversion, counterbalanced by a one month separation, while being blinded to patient information (radiologist and patient were held constant). Positive and negative ELVO cases (n=52) were randomly ordered using a balanced design (26 vs. 26) to optimize detection of changes in sensitivity and specificity; PPV/NPV were used for group comparisons, not estimation. Diagnostic performance, including sensitivity, specificity, PPV, NPV, as well as confidence, and read and detection time were examined between by experience and greyscale inversion (on/off) using generalized mixed modeling assuming a binary, negative binomial, and binomial distributions, respectively, where observations were nested within radiologist

within patient (SAS/GLIMMIX).

RESULTS

No differences were detected between greyscale inversion on/off and between groups concerning diagnostic performance (p=0.34), detection time (p=.15), overall read time (p=.97), and confidence (p=.06). Differences were observed between level of training: residents were less confident than attendings, and neurorads were faster than non-neuro rads and residents concerning read time, all p<.01). Lack of differences between on/off are not surprising, given that sensitivity, specificity, PPV, NPV where very high to begin with little room for improvement (ceiling effect).

CONCLUSION

ELVO detection with CT angiography is accurate across all levels of training and experience. Greyscale inversion offered no significant detection advantage.

CLINICAL RELEVANCE/APPLICATION

These results show that diagnostic performance and time to detection are very good, regardless of training and specialty, for an examination that must be a part of the initial hospital evaluation of stroke patients.

SSJ06-04 The Utility of Virtual Non-Contrast Images in Assessment of Acute Intracranial Pathology

Tuesday, Nov. 28 3:30PM - 3:40PM Room: N227B

mohammed.f.mohammed@gmail.com

PURPOSE

The purpose of this study is to evaluate whether virtual non-contrast (VNC) images derived from DE CT angiography (CTA) are as reliable as true non-contrast CT (NCCT) images in detecting brain hemorrhage and infarcts.

METHOD AND MATERIALS

A total of 56 patients with acute stroke symptoms were retrospectively identified between January and April 2016 from a single institution's emergency department. All the patients underwent both an NCCT and DE CTA. DE images were acquired at 90 kV and Sn 150 kV. Quantitative analysis of the NCCT and VNC Head images were performed using circular region of interests (ROIs) centered on the basal ganglia, internal capsule and the superior sagittal sinus. Mean Hounsfield Units (HU) ± noise was calculated. Two radiologists were blinded and retrospectively interpreted the VNC CT images in comparison to the routine NCCT, assessing for pathology and diagnostic acceptability. The studies were graded on a 5 point Likert scale with 1 being a non-diagnostic examination and 5 representing a diagnostic study similar to a TNC scan. Sensitivity and specificity of VNC at detecting hyperdense-vessel sign, hemorrhage and infarction.

RESULTS

There was no significant difference between attenuation values for the basal ganglia, internal capsule and superior sagittal sinus on TNC (38.6 HU ± 0.57, 30.3 HU ± 0.56 and 56.5 HU ± 1.4) and VNC (35.6 HU ± 1.6, 30.5 HU ± 1 and 56.2 HU ± 5.2) (p > 0.1).Sensitivity and specificity of VNC for detection of hemorrhage, hyperdense-vessel sign and infarct was 100% and 100%, 80% and 77.4% and 38.2% and 100% respectively.

CONCLUSION

VNC images were as reliable as TNC images for detecting hemorrhage and demosntrated acceptable performance in detecting hyperdense-vessel sign. However, VNC images did not reliably detect infarct as compared to TNC images.

CLINICAL RELEVANCE/APPLICATION

VNC images can reliably diagnose intracranial hemorrhage, however, are not as of yet reliable to forgo the inclusion of a TNC scan in cases of suspected infarction.

SSJ06-06 Temporal Changes and Spectrum of Findings on Follow-up CT Angiogram in Patients with Suspected Post-traumatic Blunt Cerebrovascular Injury

Tuesday, Nov. 28 3:50PM - 4:00PM Room: N227B

Participants

mohammed.f.mohammed@gmaail.com

PURPOSE

Blunt cerebrovascular injury (BCVI) is a rare but potentially devastating diagnosis. If left undiagnosed and untreated, the incidence of ischemic stroke is reported to be as high as 64%. Follow-up imaging is recommended in suspected or confirmed cases of BCVI within 24-48 hours. Our study establishes the temporal changes and findings on follow-up imaging.

METHOD AND MATERIALS

For this retrospective, IRB-approved study, the hospital trauma registry was queried for all poly-trauma patients undergoing CTA scans performed in the emergency department between January 1, 2010 to December 31, 2016 with ISS >= 16, yielding 3747 patients. A total of 205 patients had follow up CTs for BCVI. Note was made of the grade and location of injury as well as associated traumatic injuries. GCS at the time of admission was also recorded.

RESULTS

Vehicular collision was the most common mechanism of injury (66%). The majority of patients (62%) had a GCS of 10-15. 18 cases (9%) had GCS of 3-9 and 53 patients (26%) were unresponsive at the time of presentation. 6 patients were intubated at the scene. Vertebral fractures were the most common associated injuries (54%), Intracranial hemorrhage in 42%, skull fractures in 26% and facial fractures in 29% of patients. 16% of patients had no associated injuries.The overall incidence of BCVI in our study was 4.8%. 59% of injuries involved the vertebral arteries (101) and 41% involved the internal carotid arteries (71). On the initial CTA 48% of injuries were Grade I, 27% were Grade II, 6% were Grade III, 18% were Grade IV and 1% were Grade V. On follow-up CTA, Grade I injuries made up 43% of cases, 18% were Grade II, 18% were Grade III, 20% were Grade IV and there were no Grade V injuries on follow up. 45% of all BCVI remained unchanged on follow-up imaging, 42% improved and 13% worsened on follow-up imaging.All patients with diagnosis or suspicion of BCVI received medical therapy within 24 hours of diagnosis. 6 patients underwent image guided vascular intervention.

CONCLUSION

Aggressive screening for BCVI in trauma enables early diagnosis and management of injuries. Low grade injuries are more likely to demonstrate changes on follow-up imaging. The majority of cases demonstrated improvement compared baseline.

CLINICAL RELEVANCE/APPLICATION

It is important to recognize that BCVI may improve or worsen on follow up imaging, which may affect management and patient outcomes.

Elliot K. Fishman, MD, Baltimore, MD (*Abstract Co-Author*) Institutional Grant support, Siemens AG; Institutional Grant support, General Electric Company; Co-founder, HipGraphics Inc;

For information about this presentation, contact:

spark139@jhmi.edu

PURPOSE

Pancreatic cystic masses are detected in greater than 2% of abdominal CTs, and they vary in malignant potential based on underlying pathologic diagnosis. Many of these cystic masses share overlapping imaging features and are difficult to confidently diagnose based on visual assessment of these imaging features. The purposes of this study are to quantify the phenotype pancreas cystic neoplasms and to use these radiomics features to classify different types of pancreatic cystic masses.

METHOD AND MATERIALS

This was an IRB-approved retrospective study. 103 patients with pathologically proven pancreatic cystic masses with preoperative dual-phase pancreatic protocol CT were identified from the radiology and pathology database from 2003 to 201 6. This included 60 intraductal papillary mucinous neoplasm (IPMN), 8 mucinous cystic neoplasm, 20 serous cystadenoma, 10 solid pseudopapillary epithelial neoplasm, and 5 pancreatic neuroendocrine tumor. Primary cystic masses and whole pancreas were manually segmented using dedicated software, the Medical Imaging Interaction Toolkit (MITK) . The phenotype of each cyst was expressed by 478 radiomics features, including the first order statistics, shape, texture, and textures from wavelet and Laplacian of Gaussian. Additional 10 statistics from the whole pancreas and 2 demographic features of age and gender were also used for the analysis of the types of cyst. The minimum redundancy maximum relevance feature selection was applied for feature dimension reduction.

RESULTS

Among the whole 490 features, thirty features were found for the binary classification of IPMN. The matching results to clinical outcomes show 0.883 of sensitivity and 0.721 of specificity with 81.6% of overall accuracy (AOC area: 0.873). For all five types, thirty-five features were extracted with 72.8% of correctly classified cases by 10-fold cross validation. Age, median and mean intensities of wavelets, and fractal dimension were highly ranked for the both classifications.

CONCLUSION

Radiomics features were significantly different among different types of pancreatic cystic neoplasms and were helpful for the classification of pancreatic cystic neoplasms.

CLINICAL RELEVANCE/APPLICATION

Radiomics features can be used for the classification of pancreatic cystic neoplasms.

SSJ07-02 Radiomics Approach to Characterize Microsatellite Instability (MSI): A CT-Based Radiomic Signature for the Detection of the MSI-H Phenotype in Colorectal Cancer

Tuesday, Nov. 28 3:10PM - 3:20PM Room: E350

Participants
Yanqi Huang, Guangzhou, China (*Presenter*) Nothing to Disclose
Zaiyi Liu, MD, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

yikiann@126.com

PURPOSE

To develop and validate a CT-based radiomic signature for the preoperative detection of the MSI-H (high levels of microsatellite instability) phenotype in patients with colorectal cancer.

METHOD AND MATERIALS

Ethical approval by the institutional review board was obtained for this retrospective analysis, and the informed consent was waived. The primary cohort of this study consisted of 140 patients with clinicopathologically confirmed CRC, with data gathered from January to December 2011; while the independent validation cohort consisting of 114 consecutive patients collected from January to December 2012. 591 radiomic features were extracted from preoperative portal venous-phase computed tomography (CT) of CRC. Lasso regression model was used for data dimension reduction, feature selection, and radiomics signature building. The discrimination and calibration performance of the developed radiomics signature was assessed in primary cohort and then validated in the independent validation cohort.

RESULTS

After feature redcution and selection, 29 radiomics features were used to develop the radiomic signature. In both the primary and validation cohort, the radiomic signature was significantly associated with the MSI-H phenotype (P<0.001 for primary cohort; P=0.012 for validation cohort). The radiomic signature showed good discrimination, with a C-index of 0.914 (95%CI: 0.901, 0.927) in primary cohort and 0.702 (95%CI: 0.677, 0.727) in validation cohort. Good calibration of the radiomic signature was depicted in calibration curves in both the primary and validation cohort.

CONCLUSION

This study presents a CT-based radiomic signature that can be conveniently used to facilitate the preoperative individualized detection of MSI-H phenotype in CRC patients, which could be useful for informing patient prognosis and guiding the personalized therapy of CRC including adjuvant chemotherapy, targeted therapy, and immune checkpoint inhibitor therapy.

CLINICAL RELEVANCE/APPLICATION

The developed and validated CT-based radiomic signature could facilitate the preoperative individualized detection of MSI-H phenotype CRC, which further advances the role of MSI in informing patient prognosis and guiding the personalized therapy of CRC including adjuvant chemotherapy, targeted therapy, and immune checkpoint inhibitor therapy.

SSJ07-03 Comparison between Radiomics Analysis and Subjective Visual Assessment of T2-weighted MRI Images for the Identification Of >=T3 Rectal Cancer

ines.santiago@fundacaochampalimaud.pt

PURPOSE

To determine if radiomics outperforms visual assessment based on T2-weighted imaging (T2-W) for the discrimination between <=T2 and >=T3 rectal cancer

METHOD AND MATERIALS

The study included all patients with rectal cancer who underwent total mesorectal excision as primary curative treatment, without neoadjuvant therapy, at our institution, between October 2013 and December 2016 (n=26, 14 males, mean age=67 years). Two patient groups were formed based on pathological stage, <=T2 (n=13) and >=T3 (n=13). All patients underwent staging MRI before surgery comprising T2-W imaging in axial, coronal and sagittal planes. T2-W images were blindly reviewed in consensus by 2 radiologists and primary tumors were classified as >=T3 or <=T2. A volume of interest (VOI) was drawn in consensus by the 2 radiologists, based on axial T2-W images, encompassing the whole primary tumor and corresponding datasets were analyzed using the PyRadiomics package. Wilcoxon-Mann-Whitney test was used to define the discriminating power between the 2 groups, of each of the 1831 features separately. Feature reduction was done using a cut-off correlation coefficient of 0.99 to remove redundant features. Multiple comparisons correction was done based on an FDR test. The best performing feature was selected, and its diagnostic accuracy was compared to that of visual radiological assessment using DeLong's test

RESULTS

23 radiomics features provided with statistically significant differences (p<0.05) between the 2 groups, while the best performing feature was the Low Gray Level Run Emphasis - GLRLM of the exponential of the original image with sensitivity, specificity and area under the ROC curve (AUROC) of 0.79, 0.92 and 0.92, respectively. Sensitivity, specificity and AUROC were 0.93, 0.67 and 0.80, respectively, for visual radiological evaluation. The performance difference between visual assessment and radiomics analysis was not statistically significant (p=0.21)

CONCLUSION

Our preliminary results indicate that radiomics analysis doesn't provide higher performance compared to visual radiological assessment for the identification of >=T3 rectal cancer based on T2-W images.

CLINICAL RELEVANCE/APPLICATION

Radiomics analysis and difficult issues in rectal cancer staging: applicability in the identification of >=T3 rectal cancer

SSJ07-04 Predicting Early Recurrence of Hepatocellular Carcinoma with Texture Analysis of Pre-Operative Magnetic Resonance Imaging: A Radiomics Study

PURPOSE

To study the feasibility of using texture analysis in pre-operative magnetic resonance imaging (MRI) to predict early recurrence (ER) in hepatocellular carcinoma (HCC) post-curative surgery.

METHOD AND MATERIALS

Institutional review board was obtained. A retrospective review of all patients who underwent hepatectomy between 1 Jan 2007 and 31 Dec 2015 was performed. Inclusion criteria: pre-operative MRI, tumor size >=1cm, new cases of HCC. Exclusion criteria: Loss-to-follow-up, ruptured HCCs, movement artifacts and previous hepatectomy or interval adjuvant therapy. Patients were divided into ER and late or no recurrence (LNR) groups. Early recurrence was defined as new foci of HCC within 730 days of curative surgery. Plain, diffusion-weighted, arterial and portovenous acquisitions were imported into MATLAB (Mathworks, Matick, MA, USA). Radiomics feature extraction was performed on the largest cross-sectional area of each tumor. MaZda software (version 4.6.2.0) was used to analyze 290 texture parameters and PRTools was used for feature selection.

RESULTS

Fifty-seven patients (49 male, mean age 66.5 years) were divided into ER (n=21) and LNR (n=36) groups. Differences in alpha-fetoprotein level (p=0.021), tumor size (p=0.011), restricted diffusion (p=0.01) and vascular invasion (gross and/or microvascular, p=0.047) between the 2 groups were found to be statistically significant. Texture analysis revealed 79% accuracy in classifying arterial images using 1-nearest neighbor using parameters S(1,0)Contrast or S(5,-5)Entropy. The parameter S(5,-5)Entropy has also resulted in 77% accuracy in classifying T2 images.

CONCLUSION

Early recurrence of HCC can be predicted on pre-operative MRI with 79% accuracy using the appropriate texture analysis parameter.

CLINICAL RELEVANCE/APPLICATION

Post-operative recurrence of HCC results in mortality and the time-to-recurrence duration is an independent prognostic factor of survival. The ability to identify these high-risk patients pre-operatively will potentially guide both surgical management, such as resecting a wider margin or liver transplantation, as well as post-operative surveillance and therapeutic interventions.

PURPOSE

To quantify heterogeneity in hepatocellular carcinoma (HCC) using multiparametric (mp) magnetic resonance imaging (MRI), and to

report preliminary data correlating quantitative MRI parameters with histopathology and gene expression in a subset of patients.

METHOD AND MATERIALS

Thirty-two HCC patients (M/F 26/6, mean age 59 years) with 39 HCC lesions were included in this prospective study. The mpMRI protocol consisted of diffusion-weighted imaging (DWI), blood-oxygenation-level-dependent (BOLD), tissue-oxygenation-level-dependent (TOLD) and dynamic contrast-enhanced (DCE)-MRI. Histogram characteristics [central tendency (mean, median) and heterogeneity (standard deviation, kurtosis, skewness) MRI parameters] in HCC and liver parenchyma were compared using Wilcoxon signed-rank tests. Histogram data was correlated between MRI methods in all patients and with histopathology and gene expression in 14 patients.

RESULTS

HCCs exhibited significantly higher intra-tissue heterogeneity vs. liver with all MRI methods (P<0.042). Although central tendency parameters showed significant correlations between MRI methods and with each of histopathology and gene expression, heterogeneity parameters exhibited additional complementary correlations between BOLD and DCE-MRI and with histopathologic hypoxia marker HIF1a and gene expression of Wnt target GLUL, pharmacological target FGFR4, stemness markers EPCAM and KRT19 and immune checkpoint PDCD1.

CONCLUSION

Histogram analysis combining central tendency and heterogeneity mpMRI features is promising for noninvasive HCC characterization on the imaging, histologic and genomics level.

CLINICAL RELEVANCE/APPLICATION

The proposed mpMRI approach could potentially be used to stratify hepatocellular carcinoma treatment and to noninvasively predict treatment outcome.

SSJ07-06 Prediction of Target Therapy Related Gene Expression Level for Hepatocellular Carcinoma: Preoperative Gd-EOB-DTPA Enhanced MRI and Histopathological Correlation

Tuesday, Nov. 28 3:50PM - 4:00PM Room: E350

Participants
Kun Huang, Guiyang, China (*Presenter*) Nothing to Disclose
Zhi Dong IV, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose

Yanji Luo, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose
Zi-Ping Li, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose
Shiting Feng, MD, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Our aim of the study is to investigate the feasibility of prediction for target therapy related gene expression level in hepatocellular carcinoma (HCC) using preoperative Gd-EOB-DTPA enhanced magnetic resonance imaging (MRI).

METHOD AND MATERIALS

91 patients with solitary HCC who underwent preoperative Gd-EOB-DTPA enhanced MRI were prospectively analyzed. Features including tumor size, signal homogeneity, tumor capsule, tumor margin, intratumoral vessels, peritumor enhancement in mid-arterial phase, peritumor hypointensity during hepatobiliary phase, signal intensity ratio on DWI and apparent diffusion coefficients (ADCs), T1 relaxation times and the reduction rate between pre- and post-contrast enhancement images were assessed. HCC target therapy related gene (B-Raf,Raf-1,VEGFR2,VEGFR3) expression level in excision specimens were evaluated using immunohistochemical staining. Correlation between these MRI features and B-Raf,Raf-1,VEGFR2,VEGFR3 gene expression level were analyzed by Rank sum test, Spearman correlation and multivariate logistic regression so as to establish a prediction model.

RESULTS

Univariate analysis showed that tumor incomplete or non capsule (p<0.001), intratumoral vessels (P=0.002) were significantly related with the B-Raf gene expression level, and tumor capsule status (p=0.001), intratumoral vessels (P=0.013) significantly correlated with the Raf-1 gene expression level. There was no significant association between the expression level of VEGFR2, VEGFR3 and all the MRI features. Multivariate logistic regression analysis demonstrated that incomplete tumor capsule (P=0.002, OR=11.870, 95% CI: 2.473~56.975) or non capsule (P=0.004, OR=15.750, 95% CI: 2.373~104.537) were independent risk factors of HCC with high B-Raf gene expression level, and incomplete tumour capsule (P< 0.001, OR=11.250, 95%CI: 3.206~39.474) or non capsule (P=0.040, OR=5.556, 95%CI: 1.078~28.635) were independent risk factors of HCC with high Raf-1 gene expression level.

CONCLUSION

It is feasible to predict the expression level of B-Raf and Raf-1 gene using preoperative Gd-EOB-DTPA enhanced MRI.

CLINICAL RELEVANCE/APPLICATION

Incomplete or non capsule, or presence of intratumoral vessels are potential indicator for the high expression of B-Raf and Raf-1. Gd-EOB-DTPA enhanced MRI may facilitate the determination for choosing gene therapy for the patient with HCC.

april_chencen@163.com

PURPOSE

In this study, we used spectral CT with fat material decomposition technique and magnetic resonance (MR) IDEAL-IQ to quantify fat content. The goal of this study was to evaluate the accuracy of the two methods at different fat concentrations.

METHOD AND MATERIALS

(1) For the fat-water model (model A), a series of concentrations containing homogeneous mixed fat and water were prepared, with a fat content of 0.00, 0.02, 0.04, 0.08, 0.16, 0.32, 0.40, 0.50, 0.60, 0.70, 0.80, 0.90, 1.00 ml/ml, respectively. For the liver-fat model (model B), eleven homogeneous liver and fat tissue mixed samples with various fat content from 0-1.0 g/g (with an interval of 0.1 g fat/g). (2) All samples were scanned on GE Discovery HD750 CT. Fat material decomposition technique (water-fat base) was further applied to measure the fat density (MFD). IDEAL-IQ was utilized on GE Discovery 750w MR scanner to obtain the measured fat fraction (MFF). A linear regression was performed to analyze the relationship between the MFD or MFF and the actual fat fraction (AFF).

RESULTS

Both spectral CT fat material decomposition method and MR IDEAL-IQ method resulted good linear relationship between the measured fat content and AFF. In model A, it showed as: R2MFD=0.9936, R2MFF=0.9987. In Model B, it showed as: R2MFD=0.9946, R2MFF =0.9941. For Both models it had a P value less than 0.001. In particular at a lower fat concentration range in model A (AFF between 0-16%), the results were R2MFD=0.8927 and R2MFF=0.9687. In this circumstances, MFF showed a stronger linear correlation with AFF compared to MFD while MFD value can be well normalized to obtain AFF by the corresponding correlation equation.

CONCLUSION

Both spectral imaging fat material decomposition and MR IDEAL-IQ techniques can provide accurate and reliable quantification of fat content for both water-fat and liver-fat models. In particular, MFF has a more significant correlation with AFF in the low fat content scenario.

CLINICAL RELEVANCE/APPLICATION

This study demonstrated the feasibility of using CT spectral imaging - fat material decomposition and MR IDEAL-IQ technique to precisely quantify the fat content. The results indicated promising clinical applications of using these methods to study the fat metabolism in different tissues or organs (e.g. brain, breast, liver and bone) that contain different fat concentration in the future.

SSJ08-02 Automated Prediction of Nonalcoholic Fatty Liver Disease Activity Score (NAS) with an Advanced Multiparametric Magnetic Resonance Elastography and Machine Learning Technology

yin.meng@mayo.edu

PURPOSE

Liver stiffness has become the most accurate noninvasive imaging biomarker for detecting hepatic fibrosis. However, much less work has been done for assessing the NAFLD activity score (NAS) - which is a numerical sum of histologic grading of steatosis, inflammation, and ballooning in biopsy specimens. In animal models, we have found that the NAS can be predicted by training a machine learning algorithm with data sets of multiple parameters obtained from MR elastography (MRE) (e.g., storage and loss moduli, volumetric strain) and MRI-assessed proton density fat fraction (PDFF). In this study, we tested the same approach in a pilot clinical study to assess the potential to predict the NAS using multiparametric MRE.

METHOD AND MATERIALS

62 clinically obese patients who underwent bariatric surgery and 12 normal volunteers (BMI<30) were included. Multifrequency MRE was used to measure the various mechanical properties that correlate with ballooning and inflammation, while PDFF was used to quantify steatosis. Liver biopsies were obtained in patients for histologic grading and calculating NAS based on the NASH CRN criteria. From the MRE/MRI parameters, the three parameters that best and most significantly correlated with NAS were selected ($p<0.05$ for all three parameters). Several machine learning regression algorithms were tested to minimize cross-validation error in the training set. An ordinal logistic model was used for ordinal NAS outputs in a confusion matrix with subsequent ROC analyses.

RESULTS

The clinical model included 74 subjects: 62 obese (35 NAFLD and 27 NASH) and 12 healthy volunteers. Liver stiffness at 60 Hz, loss modulus at 30 Hz, and fat fraction were all significantly associated with the NAS in the effect tests for both linear and nonlinear (neural networks) predictions (Fig. a,b). The ordinal logistic model showed less than ±1 bias in 93% of subjects (69/74) in the resulting confusion matrix (Fig. c) and successfully distinguished each NAS score with excellent accuracy (AUROC>0.9 for all, Fig. d).

CONCLUSION

This preliminary study shows that multiparametric MRE/MRI can be used to accurately predict NAS score and represents a promising alternative to liver biopsy for NASH diagnosis and monitoring.

CLINICAL RELEVANCE/APPLICATION

Multiparametric MR elastography, coupled with machine learning, can provide a noninvasive prediction of the NAFLD activity score (NAS), which is an important metric for assessing disease severity.

PURPOSE

Proton-density fat fraction (PDFF) is an accepted quantitative imaging biomarker of liver steatosis. However, the complexity of PDFF calculation by nonlinear curve-fitting has been a barrier to more widespread adoption. The purpose of this study was to validate a simple template-matching method for liver PDFF determination as an alternative to the conventional curve-fitting method.

METHOD AND MATERIALS

This is a secondary analysis of an IRB-approved, HIPAA-compliant clinical trial of diabetic adults undergoing liver MRI. Liver MRI

This is a secondary analysis of an IRB-approved, HIPAA-compliant clinical trial of diabetic adults undergoing liver MRI. Liver MRI exams were performed at 3T using 3D spoiled gradient echo sequence, acquired at 6 echo times (TEs): 1.05, 1.84, 2.63, 3.42, 4.21, 5.01ms. The T1-bias was minimized by flip angle 2 deg for repetition time 6.2ms. On the reconstructed magnitude images, a region of interest (ROI) was placed on the liver. ROI's mean signal magnitudes were recorded for each TE.The multiecho data were analyzed by two different methods: conventional nonlinear curve-fitting using a multipeak fat spectral model, and template-matching, as follows. First, a library of signal templates (synthetic 6-element signal vectors) was pre-generated for a 2D parameter grid: PDFF 0-50% and R2* 0-1000ms. Second, the observed 6-echo signal vector was compared to each template by vector inner-product. The template resulting in the maximum inner-product was selected as the "match". Computation times for both methods were recorded.

RESULTS

51 subjects (mean age 35 yrs, range [36-71] yrs) underwent liver MRI, 40 of which completed both pre- and post-treatment MRI. All available 91 MRI exams were analyzed. Figure 1 shows near-perfect linear regression agreement between the template-matching and curve-fitting liver PDFF values. The intercept and slope were slightly different from 0 and 1, respectively (p=0.006 and <0.001), but their small effect sizes are likely not clinically relevant. Bland-Altman (Figure 2) analysis demonstrates that template-matching has <1% error margin in absolute PDFF. Per-ROI computation time was 0.9ms and 19.6ms for template-matching and curve-fitting, respectively.

CONCLUSION

Liver PDFF calculation using template-matching is equivalent to curve-fitting within 1% error margin in absolute PDFF.

CLINICAL RELEVANCE/APPLICATION

Template-matching permits simple liver PDFF calculation without complex nonlinear curve-fitting and may facilitate more widespread use worldwide.

SSJ08-04 Dual-Layer Detector Spectral CT versus Magnetic Resonance Imaging for the Assessment of Iron Overload in Myelodysplastic Syndromes and Aplastic Anemia

Tuesday, Nov. 28 3:30PM - 3:40PM Room: E353A

PURPOSE

To investigate the performance of dual-layer detector spectral CT for iron deposition in myelodysplastic syndromes and aplasic anemia,and to compare the results to MRI T2* imaging

METHOD AND MATERIALS

Thirty patients with clinical history of myelodysplastic syndromes and aplasic anemia underwent T2*-weighted hepatic and cardiac MRI on a three-tesla MRI scanner (Ingenia, Philips, Netherlands) and were scanned on a 128-row spectral detector CT (IQon, Philips, Netherlands) latterly. T2* values of liver and septal muscle were calculated with a dedicated software tool (CMR Tools©, Imperial College). HU differences (ΔHU) in liver and septal muscle were calculated between the lower (50 kVp) and higher (120 kVp) energy resulted from mono-energetic spectral imaging ranging from 40 to 200 keV, which was based on spectral base image (SBI). Regression and correlation analyses were conducted between T2* and HU differences (ΔHU) in the liver and cardiac muscle.

RESULTS

Table time for spectral CT was significantly shorter compared to MRI (mean: 3.3 min vs. 25.2 min). Liver and cardiac T2* were 13.68 ± 12.52, 27.89 ± 35.01ms,respectively. Liver and cardiac signal intensity ratio to muscle were 0.650.44,1.44 ± 0.60,respectively. Liver and cardiacΔHU were 3.12 ± 1.89, 2.35 ±2.89 Hu, respectively. The results showed strong (r = 0.8 and P <0.05) linear correlation between liver T2* and liver ΔHU, and moderate linear correlation (r = 0.61 and P <0.05) between cardiac T2* and cardiac ΔHU. Strong linear correlation (r = 0.85 and P <0.05) was found between liver to muscle (L/M) signal intensity ratio and ΔHU, and moderate linear correlation (r = 0.65 and P <0.05) between heart to muscle (H/M) signal intensity ratio and cardiac ΔHU.

CONCLUSION

Dual-layer detector spectral CT seem to be equivalent valuable for evaluating liver and myocardial iron overload, compared to MRI T2* imaging, which might help in patient staging based on the severity of iron overload.

CLINICAL RELEVANCE/APPLICATION

Dual-layer detector spectral CT might help in patient with iron overload.

SSJ08-05 Non-invasive Quantification and Grading of Liver Iron Content with Spectral CT: An Iron Overload Rabbit Model Study

PURPOSE

To assess the accuracy of spectral CT in liver iron concentration (LIC) quantification and grading at different clinically significant LIC thresholds.

METHOD AND MATERIALS

Fifty-one rabbits of iron-loaded model were established by intravenous injection of iron dextran. Abdomen CT was then performed with fast kilovolt peak switching dual energy CT. Hepatic iron concentration (HIC) imaging was derived from an iron/water, two-material decomposition using gemstone spectral imaging analysis. Hepatic attenuation on 40 Kev and 140 Kev monochromatic energy image were measured. The difference between 40 Kev and 140 Kev (ΔH) was calculated. Ex vivo hepatic pathology was obtained and postmortem assessment of LIC was conducted on inductively-coupled plasma (ICP) spectrometer. The correlations between CT measurements (HIC and ΔH) and LIC were analyzed. HIC was fitted against LIC to build linear regression. Then the prediction accuracy of the regression was tested. Diagnostic performance of HIC and ΔH in discriminating different LIC thresholds (1.8, 3.2, 7.0, 15.0mg/g dry tissue) were evaluated by receiver operating characteristic (ROC) analysis.

RESULTS

According to the pathological analysis, the iron staining increased with increasing dose of injected dextran iron. LIC was from 0.20 to 39.59mg/g measured by ICP. HIC (range, -37.41-118.03 mg/mL) had a positive linear correlation with LIC(r^2=0.943,P<0.001). The predicted HIC obtained by derived equation calculation showed a high consistency with ICP results. For discriminating clinically significant LIC thresholds (1.8, 3.2, 7.0, 15.0mg/g dry tissue), ROC analysis revealed that the corresponding optimal cutoff value of HIC was -17.56, -0.92, 7.6, 48.28 mg/mL. With the cutoff value of HIC= 48.28 mg/mL, the highest sensitivity (100%) and specificity (100%) were obtained at LIC threshold of 15.0mg/g dry tissue. HIC showed no significant differences with ΔH at different clinically iron accumulation thresholds (P>0.05).

CONCLUSION

HIC was highly linear with titrated LIC in the iron overload rabbit models. HIC could quantify LIC and had high accuracy for grading LIC especially at graveness iron accumulation situation.

CLINICAL RELEVANCE/APPLICATION

With excellent diagnostic performance for discriminating clinically significant LIC thresholds, HIC imaging might be used to guide iron chelation therapy in the clinical practice in the future.

SSJ08-06 Virtual Unenhanced Algorithms for Fast-Kilovolt Switching Dual-Energy CT: Comparison Between Dedicated and Non-dedicated Softwares for Assessment of Liver Fat Content

Tuesday, Nov. 28 3:50PM - 4:00PM Room: E353A

Participants
Tomoko Hyodo, MD, Osaka-Sayama, Japan (*Presenter*) Nothing to Disclose
Norihisa Yada, MD, Kyoto, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

In fast kV-switching dual-energy CT (DECT), a new multi-material decomposition (MMD) algorithm developed for the quantification of liver fat content includes virtual unenhanced (VUE) algorithm based on the attenuation coefficient of liver tissue. This study aims to compare the accuracy of the dedicated and non-dedicated VUE algorithms for liver fat content estimation.

METHOD AND MATERIALS

Forty-seven patients with suspected hepatic steatosis (BMI, 18-40) underwent unenhanced and tri-phase dynamic contrast-enhanced DECT scans within 4 weeks prior to liver biopsy. Hepatic fat volume fraction (FVF, %) images using MMD and CT attenuation value (CTav, HU) images using non-dedicated VUE were generated from DECT data. FVF and CTav were compared with histologic steatosis grade (0-3, as defined by the non-alcoholic fatty liver disease activity score [NAS] system) using Jonckheere-Terpstra trend tests. Agreement of the measurement between real- and virtual unenhanced images was assessed using generalized estimating equation (GEE) model and Bland-Altman analysis.

RESULTS

NAS steatosis scores were score 0 in 11 patients; 1 in 21; 2 in 12; and 3 in 3. FVF increased and CTav decreased with increasing histologic steatosis grade (trend test, P < .001 for each). GEE models revealed that scan phase was significantly associated with CTav (ß = 0.8; P < .016) but not with FVF (ß = 0.06; P =.730). The differences between real non-contrast-enhanced and contrast-enhanced FVFs for arterial, portal venous, and equilibrium phases tended to be larger (limits of agreement, -8.4 to 9.5) but there was no systemic bias. Bland-Altman analysis of real non-contrast-enhanced and each of three contrast-enhanced CTav showed significant proportional bias (r = -0.38 to -0.44; P < .001 for all).

CONCLUSION

VUE in MMD algorithm for the quantification of liver fat content is more accurate than CT attenuation value calculated with non-dedicated VUE.

CLINICAL RELEVANCE/APPLICATION

The MMD algorithm is a promising technique for less-invasively assessment of hepatic fat content, as fat volume fraction data can be derived from the contrast-enhanced scan, eliminating the need for a separate non-contrast CT scan to derive fat volume fraction.

PURPOSE

To evaluate the association of absolute total liver (T), lobar (right and left; R, L), and caudate volume (C), as well as ratios of left lobe and caudate to total liver volume (L/T and C/T) with the disease severity of PSC as determined by Mayo score. The second aim was to develop a novel radiologic model to predict Mayo score.

METHOD AND MATERIALS

This HIPAA compliant, retrospective single center study included 79 PSC patients who were imaged between 2000 and 2017. T, R, L and C were measured using Advantage Workstation (GE) on the imaging study (MR/CT) within an average of 4 months of risk score calculation. L/T and C/T ratios were then calculated. Patients were stratified into group A (low and intermediate risk; Mayo score <2) and group B (high risk; Mayo score >=2). The differences in liver volumes between the 2 groups were assessed using T test. Regression analysis was performed to test the correlation between the liver volumes and Mayo score. To assess the prognostic performance of liver volume, area under the receiver operating characteristic (AUC-ROC) curve was evaluated. P value <0.05 was considered significant.

RESULTS

Our cohort included 49 males and 30 females with the mean age of 43, with no significant differences in age between males and females (p=0.74). T, L, and C were significantly higher in group B than in group A (p<0.05). However, the difference in R was not significant (p=0.07). The differences of L/T and C/T between Group A and B were statistically significant (p<0.005). L/T had the best positive correlation with Mayo score (r=0.55). Linear regression analysis identified L/T as a significant variable for predicting Mayo score, with the prediction model as follows (p<0.001): Mayo risk score= 5.6*(L/T) - 1.5 L/T showed good ability to distinguish between mild/moderate and severe PSC patients (AUC-ROC 0.8).

CONCLUSION

Patients with severe PSC have larger total liver, left lobe, and caudate volume, and higher left and caudate to total ratio compared to patients with mild/moderate disease. Left lobe to total liver volume ratio was associated with Mayo score and it may be used to predict disease severity in patients with PSC.

CLINICAL RELEVANCE/APPLICATION

Novel volumetric liver measurements correlate with Mayo scores and may potentially be useful in supplementing Mayo score and predicting disease severity.

SSJ09-02 Postprandial Changes in Flow Dynamics of the Bile within the Common Bile Duct: Evaluation with Cine Dynamic MRCP and a Spatially Selective IR Pulse

PURPOSE

To evaluate the influence of oral ingestion in flow dynamics of the bile within the common bile duct in healthy subjects by using cine dynamic MRCP and a spatially selective IR pulse non-invasively.

RESULTS

The median grading score of antegrade bile flow after oral ingestion (score=0.85-1.18) was significantly (P<0.01) higher than that before oral ingestion (score=0.53), indicating that bile excretion was stimulated by oral ingestion. Grading score of antegrade bile flow showed a maximum peak of 1.18 at 26 minutes after ingestion, and then, began to gradually decline with a statistical difference (P<0.01). Contraction of gallbladder was associated with increased grading score of antegrade bile flow after oral ingestion with a statistical significance (p<0.01). Regarding reversed bile flow, there were no significant differences in median grading score before (0.18) and after (0.15-0.23) oral ingestion, suggesting that oral ingestion has little affect on the function of oddi sphincter.

CONCLUSION

Non-invasive cine dynamic MRCP using spatially selective IR pulse showed potential for evaluating postprandial changes of flow dynamics of bile as a physiological reaction.

CLINICAL RELEVANCE/APPLICATION

Cine dynamic MRCP using spatially selective IR pulse may contribute to the assessment of flow dynamic changes of the bile such as the impaired bile excretion in patients with digestive malabsorption.

SSJ09-03 Intrahepatic Cholangiocarcinoma: Can Imaging Phenotypes Predict Survival and Tumor Genetics?

PURPOSE

On CT, intrahepatic cholangiocarcinomas (ICC) are phenotypically heterogeneous tumors. The purpose of this study was to investigate the associations between CT imaging phenotypes, patient survival and known genetic markers. We hypothesize that visibly different tumor subtypes may be associated with survival or known genetic pathways of ICC.

METHOD AND MATERIALS

An institutional review board approved,HIPAA-compliant,retrospective study was performed with 66 patients who had surgically resected ICC. Preprocedure CT images of ICC were assessed using predominantly qualitative radiographic descriptors while blinded to tumor genetics and patient clinical data. Associations between radiographic features and overall survival (OS) and disease free survival (DFS) were performed with Cox proportional hazards regression and visualized with Kaplan Meier plots. The associations between radiographic features and imaging pathways (IDH1, Chromatin and RAS-MAPK) were assessed with Fisher's Exact test and the Wilcoxon Rank sum test, where appropriate and corrected for multiple comparisons within each pathway using the False Discovery Rate correction.

RESULTS

Three imaging features were significantly associated with a higher risk of death: necrosis (HR:2.95 95%CI:1.44-6.04, p=0.029), satellite nodules (HR:3.29, 95%CI:1.35-8.02, p=0.029), and vascular encasement (HR:2.63, 95%CI:1.28-5.41, p=0.029). Additionally, with each increase in axial size, the risk of death increased (HR:1.14, 95%CI:1.03-1.26, p=0.029). Similar to findings for OS, satellite nodules (HR:3.81, 95%CI:1.88-7.71, p=0.002) and vascular encasement (HR:2.25, 95%CI:1.24-4.06, p=0.019) were associated with increased risk of recurrence/death. No significant associations were found between radiographic features and genes in the IDH1, Chromatin or RAS-MAPK pathways (p=0.63-84).

CONCLUSION

This preliminary analysis of resected ICC suggests associations between CT imaging features and OS and DFS. No association was identified between imaging features and currently known genetic pathways.

CLINICAL RELEVANCE/APPLICATION

Intrahepatic cholangiocarcinomas are heterogeneous on CT and have qualitative radiographic features associated with survival. Possible associations with tumor genetics were not identified.

SSJ09-04 Multiparametric Response Assessment of Unresectable Intrahepatic Cholangiocarcinoma Treated with TACE: Role of Contrast Enhanced 3-D Volumetric Functional MRI Using Apparent Diffusion Coefficient Maps

PURPOSE

To assess multiparametric changes in 3-D volumetric functional parameters on contrast enhanced MRI and DWI in predicting early response of unresectable intrahepatic cholangiocarcinoma (iCCA) after transcatheter arterial chemoembolization (TACE).

METHOD AND MATERIALS

This retrospective IRB-approved, HIPAA-compliant study with waived patient consent included 94 patients (mean age, 68±12 years; 40 men) with unresectable iCCA. All patients underwent baseline and follow up MRI after TACE, and were followed up until death or December 2016. Index lesions were analysed for changes in anatomical (RECIST, volume) and functional (viable tumor, tumor burden, ADC) volumetric MR parameters. Overall survival (OS) was used to stratify cohort into low (<=15 months) and high (>15 months) OS groups. Changes in MRI and confounding clinical parameters were compared between the two groups. Their effect on OS was assessed using Cox-regression and Kaplan-Meier analysis. P <0.05 was considered significant.

RESULTS

Tumor volume did not show significant change after TACE (P=0.07) while RECIST diameter showed a small change (-2.6 mm, P=0.02). Mean absolute and percent viable tumor volume, and mean tumor burden decreased (P<0.0001, for each) while mean ADC increased (P<0.0001) after TACE. The only parameter showing significantly different change between low and high OS groups was mean ADC, both absolute (215.4±260.5 x 10-6 mm2/s vs 341.9±313.5 x 10-6 mm2/s; P=0.040) and percent (12.8±14.7 % vs 28.8±27.4 %; P=0.001) change. In Cox regression analysis, significant effect on survival outcomes was seen for percent ADC change adjusted for confounding clinical parameters. (Hazard ratio, 0.93; P<0.05). Significant differences in survival were noted when percent change in mean ADC cut off of 25%, 30% and 35% were used to classify responders and non-responders (log rank test, P=0.035, 0.019 and 0.001, respectively).

CONCLUSION

After TACE, iCCA lesions showed increase in volumetric ADC (19.9%), decrease in viable tumor volume (25.9%), and decrease in percent viable tumor volume (16.3%). Thresholds of 25%, 30% and 35% change in ADC resulted in survival differences with a 7% reduction in risk of death for a unit increase in percent ADC change.

CLINICAL RELEVANCE/APPLICATION

Volumetric functional MR changes can allow individualization of TACE therapy in iCCA with prediction of early oncologic response and overall survival. These may be utilized in future clinical trials.

PURPOSE

To evaluate the influence of cholecystectomy on the flow dynamic pattern of bile in the extrahepatic bile duct by using cine-

dynamic MRCP with spatially-selective inversion-recovery (IR) pulse non-invasively.

RESULTS

Antegrade bile flow was observed more frequently in the cholecystectomy group than in the non-cholecystectomy group (5.1 times vs 2.9 times, P=0.005). Mean grading score of antegrade bile flow was significantly greater in the cholecystectomy group than in the non-cholecystectomy group (mean grade, 0.33 vs 0.21; P=0.007). These facts suggested that antegrade bile flow is probably generated by increased intraductal pressure of CBD collecting bile, and that the common bile duct plays function of the gallbladder such as contraction and buffering. Regarding reversed bile flow, there were no significant differences in the frequency and grading score between cholecystectomy group and non-cholecystectomy group, suggesting that contraction pressure in the sphincter of Oddi is extremely higher than CBD pressure even in patients after cholecystectomy.

CONCLUSION

Antegrade bile flow was observed more frequently and predominantly in patients after cholecystectomy in cine-dynamic MRCP with a spatially selective IR pulse probably due to the increased intraductal pressure of CBD collecting the bile while reversed bile flow was observed equivalently because of the preserved function of Oddi sphincter.

CLINICAL RELEVANCE/APPLICATION

Cine-dynamic MRCP with a spatially selective IR pulse may play a role in evaluating the alteration of bile flow pattern in patients with postcholecystectomy syndrome and sphincter of Oddi dysfunction.

SSJ09-06 Can MRI Distinguish Between Hepatocellular Carcinoma, Intrahepatic Cholangiocarcinoma and Biphenotypic Tumors?

PURPOSE

Accurate differentiation between hepatocellular carcinoma (HCC), intrahepatic cholangiocarcinoma (ICC) and biphenotypic tumors (BPT) at imaging is clinically important but often a challenge. The purpose of this multi reader study was to assess the ability of contrast enhanced multiphase MRI to differentiate between HCC, ICC, and BPT.

METHOD AND MATERIALS

Patients with histologically confirmed HCC, ICC or BPT and who had undergone liver MRI were identified using pathology and radiology databases. Patients with therapy prior to imaging were excluded. MRI studies were reviewed by 4 abdominal radiologists blinded to tumor type. Disagreement was resolved by majority and if necessary, a blinded fifth reader. Readers reviewed imaging findings of each tumor on T2W, DWI and T1W images. Dynamic enhancement (arterial, portal and delayed phase) characteristics were reviewed and 1 of 4 enhancement patterns (see figure) was assigned to each tumor. The most likely diagnosis (HCC, ICC or BPT) was recorded. Fisher's exact test was used to compare proportions. Krippendorff's a was used to compare variability amongst readers.

RESULTS

MRI exams from 50 patients (age 64±12 years, 19M, 31F) with 24 HCC, 20 ICC and 6 BPT were included. 20 (83%) HCC, 3 (50%) BPT and 19 (95%) ICC were correctly identified. 21 (88%) HCC had type 1 and 18 (90%) ICC had type 2 enhancement pattern while BPT showed a mix of type 1 (33%), type 2 (50%) and type 4 (17%) enhancement. Type 1 was seen more frequently in HCC than ICC or BPT and type 2 was seen more frequently in ICC than in HCC. Rate of T2 hyperintensity was seen more frequently in ICC than BPT (100% vs 66%), while washout was seen more frequently in HCC compared to either BPT and ICC (83% versus 0% and 5% respectively). Capsule was seen more frequently in HCC than ICC (58% vs 5%) ($p<0.05$ for all listed comparisons). Krippendorff's a ranged from 0.308 to 0.515 for individual findings and was 0.739 for final diagnosis.

CONCLUSION

While characteristic enhancement patterns allow accurate diagnosis of HCC and ICC, BPT were more diverse in their enhancement pattern and therefore more difficult to diagnose. BPT should be considered in the differential diagnosis of a hepatic mass which lacks characteristic features of HCC or ICC such as T2 hyperintensity, washout or capsule.

CLINICAL RELEVANCE/APPLICATION

Biphenotypic tumors cannot be accurately differentiated from HCC and ICC using multiphasic MRI.

PURPOSE

To evaluate MRI findings of symptomatic fibroids causing acute lower abdominal and/or pelvic pain in pregnancy and compare them with non-symptomatic fibroids.

METHOD AND MATERIALS

MRI studies of pregnant patients with uterine fibroids performed for acute lower abdominal and/or pelvic pain between 1/2010-9/2016 were retrospectively evaluated. Patient age, gestational age, fibroid size, fibroid number, fibroid location, signal intensity of the fibroid relative to myometrium on T1- weighted imaging, T2-weighted imaging, and diffusion weighted imaging (DWI), and ADC values were recorded along with final discharge diagnoses. Kruskal-Wallis and chi-squared tests compared continuous and categorical variables, respectively, between symptomatic and non-symptomatic fibroids.

RESULTS

Twenty-seven pregnant patients (mean age of 33 [range: 24-47] and mean gestational age of 18 [range: 4-33]) with a total of 57 fibroids comprised the study cohort, with 13 fibroids in 13 patients ultimately identified as the cause of pain based on clinical examination and final discharge diagnoses. Larger size (5.8 versus 3.4 cm in diameter, $p = 0.00012$), T2 hyperintensity relative to myometrium ($p = 0.000049$), and hyperintensity on DWI ($p = 0.00054$) were significantly associated with symptomatic fibroids. ADC values were slightly lower in symptomatic fibroids but not statistically significant (1401 versus 1493 x 10-6 mm2/s, $p = 0.32$). No difference in T1 signal intensity was seen between symptomatic and non-symptomatic fibroids ($p = 0.73$).

CONCLUSION

MRI characteristics of fibroids causing acute pain in the setting of pregnancy have not previously been described, with the exception of T1 hyperintensity seen with red degeneration. In our cohort, larger size and hyperintensity on DWI and T2-weighted imaging relative to myometrium are significantly associated with symptomatic fibroids. These imaging features may also be useful indicators of fibroid degeneration.

CLINICAL RELEVANCE/APPLICATION

MR signal characteristics associated with symptomatic fibroids are described in our cohort of pregnant patients presenting with acute pain, and may be useful indicators of fibroid degeneration.

SSJ10-02 Malformations of Cortical Development Associated with Corpus Callosum Dysgenesis (CCD): Diagnostic Value of Fetal MRI in Prenatal Counseling

PURPOSE

To define the diagnostic role of fetal MRI in the assessment of cortical dysplasias and other malformations of the developing cerebral cortex, in fetuses with different forms of Agenesis of the Corpus Callosum (ACC).

METHOD AND MATERIALS

104 MR images of fetal CNS with a US suspicion of ACC were retrospectively reviewed. Fetal MRI was performed at 1.5 T Magnetom Avanto (Siemens, Erlangen, Germany) without mother-fetal sedation. Polymicrogyria, lissencephaly, schizencephaly, subependymal heterotopias and migration disorders were evaluated. Cortical findings were compared to three types of ACC (complete agenesis, partial agenesis and hypoplasia). Genetic tests were collected. Post-natal MRI or fetopsy for diagnostic confirmation were collected.

RESULTS

On 104 fetuses, fetal MRI was able to detect cortical malformations in 32 cases even in early gestational ages (<24GW). The mean Gestational Weeks (GW) at MR diagnosis was 26 (range: 22-36GW). MR imaging found 13/32 polymicrogyria, 7/32 lissencephaly, 5/32 schizencephaly, 4/32 subependymal heterotopias and 3/32 neuronal migration disorders. 22/32 had complete ACC, 4/32 had partial ACC and 6/32 had CC hypoplasia. Statistically significant correlations ($p<0.005$) between complete ACC, focal polymicrogyria and cortical dysmorphism affecting frontal lobes were found.

CONCLUSION

Fetal CNS MRI can detect cortical development malformations in complex ACC, providing further information for the clinician to assess the severity of perinatal outcome.

CLINICAL RELEVANCE/APPLICATION

MRI is a useful tool in improving obstetrical genetic prenatal counselling to predict pregnancy and fetal prognosis.

SSJ10-03 The Safety of MR Imaging at 3.0 T in Fetuses: Is Fetal Birth Weight or Hearing Impaired?

PURPOSE

To evaluate the effects of magnetic resonance imaging at 3.0 T during pregnancy on fetal growth and neonatal hearing in healthy newborns who are at low risk for congenital hearing impairment and brain or chromosomal abnormalities.

METHOD AND MATERIALS

This single-center retrospective case-control study was IRB approved. Informed consent was waived. 81 consecutive healthy newborns who were exposed to MR imaging at 3.0 T while in utero and were born between January 2011 and January 2016 were included. Each MR exposed newborn was matched 1:2 by birth date to a randomly selected healthy control newborn who was not exposed to MR imaging as a fetus. A total of 162 control newborns were included. For each MR exposed newborn, the estimated gestational age at MR exposure was recorded. For each MR exposed and control newborn, infant birth weight was recorded. In concordance with national guidelines, neonatal hearing screening was performed using auditory brain stem response. All hearing tests for the MR exposed and control neonates were recorded. Comparison of the average birth weight between the two groups was performed using an unpaired Student *t* test. The prevalence of hearing impairment was compared between the two groups by using Fisher's exact test.

RESULTS

The average estimated gestational age of fetal MR exposure was 148 days (range 35 days to 265 days). There was no significant difference in average birth weight between the MR exposed and control neonates; 3398 grams vs. 3510 grams, respectively [P = 0.06]. The prevalence of hearing impairment in the MR exposed neonates was 0% (0 out of 81); the prevalence of hearing impairment in the control group was 1.8% (3 out of 162). There was no significant difference between the two groups [P =0.55].

CONCLUSION

This study showed no evidence that fetal exposure to MR imaging at 3.0 T is associated with fetal growth restriction or neonatal hearing impairment.

CLINICAL RELEVANCE/APPLICATION

The data from this study suggests that fetal exposure to MR imaging at 3.0 T is safe.

SSJ10-04 Use of a Telerobotic Ultrasound System for Prenatal Imaging

PURPOSE

To determine the feasibility of using a telerobotic ultrasound system to remotely perform prenatal ultrasound examinations and generate images of diagnostic quality, and determine the acceptability of the system to patients and sonographers.

METHOD AND MATERIALS

Thirty participants (mean gestational age 22.8 weeks, range 15-36 weeks) were prospectively recruited. Participants underwent a limited examination (consisting of biometry, placental location, and amniotic fluid; n=21) or detailed examination (biometry, placental location, amniotic fluid, and fetal anatomic survey; n=9) performed using a conventional ultrasound system (EPIQ 5, Philips). This was immediately followed by an equivalent examination performed by a different sonographer using a telerobotic system consisting of a robotic arm (MELODY System, AdEchoTech), ultrasound unit (SonixTablet, BK Ultrasound), and videoconferencing system. Using this system, radiologists or sonographers remotely control all ultrasound settings and fine movements of a transducer from a distance. Telerobotic images were read independently from conventional images. Patients and sonographers were surveyed to assess acceptability of the system.

RESULTS

A paired sample t-test showed no statistically significant difference between conventional and telerobotic measurements of fetal head circumference or single deepest vertical pocket of amniotic fluid; however, a small but statistically significant difference was observed in measurements of biparietal diameter, abdominal circumference, and femur length (p-values <0.05). Intraclass correlations displayed excellent agreement (>0.90) between telerobotic and conventional measurements of all four biometric parameters. Of 21 fetal structures included in the anatomic survey, 82% (range 68-100%) of the structures attempted were sufficiently visualized using the telerobotic system. Ninety-seven percent of patients strongly or somewhat agreed they would be willing to have another telerobotic examination in the future.

CONCLUSION

The telerobotic ultrasound system assessed is feasible for performing prenatal ultrasound examinations. Telerobotic ultrasound systems may allow for the development of satellite ultrasound clinics in rural, remote, or low-volume communities, thereby increasing access to prenatal imaging.

CLINICAL RELEVANCE/APPLICATION

Telerobotic sonography may increase access to prenatal imaging for patients in rural, remote, or low-volume communities.

SSJ10-05 Magnetic Resonance Imaging Evaluation of Invasive Placentation: Accuracy and Impact on Delivery Management

mofilippo@hotmail.it

PURPOSE

To assess accuracy and reproducibility of Magnetic Resonance Imaging (MRI) findings in the diagnosis of Invasive Placentation (IP) in high risk patients. To evaluate the impact of interventional radiological assistance (IRA) on delivery outcomes.

METHOD AND MATERIALS

Twenty-one patients (mean age 36.05 years) with risk factors for IP underwent 1.5T MR examination. Images were reviewed by two readers. Gold standard was histology in 11 and obstetrical diagnosis in 10 patients. Sensitivity and specificity of MRI findings were calculated and reproducibility was estimated with Cohen's K-test. Impact of eventual IRA was evaluated regarding multiple maternal-child factors during and after delivery.

RESULTS

IP was found in 13 patients (61.90%), placenta accreta/increta in 10 (47.62%) and percreta in 3 (14.29%). MRI had sensitivity of 100% and specificity of 87.5%. MRI findings with higher sensitivity were placental heterogeneity, uterine bulging, black intraplacental bands, myometrial interruption and thinning of the uterine-placental interface. Findings with higher specificity were uterine scarring, placental heterogeneity, myometrial interruption and tenting of the bladder. MRI inter-rater agreement was high (K=1). IRA was performed in 10 women among 13 with diagnosis of IP, with global positive impact on delivery's outcome. Factors with statistical significant difference ($p<0.05$) were: blood loss (1405 ml vs 3080 ml), days in surgical intensive care unit (1 vs 3), APGAR at first minute (6.11 vs 4) and overall days of hospitalization (12.00 vs 41.77).

CONCLUSION

MRI is an accurate and reproducible tool in prenatal diagnosis of IP and can be used to plan safe delivery in an appropriate setting with eventual IRA, that positively affects delivery's outcomes.

CLINICAL RELEVANCE/APPLICATION

MRI is extremely accurate in the diagnosis of invasive placentation and it has a strong indication in high risk patients allowing to plan delivery with eventual interventional radiological assistance.

SSJ10-06 The Ringed Placenta on Fetal MRI: 11 Cases Linked with Fetal Ventral Body Wall Defects

Tuesday, Nov. 28 3:50PM - 4:00PM Room: E351

brpbrown@iupui.edu

PURPOSE

Fetal MRI is increasingly used in high-risk pregnancies not just for diagnosis and treatment planning, but also for prognostication of neonatal outcomes. Ventral Body Wall Defects (VBWD) of variable manifestation are well-recognized on fetal MR imaging and have been described in the literature. In more severe cases, outcomes can be highly variable, and counseling in these cases can be extremely challenging. We present here a pattern of abnormal placental MRI signal not previously described, which we found to correlate with extremely high mortality in patients born with VBWD. Specifically, we identified abnormal T1 hyperintense signal in the placenta in a multi-ringed pattern in several cases of fetal VBWD which correlated with extremely high mortality. We have termed this finding, the "ringed placenta."

METHOD AND MATERIALS

A local database of prenatal imaging studies was used to retrospectively review prenatal cases with MR imaging which demonstrated the characteristic appearance of ringed placenta in patients with VBWD. Electronic medical records were also used to follow up on the outcome of the patients identified as having these same areas of signal abnormality.

RESULTS

The "ringed placenta" appearance was identified in 11 fetal MRI studies, with the neonates later confirmed at birth to have VBWD. On pathology, these placentae were variably described as containing massive perivillous hemorrhage, intervillous thrombosis, villous edema, and diffuse chorionic villitis. Out of the 11 identified cases, only one neonate survived beyond 3 months of life.

CONCLUSION

This work presents cases of VBWD in the fetus, demonstrating the presence of T1 hyperintense ringed patterns in the placenta, which correlate with subsequent high perinatal mortality. Given the pathologic findings, this MRI appearance may be secondary to global placental ischemia with reperfusion hemorrhage. In evaluating VBWD patients, accurate prognostic information can be critical for appropriate parental counseling, and it may also affect the approach to perinatal management. Further studies will be necessary to better evaluate the prognostic accuracy of this MR imaging sign.

CLINICAL RELEVANCE/APPLICATION

This novel sign may enable improved planning and more accurate counseling for parents, many of whom face very high levels of uncertainty during the pre-natal management of complex fetal anomalies.

PURPOSE

To evaluate the usefulness of MRI reporting of uterine fibroids using a structured disease-specific template vs narrative reporting for planning fibroid treatment by gynecologists and interventional radiologists.

METHOD AND MATERIALS

This is a HIPAA-compliant, IRB-approved study with informed consent waived given its retrospective nature. In April 2016, a structured reporting template for fibroid MRI examinations was developed in collaboration between gynecologists, interventional radiologists and diagnostic MRI radiologists. Study population included 29 consecutive women who underwent myomectomy for uterine fibroids and a pelvic MRI prior to implementation of structured reporting; and 42 consecutive women with MRI for uterine fibroids after implementation of structured reporting. Subjective evaluation by gynecologists and radiologists and objective evaluation for the presence of 19 key features were performed to assess the clarity and usefulness of the reports for treatment planning. Statistical analysis was performed using the Student t test, Fisher exact test and Wilcoxon signed-rank test.

RESULTS

More key features were absent from the narrative reports 7.3±2.5 (range 3-12) than from structured reports 1.2±1.5 (range 1-7), ($p<0.0001$). Compared to narrative reports, gynecologists and radiologists deemed structured reports both more helpful for surgical planning (gynecologists: 8.5±1.2 vs. 5.7±2.2, ($p<0.0001$); radiologists: 9.6±0.6 vs. 6.0±2.9, ($p<0.0001$)) and easier to understand (gynecologists: 8.9±1.1 vs. 5.8±1.9, ($p<0.0001$); radiologists: 9.4±1.3 vs. 6.3±1.8, ($p<0.0001$)).

CONCLUSION

Structured fibroid MRI reports miss less key features essential for treatment planning than narrative reports. Gynecologists and radiologists described structured reports to be more helpful for treatment planning and easier to understand.

CLINICAL RELEVANCE/APPLICATION

Structured reports for uterine fibroid MRI are more helpful, easier to understand and miss less key features essential for procedural planning than narrative reports.

SSJ11-02 Efficacy of Vaginal and Rectal Distension Using Gel in MRI for Deep Pelvic Endometriosis

PURPOSE

To study MR performance without and with per vaginal (PV) and per rectal (PR) gel distension for the detection of posterior compartment deep pelvic endometriosis (DPE).

METHOD AND MATERIALS

IRB approval and informed consent were obtained for this prospective study.Female patients presenting with clinically suspected DPE to a single centre underwent MRI to map their disease. Multiplanar T2 and axial T1W images were acquired without and with PV and PR gel. Each patient went on to laparoscopy.8 expert readers from 6 countries, all blinded, recorded sites of disease on 2 datasets with a minimum of 10 days between the readings. Each dataset comprised a mixture of without and with gel studies. Findings were collated and compared with gold standard laparoscopic data. MR performance without and with PV/PR gel was evaluated by calculating sensitivity, specificity, positive and negative predictive values. Variability between readers was calculated using the Fleiss' kappa coefficient.

RESULTS

Posterior compartment disease was recorded in a total of 22 sites in 9 women (mean age 34.8 years) in whom complete imaging and surgical data were available. With 8 readers, this gave a total of 176 potential sites of disease to be detected across all reads. 107 of 176 locations were identified on MR without gel and 139 of 176 with gel distension. There was a significant improvement in sensitivity, PPV and NPV between MR images without and with PV/PR gel distension for all regions assessed (p=0.006, 0.029 and 0.002 respectively). There was no statistically significant difference in specificity between groups.Interobserver concordance was substantial with a Fleiss' kappa coefficient of 0.76 without and 0.74 with gel distension.

CONCLUSION

Vaginal and rectal distension with gel significantly improved the sensitivity of MR for the detection of DPE.

CLINICAL RELEVANCE/APPLICATION

The use of PV/PR distension in MRI for DPE remains controversial. This study, with 8 expert readers, showed a significant improvement in sensitivity, PPV and NPV following the administration of gel.

SSJ11-03 Accuracy of Non-Contrast CT in Characterizing Simple Cysts in Late Post-Menopausal Patients: Do We Really Need to Perform an Ultrasound in All Cases?

dr.musmanaziz@ymail.com

PURPOSE

Contrast enhanced CT (CECT) is accurate at characterizing simple appearing cysts with benign features relative to US. We sought to determine the accuracy of non-contrast CT (NCCT) in characterizing adnexal lesions found in late postmenopausal (>55 years) women and whether a probably benign adnexal cyst >1 cm on NCCT needs further US evaluation in all cases as is the case with current ACR guidelines.

METHOD AND MATERIALS

We performed an IRB approved HIPAA compliant retrospective review of 101 patients with 110 ovarian lesions found on NCCT with an associated CECT (reference standard) within 180 days (median: 7 days, 72% within 30 days). NCCT and CECT images were reviewed by different readers, blinded to the images from the other modality and patients' clinical information. Readers characterized each lesion by presence/absence of complex features (e.g., solid component, mural nodules and septae) and then classified lesions as simple cystic, complex cystic, solid-cystic or solid. Lesion classifications and characteristics were compared between modalities using Bhapkar's or the sign test. Cohen's kappa was used to assess agreement between modalities.

RESULTS

The average age was 68 years ± 10 (SD). Of 110 lesions, 72 (65%) were simple cysts, 22 (20%) were complex cysts, 9 (8%) were

solid-cystic and 7 (6%) were solid on CECT compared with 49 (45%), 39 (35%), 13 (12%), and 9 (8%) for the same categories, respectively, on NCCT. There was overall moderate agreement in lesion classification (kappa: 0.56), though more cysts were simple-appearing on CECT than NCCT (65% vs. 45%, p<0.001). This was primarily due to the increased number of perceived mural nodules (1% vs. 13%, p=0.01) and septae (12% vs. 37%, p<0.001) seen on NCCT compared with CECT. Of 49 simple cysts by NCCT, 48 were found to be simple cysts on CECT (PPV = 98.0%, 95% CI: 87.8-99.9%). Of 61 non simple cystic lesions by NCCT, 37 were also found to be non-simple cystic lesions on CECT (NPV = 60.7%, 95% CI: 48.3-73.0%).

CONCLUSION

Our study confirms the high accuracy of non-contrast CT in characterization of simple cysts seen in late postmenopausal women. On the other hand, non-simple cystic lesions were not as accurately characterized.

CLINICAL RELEVANCE/APPLICATION

Non-contrast CT accurately characterizes simple cysts; so if incidentally detected, these may not need further imaging characterization. Non-simple cysts may still need further imaging workup.

SSJ11-04 DTI and Tractography Correlated With Symptoms and Site of Pelvic Endometriosis

Tuesday, Nov. 28 3:30PM - 3:40PM Room: E353B

valeriavinci87@yahoo.it

PURPOSE

The aim of the present study was to evaluate the sacral nerve roots aspects by the means of DTI tractography in women with endometriosis and to analyze the correlation between DTI abnormalities, the presence and intensity of different pain symptoms, and the endometriotic lesions found at surgery.

METHOD AND MATERIALS

In 2 years time, we enrolled 66 women affected by endometriosis and scheduled for surgery; they were asked for the presence of dysmenorrhea, deep dyspareunia and/or chronic pelvic pain (CPP), intensity of pain was recorded on a Visual Analog Scale (VAS) score. MRI was performed on 3T Magnet,DTI sequences was acquired and a 3D reconstruction of S1, S2 and S3 was achieved . FA was calculated for every root as described. Univariate analysis was performed collecting also data from the following laparoscopy.

RESULTS

DTI of sacral roots revealed a regular and homogeneous appearance in 17 (25.8%) patients, while 44 (66.7%) women showed abnormalities in microstructure reconstructions, consisting mainly of fiber irregularities and disorganization combined with the loss of the simple unidirectional course. In 5 (7.6%) women the reconstruction of the sacral roots was not possible. Pathological DTI was significantly associated with the severity of dysmenorrhea and CPP , but no association with dyspareunia (Pv=0.398) or dyschezia (Pv=0.738) was found. Furthermore, a higher duration of pain was significantly associated with a pathological DTI. Adhesions in Douglas Pouch resulted significantly associated with pathological DTI (Pv=0.001), as well as DIE (Pv=0.001) and tubo-ovarian adhesions.

CONCLUSION

Pathological DTI of the sacral nerves is associated to the presence of CPP, but also it is related to the type and the site of endometriosis being obliteration of the cul-de-sac, tubo-ovarian adhesions and DIE responsible of DTI abnormalities. This new noninvasive method may help both clinicians and surgeons to select a better and more personalized therapeutic approach or select those patients who might benefit from alternative treatments, such as presacral neurectomy, anaesthetic nerve infiltration, neurostimulation or different types of pain killers that target neuropathic pain

CLINICAL RELEVANCE/APPLICATION

DTI alteratons may help to select an alternative therapeutic approach such as presacral neurectomy, anaesthetic nerve infiltration, neurostimulation or different types of pain killers that target neuropathic pain

SSJ11-05 Virtual Histerosapingography in Daily Practice in 14200 Cases

PURPOSE

To illustrate the typical findings of virtual hysterosalpingography(VHSG) by MDCT in daily practice and the differential diagnosis with

To illustrate the typical findings of virtual hysterosalpingography(VHSG) by MDCT in daily practice and the differential diagnosis with other pathologies in patients studied between 2006 and 2014

METHOD AND MATERIALS

We evaluated the V-HSG studies of 14200 patients derived from our institution. Studies were performed using 64,128 and 256 multislice CT scanners. Scanning parameters were: On 64-row CT: slice thickness of 0.9 mm 120 kV and 100-250 mAs, with an average duration of each scan of 3.6 seconds. On 128 and 256-slice CT: slice thickness of 0.6 mm and a reconstruction interval of 3 mm, 80 kV and 100-150 mAs, with an average duration of each scan of 1.3 seconds. A a dilution of low-osmolality iodinated contrast (10-20 ml) was instilled into the uterine cavity. Images were analyzed using multiplanar reconstructions, 3D and virtual endoscopy.The duration of the CT scan, the radiation exposure and the degree of discomfort of the patients were documented.

RESULTS

The scan time was 3.5 and 1.3 seconds using 64-slice or 128-256-slice CT scanners respectively. The mean radiation dose was 0.9 and 0.3 mSv using 64-slice or 128-256-slice CT scanners respectively for each scan. In the cervical region were identified parietal irregularities (22%), thickening of folds (8%), polyps (7%), diverticula (5%), stenosis (5%) and sinechiaes (1%). In the uterine cavity were visualized polyps (35%), submucosal myomas (7%) and adhesions (3%). In addition changes were observed in the wall of the uterus: myomas (15%), malformations (3.2%), adenomyosis (5%) and cesarean section (12%). Fallopian tubes showed hidrosalpinx in 5% cases ;unilateral (3.4%) and bilateral (1.6%). Patients reported no or mild discomfort in 85% of the cases.

CONCLUSION

The VHSG allowed a proper assessment of the internal genital organs, providing useful diagnostic information on infertility and other gynecological disorders. The technique is painless, well tolerated by patients with low doses of radiation. These advantages place this modality as a valid alternative algorithm study in patients with infertility

CLINICAL RELEVANCE/APPLICATION

Virtual hysterosalpingographyis an useful diagnostic tool to obtain information on infertility and other gynecological disorders.

SSJ11-06 Prospective Comparison of 3D FIESTA versus 2D SSFSE MRI in Evaluating Pelvic Floor Dysfunction Disease

Tuesday, Nov. 28 3:50PM - 4:00PM Room: E353B

Participants
Yanbang Lian, Zhengzhou, China (*Presenter*) Nothing to Disclose
Zhiyang Zhou, PhD, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose
Wuteng Cao, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose
Dechao Liu, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose
Zhicheng He, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To compare fast imaging employing steady state acquisition (FIESTA) sequence with single shot fast spin echo (SSFSE) sequence in terms of acquisition time, image quality, artifacts, and lesion detection.

METHOD AND MATERIALS

Fifty-three patients (mean age, 49 years; range, 21-81 years) suspected pelvic floor dysfunction disease (PFDD) were enrolled in this study and underwent high resolution dynamic magnetic resonance defecography (MRD). The MR imaging protocol included static T2-wighted fast spin-echo sequence in three planes and a single sagittal dynamic sequence of FIESTA and SSFSE for rest, left and defecation phase. The acquisition time of dynamic sequence was calculated. The sagittal data sets of FIESTA were compared with SSFSE data sets with respect to image quality, artifacts, and lesion detection. Quantitative values of acquisition time and lesion detection and qualitative analyses of image quality and artifacts were analyzed by using a paired Student's t test and the Kappa test, respectively.

RESULTS

Mean acquisition time of FIESTA sequence (80-slice/53 seconds) was significantly shorter than that of SSFSE sequence (40-slice/57 seconds) ($p<0.05$). More pelvic organ prolapse (39/53 VS. 22/53) and rectocele (21/53 VS. 11/53) were detected with FIESTA than SSFSE ($p<0.05$). There was no significant difference between FEISTA and SSFSE in image quality and artifacts (kappa=0.905, $p>0.05$). Readers preferred the FIESTA sequence for showing more details.

CONCLUSION

For time savings and the versatility of showing greater degree of lesions without compromise of image quality, the near real-time continuous imaging with FIESTA sequence should be included in MRD protocols to better evaluate pelvic floor dysfunction disease.

CLINICAL RELEVANCE/APPLICATION

We recommend that FIESTA sequence should be included in MRD protocols to better assess pelvic floor dysfunction disease.

PURPOSE

A subset of radiography outpatients in a large pediatric academic medical center were uncertain and sometimes anxious about how to receive their results. Our aim was to develop a practical system to offer results to these patients directly from a radiologist on the same visit. Goals were to achieve a high degree of patient declared understanding of results and positive feedback of their face to face interaction with the radiologist.

METHOD AND MATERIALS

The service evolved through four phases. In phase 1 (408 days) technologists screened outpatients and included those nervous about, or simply requesting, their results. We excluded any non-outpatient or those who would otherwise get results the same day from another provider. Patients completed an anonymous feedback survey after result delivery. Technologists and radiologists completed weekly feedback surveys. Phase 2 (55 days) expanded inclusion to outpatients without scheduled follow up. Phase 3 (21 days) expanded inclusion to offer results to all radiography outpatients using a patient self-screening survey at check in. Phase 4 (21 days) simply removed the wait time notification (10-20 min) from the self-screening survey.

RESULTS

The phase 1 direct result delivery rate was 1 patient per month, possibly due to technologists not identifying all potential patients. Phase 2 direct results tripled to 3 per month. Phase 3 results again tripled to 9 per month, but notably 92% of screened patients opted to receive results through their primary physician. In phase 4, with the wait period notification removed, results were delivered at a rate of 30 per month. More than 97% of patients reported understanding the radiologist delivered results. Patient feedback comments were 92% positive, 3% neutral, and 5% left blank. More than 84% of radiologists agreed that they experienced a sense of satisfaction afterward.

CONCLUSION

Having radiologists discuss results with patients was feasible, positive for radiologists, and clearly valued by patients. The highest, but manageable response was achieved when patients screened themselves. Still, direct result delivery may fall short of increasing patient awareness of radiologists' role in their care due to limited demand.

CLINICAL RELEVANCE/APPLICATION

Implementation of a service delivering results from radiologist to patient is feasible even when utilizing patient self-screening methods, and is a strongly positive experience for patients and radiologists.

SSJ12-02 Point-of-Care Virtual Radiology Consultations in Primary Care: A New Model for Patient-Centered Care in Radiology

PURPOSE

The use of virtual visits for routine outpatient care delivery has been steadily increasing. Limited data are available on the role of such visits in radiology. The goal of this study is to assess the value of point-of-care virtual consultations in radiology, through the implementation of synchronous video-based virtual consultations whereby referring primary care physicians can consult with a radiologist virtually and review studies in real-time while seeing a patient.

METHOD AND MATERIALS

We conducted an IRB-approved feasibility study of video-based radiology consultations in an internal medicine primary care clinic at a quaternary academic medical center. The study included 3 primary care providers (PCP) and enrolled 40 patients. Inclusion criteria consisted of the following: age >18, English speaking, recent radiology exam at our institution, and patients indicating verbal consent. Patients completed a pre- and post-visit survey. PCPs completed a post-visit survey. Primary study endpoints included the effect on patient and provider satisfaction, effect on patient experience and understanding of medical condition, and impact on PCP's management decisions. Statistical significance was assessed using student's t-test and Fisher's exact test.

RESULTS

Both patients and primary care providers indicated high satisfaction with the virtual radiology consult experience on a Likert scale of 1 to 5 (92 and 96% respectively). 89% of the patients reported increased understanding of their disease and improved patient experience as a result of the radiologist virtual visits. PCPs indicated that the consult was helpful for their management decisions in 83% of the visits. Virtual visits increased patient interest in receiving their imaging results from radiologists; 56% indicated interest in the pre-visit survey versus 88% in the post-visit survey (p=0.03).

CONCLUSION

Initial experience with virtual radiology consults show high rates of patient and provider satisfaction and increasing demand for the availability of these visits.

CLINICAL RELEVANCE/APPLICATION

Virtual radiology consults have the potential to advance radiology's value in care delivery by providing more personalized radiology care and by promoting patient-centered practice models.

SSJ12-03 Incidental Findings in Whole-Body MR Imaging of a Population-based Cohort Study: Frequency, Management and Psychosocial Consequences

PURPOSE

Management of incidental findings (IF) in whole-body magnetic resonance (MR) imaging remains controversial but highly relevant. We aimed to assess the frequency, management and psychosocial consequences of IF reporting in a population-based cohort study.

METHOD AND MATERIALS

From a population-based sample, a set of 400 participants underwent 3T whole-body MR imaging using a comprehensive protocol, including cranial (FLAIR, T1, SWI TOF), thoracoabdominal (T1 DIXON, multi-echo) and cardiovascular sequences (cine imaging, T1 mapping, LGE). All images were reviewed by a board-certified radiologist for presence of relevant IF according to a recommended list of relevant and non-relevant IFs based on current literature. In case of deviation the finding was referred for interdisciplinary panel adjudication. A participants' survey was conducted prior and 6 months after the MR scan regarding personal expectations, psychosocial consequences and experiences with IF reporting.

RESULTS

A total of 116 IF were reported in 89 participants (22.3%), of which 27 cases were reviewed by the panel. Additionally, 22 cases (5.5%) were referred to the panel but classified as not relevant for reporting. Among the reported IF, "Unclear Liver Lesion" (n=13), "Silent Myocardial Infarction" (n=12) and "Complex Renal Cyst" (n=9) were most common. Pre-/post-scan survey data were available in 251 participants. More than half of the participants (57.4%) noted in the pre-scan survey that reporting IF in general would be "very important" for them, which decreased to 43.0% after the scan ($p<0.001$); this decrease did not differ whether the participant had an IF reported or not ($p=0.75$). A small portion (2.3%) reported that waiting for the IF reporting was "very burdening" or "burdening". Of participants with reported IF, 9.1% felt that the results were "very burdening" while in contrast 56.8% classified the results as "very helpful".

CONCLUSION

In this cohort, the prevalence of IF was high, and many findings were adjudicated by an interdisciplinary panel. For participants, reporting of potential IF was highly important and added only minor psychological burden.

CLINICAL RELEVANCE/APPLICATION

Assessment of IF in population-based imaging research is important to study participants but associated with substantial resources of the investigators. Thus, optimized, workflow-oriented tools. such as structured reporting or deep learning algorithms may prove beneficial in this setting.

SSJ12-04 Radiological Counselling: A New Approach to Radiologist-Patient Relationship

francesca.rigiroli@unimi.it

PURPOSE

Patients are more and more interested in improvements within medicine, curious about alternative methods of treatment and more conscious about their health. This leads the patients to look often for medical specialists to get information about the best diagnostic procedure.

RESULTS

The service started in September 2015 and the patients involved were 215. The need of radiological counselling was greater for complex imaging modalities, such as magnetic resonance imaging (48%) and computed tomography (31%) than, for example, X-rays (14%). The survey on the first 50 patients showed complete satisfaction of the meeting with the radiologist, with a score of 4,5/5. The 60% of the cases were under 60 years-old, which highlights the increased concern, within the younger generation, about their health. The majority of the patients answered that they preferred to receive the radiological report by a meeting with the radiologist: 50% if there are normal findings and 80% if pathological.

CONCLUSION

The Radiological Counselling is a useful service and can improve the relationship between the patient and the radiologist, who gains a new clinical role. The results are satisfying and will help the management to improve this service and to raise the patient's trust in the institution. In particular, the intention is to monitor patients after a pathological diagnosis, during their radiological follow-up and to research in which sub-specialty the service is more needed (neuroradiology, breast radiology, oncologic imaging, musculoskeletal radiology, thoracic radiology).

METHODS

To meet our patients' needs, the "Radiological Counselling" was introduced, a service which allows patients to have a meeting with the radiologist. This is useful for patients to learn the different and best imaging modalities, to have an explanation of what is written in the radiological report and to have recommendation about the best diagnostic process. Every radiologist reserved 2-3 hour a week for this service and the appointments were taken by the administrative office. The patients usually met the doctor who signed the report. The service outcome has been investigated by a survey on the first 50 patients that used radiological counseling: after the meeting with the radiologist, they answered a questionnaire about their age and sex, their satisfaction as well as the preferred method of communication in normal or pathological findings. In particular, It was asked if they preferred to receive the report: 1) at the reception of the radiology department (which is the method currently in use), 2)by the general practitioner,3) by a phone call from the radiologist 4) by a meeting with the radiologist or 5) by email or internet.

For information about this presentation, contact:

swoolen@med.umich.edu

PURPOSE

The electronic patient portal is used by patients to access their imaging results. The objective of this study is to determine patient expectations for receiving imaging results.

METHOD AND MATERIALS

A prospective HIPAA-compliant multicenter outpatient survey using questions administered by a trained interviewer. The survey was reviewed by patient advocates with experience in survey design and underwent patient precognitive testing for readability. Over a four month period, outpatients receiving imaging tests were asked to participate in a survey regarding patient expectations for receiving imaging results. Descriptive statistics were calculated.

RESULTS

The response (93% [202/218]) and completion (100% [202/202]) rates were excellent. Patient expected median imaging result turn around in different scenarios are the following: 3 days (IQR 5) after screening, 2 days (IQR 3) after CXR for chest pain, 1 day (IQR 2) after CXR for pneumonia, 2 days (IQR 2) after MRI/CT for back pain, 1 day (IQR 2) after MRI/CT for brain tumor, and 1 days (IQR 3) after CT for cancer treatment. If patients do not have their imaging results yet, they will call their provider to inquire about results by the following median days in different scenarios: 5 days (IQR 4) after screening, 2 days (IQR 4) after CXR for chest pain, 1 day (IQR 2.75) after CXR for pneumonia, 2.5 days (IQR 3) after MRI/CT for back pain, 1 day (IQR 3) after MRI/CT for brain tumor, and 2 days (IQR 3) after CT for cancer treatment. Waiting on imaging results causes a negative effect on patient state of mind in 20% [38/188] and emotional change in 45% [91/202] with the majority (85% [77/91]) of emotional distress being anxiety (minimal 28%, mild 45%, moderate 22%, severe 4%, extreme 1%).

CONCLUSION

Patients expect their imaging results by 3 days and will call outpatient clinics by 5 days.

CLINICAL RELEVANCE/APPLICATION

The results support delivering imaging results within 3-5 days. These data can be used to inform institutional policy regarding automated imaging result release.

Honored Educators

Presenters or authors on this event have been recognized as RSNA Honored Educators for participating in multiple qualifying educational activities. Honored Educators are invested in furthering the profession of radiology by delivering high-quality educational content in their field of study. SSJ12-06 Radiologist Experiences with Direct Patient Interactions

Tuesday, Nov. 28 3:50PM - 4:00PM Room: S104B

Participants
Jieming Fang, Boston, MA (*Presenter*) Nothing to Disclose
Johannes Boos, MD, Dusseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Andrea Franconeri, MD, Boston, MA (*Abstract Co-Author*) Nothing to Disclose
Olga R. Brook, MD, Boston, MA (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

jieming.fang@gmail.com

PURPOSE

To evaluate radiologists' attitudes and experiences with direct patient contact and how interactions with patients affect the workflow.

METHOD AND MATERIALS

This prospective survey of staff and trainee radiologists (n=128) at tertiary academic institution was performed with approval of our institutional review board. A multiple choice questionnaire with optional free text comments was distributed via departmental email between June 2016 and July 2016. Participation in the survey was voluntary and anonymous and responses. Statistical analysis of categorical responses was performed with the chi-squared test with statistical significance defined as $p<0.05$.

RESULTS

Response rate was 73.4%, (94/128), with 54.3% (51/94) of the respondents being staff radiologists and 45.7% (43/94) trainee radiologists. Majority of the respondents , 78.7% (74/94), found interactions with patients to be satisfying experiences. 51/94 (54.3%) of radiologists desired more opportunities for patient interaction. Similar percentage of staff and trainees desired more patient interaction (56.9% (29/51) vs. 51.2% (22/43), p=0.58). Staff radiologists who specialized in vascular and interventional radiology and breast imaging were significantly more likely to want more patient interaction compared to those who specialized in other areas (77.8% (14/18) vs 45.5% (15/33), p=0.03). Only 4.2% (4/94) of radiologists found patient interactions to be detrimental to normal workflow. Most interactions between radiologists and patients, 80.9% (76/94), took less than 15 minutes. Only 14/94 (14.9%) of radiologists indicated they had ever refused to communicate directly with a patient when the patient requested discussion with radiologist. Majority of radiologists 62/94 (66.0%) were comfortable discussing potentially distressing and ominous results directly with their patients.

CONCLUSION

A majority of radiologists are open for more opportunities for interactions with patients and find them satisfying experience. Meeting a patient takes usually takes less than 15 minutes and is not felt to significantly affect the workflow.

CLINICAL RELEVANCE/APPLICATION

The should be opportunities for more direct patient-radiologist contact in clinical practice, as these interactions are rarely detrimental to the radiologists' workflow, while majority of radiologists find these interactions to be a satisfying experience.

Philipp.Brantner@usb.ch

PURPOSE

Procedural training is a vital element to become confident in interventional procedures yet training models are expensive, not universally available and not patient-specific. We demonstrate an easy, cost-effective and reproducible approach to create vascular and tissue models with a combination of 3d printed scaffolding and silicone molding.

METHOD AND MATERIALS

With the use of open source 3D-Modelling software the model of a generic stenosis was developed with defined connections for an angiography simulator. A negative form of the model was derived and printed on an consumer fused filament fabrication 3d printer. The form was then casted using a clear yet flexible silicone. After curing the form was scanned in a CT scanner and registered on the initial model to ensure production precision. A second model was developed to train venous access management for technologists and students using a CT scan of a forearm that was segmented for bone and soft tissue. Intravenous lines were used to simulate veins with a diameter of 4 and 2 mm as well as to ensure easy compatibility to iv-systems of the hospital. After curing the lines were removed and the proximal entry was connected to an infusion to provide simple gravity-based vascular flow.

RESULTS

Reproducibility of stenosis model to the original file was excellent. The model is to be used as a training modality for interventional radiology and vascular surgery courses and was received with great interest. Material properties of the chosen silicone are reported to be vascular like. The second model is being used in the education for technologists yet the material characteristics of the soft tissue need to be improved.

CONCLUSION

A combination of segmentation, modelling and 3d printed scaffolding together with silicone casting proves to be a great way to develop easy, cost-effective and reproducible models. This approach can be used to create generic training models for the education of technologists and interventional radiologisty residents as well as patient-specific models for training and planning before high-risk interventions.

CLINICAL RELEVANCE/APPLICATION

The use of 3d-printed scaffolding and silicone molding allows to create cost-effective models for procedural training that help technologists and residents to become more confident in interventional procedures.

SSJ13-02 Patient-Specific Orbital Implant Shaping Guide for Orbital Wall Fracture Repair Using 3D Printing

Tuesday, Nov. 28 3:10PM - 3:20PM Room: N230B

nisroeld2@gmail.com

CONCLUSION

The implant shaping guide using 3D printing can be used for shaping the surgical implant precisely in orbital wall fracture repair. This exact mapping of shape and surface of defect site into a surgical implant would let surgeons secure the defect margin more confidently, and promise shorter operation time and convenience as well.

Background

The commercialized orbital implant is usually used to reconstruct bone fracture region in patients with orbital wall fracture. In the existing surgical method, surgeons guess the bone fracture region visually during surgery and shape the planar orbital implant manually before inserting it into the fracture site. It is very hard to match the implant to the 3D shape and size of the defect by use of the conventional 2D cutting method. Any discordance would lead to postoperative complications such as enophthalmos and diplopia.

Evaluation

From CT images, the fracture site of volume of interest was segmented in Fig. 1-A. The implant surface was created by an expert so that the damaged part could be covered. (Fig. 1-B) The 3D model was generated from the segmented 2D mask and fitting of orbital bone and implant were checked, which was converted into a STL format in Fig. 2. Planar orbital implants were regenerated as the created surfaces, and the zig molder, press was generated and used for shaping of the implant. (Fig. 3) The guide was washed and sterilized with isopropanol or EO gas for clinical use after remove supporter, and transported to the operating room. For surgery, the surface of zig molder was coated with surgical film not to direct contact with molder and patient. During the operation, the Implant plate was compressed using a sterilized molding model, and inserted into the fracture site.

Discussion

Seven eyes of 6 patients underwent orbital wall reconstruction using 3-dimensional printing between November 2016 and December 2016. Follow-up time ranged from 3 to 4. There were 4 men and 2 women. There were no complications such as loss of vision, infection, displacement or exposure of the implant. There was no significant difference in the orbital volume between the undamaged orbit and reconstructed orbit (21.84 ± 1.67 vs 21.83 ± 1.72 cm3, P = 0.89).

SSJ13-03 Utilizing the Power of the EMR, RIS, and VNA for 3D Printing Lab

sferreira@sidra.org

CONCLUSION

Building a 3D workflow in an existing EMR has potential benefits to facilitate the 3D service delivery process. It allows 3D printing to rank amongst other modalities important for patient care by living where all other clinical care orders reside. It also allows 3D Lab staff to document the process through quick communication with clinicians. The easier use and availability of 3D printed models will ultimately provide better patient care.

Background

In recent years' 3D printing, has shown exponential growth in clinical medicine, research, and education (Carlos et al.). Imaging departments are at the center of 3D printing service delivery, efforts of establishing a 3D printing lab, and making it a unique contribution towards patient care (Kent Thielen et al.). Building a fully electronic medical record (EMR) integrated workflow to deliver 3D services offers unique advantages for clinicians.

Evaluation

We have successfully tested the electronic process by generating 3D orders and delivering the printed models such as of the heart, skull, face, and ear.

Discussion

To facilitate clinicians and 3D printing lab staff, we developed an automatic workflow in our EMR and radiology information system (RIS). Clinicians use our Cerner EMR to order 3D printing services by selecting the available 3D printing orders for each modality i.e. MR, CT, and US. The order also allows them to add their requirements by filling out relevant Order entry fields (OEFs). 3D printing orders populate the RIS worklist for 3D lab staff to start, complete, and document the service process. Consultation with ordering clinicians and radiologists is also vital in 3D printing process, so we developed a message template for the communication between lab staff and clinicians, which also has the capability to attach 3D model PDFs. 3D Lab staff upload the models to our Vendor Neutral Archive (VNA) before completing, storing the models in the patient's record.

SSJ13-04 A 'Super-resolution' Algorithm for Generating Optimal 3D Printed Models From Multiple Sub-Optimal Non-Isotropic Resolution Clinical Images

Tuesday, Nov. 28 3:30PM - 3:40PM Room: N230B

dmitsouras@alum.mit.edu

CONCLUSION

A method has been developed to "super-resolve" anatomy imaged in multiple independent, lower resolution CT/MR data sets for more accurate 3D printing than possible using the underlying images individually

Background

Clinical protocols often do not acquire high resolution data (<1-1.5mm slice thickness) to successfully 3D print anatomy. When the need for 3D-printing is known ahead of imaging, protocols can be adjusted to obtain appropriate data. However, this is not always possible due to signal-to-noise ratio vs imaging time in MR, and radiation dose in CT. For example, for pelvis CT in a large teaching hospital where ALARA principles are applied, 3mm thick slices in all 3 planes (axial [ax], sagittal [sag] and coronal [cor]) are obtained, but reconstructing 1mm slices for printing yields images too noisy to segment. On some CT equipment, sag/cor reconstructions are produced directly from the sinogram, rather than reformatting of axial images. In those cases, image voxels reconstructed at each plane contain intrinsically different information. Similarly, MR images at different planes contain information from intrinsically different spins excited for each slice

Evaluation

We developed a method to combine data from independent multi-planar images into a single "super-resolution" 3D image set, using the highest resolution for each axis amongst the available image data sets, that can be more easily and accurately segmented. The method uses the voxel size and location of all low-resolution images (with or without registration as necessary) to produce a single higher-resolution voxel grid whose image intensities satisfy the lower-resolution images as mathematical constraints. The method was used on CT images of a pelvis with prior periacetubular osteotomy and fracture. Bone was automatically segmented from each ax/sag/cor 3mm images interpolated to 0.5mm, and from super-resolved images reconstructed using the new method at a 0.5 mm grid

Discussion

The method enabled accurately segmenting anatomy demonstrating a superior pubic ramus fracture and prior hardware that none of the individual (ax/sag/cor) clinical CT images allowed despite being interpolated to a higher resolution grid

SSJ13-05 Creation of Low-Cost Multi-colored Clear 3D Printed Models

Tuesday, Nov. 28 3:40PM - 3:50PM Room: N230B

CONCLUSION

With minimal post-processing, it is possible to create low-cost, clear 3D printed models with colored components using consumer grade Stereolithography printers. These models are ideal for percutaneous and endovascular pre-procedure planning.

Background

While there has been rapid expansion of low-cost solutions for creation of opaque 3D printed models in Radiology, the creation of clear models with colored internal components has been limited. PolyJet printers offer the ability to create clear models with multi-color components, but printer costs are >$150,000 and material costs are often prohibitive. Here, we present a technique to create low-cost clear models with colored components using a consumer-grade stereolithography printer at <5% of the cost of traditional techniques.

Evaluation

Clear visceral, bony and vascular 3D printed models with colored internal components are valuable for visualizing internal structures relative to more superficial anatomy. Examples include renal tumors and bony lesions. PolyJet printers are directly able to create multi-color models with clear components; however, the printers and their materials cost hundreds of thousands and hundreds of dollars respectively. Desktop stereolithography printers cost <$5000 and allow creation of clear 3D printed models at low cost. However, these printers can only print with one material at a time. Our technique centers on creating models with internal structures modeled as hollow cavities. These cavities are then filled with paint. As an example, when creating clear renal models with colored components depicting the collecting system and tumor (figure), traditional polyjet techniques result in model costs of $1000. Using our techniques, models cost an average of $29.01 (SD: $6.79, n = 5).

Discussion

Here, we present a technique for creating multi-color models using low cost SLA 3D printers with relatively easy post-processing. Our experiences show that creation of low-cost, high-quality clear models with colored components is feasible and can be done at a tiny fraction of the cost of traditional techniques. This results in the removal of a primary barrier for implementation of 3D printing in hospitals.

SSJ13-06 Characterization of 3D Printing Materials: Hounsfield Unit Energy Dependence and Comparison to Commercially-Available Tissue Equivalent Materials

Tuesday, Nov. 28 3:50PM - 4:00PM Room: N230B

wfsensak@gmail.com

PURPOSE

To compare Hounsfield Units (HU) of commonly used 3D-printing materials (3DMs) to tissue-equivalent materials (TEMs) from commercially-available phantoms. Further, to examine the energy dependence of 3DMs and estimate visibility of 3D-printed implants or instruments in computed tomography (CT).

METHOD AND MATERIALS

A Stratasys Object 350 Connex3 printer produced 1"x 1"x 1" cubes of six common materials. Stratasys materials were chosen because it has the largest commercial install base in the world. Silicone used to fill 3D-printed molds was also characterized. TEMs from the American College of Radiology (ACR) Image Quality Phantom and the RMI 641A phantom were characterized for comparison. All materials were CT scanned at 80, 100, 120, and 140 kV on a Philips Ingenuity 128 and GE VCT 64. 3DM: 1. RGD-CW-004-DM (mix of VeroWhite+ & VeroCyan), 2. FLX9870-DM (mix of TangoBlack+ & VeroWhite+), 3. RGD835 (VeroWhite+), 4. RGD8525-DM (mix of TangoBlack+ & VeroWhite+), 5. RGD843 (VeroCyan), and 6. FLX980 (TangoBlack+). Silicone: Smooth-on platinum cure silicone rubber compound

RESULTS

All 3D-printed materials were between 40HU and 140HU and demonstrated a slightly increasing HU trend with tube voltage. ACR acrylic also demonstrated a slightly increasing HU trend with tube voltage. Four of the six 3DMs were equivalent to ACR acrylic. Material 6 (TangoBlack+) had an HU between water surrogates and ACR acrylic. Material 2, a mixture of TangoBlack+ and VeroWhite+, had an HU higher than TangoBlack+ alone demonstrating how mixtures could be used to produce low contrast structures if desired. Silicone had a strong non-linear decreasing dependence with tube voltage. Unfortunately, none of the 3DMs investigated were similar to water, fat, or bone. Scanner make/model did not significantly impact HU of the investigated materials ($p = 0.21$).

CONCLUSION

Materials typically used in 3D-printing have a slight energy dependence and their HU is between that of soft-tissue and muscle. 3DMs investigated here would be suitable to model organs and muscle in CT phantoms; however, printed implants or instruments using these 3DMs may not be visible in muscle or organs due to their similar HU and thus low contrast.

CLINICAL RELEVANCE/APPLICATION

The 3D-printed materials investigated here are suitable for organ and muscle modeling, but implants and instruments made from these materials could be invisible on CT scans due to the HU similarity to organ and muscle.

SSJ14-01 Multimodal Imaging of BAT Activity in Type I and Type II Diabetes Mouse Models Using 7T MRI and Intravital Microscopy

Tuesday, Nov. 28 3:00PM - 3:10PM Room: S504CD

Harald Ittrich, MD, Hamburg, Germany (*Abstract Co-Author*) Nothing to Disclose
Jorg Heeren, Hamburg, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To determine the metabolic activity of brown adipose tissue (BAT) in type I and type II diabetes mouse models using superparamagnetic iron oxide nanoparticles (SPIO - for MRI) or quantum dots (QD - for intravital microscopy (IVM)) embedded into triglyceride-rich lipoproteins (TRL).

METHOD AND MATERIALS

C57BL/6J wild-type were either treated with Alloxan which is selectively toxic to pancreatic beta cells (100µl iv; Alloxan monohydrate, Abcam) to induce type I diabetes or received a 35% Lard-based high fat diet over 16 weeks to induce type II diabetes. BAT activity was stimulated by treatment with the ß3 receptor agonist CL316,243. All mice were starved for 4 hours before imaging. MRI at 7T ClinScan (Bruker) was performed before and 20 minutes after iv injection of TRL-SPIOs using a T2*w Multiecho-GRE sequence (TR/TEfirst 400/2ms, ETL 12, ES 1ms, FA 25°). In addition to the MRI set up, IVM analysis was performed for real time imaging of TRL-QD uptake into BAT. In order to quantify TRL clearance, the fate of radioactively labelled TRLs were analysed under the same experimental conditions.

RESULTS

While control mice showed a significant signal drop after CL treatment, no significant signal difference in BAT before and after the injection of TRL-SPIO was detectable neither for type I nor for type II diabetes mouse model. Analogy real time IVM analyses showed a clear reduction of TRL-QD in case of diabetes disease mouse models. MRI and IVM results were confirmed by quantitative metabolic studies using radioactive lipid tracers. In both setups diabetes type I and type II lead to a reduction of TRL uptake into BAT.

CONCLUSION

ß3-receptor activation via CL with following acute insulin release lead to BAT activation, which can be visualised in vivo by MRI using TRL-SPIO. However, in case of diabetic disease, the uptake of TRL into BAT is diminished, indicating a loss of BAT activity in this case. Thus, MRI can visualize physiological lipid processing in the vascular endothelium of activated BAT.

CLINICAL RELEVANCE/APPLICATION

MRI in combination with nanoparticle-labelled lipoproteins can be used to noninvasively monitor the molecular pathway of insulin-dependent lipoprotein metabolism.

SSJ14-02 Evaluation of Early Renal Injury Development in Diabetic Rats by BOLD-MRI

PURPOSE

To observe changes in renal oxygenation levels by BOLD-MRI, and sought to evaluate the usefulness of BOLD-MRI in development of early diabetic renal injury.

METHOD AND MATERIALS

80 male SD rats with left uninephrectomy were randomly divided into normal control (NC) group and diabetes mellitus (DMN) group. Streptozotocin (65 mg/kg) was intraperitoneally injected in DMN group, and the NC group given with saline. BOLD-MRI scans were performed for the two groups at different time points ,NC group as baseline and DMN group at 3, 7, 14 ,21, 28, 35, 42, 49, 56, 63 and 70 days following streptozotocin injection. Renal cortical and medullary R2*(CR2*, MR2*) signals were measured and R2* ratio of medulla and cortex (MCR) was calculated. Urinary protein excretion(UAE) and histopathological examination were evaluted at different time points.

RESULTS

CR2* and MR2* values of diabetic rats were significantly higher than control group rats at different time points after induction of diabetes ($P < 0.01$). Those R2* values raised gradually and reached the peak at day 35 (CR2*=33.95±0.34 s-1,MR2*=43.79±1.46 s-1), then dropped gradually until day 70 (CR2*=33.17±0.69 s-1, MR2*=41.61±0.95 s-1) , but still significantly higher than the control group (CR2*=28.41±0.56 s-1,MR2*=31.77±0.87 s-1) ($P < 0.01$). MCR in DM group rose gradually from 1.12 to 1.32 at day 42, and then decreased to 1.25 at day 70. UAE of DMN group increased gradually, it was significantly higher than that of NC group since day 7($P < 0.01$).The GSI was higher in DMN group compared to NC. Mesangial volume density (Vvmes) and the capillary surface density (Svcap) was increased in the DMN group when compared to NC .

CONCLUSION

BOLD-MRI can non-invasively evaluate the renal hypoxia in diabetes and detect diabetic renal injury earlier than UAE. The dynamic changes MCR like a downward parabola in our study diabetic would be adopted to reflect the dynamic changes from stage II to stage of diabetic renal injury proved by Mesangial proliferation and nodular sclerosisis appearing pathologically.

CLINICAL RELEVANCE/APPLICATION

BOLD-MRI can non-invasively evaluate the renal injury early and dynamically

SSJ14-03 VLA-4 Targeted Liposomes for Noninvasive Visualization of Vulnerable Plaques in ApoE(-/-) Mice by MRI

PURPOSE

Currently, there is no approved method for diagnosing cardiovascular complications of atherosclerosis which delineates the cellular and molecular components that predict plaque stability (1). Activated monocytes/macrophages and T-lymphocytes constitute about half the cellular makeup of vulnerable plaques and contribute to weakening and eventual rupture (2). We report herein, a nanoparticle targeted to VLA-4 (a surface receptor on leucocytes), that labels and enables noninvasive visualization of vulnerable plaques in ApoE(-/-) mice by MRI at 1 Tesla.

METHOD AND MATERIALS

A lipid mixture containing lipid-PEG-THI567 conjugate, DSPE-PEG-DOTA-Gd complex, and Rhodamine DHPE was subjected to a standard liposome formulation protocol to achieve targeted particles with size ~170±10nm. A control untargeted formulation was also prepared. Flow cytometry was used to evaluate particle binding and receptor specificity in vitro, and leukocyte cell subset binding distribution in vivo. MR imaging in ApoE(-/-) mice mice (protocol approved by the IACUC, N=7 for controls, N=9 for the test group), was performed on a 1.0 Tesla MRI scanner. Images were acquired pre-, immediately after, and 72-96 hours post contrast injection. Following the last scan, animals were sacrificed, and the aortic arch, carotids and descending aorta were frozen for histology.

RESULTS

VLA-4 targeted particles bind activated monocytes and T-lymphocytes both in vitro and in vivo with picomolar binding constants. In delayed phase imaging, animals injected with the targeted liposomes showed enhanced regions in the aortic arch or the descending aorta, with 4-fold greater mean signal than the animals injected with the untargeted agent. Histochemical analysis of tissue sections from the treated animals showed co-localization of the targeted particles and immune cells within the plaques as shown in Figure 1.

CONCLUSION

Liposomal nanoparticles bearing a T1 contrast agent, targeted to monocytes/macrophages and T-lymphocytes allows for noninvasive visualization of vulnerable plaques in ApoE(-/-) mice by MRI at 1T.

CLINICAL RELEVANCE/APPLICATION

A sensitive, specific method to identify vulnerable plaques before they rupture and could dramatically change the therapeutic course for patients with atherosclerotic lesions.

SSJ14-04 Identification of Metabolic Regulation Mechanism Involved in Diabetes Comorbid Depression by Ex Vivo High Resolution 1H-NMR Spectroscopy

Tuesday, Nov. 28 3:30PM - 3:40PM Room: S504CD

Participants
Wen Xu, Hangzhou, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

xwmmmm@163.com

PURPOSE

To investigate the mechanism and find related biomarkers of diabetes comorbid depression, 1H nuclear magnetic resonance (1H NMR)-based metabonomics were applied to study the metabolic changes in the prefrontal cortex(PFC), hippocampus(HI) and hypothalamus(HY) of the comorbidity rats.

METHOD AND MATERIALS

Male wistar rats were divided into two groups: control group(group Con) and diabetes combined depression group(group DD). Rats of group DD were injected intraperitoneally with STZ, the control rats received sham injections of citrate buffer alone. Group DD were then exposed to chronic unpredictable mild stress(CUMS) for 28 days. All rats were submitted to the open-filed and Morris water maze tests immediately after the CUMS procedure. After brain tissue collection, a part of tissue were used for measuring the expression of glial fibrillary acidic protein(GFAP), glutamine synthetase(GS), glutaminase(GLS), glutamate decarboxylase(GAD) in PFC, HI and HY by immunohistochemistry. The rest of tissue underwent NMRS to find out metabolic changes in these cerebral regions.

RESULTS

Group DD showed high blood glucose level (>33.3mol/L), declined body weight (P<0.01), and exhibited other typical signs of diabetes. In the open-field test, group DD showed reduced total traveling distance and locomotor activity (P<0.05). Throughout the probe trial of Morris water maze test, group DD performed less times of crossing the former platform area (P<0.05). The mean optical density(MOD) of GFAP and GLS in aforementioned regions of group DD were elevated, while declined MOD of GS in these regions and GAD in the PFC increased (P<0.05). The level of Lac increased in all three regions of group DD compared with group Con. Decreased Glu, Gln, NAA, Cre and Cho, but increased Tau were obtained in PFC and HI. Besides, declined levels of Asp and Gly were observed in PFC, decreased Ala but increased m-Ins were presented in HI. In HY, concentrations of GABA, NAA, Ala, Glu, Gln, Cho, Gly, Asp all decreased.

CONCLUSION

Alterations in energy metabolism and amino acid neurotransmitters metabolism might be associated with the pathogenesis of diabetes comorbid depression, and disordered Gln-Glu-GABA cycle plays a crucial role in neuron injury of the comorbidity.

CLINICAL RELEVANCE/APPLICATION

The overall findings may contribute to the understanding of the underlying mechanism and provide some potential targets for treatments to ameliorate the effects of the comorbidity.

SSJ14-05 Hyperpolarized [13C1] Pyruvate Metabolism in Precision-Cut Mouse Liver Slices

PURPOSE

[13C1]Pyruvate metabolites in a hyperpolarized state have been visualized in whole rodent liver in vivo and ex-vivo. However, this approach does not permit the necessary radiology-histopathology needed to adequately evaluate the technique as a marker of the relevant biologic process. Precision cut liver slices have the potential to breach this obstacle. We aimed to validate the use of precision cut liver slices for hyperpolarized metabolic investigation in a mouse model. Following validation of the slices viability by 31P NMR spectroscopy and detection of ATP signals, hyperpolarized [13C1]pyruvate was administered to the slices and its metabolism was followed.

METHOD AND MATERIALS

Fresh normal livers were harvested from five mice. The livers were sliced with a microtome-tissue slicer to 500 µm thickness slices and placed in an ice-cold recovery medium. The slices were then placed in an NMR spectrometer (5.8 T, RS2D, France) and perfused continuously with oxygenated growth media at 37 °C. 31P spectra were acquired to evaluate the presence of ATP. After

ATP production was seen, hyperpolarized [13C1]pyruvate was flushed into the NMR tube in the spectrometer, into the liver. Consecutive 13C NMR spectra were acquired immediatly after the injection. Spectral analysis was performed using MNova (Mestrelab Research, Santiago de Compostela, Spain).

RESULTS

The 31P spectra collected from each liver showed the characteristic signals of ATP, confirming the viability of the tissues slices in the spectrometer. After each of the [13C1]pyruvate injections, both [13C1]lactate and [13C1]alanine signals were detected within 20 sec, for a duration of 1.5 min.

CONCLUSION

We were able to maintain and show the viability of precision-cut mouse liver slices in an NMR spectrometer as well as record hyperpolarized [13C1]pyruvate metabolism for the first time. This suggests that it can be used for ex-vivo evaluation of liver metabolism. This strategy is translational to the study of human liver metabolism ex-vivo as very small amounts of tissue are required. This approach is likely to lead to more accurate assessment of intracellular processes in a personalized manner.

CLINICAL RELEVANCE/APPLICATION

The validation of precision-cut mouse liver slices has great impact on the ability to increase evaluation accuracy and metabolites quantification. This new translational finding can improve evaluation of numerous biological processes in liver diseases.

PURPOSE

Optoacoustic imaging (OPUS), a novel technique based on measuring the differential absorption characteristics of oxy/deoxyhemoglobin in perfused tissues, has the potential to assess changes in tissue oxygenation during renal cortical ischemia. The aim of our proof of principle study was to explore the potential of optoacoustic imaging to detect quantitative changes in oxygen saturation in the renal cortex of revascularized porcine kidneys under ex-vivo normothermic perfusion conditions.

METHOD AND MATERIALS

Four porcine kidneys harvested by the animal licence holder on two separate occasions were evaluated. The harvested organs were perfused with a fully oxygenated (100%) warm red cell solution at a constant flow rate of 85 mls/min. An OxyLite probe was placed within the renal cortex under imaging guidance, distal to the external optoacoutic probe but within the same pyramid, approximately 1 cm apart (to avoid interference between the tip of the probe and the optoacoustic scanner). Real time measurements correlating the detected OPUS signal with the measurements from the OxyLite probe were made while clamping the renal artery intermittently until the kidney infarcted.

RESULTS

Kidneys 1 and 4 infarcted when connected to EVNP before results were obtained. Kidneys 2 and 3 showed a good temporal correlation between the indirect OPUS-derived oxygen saturation measurements and the OxyLite probe. The results are summarised in the figure uploaded.

CONCLUSION

Our preliminary results indicate that renal cortical ischemia can be assessed with a clinical optoacoustic system and OPUS measurements correlate with invasive OxyLite measurements in revascularised porcine kidneys under ex-vivo normothermic perfusion conditions. This first, but important step, opens the possibility of further evaluating the utility of this technique to assess transplant viability and develop it further as a method to detect renal ischemia.

CLINICAL RELEVANCE/APPLICATION

The ability to non-invasively quantify renal cortical ischemia is an important advance in treatment planning and assessing the viability of a transplant kidney.

PURPOSE

To evaluate age-related characteristics of thigh muscles by applying multi-parametric quantitative MRI and to investigate relationships between age and the parameters.

METHOD AND MATERIALS

Ninety-five healthy subjects (47 men, 48 women; median, 47 years; IQR, 39-58 years) with normal body mass index (18.5-24.9) were included for this prospective study. No subject had muscle disorder, diabetes, history of operation or trauma in the thigh region or was on medication. Age groups were as follows: 30-39 years (n=25), 40-49 years (n=25), 50-59 years (n=25), 60-69 years (n=20). Multi-parametric (intravoxel incoherent motion (IVIM) diffusion-weighted imaging (DWI), diffusion tensor imaging (DTI), multi-echo Dixon imaging, and dynamic contrast-enhanced (DCE)) MRI was acquired at 3.0 T. Parametric maps were evaluated by two radiologists independently in the following muscles: (1) anterior compartment: rectus femoris, vastus lateralis, medialis and intermedius; (2) medial: adductor longus and magnus; (3) posterior: biceps femoris, semitendinosus and semimembranosus. Significance of differences in multiple parameters in three thigh compartments between four age groups was determined by one-way analysis of variance (ANOVA) with post hoc Tuckey. Strength of relationships between multiple parameters and age was evaluated using Pearson correlation analysis. Interrater reliability was also assessed.

RESULTS

Significant differences between different age groups were appreciated for ADC, true diffusion (D), fractional anisotropy and Ve of anterior compartment muscles, as well as fat percentages of all three compartments ($p<0.05$). Moreover, fractional anisotropy and Ve in anterior compartment ($r=0.428$, 0.309, respectively) and fat percentages in all three compartments ($r=0.481$, 0.475, and 0.667, respectively) showed positive relationships to age ($p<0.05$). Interrater reliabilities were excellent (ICC, 0.786-0.992, $p=0.000$ for all).

CONCLUSION

Our study suggests that a number of MRI parameters are associated with age-related changes in thigh muscles. These parameters may reflect histologic and microstructural alterations in aging muscles.

CLINICAL RELEVANCE/APPLICATION

Multi-parametric MRI offers potential for non-invasive characterization of histologic changes in aging skeletal muscles. Our study provides a baseline data for further research on sarcopenia.

SSJ15-02 Fibrosing versus Non-Fibrosing Scleroderma-Related Myopathy: Role of Thigh Muscle MRI

PURPOSE

Systemic sclerosis (SSc)-associated myopathy has variable clinical outcomes. SSc patients with fibrosing myopathy (FM) have a rapidly progressive course and higher mortality than those with non-fibrosing myopathy (NFM). The purpose of our study was to describe MRI features in patients with SSc that may be predictive of FM and therefore, patient outcome.

METHOD AND MATERIALS

Following IRB approval, patients with SSc myopathy were included who had undergone a rheumatologic evaluation, thigh MRI and muscle biopsy. MRI included T1-weighted, STIR and DWI with ADC mapping (b-values 0,800 s/mm2) of both thighs. Two musculoskeletal radiologists (in consensus), without knowledge of histopathological findings, evaluated 36 individual muscles in each patient for the presence of intramuscular edema, fascial edema, fatty replacement and atrophy on all sequences using a 4-point score (absence,mild,moderate,maximal). Each patient was categorized by histologic results, as having FM (endomysial/perimysial fibrosis) or NFM (necrosis/inflammation etc.), and comparison of the two groups was performed.

RESULTS

There were 11 patients with FM (mean age 47; 9 women/2 men) and 14 with NFM (mean age 51; 10 women/4 men). Comparing STIR muscle appearance in FM (n=356) and NFM (n=498), intramuscular edema (65%(232/356) vs 49%(245/498), p<0.0001) and fascial edema (22%(79/356)vs17%(84/498), p=0.07), respectively, were more common in FM. DWI showed a greater difference in muscle signal in FM compared with NFM, at low b-value (54%(133/246) vs.23% (64/280), p<0.0001) and high b-value (46% (113/246) vs. 23%(65/280), p<0.0001) images, respectively. Minimum, average and maximum ADC values were not different between the two groups. NFM had chronic changes more often than FM, with fatty replacement (45%(223/498) vs. 26%(92/356), p=< 0.0001) and atrophy (52%(261/498) vs. 33%(118/356), p=< 0.0001), respectively.

CONCLUSION

In patients with SSc-related myopathy, intramuscular and fascial edema (as identified by STIR and DWI) on thigh MRI are more common in FM than NFM, while markers of chronic muscle damage are more often associated with NFM, potentially related to the rapid and fatal course of FM.

CLINICAL RELEVANCE/APPLICATION

Thigh muscle MRI maybe serve as an adjunct tool to distinguish between fibrosing and non-fibrosing SSc related myopathy and as such serve as a biomarker for prognosis.

SSJ15-03 Pudendal Nerve Entrapment: Comparing Pudendal MRI with Surgical Findings, Lessons Learned

Tuesday, Nov. 28 3:20PM - 3:30PM Room: E450B

Participants
Matthew L. Harwood, MD, Phoenix, AZ (*Presenter*) Nothing to Disclose
Olga M. Kalinkin, MD, Goodyear, AZ (*Abstract Co-Author*) Nothing to Disclose
Mario E. Castellanos, MD, Phoenix, AZ (*Abstract Co-Author*) Nothing to Disclose
Michael Hibner, MD, PhD, Phoenix, AZ (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the performance of pudendal MRI in patients with pudendal nerve entrapment (PNE) in comparison with transgluteal pudendal neurolysis, which is the gold standard for detection of PNE caused by scar, dilated vessels, or both.

METHOD AND MATERIALS

We performed a retrospective chart review to obtain basic patient information, operative report data, and presurgical pudendal MRI findings. All patients underwent a dedicated pudendal MRI with and without contrast performed on a 1.5T scanner. Surgical and MRI data were categorized by side (left, right, or bilateral), location [anatomically narrowed spaces, either Alcock's canal (AC) or the interligamentous space (ILS)], and surgical pathology (scar, dilated vessels, or both). Data underwent sensitivity analysis, and descriptive statistics were computed using R (www.r-project.org).

RESULTS

391 patients had dedicated pudendal MRIs between 8/2010 and 12/2016. We identified 67 patients who underwent transgluteal pudendal neurolysis after MRI. There were 55 women and 12 men, whose age ranged 24 to 77 years, mean age 51. 40 surgeries were on the left side; 21 were on right side; and 6 were bilateral. The surgeons saw 70 total scars (51 in ILS, 10 in AC, and 9 in both ILS and AC) and 16 dilated vessels (12 in ILS, 2 in AC, 2 in both ILS and AC). 64 (91%) of the scars and 13 (81%) of the dilated vessels were not discernable on MRI. Only 3 (4%) MRI findings of scar and only 2 (13%) MRI findings of dilated vessels matched findings seen at surgery exactly. Though not exactly quantified at the time of surgery, small scars (<= 2 mm thickness) and mildly dilated vessels (<= 3 mm diameter) predominated the findings at surgery.

CONCLUSION

Pelvic MRI with pudendal protocol has a low detection rate of small scars and mildly dilated vessels in the interligamentous space and in Alcock's canal. In spite of the limitations of current MRI technique, from our experience, clinicians should continue to use MRI to assess for unexpected causes of pudendal nerve entrapment.

CLINICAL RELEVANCE/APPLICATION

This study quantifies the detection rate of scars and dilated vessels to further clarify the role of pelvic MRI with pudendal protocol in patients with clinically determined pudendal nerve entrapment.

SSJ15-04 Will Pre-Operative Combined MRI and HRUS Redefine Brachial Plexus Imaging? A Comparative Study of Pre-Operative MRI versus HRUS in Assessing C5, C6 Viable Root-Stump Length, a Predictor of Intra-Plexal Nerve Grafting

Tuesday, Nov. 28 3:30PM - 3:40PM Room: E450B

drjyoticmch@gmail.com

PURPOSE

MRI is the preferred imaging modality for the traumatic brachial plexus (BP) imaging. From a surgeon's perspective locating viable root stumps is important as they are a source of axons for intra-plexal grafting. Hence predicting its presence preoperatively is of high priority. We argue that the presence of a viable nerve root stump is better assessed pre-operatively with high resolution ultrasonography (HRUS) rather than MRI in patients undergoing BP surgery. This study was undertaken to compare the diagnostic accuracy of combining HRUS with MRI versus MRI alone in the preoperative assessment of viable nerve root stumps of the BP.

METHOD AND MATERIALS

After approval by the institutional review board 56 adult patients with unilateral BP injury who were planned for BP nerve surgery between July 2015 to April 2016 and consented for this prospective study were included. This cohort underwent pre-operative imaging using both MRI and HRUS and an analysis for the presence of viable nerve roots and its length if present were done using the above two modalities. Undisrupted plexuses were deemed as "continuous" while discontinuous plexuses with "viable" root stumps were termed as "present" and those without as "absent". A viable stump was one with preserved epineurium and fascicular architecture and devoid of pre-ganglionic injury. Stump lengths were measured using both imaging modalities and compared with intraoperative (IO) measurements for their concordance.

RESULTS

We observed a greater agreement between the HRUS and IO findings in categorizing BP root stumps (Kappa value 0.70) as compared to MRI and IO (Kappa value 0.42). Similarly, there was a higher correlation (intra-class correlation-ICC) of the stump length measured, between HRUS and IO (0.94) than that of MRI and IO (0.53).

CONCLUSION

Combining HRUS with MRI in the pre-operative assessment of patients with adult BP injury can predict better, the presence of viable nerve root stumps as well as accurately measure its length compared to MRI alone.

CLINICAL RELEVANCE/APPLICATION

Knowing the quality of the root stump pre-operatively will help the surgeon in choosing an appropriate nerve grafting procedure and have possible better clinical outcomes. Hence, all pre-operative BP imaging protocols should include HRUS imaging along with standard MRI sequences for a comprehensive radiological evaluation.

SSJ15-05 Parsonage-Turner Syndrome: Not a Brachial Plexitis

Tuesday, Nov. 28 3:40PM - 3:50PM Room: E450B

SneagD@hss.edu

PURPOSE

Parsonage-Turner syndrome (PTS) - commonly known as neuralgic amyotrophy and brachial neuritis - is described etiologically as a 'brachial plexitis,' implying diffuse plexus involvement, but recent electrodiagnostic research suggests otherwise. We sought to characterize lesion distribution in PTS using high-resolution MRI.

METHOD AND MATERIALS

We searched our institution's MRI database for patients with a clinical diagnosis of PTS. Two radiologists specializing in peripheral nerve MRI independently evaluated signal characteristics and morphology of the brachial plexus on high-resolution MRI, including terminal branches of the plexus, as well as peripheral nerves when imaged. A physiatrist with expertise in PTS reviewed all charts to confirm the diagnosis of PTS using history, exam, and electromyographic (EMG) findings of complete/near-complete motor loss.

RESULTS

24 patients (18 M, 6 F; age 41 ± 15 years) had >=1 clinically involved nerves: suprascapular (15), long thoracic (7), axillary (5), radial (2), anterior interosseous (2), thoracodorsal (1), phrenic (1), musculocutaneous (1), and median nerve branch to pronator

teres (1). 75% of patients developed severe weakness following a prodrome of sudden-onset intense pain, while 25% had onset >12h following a surgical procedure. Mean time between symptom onset and initial EMG was 5.5 ± 4.6 months and 8 ± 6.7 months between onset and MRI. On MRI, the plexus proper appeared normal in 21/24 patients; in 3 others, T2-weighted signal hyperintensity was seen immediately proximal to the terminal branch take-off. Focal caliber decreases of terminal branches, suggesting intrinsic constrictions, were detected in 19/24. Hyperintensity and enlargement of involved peripheral nerves were present in all patients, except the phrenic nerve (too small to identify). MRI inter-reader agreement was nearly perfect (Cohen's kappa = 0.833).

CONCLUSION

MRI findings, corroborated by EMG, localize abnormalities to the plexus branches and peripheral nerves, suggesting PTS is a mononeuropathy multiplex rather than a diffuse brachial plexitis.

CLINICAL RELEVANCE/APPLICATION

'Brachial plexitis' is a misnomer that erroneously implies diffuse plexal involvement. Accurate disease terminology may improve diagnosis and management.

SSJ15-06 T1 and T2* MRI Mapping for Detection of Early Tendon Degeneration: A Phantom Study

Tuesday, Nov. 28 3:50PM - 4:00PM Room: E450B

Participants
Andrea Rosskopf, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose
Elias Bachmann, MSc, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose

Michael A. Fischer, MD, Stockholm, Sweden (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To quantitatively assess early tendon degeneration using T1 and T2* mapping in healthy and chemically degenerated bovine flexor hallucis tendons

METHOD AND MATERIALS

Twelve cadaveric specimens unterwent MRI at 3T before and after chemical tendon degeneration. Fibre cross-linking or protein denaturation resembling the first or the second step of tendon degeneration was chemically induced in a total of 10 tendons. A variable-echo-time sequence and variable-flip angle sequence was used for T2* mapping and T1 mapping respectively. Each scan (untreated and treated tendons) was repeated twice at different time points and T1 and T2* times were correlated with different grades of early tendon degeneration. Standard T1- and T2-weighted spin-echo (SE) sequences were acquired for visual assessment of tendon texture. Degree of tendon degeneration was verified by histopathological analysis.

RESULTS

The degree of tendon cross-linking and denaturation ranged from mild to strong. T1 times were reproducible, showing no difference between scan 1 and 2 for untreated and treated tendons (both, $P<0.01$). The mean T1 and T2* times were significantly different between normal and degenerated tendons ($P<0.01$) and correlated well with the degree of tendon degeneration ($R=0.86$, $P<0.05$). Standard T1 and T2 SE sequences showed no visual signal differences both in treated and untreated tendons.

CONCLUSION

T1 and T2* mapping has the potential to detect and quantify early tendon degeneration before changes in tendon structure become visible on standard MR sequences.

CLINICAL RELEVANCE/APPLICATION

Early tendon degeneration in symptomatic patients might be diagnosed much earlier as with routine MR sequences.

PURPOSE

To define the ability of T2 mapping sequences to evaluate the efficacy of PRP injections characterizing qualitatively and quantitatively knee cartilage composition in patients with early osteoarthritis

METHOD AND MATERIALS

40 patients (17 men, 23 women, mean age 35.8 years), with clinical suspicion of tibiofemoral and patellofemoral chondropathy were examined on a 3T MRI scanner. T1WI, T2WI, and PDWI sequences were used for morphological evaluation of cartilage lesions, using a modified WORMS score. T2 mapping sequences were used for the qualitative and quantitative analysis of cartilage by means of color-scale representation and ROI measurements of T2 relaxation time values. Patients were assigned to 2 groups: 20 patients (group A) were treated with intra-articular PRP injections (3 times, 3 weeks apart), 20 patients (group B, control) were submitted to conservative therapy. MRI follow-up was performed at 6 months

RESULTS

Before treatment the two study groups were homogeneous in terms of age, sex and BMI. The morphologic evaluation showed mean WORMS score of 8.4 (pre-treatment) and 6.6 (post-treatment) in Group A ($p < 0.0001$). In Group B mean WORMS scores were 8.6 (pre-treatment) and 7.9 (post-treatment) ($p = 1,323$). Mean T2 relaxation times values in Group A were 51.39 ms (pre-treatment) and 44.19 ms (post-treatment) ($p < 0.001$). In Group B, 51.86ms (pre-treatment) and 50.7ms (post-treatment) ($p = 0.274$)

CONCLUSION

Our imaging results confirm the clinical evidence of the efficacy of PRP injections for the treatment of knee osteoarthritis. Evaluation of cartilage T2 relaxation times provides additional quantitative information that may not be directly discernible from standard morphological sequences

CLINICAL RELEVANCE/APPLICATION

Cartilage repair is a challenging clinical issue. The efficacy of novel therapies aiming at tissue regeneration (such as PRP) is strictly dependent on early detection of cartilage pathology and a close monitoring of the treatment effects. Characterization of the cartilage matrix composition with T2 relaxation time measurements could potentially help in prevention of OA progression, allowing better monitoring of the disease and treatment-related changes in the cartilage matrix over time

SSJ16-02 Articular Cartilage Reliably Predicts Symptomatic Osteoarthritis Progression from T2 Maps Using Transport-Based Morphometry

shk71@pitt.edu

PURPOSE

Articular cartilage in the knee undergoes early biochemical changes in the development of osteoarthritis (OA). We determine whether texture change in articular cartilage as assessed by T2 maps is a reliable predictor of future symptomatic osteoarthritis.

METHOD AND MATERIALS

70 subjects (39 progressors, 31 controls) were chosen from the Osteoarthritis Initiative (OAI) database (age = 58.5 ± 9.2, BMI = 27.2 ± 4.8). At baseline, subjects had no evidence of OA either clinically (Western Ontario and McMaster Universities Arthritis Index (WOMAC) <10) or radiographically (Kellgren-Lawrence score <=2). On 3-year follow up, progressors were identified as subjects with >10 increase in WOMAC from baseline. Femoral cartilage was segmented from baseline T2 maps and co-registered. The transport-based morphometry (TBM) technique was applied to characterize T2 spatial variation within each subject individually and compared to a common template image. A penalized linear discriminant analysis classifier was constructed in the transport space and test accuracy in predicting symptomatic OA progression was determined using complete leave-two-out cross-validation. Characteristic patterns of injury were visualized through inverse TBM transformation.

RESULTS

TBM enables 86.2% test accuracy in predicting future symptomatic OA three years in advance of symptoms using T2 spatial variation of articular cartilage (sensitivity=86.6%, specificity=85.9%, Cohen's kappa = 0.72), significantly outperforming classification based on age and BMI alone. By defining signature patterns of injury in the femoral cartilage, we found that a central defect in the medial condyle and diffuse fissuring in the medial aspect of the lateral condyles were predictive of future OA.

CONCLUSION

The development of symptomatic OA can be reliably predicted based on the T2 map of knee articular cartilage using TBM, yielding the highest accuracy to date when compared to other predictive studies. In addition, TBM enables visualization of signature patterns of injury that are predictive of future OA for the first time.

CLINICAL RELEVANCE/APPLICATION

The early changes in T2 spatial variation revealed by TBM enhance our understanding of OA progression and yield markers that may be used prognostically and monitor success of disease-modifying therapies in the future.

SSJ16-03 Are Different Weight Loss Regimens in Obese and Overweight Individuals Associated With Different Degrees of Cartilage Degeneration Over 96 Months? Data from the Osteoarthritis Initiative

Tuesday, Nov. 28 3:20PM - 3:30PM Room: E451A

Participants
Alexandra S. Gersing, MD, Munich, Germany (*Presenter*) Nothing to Disclose
Benedikt J. Schwaiger, MD, Munich, Germany (*Abstract Co-Author*) Nothing to Disclose

Thomas M. Link, MD, PhD, San Francisco, CA (*Abstract Co-Author*) Research Grant, General Electric Company; Research Consultant, General Electric Company; Research Consultant, InSightec Ltd; Research Grant, InSightec Ltd; Royalties, Springer Nature; Consultant, Springer Nature; Research Consultant, Pfizer Inc;

PURPOSE

To investigate MR-based cartilage biochemical degeneration and morphologic joint abnormalities over 96 months in overweight and obese subjects with stable weight and weight loss and to assess how these changes are affected by different weight loss regimens.

METHOD AND MATERIALS

Subjects with a BMI>25kg/m2 from the Osteoarthritis Initiative (n=760; age 62.6±9.0y; 465 females) with risk factors for or radiographic mild to moderate osteoarthritis were included. Subjects losing weight (>5% of baseline BMI; N=380) were frequency matched to controls with stable weight (N=380) and categorized into groups regarding the weight loss method (diet and exercise, diet only, exercise only). 3T MRI of the right knee was performed at baseline, 48- and 96-months. T2 relaxation time changes of cartilage composition, including laminar and texture analysis as well as morphological knee abnormalities, assessed with Whole-Organ-Magnetic-Resonance-Imaging-Scores (WORMS) were analyzed using mixed random effects models to calculate associations between amount of weight loss and regimen.

RESULTS

Progression of cartilage WORMS was significantly lower in the weight loss group compared to controls (P<0.001) over 96 months. Subjects with weight loss showed significantly less T2-value increase in the bone layer of all compartments (P<0.03, for each) compared to the controls with stable weight, suggesting less cartilage degeneration over 96 months in the subjects with weight loss compared to their controls. Rates of increase in cartilage T2 averaged over all compartments were lowest in the diet and diet and exercise groups compared to the stable weight group (P=0.042 and P=0.003, respectively). Weight loss through exercise alone showed no significant difference in change of T2 over 96 months compared to subjects with stable weight (P=0.56).

CONCLUSION

Results suggest that cartilage degeneration is slowed through weight loss in obese and overweight subjects over 96-months. This

protective effect was, however, only found in subjects losing weight through diet and combined exercise and diet programs.

CLINICAL RELEVANCE/APPLICATION

MR-based knee cartilage T2 measurements and semiquantitative grading allow monitoring of the protective effect of weight loss on joint health and are useful to determine which weight loss regimen is most beneficial in overweight and obese patients.

SSJ16-04 Type 2 Diabetes Patients show Accelerated Cartilage Matrix Degeneration Compared to Age, Gender and BMI-matched Diabetes Free Controls: Data from the Osteoarthritis Initiative

PURPOSE

The relationship between osteoarthritis (OA) and type 2 diabetes mellitus (T2DM) is poorly understood with both diseases showing common risk factors. The purpose of this study was therefore to longitudinally investigate over 24 months cartilage matrix changes measured with MR-based T2 relaxation time including texture measurements in patients with T2DM compared to diabetes-free controls.

METHOD AND MATERIALS

Patients were recruited from the Osteoarthritis Initiative. In total 196 subjects with T2DM were group-matched for age, sex, BMI and Kellgren-Lawrence score with 196 diabetes free controls. T2DM was ascertained either by self-report or by use of anti-diabetic medication. Knee cartilage semi-automatic segmentation was performed on 2D multi-slice multi-echo spin-echo sequences; Cartilage T2 maps were calculated using a mono-exponential decay model. Texture of cartilage T2 maps was obtained with grey level co-occurrence matrix analysis, calculating the spatial distribution of neighboring pixels within the cartilage for contrast, variance, and entropy. Conditional logistic regression analysis was used to compare cross-sectional and changes in T2 and texture parameters between both groups.

RESULTS

Averaged over all compartments, subjects with T2DM increased almost twice as fast as the control group in the global knee T2 values (mean T2 (ms) [95% CI]: 1.77 [1.51,2.03] and 0.98 [0.68,1.28], respectively ($p<0.001$). The 24-month cross-sectional analysis showed significantly higher T2 values in subjects with diabetes in the global knee ($p=0.009$), patella ($p=0.01$), medial tibia ($p=0.02$), and lateral tibia (0.006). Moreover, T2DM showed texture parameters consistent with increased cartilage matrix inhomogeneity at baseline for contrast, variance and entropy ($p<0.05$) and after 24 months for contrast and variance ($p<=0.05$).

CONCLUSION

Subjects with T2DM showed a significantly faster increase in T2 values when compared to diabetic-free controls, and had also significantly higher T2 values in the cross-sectional analysis at 24 months, indicating an accelerated degeneration of the cartilage matrix. Furthermore, T2DM subjects showed more heterogeneous cartilage texture composition at both time points.

CLINICAL RELEVANCE/APPLICATION

Altered cartilage composition and collagen architecture in subjects with T2DM and accelerated cartilage matrix deterioration, suggest that T2DM is an important risk factor for OA.

SSJ16-05 MRI-Based Indicators of Patella Cartilage Volume Loss over 24-Month Interval: Initial Assessment Using Data from the FNIH OA Biomarkers Consortium

PURPOSE

To investigate whether key patellofemoral alignment indicators on 3T magnetic resonance imaging (MRI) are associated with baseline cartilage volume differences and 2-year progression of patella cartilage volume loss.

METHOD AND MATERIALS

One index knee from each of 600 subjects in the Osteoarthritis Biomarkers Consortium FNIH project were included. Four key patellofemoral alignment markers were assessed on baseline imaging including: tibial tuberosity-trochlear groove distance (TT-TG), Insall-Salvati (IS) ratio, trochlear groove depth (TGD) and presence or absence of superolateral Hoffa's fat pad edema. Patella cartilage volume was determined at baseline and 24-month follow up MRI using validated automated software. Cross-sectional analysis of baseline data was performed by comparing cartilage volumes for each alignment index, with abnormal values considered TT-TG greater than 15 mm, IS ratio greater than 1.4, TGD greater than 3 mm, and presence of fat pad edema. Multivariable logistic regression analysis was performed with odds-ratios determined for future cartilage volume loss, adjusted for age, gender, BMI and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC).

RESULTS

On baseline cross-sectional analysis, abnormal IS ratio and abnormal TGD were associated with lower baseline patella cartilage volume (IS ratio: 2445 mm3 vs 2664 mm3, p:0.028; TGD: 2697 mm3 vs 2369 mm3 p<0.001). Multivariate logistic regression analysis showed only presence of superolateral Hoffa's fat pad edema to be predictive of significant 2-year interval decrease in patellofemoral cartilage volume (OR: 1.82, p: 0.003).

CONCLUSION

Presence of superolateral Hoffa's fat pad edema is associated with 2-year progression of patella cartilage volume loss. Furthermore, subjects with abnormal IS ratio and TGD had lower baseline patella cartilage volumes, suggestive of cartilage loss prior to initiation of this study.

CLINICAL RELEVANCE/APPLICATION

Routine indicators of patellofemoral alignment on MRI could allow for prediction of future patellofemoral cartilage loss.

SSJ16-06 Comparison of T2 Relaxation Values in Subtalar Cartilage between Patients with Lateral Instability of the Ankle Joint and Healthy Volunteers

Tuesday, Nov. 28 3:50PM - 4:00PM Room: E451A

Participants
Hyun Su Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Young Cheol Yoon, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

calmuri@naver.com

PURPOSE

To evaluate the difference between the T2 relaxation values of the subtalar cartilage in patients with lateral instability of the ankle joint and the values in healthy volunteers.

METHOD AND MATERIALS

Twenty-seven ankle magnetic resonance imaging (MRI) examinations of 26 patients who underwent lateral ankle ligament repair between January 2011 and November 2013 were included. The datasets of previously enrolled healthy volunteers, 13 ankle MRI examinations of 12 volunteers, were used as a control group. Two radiologists independently measured the T2 relaxation values of the cartilage in the posterior facet of the subtalar joint comprising of eight compartments as follows: central calcaneus anterior (CCA), central calcaneus posterior (CCP), central talus anterior (CTA), central talus posterior (CTP), lateral calcaneus anterior (LCA), lateral calcaneus posterior (LCP), lateral talus anterior (LTA), and lateral talus posterior (LTP). The T2 relaxation values of the patient group were compared with those of the control group using linear regression analysis. Interobserver agreement and intraobserver agreement for the measurement were calculated using the intraclass correlation coefficient (ICC).

RESULTS

Readers found significantly higher mean T2 relaxation values in all compartments except that in LTP compartment measured by reader 1. For reader 1, the CCA findings were 44.9 for patients and 40.5 for healthy volunteers (p=0.002); CCP, 46.0 and 40.8 (p=0.002); CTA, 50.1 and 46.0 (p=0.001); CTP, 52.8 and 46.3 (p<0.001); LCA, 43.7 and 39.1 (p=0.002); LCP, 45.1 and 38.8 (p<0.001); LTA, 50.8 and 47.5 (p=0.019); and LTP, 50.4 and 47.6 (p=0.085). For reader 2, the CCA findings were 45.5 for patients and 41.5 for healthy volunteers (p=0.005); CCP, 45.8 and 40.1 (p<0.001); CTA, 49.7 and 45.6 (p=0.009); CTP, 52.7 and 47.0 (p<0.001); LCA, 44.3 and 39.2 (p<0.001); LCP, 45.8 and 38.8 (p<0.001); LTA, 50.4 and 47.6 (p=0.040); and LTP, 52.9 and 48.0 (p=0.002). Interobserver agreement and intraobserver agreement were excellent for all measurements (ICC>0.75).

CONCLUSION

The T2 relaxation values of the subtalar cartilage were significantly higher in patients with lateral ankle instability compared with those of healthy volunteers.

CLINICAL RELEVANCE/APPLICATION

Quantitative T2 mapping in the subtalar joint is feasible and may have a role for diagnostic evaluation of cartilage degeneration in patients with lateral ankle instability.

PURPOSE

Newer high-performance TOF PET systems have the capability to maintain diagnostic image quality even with low count density, while maintaining a high raw photon detection sensitivity that would allow for a reduction in injection dose or rapid data acquisition. To assess this, we performed quantitative and visual assessments of the PET images acquired using a highly-sensitive large field-of-view silicon photomultiplier (SiPM)-based TOF-PET integrated with 3T-MRI in comparison to PET images acquired on non-TOF PET/CT systems.

METHOD AND MATERIALS

Whole body FDG-PET/CT was acquired for fifteen patients followed by whole body PET/MRI. The PET list mode data from PET/MRI were reconstructed using full datasets (4 min/bed) and reduced datasets (2, 1, 0.5 and 0.25 min/bed). Qualitative assessment between PET(/CT) and PET(/MR) images were made. A Likert-type scale between 1 and 5, 1 for non-diagnostic, 3 equivalent to PET(/CT) and 5 superior quality, was used. Maximum and mean standardized uptake values (SUVmax and SUVmean) of normal tissues and lesions detected were measured and compared.

RESULTS

Mean visual assessment scores were 3.54±0.32, 3.62±0.38 and 3.69±0.35 for the brain and 3.05±0.49, 3.71±0.45 and 4.14±0.44 for the whole-body maximum intensity projections (MIPs) for 1, 2 and 4 min/bed PET(/MR) images, respectively. The SUVmean values for normal tissues were lower and statistically significant for images acquired at 4, 2, 1, 0.5 and 0.25-min/bed on the PET(/MR), with values of -27±18%, -26±18%, -26±19%, -25±19% and- 25±18% ($p<0.05$) respectively. SUVmax and SUVpeak values of all lesions were higher and statistically significant ($p<0.05$) for 4, 2, 1, 0.5 and 0.25 min/bed datasets.

CONCLUSION

High-sensitivity TOF-PET showed comparable but better visual image quality even at much reduced activity in comparison to lower-sensitivity non-TOF-PET. Our data translates to a 7 times reduction in either injection dose for the same time or total scan time for the same injected dose. This 'ultra-sensitivity' PET system provides a path to extremely low-dose FDG-PET studies (e.g, sub 1 mCi injection or sub-mSv effective dose) or studies as short as 1 min/bed (e.g., 6 minutes of total scan time time) to cover whole-body without compromising diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

'Ultra-sensitive' TOF PET system can provide clinically acceptable FDG-PET studies for sub-mSv or short aquisition times (1 min/bed) to cover the whole-body.

PURPOSE

The aim of this pilot study is to determine if a new generation PET/CT scanner using silicon photomultipliers (SiPM), GE Discovery Molecular Insights - DMI PET/CT (GE Healthcare, Waukesha, WI), recently installed in our Department, provides equivalent results compared to the standard of care PET/CT scanners (GE Discovery 600 or GE Discovery 690) used in our clinic and to explore any possible differences in semi-quantitative measurements.

METHOD AND MATERIALS

We enrolled 50 patients who had a clinical indication for standard of care PET/CT. The local Institutional Review Board approved the protocol and written informed consent was obtained from each patient. All patients underwent a single injection dual imaging protocol including the standard of care PET/CT scan followed immediately by image acquisition using the DMI PET/CT scanner. We measured SUVmax and SUVmean of different background organs and up to 4 lesions per patient from data acquired using both scanners

RESULTS

DMI PET/CT scan did not miss any of the 107 lesions detected by standard PET/CT scanners and identified additional 37 areas of focal 18F-FDG uptake compatible with putative sites of disease. The results of equivalence tests, with an equivalence interval of [-0.7,0.7], performed on each of the normal tissues matched per patient showed an equivalence for all background tissues except for the cerebellum (P value < 0.01). The SUVmax measurements for all 107 lesions were 2.8 ± 2.8 higher on DMI PET/CT compared with standard of care PET/CT (P <0.0001) and this difference was not related to time delay between two scans (P <0.0001). Lesion:aortic arch ratios and lesion:liver ratios were 3.2 ± 2.6 and 1.9 ± 1.4 higher on DMI PET/CT compared with standard of care PET/CT (P <0.0001).

CONCLUSION

The performance of SiPM PET/CT is at least comparable to that of standard PET/CT. While delayed imaging can lead to detection of additional lesions, our data suggests that in this series the lesions identified only on DMI PET/CT indicate superior performance of the scanner. Further evaluation needed to confirm our data. Differences in semi-quantitative measurements between standard PET/CT and SiPM PET/CT are important factors when adopting the new technology.

CLINICAL RELEVANCE/APPLICATION

DMI PET/CT new generation scanner allow to reduce the injected dose or the scan time without missing images quality, helping to diagnose and stage disease earlier and better guide treatment strategies.

SSJ17-03 Effect of Tumor Burden on Standard Uptake Values within the Brain, Blood, and Liver: Implication for Quantitative PET/CT Imaging

PURPOSE

We have previously described the effect of patient specific factors, specifically plasma blood glucose, had on quantitative standardized uptake value (SUV) measurements within target organs/tissues of interest, particularly the relationship to brain cortical metabolism and liver parenchyma. During analysis of that patient population, there was suggestion that metabolic burden (total lesion glycolysis, TLG) either from tumor and/or heart can also be a confounding factor of FDG uptake within these reference

tissues.

METHOD AND MATERIALS

Previously published 436 FDG PET/CT studies performed for oncology staging from 229 patients (436 exams) at the Ann Arbor Veterans Administration Healthcare System were reviewed. An additional 107 exams from 50 patients were performed and TLG was obtained based on auto-segmentation of the tumor and/or the heart. The absolute and normalized uptake in target tissues for these studies were then compared to the entire group (previously published non censored data) as a function of TLG to determine if metabolic burden had an effect on uptake in reference tissue.

RESULTS

Metabolic tissue burden (tumor and/or heart) had a statistical significant effect on the uptake of FDG within reference tissue (blood, liver and brain) compared to the population average at similar plasma glucose. However, this effect was absent and or significantly mitigated when normalization to a reference tissue (blood) occurred.

CONCLUSION

The effects metabolic burden (tumor and or hear) upon brain SUV and various reference tissue can have a significant effect on absolute SUV measurements. This effect can be mitigated if normalization to a reference tissue occurs.

CLINICAL RELEVANCE/APPLICATION

Finding of this reserach could have implications in the implementation of PERCIST criteria in tumor imaging.

SSJ17-04 Whole Body Metabolic Tumor Volume is a Prognostic Marker for Overall Survival in Patients with Newly Diagnosed Stage 3B Non-Small Cell Lung Cancer Confirmed with External Validation

PURPOSE

This study aimed to evaluate the prognostic value of quantitative FDG measurements, namely whole body Metabolic Tumor Volume (MTVwb), Total Lesion Glycolysis (TLGwb), and maximum Standardized Uptake Value (SUVmaxWB), on baseline FDG PET/CT in patients with newly diagnosed Stage 3B Non-Small Cell Lung Cancer (NSCLC).

METHOD AND MATERIALS

IRB approved retrospective study identified patients diagnosed with Stage 3B NSCLC (restaged according to 8th edition TNM classification) on baseline FDG PET/CT between Feb 2004 and Dec 2014. Exclusion criteria included a second primary cancer diagnosed from 5 years before to 2 months after this FDG PET/CT scan and any prior NSCLC treatment. MTVwb, TLGwb, and SUVmaxWB were calculated from the baseline PET/CT using Edge method with Mimvista software. The study included a training dataset from one medical center, and a validation dataset from an outside hospital. The primary endpoint was overall survival (OS). Cox regression models were used to test for an association between patient characteristics, quantitative FDG measurements and OS.

RESULTS

110 patients with clinical Stage 3B NSCLC met inclusion/exclusion criteria. 78.2% expired during follow-up. The median OS was 14 months. 1-year, 2-year, and 5-year OS was 56.5%, 34.6% and 13.9 %, respectively. The median follow-up among survivors was 26.0 months (inter-quartile range 13.6 to 57.2 months). Univariate analysis showed no significant difference in OS on the basis of age, gender, histology, ln(TLGwb), or ln(SUVMAXwb). However, increasing ln(MTVwb) was associated with worse OS (hazard ratio (HR) of 1.23). This association persisted on multivariate Cox regression analysis (HR of 1.28), when adjusted for age, gender, treatment and tumor histology. The second external dataset of 44 patients validated the significant correlation between MTVwb and survival. Specifically, a MTVwb cut-off point of 85.6 mL able to further stratify patient prognosis among patients with Stage 3B NSCLC, with increasing MTVwb predictive of significantly worse survival.

CONCLUSION

MTVwb is a prognostic marker for OS in patients with Stage 3B NSCLC, independent of age, gender, treatment, and tumor histology, with increasing MTVwb predictive of significantly worse OS.

CLINICAL RELEVANCE/APPLICATION

An MTVwb of 85.6 mL may be used as a threshold to further stratify Stage 3B NSCLC patients, with MTVwb >= 85.6 mL on baseline PET/CT predictive of worse prognosis.

SSJ17-05 Who is Hot and Who is not? The Diagnostic Dilemma of Paraneoplastic Syndromes and Who to Image with FDG-PETCT

PURPOSE

Paraneoplastic syndromes are a rare phenomenon that pose a diagnostic challenge and are sometimes the first clinically detectable evidence of occult disease.:The dilemma occurs as many of the signs/symptoms associated with them can be features of conditions without an underlying malignancy.Given the higher radiation doses associated with a full body FDG-PETCT over conventional CT or non-ionising radiation imaging we wanted to evaluate its usefulness as a first line investigation for patients with suspected paraneoplastic syndromes.The challenge is 'who to PETCT?'.

METHOD AND MATERIALS

We conducted a retrospective review of patients who underwent FDG PETCTbetween 01/01/2009 and 31/01/2017, to investigate occult malignancy in suspected paraneoplastic syndrome. We collected information on age, sex, primary diagnosis, incidental pathology, other causative pathology, presence of antibodies and final diagnosis. Evaluation of cases where a positive neoplasm was identified was carried out to evaluate if other first line investigations were obtained, and if not, would alternative imaging have been suitable.

RESULTS

113 patients were identified as having PETCT. 3.5% (n=4) had a primary neoplasm identified. The commonest source of referral was from neurology n=73 (64%), followed by rheumatology (n= 38, 34%), and endocrinology (n=2, 2%). In our study, PETCT had a true positive = 4, true negative = 94, false positive = 14, false negative = 1. The PPV was 22%, NPV was 98%, sensitivity was 80% and the specificity was 87%. A review of the positive cases was carried out to identify if other imaging would have yielded the same result. The neoplasms identified were oropharyngeal, primary lung, phaemochromocytoma and Hodgkins lymphoma. 75% of malignancy detected on PETCT was also detectable on conventional CT.

CONCLUSION

To our knowledge this is the largest retrospective analysis in the UK of PETCT in the investigation of patients with suspected paraneoplastic syndrome. PETCT has a high NPV and is therefore an excellent diagnostic test to exclude malignancy. The low positive yield for malignancy adds support to our current national imaging and neurology guidelines which advise against using PETCT as a first line investigation.

CLINICAL RELEVANCE/APPLICATION

Paraneoplastic syndromes are a diagnostic challenge. Radiation burden and resource management must be considered when deciding on the primary radiological investigation.

SSJ17-06 Synthesis, Quality Control and Bio-Distribution of PET Tracer (18F-FP-Chlorotoxin) and Preliminary Evaluate the Imaging Features of 18F-FP-Chlorotoxin in C6 Glioma Model

Tuesday, Nov. 28 3:50PM - 4:00PM Room: S505AB

zhaojing_sysu@126.com

PURPOSE

To synthesize, describe the bio-distribution of 18F-FP-Chlorotoxin and do quality control of this PET-tracer. Further, to preliminary evaluate its imaging feature in C6 glioma model.

METHOD AND MATERIALS

18F- was generated by medical cyclotron and 18F-NFB was synthesized through fluorination reaction, then, dissolved 18F-NFB and Chlorotoxin in Na2HPO4 or borate buffer. Quality control experiments of 18F-FP-Chlorotoxin were performed. 20 normal Kunming mice were randomly divided into four groups and each mouse was injected 18F-FP-Chlorotoxin (22-23 μCi) via the tail vein. They were sacrificed after injection in 10 min, 30 min, 60 min and 120 min, respectively. Blood and organs of each mouse were resected and weighed separately. 18F-FP-Chlorotoxin (60min, 90min, 120min) and 18F-FDG micro PET-CT (60min) was performed on the same rat with orthotopic C6 cell-bared glioma (n=2) at different scan time points and their imaging features were analyzed.

RESULTS

18F-FP-Chlorotoxin was successfully made. The chemical purity of 18F-FP-Chlorotoxin was greater than 98% and the radiation purity was greater than 95%. The brain had a low and relatively stable uptake of 18F-FP-Chlorotoxin and, it was 0.37±0.10% ID/g in 10 min which was slightly decreased to 0.28±0.06%ID/g in 60min. Among all the organs, kidney showed the highest uptake. 18F-FP-Chlorotoxin and 18F-FDG micro PET-CT were successfully performed on the same rat with orthotopic C6 cell-bared glioma. Compared with 18F-FDG, a low uptake of 18F-FP-Chlorotoxin was detected in normal brain parenchyma while a higher level of 18F-FP-Chlorotoxin was found in the gliomas tissue. The glioma tumor/normal brain parenchyma in 18F-FP-Chlorotoxin was higher than the ratio in 18F-FDG. Further, the diagnostic performance of 18F-FP-Chlorotoxin in 90 min was better than it in 60 min.

CONCLUSION

The main quality control indexes of 18F-FP-Chlorotoxin had reached the positron radiopharmaceuticals quality requirements. Normal brain parenchyma has a low and stable uptake on 18F-FP-Chlorotoxin and, compared with 18F-FDG, 18F-FP-Chlorotoxin has a better performance in diagnosis of glioma.

CLINICAL RELEVANCE/APPLICATION

18F-FP-Chlorotoxin as a new PET-trace with a low and stable uptake in normal brain parenchyma and, compared with 18F-FDG, it has a better performance in diagnosis of glioma.

Arlene Weir, MBBS, Galway, Ireland (*Abstract Co-Author*) Nothing to Disclose
Bruno Voisin, PhD, Galway, Ireland (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

Declan.Sheppard@hse.ie

PURPOSE

The new ACR TI-RADS guidelines were published on-line on March 31st 2017 http://dx.doi.org/10.1016/j.jacr.2017.01.046 Existing guidelines can be difficult to apply. The new risk stratification model was published with the aim of reducing the number of unneccessary thyroid biopsies. Our study aims to: 1. Determine the accuracy of the new guidelines 2. Look specifically at the biopsy rates and the number of malignancies that might be missed with the application of these new guidelines.

METHOD AND MATERIALS

The new guidelines were applied against a pre-existing electronic database of 200 pathologically confirmed cases. 200 cases had already been scored by 5 readers (4 using a newly developed on-line 'app') using an extended version of the 2015 ACR TI-RADS lexicon. The sonographic features scored included the ACR lexicon which had been extended to allow for the assessment against the pre-existing ATA, AAC/AME/ETA, BTA, Kim, Koreean, ASRU and a number of the earlier versions of 'TI-RADS' scoring system. The readers included 3 faculty (> 10 years post fellowship training), a 4th year Resident and an intern(planning a career in Radiology) - all had been involved with thyroid US projects previously.

RESULTS

Using the summed scores of all readers the mean sensitivivity for the new ACR TI-RADS was 57% (range,40-93) while the specificity was 52% (range, 42-60). Initial experience from the readers that it was slow to use but with time productivity improved sunstantially. Average time with experience varied from 40 sec to 5 min. Less experienced users were more likely to use if available as a clinical decision support tool.

CONCLUSION

Initial experience with the new guidelines might suggest a lower specificity and consequently the expected reduction in biopsy numbers may not be achieved. A slightly lower sensitivity for biopsies is compensated for by combining the true positive biopsy rate and the follow-up rate of the 'false negatives' The app may be more useful for less experienced operators

CLINICAL RELEVANCE/APPLICATION

Further investigation is required to determine whether the new ACR guidelines constitute the correct balance of sensitivity and specificity to reduce the number of unnecessary thyroid biopsies while avoiding missing clinically signifcant cancers.

SSJ18-02 Preliminary Study on Spectral Parameters of Various Pathological Types of Malignant Tumors of Thyroid

Tuesday, Nov. 28 3:10PM - 3:20PM Room: N226

Participants
Lin Li, MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To analyze the imaging manifestations and spectral parameters of various pathological types of malignant tumors of thyroid.

METHOD AND MATERIALS

67 cases of malignant tumors of thyroid were included in the retrospective study(44 papillary carcinomas, 2 follicular carcinomas,9 medullary carcinomas, 7 anaplastic carcinomas and5 primary thyroid lymphomas). The morphological manifestations and the spectral parameters were analyzed. All the patients underwent spectral CT scan with Discovery CT750HD scanner in GSI mode. The morphological manifestations of lesions were analyzed on the optimal monochromatic images. The iodine concentration (IC), water concentration (WC), normalized iodine concentration (NIC),spectral HU curve slope values (λHU) were measured and analyzed by GSI Viewer. SPSS 19.0 software was used for statistical analysis of the data.

RESULTS

The morphological features of malignant tumors of thyroid were as follows: single lesion (57 cases, 85.1%), irregular shape (46 cases, 68.7%), indistinct margin (45 cases, 67.2%), heterogeneous density (48 cases, 71.6%) and detection of calcification (21 cases, 31.3%). There was no significant difference among various types of malignant tumors on WC($P>0.05$). The IC, NIC and λHU values of papillary carcinoma, follicular carcinoma and medullary carcinoma were higher than that of anaplastic carcinoma and lymphoma($P<0.05$). The NIC of papillary carcinoma was lower than that of medullary carcinoma($P>0.05$).There were no significant differences on the parameters between each two groups remained($P>0.05$).

CONCLUSION

The morphological features and spectrum parameters are different in various pathological types of thyroid malignant tumors, and it is helpful for the diagnosis and differential diagnosis.

CLINICAL RELEVANCE/APPLICATION

Spectral CT imaging is helpful to differentiate various pathological types of thyroid malignant tumors.

SSJ18-03 Computer-aided Diagnosis System for Thyroid Nodules on Ultrasound: Initial Clinical Experience

Tuesday, Nov. 28 3:20PM - 3:30PM Room: N226

Participants
Youngjin Yoo, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose
Eun Ju Ha, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Miran Han, MD, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Yoon Joo Cho, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To prospectively evaluate the diagnostic performance of a computer-aided diagnosis (CAD) system (S-Detect for ThyroidTM) for thyroid US in the differential diagnosis of thyroid nodules and to determine interobserver agreement between the CAD system and experienced radiologist.

METHOD AND MATERIALS

This study was approved by the ethics committee of the institution, and all patients provided written informed consent. We consecutively enrolled patients with thyroid nodules with final diagnoses whether benign or malignant between June 2016 and July 2016. An experienced radiologist reviewed US characteristics of thyroid nodules, and a CAD system provided nodule diagnosis whether benign or malignant in a prospective design. We compared the diagnostic performance of experienced radiologist, CAD system, and CAD system assisted radiologist for detecting thyroid cancer and determined interobserver agreement between the CAD system and experienced radiologist.

RESULTS

A total of 117 thyroid nodules from 50 consecutive patients were included. The mean size of nodules was 1.5 ± 1.1 cm (range: 0.5-10.0 cm) and final diagnoses were 67 (57.3%) benign nodules and 50 (42.7%) malignant nodules. The CAD system showed similar sensitivity and specificity compared with the experienced radiologist (sensitivity: 80.0% versus 87.0%, P= 0.754; specificity: 88.1% versus 95.5%, P= 0.180). The diagnostic accuracy was not significantly different between the CAD and experienced radiologist (84.6% versus 90.6%, P= 0.646). The CAD system assisted radiologist reached the higher diagnostic sensitivity when compared to the radiologist without the CAD system (91.8% versus 87.0%, P= 0.031). The interobserver agreement between radiologist and CAD system were substantial agreement for a final diagnosis (kappa=0.661).

CONCLUSION

The diagnostic performance of CAD system for differentiating thyroid nodule was as good as that of the experienced radiologist with a substantial agreement. The CAD system assisted radiologist could achieve the highest diagnostic sensitivity for thyroid cancer.

CLINICAL RELEVANCE/APPLICATION

The CAD system could be used as a good decision-making supporter for the experienced radiologist with achieving the highest sensitivity up to 91.7% as well as for the beginner or non-thyroid radiologist with achieving comparable diagnostic performance with the experienced radiologist.

SSJ18-05 Can 4D-MRI Be an Alternative Modality for the Detection of Parathyroid Lesions in Primary Hyperparathyroidism?

Tuesday, Nov. 28 3:40PM - 3:50PM Room: N226

PURPOSE

To compare ultrasonography (USG), Tc99 MIBI, 4D-CT & 4D-MRI in the detection & localisation of parathyroid lesion in patients with primary hyperparathyroidism (PHPT).

METHOD AND MATERIALS

In this prospective institutional ethics committee approved study, 39 patients with PHPT underwent USG, 4D-CT, 4D-MRI & Tc99 MIBI in the period, May 2016 - Feb 2017. Children & pregnant patients was excluded from study. 4D-CT was performed in 3 phases (NCCT, arterial & venous) on a 256 slice scanner & 4D-MRI was performed on a 1.5T scanner. Sixteen patients underwent surgery & only those were included for analysis. Surgical findings confirmed on histopathology & normalisation of parathormone (PTH) after excision of lesion were taken as the gold standard. The images were analysed for the presence & quadrant wise location of parathyroid lesions by two experienced radiologists & a nuclear medicine physician.

RESULTS

Of the 16 patients analysed, parathyroid hyperplasia was seen in 2 (12.5%), parathyroid adenoma in 12 (75%) & parathyroid carcinoma were found in 2 (12.5%) patients. In all patients, preoperative localisation was confirmed at surgery & this included ectopic lesions (mediastinum & parapharyngeal region) in two patients. PTH values returned to normal after surgery in all patients. 4D-CT, 4D-MRI showed 100% sensitivity whereas USG & MIBI showed 81.25% sensitivity each, for lesion detection & quadrant localisation. Two ectopic parathyroid adenomas were missed on USG & MIBI scan.

CONCLUSION

4D-CT & 4D-MRI had a high accuracy for parathyroid lesion detection & localisation in patients of PHPT whereas USG & MIBI showed moderate accuracy. 4D-MRI, being a modality without radiation exposure may provide a viable alternative for the localisation of parathyroid lesions.

CLINICAL RELEVANCE/APPLICATION

4D-CT & 4D-MRI have comparable high accuracy for detection & localization of parathyroid lesions in patients with PHPT. Due to better safety profile, the latter may become the modality of choice in the future

SSJ18-06 Parathyroid Adenoma Identification Using Spectral Dual Energy CT Texture Analysis

james.alexander@mail.mcgill.ca

PURPOSE

The purpose of this study was to (1) determine the accuracy of texture analysis performed on multi-energy or single energy (65 keV) virtual monochromatic images (VMIs) from dual energy CT (DECT) scans for parathyroid adenoma classification and (2) to compare accuracy using a single phase or multiple phases from the 4D-DECT scan.

METHOD AND MATERIALS

16 patients with pathologically proven parathyroid adenomas having a 3-phase 4D-DECT including a non-contrast (NC), arterial (CTA), and delayed phase (DEL) scan were included. Texture analysis was performed using a commercial software (TexRAD®) by manually delineating a region of interest around the largest diameter of the PA, thyroid, and a lymph node on VMIs ranging from 40 to 140 keV in 5 keV increments or VMIs at 65 keV alone. Random forests (RF) models were constructed using various histogram-based texture features for outcome prediction with internal cross-validation in addition to use of separate randomly selected training and validation sets. Sensitivity (Sens), specificity (Spec), positive predictive value (PPV), and negative predictive value (NPV) were determined for PA distinction from thyroid tissue or lymph nodes.

RESULTS

With RF models, the highest accuracy for PA prediction was achieved using a combination of NC-CTA-DEL phases with estimated Sens, Spec, PPV, and NPV of 100%. The CM-CTA and CTA-DEL combinations had similar accuracy with Sens, Spec, PPV, and NPV of 100%, 90%, 83%, and 100%, respectively. Multi-energy analysis was superior to analysis of 65 keV VMIs alone. For the latter, the highest accuracy achieved was Sens, Spec, PPV, and NPV of 60%, 100%, 100%, and 83%, respectively.

CONCLUSION

Multi-energy VMI texture analysis can correctly classify PAs with high accuracy at least similar to an expert radiologist, and is

superior to texture analysis of single energy image sets at 65 keV.

CLINICAL RELEVANCE/APPLICATION

DECT texture analysis has high accuracy for PA identification, improving diagnostic performance or potentially enabling a reduction in the number of phases acquired and patient radiation exposure.

PURPOSE

The risk of under-estimating local CBF in cerebrovascular disease patients as well as the underlying low SNR of the arterial spin labeling(ASL) techniques calls for new approaches. Here we proposed and evaluated a Deep Learning method to boost image quality and improve cerebral blood flow(CBF) and arterial transit delay(ATD) estimation using multi-delay ASL.

METHOD AND MATERIALS

We developed a Deep Learning based method, a local Residual-Encoder-Decoder Convolutional Neural Network (CNN), to improve the ASL image quality. At 3T, we collected two multidelay ASL datasets in 7 normal subjects: (1) input images: low SNR/resolution (5.6mm resolution,1 repetition,4min); (2) gold-standard reference images: high SNR/resolution (3.8mm resolution,3 repetitions,24min). Label Duration(LD) was 2sec and 5 Post-Labeling-Delays(PLD) were used (0.7sec,1.4sec,2.1sec,2.8sec,3.5sec). We trained the network to reduce artifact/noise in the input ASL images by approximating the gold-standard reference images. The method takes in image patches from low-SNR/resolution ASL and the corresponding un-labeled proton-density-weighted data, forward-passes through the network and outputs improved image patches to approximate the high-resolution-high-SNR patches from the gold-standard reference ASL. Once trained, we applied the model to improve new ASL clinical scans which do not necessarily include gold-standard reference scans (n=5, patients with cerebrovascular and neoplastic disease). Application of the model is efficient, requiring only 1 sec per slice to apply.

RESULTS

To evaluate the proposed method, we compared the error metrics(normalized RMSE and PSNR) between the model outputs and the gold-standard reference. It showed the proposed method could reduce RMSE from 29.3% to 10.8% and increase PSNR by 4.3 dB on average. For data with pathology we compared the ASL images, CBF maps and ATD maps, demonstrating that the proposed method preserves the pathology while significantly improving the ASL image quality.

CONCLUSION

The proposed Deep Learning method significantly reduces(6 fold) the acquisition time required to obtain high-quality ASL imaging, improving CBF estimation and more detailed ATD maps in clinical patients.

CLINICAL RELEVANCE/APPLICATION

The proposed Deep learning method significantly improves ASL image quality, reduces scan time and increases SNR/resolution, potentially allowing it to be used in a wider variety of clinical settings.

SSJ19-02 Texture Analysis for Differentiating Glioblastoma Multiforme and Primary Cerebral Lymphoma: Benefits of Machine Learning Based on Multi-parametric MRI

PURPOSE

To determine whether a prediction model using machine learning based on multi-parametric magnetic resonance imaging (MRI) texture features can offer adequate diagnostic performance for differentiating glioblastoma multiforme (GBM) and primary cerebral lymphoma (PCL).

METHOD AND MATERIALS

This retrospective study was approved by the institutional review board. The requirement to obtain informed consent was waived. We included 70 patients who underwent contrast enhanced brain MRI at 3T with brain tumors diagnosed as GBM (n = 45) and PCL (n = 25). We measured minimum value, mean value, standard deviation and maximum value in apparent diffusion coefficient (ADC) and cerebral blood volume (rCBV), and eight types of histogram and texture parameters (skewness, kurtosis, homogeneity, energy, contrast, correlation, entropy, dissimilarity) for ADC, rCBV, T2 weighted images (T2WI), and contrast-enhanced T1WI (CE-T1WI). We developed a prediction model using a machine learning method (extreme gradient boosting) and calculated the area under the receiver operating characteristic (ROC) curve of this model via 10-fold cross validation. In addition, we compared the performance of machine learning with the judgments of two board certified radiologists.

RESULTS

Skewness in CE-T1WI had the strongest influence (GBM 0.237 ± 0.439; PCL -0.328 ± 0.679, p = 0.0006), followed by standard deviation in rCBV (GBM 703.4 ± 337.0; PCL 382.9 ± 223.1, p < 0.0001), mean ADC value (GBM 1.379 ± 0.403; PCL 1.114 ± 0.209, p = 0.0005), kurtosis in CE-T1WI (GBM 2.612 ± 0.644; PCL 4.998 ± 1.796, p = 0.0009), and skewness in rCBV (GBM 1.100 ± 0.663; PCL 1.799 ± 1.222, p = 0.0124). Validation analysis showed that the AUC for the machine learning method and the two radiologists were 0.90, 0.84 and 0.79, respectively.

CONCLUSION

The performance of machine learning based on texture futures in multi-parametric MRI was comparable to that of experienced radiologists in differentiating GBM and PCL.

CLINICAL RELEVANCE/APPLICATION

The current results suggest that machine learning based on texture features with multi-parametric MRI may provide a useful method for differentiating GBM and PCL.

SSJ19-03 Radiogenomics of Glioblastoma: Prediction of Molecular Subtype by Using Multiregional MR Imaging Features and Machine Learning Techniques

PURPOSE

To evaluate the association between multiregional radiomic features from MR imaging and molecular subtypes in patients with newly diagnosed glioblastoma.

METHOD AND MATERIALS

Preoperative MR imagings from 121 consecutive patients with newly diagnosed glibolastoma were retrospectively reviewed. 787 multiregional (contrast-enhancing regions and hyperintense regions at FLAIR images) radiomic features were extracted from on postcontrast T1-weghted, T2-weighted, FLAIR images, and ADC map. Molecular subtypes consisting of MGMT promoter methylation, IDH1 mutation, EGFR amplification and 1p/19q codeletion status were reviewed. The features that showed significant

difference (<0.05 by Wilcoxon test) or discriminative value (area under the receiver operating characteristics curve [AUROC] > 0.7) were selected on univariate test, and redundant features were removed. The strength of association between selected radiomic features and molecular subtypes was assessed via machine learning algorithms (stochastic gradient boosting machine, penalized logistic regression, and random forest). To prevent overestimation and overcome data imbalance, bootstrapping with 100 repetition and data subsampling were performed.

RESULTS

On univariate analyses, 11, 9, 6 and 15 radiomic features remained after removing redundant features to predict MGMT, IDH1, EGFR, and 1p/19q codeletion status, respectively. Applying machine learning to radiomic features yielded moderate performance (AUROC : 0.691-0.800) to predict MGMT status, and good to excellent performance to predict IDH1 mutation (AUROC : 0.868-0.971), EGFR amplification (AUROC : 0.729-0.874) and 1p/19q codeletion status (AUROC : 0.771-0.960). Nonetheless, in terms of accuracy, only a few machine learning models showed higher accuracy than prediction by change, which was resulted from data imbalance.

CONCLUSION

The authors found associations between MR radiomic features and molecular subtypes, although some of them may not be significant considering the data imbalance and prediction by chance.

CLINICAL RELEVANCE/APPLICATION

Radiomic profiling may have association with molecular subtypes in glioblastoma, although some of them may not be significant considering the data imbalance and prediction by chance.

SSJ19-04 Machine Learning Prediction and Classification of Working Memory Performance Based on Brain Microstructure in Healthy Adults: A Diffusion Kurtosis Imaging Study

Tuesday, Nov. 28 3:30PM - 3:40PM Room: N228

Yvonne W. Lui, MD, New York, NY (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

sohae.chung@nyumc.org

PURPOSE

The goal of this study is to predict working memory performance based on white matter (WM) microstructure in healthy adults by using machine learning approaches. White matter tract integrity (WMTI) metrics as well as diffusion tensor imaging (DTI) and diffusion kurtosis imaging (DKI) metrics were used to assess WM microstructure, and WAIS-IV letter-number sequencing (LNS) test was used to assess working memory.

METHOD AND MATERIALS

We studied 21 healthy individuals (34±9m 19-50 years old) using a 3T MR scanner (Skyra, Siemens). DKI was performed with 5 b-values (up to 2.5ms/μm2 with up to 60 directions). WMTI (axonal water fraction (AWF), intra-axonal diffusivity, extra-axonal axial/radial diffusivities, extra-axonal tortuosity (a)), DTI (FA, MD, AD, RD) and DKI (MK, RK, AK) metrics were calculated. Tract-based spatial statistics (TBSS) was performed with age and gender as covariates to test for significant correlations between diffusion metrics and LNS z-scores. For each metric, regions-of-interest (ROIs) were selected if $p<0.1$ after family-wise error (FWE) correction, and then were averaged as input features. The gradient boosted regression trees (GBRT) model was used to predict LNS and Logistic regression was used to classify individuals into arbitrary groups with LNS z-score above 1, below -1 and in between ±1. All data were randomly split into train (70%) and test (30%) sets.

RESULTS

Fig.1 shows ROIs for AWF, tortuosity a, FA, MK, and RK that were positively correlated with LNS. Using all 5 metrics as input features, we achieved a 95.4% accuracy in predicting LNS and a 79.6% accuracy in classifying individuals into two groups with LNS z-score above 1 and in between ±1 (Fig.2)

CONCLUSION

This study shows WM microstructural associations with working memory which can be predictable by using machine learning approaches. Our findings of higher AWF and tortuosity a with better performance on LNS go along with greater number of axons and greater myelination in these regions, causing efficient and faster information processes. Our results demonstrate the potential utility of diffusion metrics to serve as early biomarkers of working memory impairment.

CLINICAL RELEVANCE/APPLICATION

Our study elucidates the underlying relationship between white matter microstructure and working memory, and raises the potential utility of diffusion metrics to predict impairment of working memory.

SSJ19-05 Estimating the Age from Time of Flight MR Angiography Using Deep Learning

znee@catholic.ac.kr

PURPOSE

Age-related changes involve the brain vasculatures as well as the brain itself. Previous studies suggested that time of flight MR angiography (TOF-MRA) could visualize morphological changes of aged intracranial arteries. Because atherosclerotic changes were similar with changes of aged brain arteries histopathologically and morphologically, findings of brain TOF-MRA could be used as a biomarker of aging and other age-related changes. However, previously suggested analysis using hand-crafted features were limited to formulate an integrated biomarker for various features. Moreover, developing quantitative indices for those features is very challenging. To overcome these limitations, we introduced deep learning to estimate the age-related changes from TOF-MRA, instead of developing domain-knowledge based analysis. In this study, we investigate the feasibility of deep learning as a tool to extract and quantify age-related change of brain vasculatures.

METHOD AND MATERIALS

A total 954 TOF-MRA images were collected from two public databases of healthy volunteer and our own database of participants without any neurological or neurovascular disease. A deep neural network based on Alexnets was trained using axial MIP images as input data and actual ages as labels to minimize mean absolute errors (MAE) using TensorFlow framework. Spatial normalization and data augmentation were performed before train. For training and validation purpose, 689 subjects (augmented to 22,737) and 93 subjects were used. Remaining 203 subjects were used as test set. To evaluate the model accuracy, correlation coefficients (r) and MAE were calculated.

RESULTS

A deep learning model was built to estimate subjects' age solely using TOF-MRA successfully. For validation set, high correlation coefficient (r=.847) with good MAE (6.774) was obtained. For test set, performance was slightly decreased (r=.825, MAE= 7.765), but results were acceptable. Using trained network, a subject's age can be estimated from TOF-MRA data within a second.

CONCLUSION

We demonstrated the potential of deep learning technology for the assessment of age from the brain MRA. Estimated age from TOF-MRA showed good concordant with subject's biologic age.

CLINICAL RELEVANCE/APPLICATION

Estimated age from TOF-MRA can be used as an imaging biomarker for the brain vasculature. For example, a subject with atherosclerosis might have higher estimate age from brain TOF-MRA than subject's biological age.

SSJ19-06 Convolutional Neural Network based Deep Learning to Diagnosis the Sinusitis with Paranasal Sinus X-Ray

Tuesday, Nov. 28 3:50PM - 4:00PM Room: N228

Woo Suk Choi, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Seong Jin Park, MD, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Sinusitis is diagnosed by the opacification of the sinuses and air/fluid level best seen in the maxillary sinus with the paranasal sinus (PNS) X-ray scan. It is hard to represent these features to discriminate sinusitis from normal cases. Deep learning is a branch of machine learning used in acquiring useful representation of features directly from data. The most important factors that determine the performance of deep learning is data quality and quantity. The objective of this study was to investigate the ability of deep learning to improve the diagnosis of sinusitis using the PNS X-ray image.

METHOD AND MATERIALS

A total of 496 patients, which included 248 normal and sinusitis subjects each, underwent PNS X-ray scan. All subjects were independently labeled twice by two radiologists. We used three input data type to investigate the efficiency classification tuning: 1) 248 images without patch and data augmentation, 2) 992 images with data augmentation that is rotated data, and 3) 992 images with extracted maxillary sinus patch and rotated data. We implemented on the data to differentiate between normal and sinusitis subjects with the AlexNet convolutional neural network (CNN) model for imaging classification. Finally, classification results were quantitatively assessed by accuracy.

RESULTS

We compared the results of our approaches to optimize classification model. The results of accuracy for training/test data set were 70.3 %/60.9 %, 75.6 %/59.6 %, and 75.6 %/59.6 %, , respectively. Fig.1 shows that representation for the learned hierarchical feature maps with PNS X-ray image. Original data: a (normal) and e (sinusitis), Patched data: b (normal) and f (sinusitis), Feature maps: .c (1st layer), g (2nd layer), d and h (normal and sinusitis in final fully connected layer, respectively). Arrow indicates the characteristic to evaluate the sinusitis in the maxillary sinus.

CONCLUSION

The diagnosis for sinusitis using deep learning with PNS X-ray depends on the quantity and quality of data. To improve the accuracy of sinusitis, it is necessary to run the pre-processing steps such as extracted patch and data augmentation. Deep learning with PNS X-ray can be used to classify between normal and sinusitis cases.

CLINICAL RELEVANCE/APPLICATION

Optimized deep learning study with PNS X-ray image can demonstrate to be used to classify normal and sinusitis cases indicating it as a practical method for early diagnosis.

PURPOSE

This study aimed to assess the impact of intravenous (IV) tPA treatment before mechanical thrombectomy in acute ischemic stroke patients.

METHOD AND MATERIALS

We studied patients prospectively included in SONIIA registry (2011-2015), a mandatory, externally audited registry that monitors the quality of reperfusion therapies in Catalonia. We included the total number of thrombectomy cases from all participant centers to simulate "real-world" clinical practice. Analysis and outcome parameters: any recanalization (TICI >=2a), complete recanalization (TICI >=2b), procedural time, symptomatic intracranial hemorrhage (SICH), neurological improvement (>=4 points decrease in the NIHSS score at 24 hours), independent functional outcome (mRS <=2), mortality at three months.

RESULTS

Among the 1640 patients included, 48.1% received IV tPA. Mean age at treatment was 67.5±13.5, 54.4% male. Diabetes mellitus (p=0.024), atrial fibrillation (p<0.001), and ischemic cardiomyopathy (p=0.018) prevalence rates were higher in IV tPA patients. There were no other statistically significant differences in baseline characteristics between treatment groups. Median NIHSS score was 17 (12-21) on arrival and 9 (3-18) at 24 hours. The overall complete recanalization rate was 77.8%. The rate of complete recanalization was not different according to IV tPA administration: TICI >=2b: 79.8% IV tPA patients vs. 75.9% no IV tPA (p=0.065). However, patients who received IV tPA achieved higher any recanalization rate: TICI >=2a: 88.3% vs. 84.2% (RR, 1.0; 95% CI 1.0-1.1; p=0.018). IV tPA was associated with shorter procedural time: 82.4±70.1 min vs. 93.3±74.9 min (p=0.002). There were no differences in SICH: 3.0% vs. 3.2% (p=0.064). No differences were observed in early neurological improvement: 70.1% vs. 71.8% (p=0.491). IV tPA patients achieved higher functional independence: 43.9% vs. 53.3% (RR, 1.2; 95% CI 1.1-1.3; p=0.046), and less mortality: 21.4% vs. 14.7% IVT (RR, 0.7; 95% CI 0.6-0.8; p=0.001).

CONCLUSION

IV tPA before mechanical thrombectomy is associated with better recanalization rate, shorter procedural time, better functional independence, and less mortality. In addition, preceding IV tPA does not seem to influence in SICH development.

CLINICAL RELEVANCE/APPLICATION

Endovascular stroke therapy has revolutionized the management of patients with acute brain infarction. There is a lack of evidence-based data concerning the impact of including IV tPA before mechanical thrombectomy.

SSJ20-02 New Detector with Special High Definition (Hi-Def) Zoom Feature for Neuro Interventional Procedures

PURPOSE

Traditional Flat Panel Detectors (FPDs) have increasing difficulty in visualizing improved neuro interventional devices which have more complex finer structures. A new unique single package High Definition detector with a special Hi-Def zoom feature was developed. Initial subjective evaluations of Pipeline Embolization Device (PED) images acquired using the FPD and the Hi-Def zoom of this detector are presented.

METHOD AND MATERIALS

A PED was placed inside a neurovascular phantom with anatomically accurate 3D printed vessel structures embedded in a skull and having PMMA attenuating material. For image quality comparison, PED images were acquired with FPD and Hi-Def zoom in identical Fields-of-View. Ten Image sets each composed of one FPD and one Hi-Def zoom image acquired under the same x-ray exposure conditions were presented together to two blinded-neuro-interventionists who were asked to select the better image of the two and rate the selection as either Similar, Preferred or Much Preferred. Their annotations about the better images were also recorded.

RESULTS

For all the image sets generally, the Hi-Def zoom images were Much Preferred over FPD images by both the raters. Both the raters commented that the visualization of the stent structures in the Hi-Def zoom images were superior compared to those of the FPD and indicated that such imaging can be very helpful during interventions.

CONCLUSION

A new High Definition detector with high resolution Hi-Def zoom was developed and evaluated in simulated clinical settings by neurovascular interventionists. The Hi-Def zoom images were generally Much Preferred due to their superior image quality. Information regarding delicate movements and structural changes of the devices during deployment, navigation of the microwire through the stent, and stent to vessel wall apposition are critical to an intervention's success. The new high resolution imaging can improve real time visualization of such information and could potentially improve endovascular treatment outcomes.

CLINICAL RELEVANCE/APPLICATION

Superior real time imaging of devices during a neuroendovascular intervention treatment of diseases such as strokes and aneurysms is critical to its success and to ensure good treatment outcomes.

SSJ20-03 Intraoperative Thermal Imaging During Awake Craniotomy

Tuesday, Nov. 28 3:20PM - 3:30PM Room: N229

Participants
Michael Iorga, Chicago, IL (*Presenter*) Nothing to Disclose
Todd Parrish, PhD, Chicago, IL (*Abstract Co-Author*) Owner, Pain Id, LLC

michael.iorga@northwestern.edu

PURPOSE

Gliomas represent a diverse and deadly class of brain tumors, for which aggressive surgical resection of the tumor is the best treatment. Resection is limited in a majority of patients by tumor invasion into critical functional regions, which are avoided in resection through direct cortical stimulation mapping during awake craniotomy.. However, this method has poor spatial resolution (~10 mm), limiting the extent of resection and therefore survival.

METHOD AND MATERIALS

Neural activation creates a downstream compensatory vasodilation, increasing local perfusion. Intraoperatively, this mechanism causes a focal increase in cortical temperature, which can be measured by infrared thermal imaging. This approach captures small temperature deviations (>0.03 °C) at high spatial and temporal resolution (~0.5 mm, 30 Hz). In this study, we examine cortical

temperature gradients during a behavioral task to construct a neural activation map for guidance of surgical resection.

RESULTS

Cortical temperature changes were measured in two patients undergoing routine direct cortical stimulation during glioma resection surgery. The first patient performed a lip pursing task, which created diffuse temperature elevation (+0.3 °C) throughout facial motor and sensory regions. The region of maximal temperature elevation (+0.5 °C) coincided with the area of positive direct cortical stimulation. A second patient performed a right hand clenching task, which created temperature elevation (+0.5 °C) in the left motor cortex in the areas of positive direct cortical stimulation. This thermal signature was not observed during left hand clenching, which produced an activation pattern similar to the cortical temperature pattern measured at patient baseline.

CONCLUSION

Intraoperative thermal imaging may delineate activated cortical regions during awake craniotomy, and appears grossly consistent with direct cortical stimulation. While further measurements are necessary to conclude efficacy across tasks and patients, the utility of thermal imaging as an intraoperative mapping tool is promising. Future work will parse networks and functional regions by examining the dynamics of small temperature fluctuations within gross activation.

CLINICAL RELEVANCE/APPLICATION

Infrared thermal imaging is a promising approach for intraoperative cortical mapping, permitting increased extents of resection which can prolong patient survival after glioma resection surgery.

SSJ20-04 Development of Patient-Specific CT/MR "Bio-mimicking" 3D-Printed Phantoms, with Application to Minimally-Invasive Image-Guided Thermal Ablation Planning and Simulation

Tuesday, Nov. 28 3:30PM - 3:40PM Room: N229

dmitsouras@alum.mit.edu

PURPOSE

Image-guided percutaneous ablations in the head/neck, spine, chest, and abdomen have a steep learning curve and safety is a concern as new application sites such as the posterior spinal elements are explored. We developed a technique to 3D print "bio-mimicking" phantoms that replicate the patient-specific anatomy in both CT and MRI, and used it to simulate an image-guided cryoablation

METHOD AND MATERIALS

A model was designed from pre-procedure CT and MRI of a patient w/ L1 left lamina osteoblastoma. Cortical and cancellous bone and osteoblastoma were segmented from the CT. Cerebrospinal fluid, spinal nerves and foraminal fat were segmented from the T1- and T2-W MRI. Tissues segmented from each image set were combined in a single model using cancellous bone, aorta, and diaphragmatic crura as landmarks. The combined model was 3D-printed using a different mixture of 2 MRI-visible and 1 non-MRI-visible material for each tissue, and imaged identical to the patient (120 kVp CT, T1/2W FSE MRI). Signal intensity and contrast-to-noise ratio (CNR) of tissues in patient and model images were compared with ANOVA to determine if tissues separable in vivo were also separable with the printed model. Finally, CT-guided power drilling and subsequent MRI-monitored cryoablation was performed on the model identically to the patient procedure.

CONCLUSION

Bio-mimicking 3D-printed models can be produced that replicate patient anatomy in both CT and MRI. These models enable targeting and monitoring key anatomic structures during CT- and MRI-guided procedures such as thermal ablations.

CLINICAL RELEVANCE/APPLICATION

Patient-specific bio-mimicking 3D printed phantoms are now possible for simulating and hands-on teaching of CT/MR image-guided thermal ablations toward enhancing procedure safety and efficacy.

SSJ20-05 Clinical and Imaging Evaluation of Lumbar Disc Herniation after Different Oxygen-Ozone (O2-O3) Chemiodiscolysis Treatment Sessions: Which is the Best Treatment Protocol Management in Partially-Responder Patients?

Tuesday, Nov. 28 3:40PM - 3:50PM Room: N229

PURPOSE

To compare the therapeutic outcome of different treatment sessions of oxygen-ozone (O2-O3) therapy in patients with lumbar disc herniation

METHOD AND MATERIALS

We retrospectively evaluated 432 patients (mean age 44.3 years, range 26-69), who underwent multiple treatment sessions of O2-O3 lumbar chemiodiscolysis in the period between January 2014 and January 2017. We excluded patients with multiple level pathology, patients with multiple causes of low back pain, patients who underwent surgery during the follow-up period. For each patient we evaluated the number of treatment sessions and the type of treatment performed. Treatment outcome was assessed using a modified MacNab method to assess the clinical response and performing MRI to evaluate the modifications of the disc herniation area

RESULTS

235 patients were treated with 2 sessions of intradiscal injection associated with periganglionic steroid injection (Group A); 197 patients received an intradiscal-periganglior injection of O2-O3 and a second periganglionic injection with steroids (Group B). The mean time interval between each treatment was 32.6 days (range 15-62). Treatment was successful in terms of clinical outcome in 82.3% of patients of group A and 78.7% in group B. Statistical analysis showed no statistically significant difference between the two groups in terms of both clinical results and reduction of the disc herniation area ($p<=0.001$)

CONCLUSION

Multiple intradiscal ozone injections arenot associated with a superior herniation volume reduction nor better clinical outcome compared to a single intradiscal O2-O3 injection followed by periradicular steroids

CLINICAL RELEVANCE/APPLICATION

According to the results of our follow-up, in partially or non-responder patients after a first O2-O3 intradiscal injection, a better cost-effective protocol should include a second periradicular steroid injection rather that additional intradiscal treatments

SSJ20-06 Efficacy and Safety of Ethanol Ablation for Branchial Cleft Cysts

Tuesday, Nov. 28 3:50PM - 4:00PM Room: N229

Participants
Eun Ju Ha, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose
Jung Hwan Baek, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Branchial cleft cyst (BCC) is a common congenital lesion of the neck. This study evaluated the efficacy and safety of ethanol ablation (EA) as an alternative treatment to surgery for BCC.

METHOD AND MATERIALS

Between September 2006 and October 2016, EA was performed in 22 patients who refused surgery for a second BCC. After the exclusion of two patients who were lost to follow-up, the data of 20 patients were retrospectively evaluated. All index masses were confirmed as benign before treatment. Ultrasound-guided aspiration of the cystic fluid was followed by injection of absolute ethanol (99%) into the lesion. The injected volume of ethanol was 50-80% of the volume of fluid aspirated. Therapeutic outcome, including volume reduction ratio (VRR), therapeutic success rate (VRR > 50% and/or no palpable mass), and complications, were evaluated.

RESULTS

The mean index volume of the cysts was 26.4 ± 15.7 mL (range: 3.8-49.9 mL). After ablation, the mean volume of the cysts decreased to 1.2 ± 1.1 mL (range: 0.0-3.5 mL). The mean VRR at last follow-up was 93.9 ± 7.9% (range: 75.5-100.0%, $P < 0.001$). Therapeutic success was achieved in all nodules (20/20; 100%), and the symptomatic ($P < 0.001$) and cosmetic ($P < 0.001$) scores had improved significantly by the last follow-up. In one patient, intracystic hemorrhage was developed during the aspiration; however, no major complications occurred in all patients.

CONCLUSION

EA is an effective and safe treatment for patients with BCC who refuse, or are ineligible for, surgery.

CLINICAL RELEVANCE/APPLICATION

1. This study evaluated the efficacy and safety of EA for the treatment of BCCs, based on the largest number of cases (drawn from two hospitals) reported thus far. 2. A mean volume reduction in the EA-treated BCCs of 93.0%, as well as improvements in clinical symptoms and cosmetic problems. There were no major complications or procedure-related deaths. 3. After a single session, 55.0% of the patients had incompletely resolved clinical problems but they responded well to additional EA, which was effective and safe and had a therapeutic success rate of 100.0%. These results support the use of EA as a first-line treatment for BCC.

PURPOSE

At optimum incident acoustic output (IAO), subharmonic aided pressure estimation (SHAPE), based on subharmonic signals from microbubbles, is useful for estimating clinical pressures. However, real-time SHAPE application is impeded because the optimum IAO level varies on a case-by-case basis. Purpose of this work was to address this problem by identifying the optimum IAO for SHAPE in real-time.

METHOD AND MATERIALS

The SHAPE algorithm was developed to sequentially step through each available IAO level, extract the subharmonic amplitude, perform a spline fit (subharmonic amplitude vs. IAO), and identify the IAO level with maximum derivative as the optimum IAO. This algorithm was implemented using a customized interface on a SonixTablet scanner (BK Ultrasound, Peabody, MA) using C/C++ and Qt libraries (The Qt Company, Oslo, Norway). In vitro tests were conducted using a closed-loop flow system with activated Definity (Lantheus Medical Imaging, N Billerica, MA, USA; 0.1 mL) mixed in 750 mL isotonic diluent. A pressure catheter (Millar Inc., Houston, TX) provided ambient pressure values. A pulsed Doppler gate was placed within the lumen of the vessel in the flow system, then the SHAPE algorithm was initiated (ftransmit: 5.6 MHz; chirp down transmit pulse in pulse inversion mode). Catheter pressure and subharmonic data were acquired simultaneously at, below and above the optimum IAO level (10secs; n=3), then a linear correlation was performed between the subharmonic and catheter data using Matlab (MathWorks, Natick, MA, USA).

RESULTS

Correlation coefficient values between SHAPE and the pressure catheter data at, below and above the optimum IAO level were -0.73±0.1, -0.55± 0.2, and -0.70±0.1, respectively, confirming best correlation occurring at the identified IAO level. At the optimum IAO, the sensitivity of the subharmonic signal to the ambient pressure was 13.5±1.0 mmHg/dB. Occasionally at relatively higher IAO levels (2.9 MPap-p), correlation coefficients as high as -0.9 were also noted, presumably due to bubble destruction.

CONCLUSION

Identification of optimum IAO (in real-time) for insonating microbubbles to be utilized for SHAPE has been demonstrated; this will pave the way for real-time clinical applications.

CLINICAL RELEVANCE/APPLICATION

Real-time implementation to determine optimum IAO for insonating microbubbles for SHAPE has been demonstrated and verified; this paves the way for real-time SHAPE applications.

SSJ21-02 Contrast-Enhanced Ultrasound Assisted Percutaneous Nephrostomy: A Technique to Increase Success Rate for Patients with Non-dilated Renal Collecting System

Tuesday, Nov. 28 3:10PM - 3:20PM Room: S403A

xian_1121@163.com

CONCLUSION

CEUS assisted PCN in patients with nondilated renal collecting system is valuable with high technical success rate and acceptable complications.

Background

For percutaneous nephrostomy (PCN), lack of proper guidance system may lead to hazardous results, especial for these patients with nondilated renal collecting systems. The purpose of our study is to report our single-center experience of contrast-enhanced ultrasound (CEUS) assisted PCN for patients with nondilated renal collecting system.

Evaluation

From November 2011 to September 2015, 47 patients(mean age, 51.9±16.2 years; range, 11-80 years) with clinical necessity to urinary drainage, urinary diversion, or provision of access to the collecting system and with nondilated renal collecting system were performed 48 CEUS assisted PCNs. Ultrasound contrast agent was injected through the puncture needle and the drainage catheter to confirm successful PCN. The technical success rate was 100%(47/47, 95%CI: 93.8%, 100%) per patient and 100% (48/48, 95%CI: 94.0%, 100%) per kidney. For each kidney, the mean number of needle passes was 1.4 ± 0.5 (rang, 1-3). The mean duration of the complete procedure was 18.9±4.8 min (range, 8-30 min). The mean dose of contrast-enhanced agent was 12.9 ± 3.2 ml (range, 8-25 ml). No major complication was observed. Only 4 patients (4/47, 8.5%, 95%CI: 2.37%, 20.4%) had minor complications, including perirenal hematoma last 9 days on ultrasound images in 1 and transitant macroscopic hematuria last about 1-2 days in 3.

Discussion

Several modalities are considered to assist PCN in a nondilated collecting system. CEUS is known to have exclusive advantages including real-time scanning, no radiation, and easy operation, which is also recommended for intracavitary administration. Although PCN in the nondilated collecting system is a technical challenging, our results displayed that CEUS assisted PCN showed comparable success rate with conventional PCN placement in patients with dilated collecting systems.

SSJ21-03 Comparison of Computerized Analysis for Uniformity Assessment in Ultrasound QA

Tuesday, Nov. 28 3:20PM - 3:30PM Room: S403A

zhiminli@wisc.edu

zhiminli@wisc.edu

CONCLUSION

The MBCA method with the mean image shows good sensitivity for UA compared to UiQ, although this is a limited cohort of data available. We will enlarge our sample pool by acquiring cine loops routinely to facilitate this analysis for all probes.

Background

Performing uniformity assessment (UA) and detecting transducer defects of concern is an important component of Ultrasound QA testing. Although visual inspections of acquired phantom images are most frequently done, there is an increasing trend toward computerized analysis of cine files acquired during QC. It is important to understand performance differences between various computerized analysis methods for UA.

Evaluation

We developed a Matlab-based computerized analysis (MBCA) program for UA. It creates a mean image of frames in a cine loop acquired while a transducer is translated over a phantom. Element dropout defects are recognized as "shadows" emanating from the transducer surface. The code calculates a defect cutoff threshold (DCT) based on 3 standard deviations below the data's mean or 3 Median absolute deviations (MAD) below the data's median by utilizing only the ring-down portion of the phantom images. The detection performance was compared with that of a commercial program, UltraiQ(UiQ) that analyzes image data from a ROI having a 12 mm axial extent in the gray scale image. The comparisons were done for linear array transducers (LTA) and GE Logiq scanners evaluated during annual tests during the past year. Nine probes were judged defective, and three of these had recorded cine loops. Seven defects had been visually identified in this data set. Using the cutoff threshold described, the MBCA program applied to the mean image detected all 7 dropout areas (visually identified) from the 3 transducers with no false positive detection. On the other hand, the UiQ only detected four of the dropout areas with three false detections.

Discussion

Our MBCA currently works for LTAs but can be modified to analyze curvilinear arrays. The improved performance over UiQ can be related to a high signal to noise ratio in the ring-down part of the image and to the minimal spread of the defect shadow in this area.

SSJ21-04 Freehand 3D Ultrasound Construction via Preoperative MRI Co-Registration for Spine Needle Interventions

PURPOSE

Ultrasound (US)-guided spine needle interventions have limited clinical adoption due to confounding visualization of deep bony anatomy. Image registration between previously acquired MRI and real-time US could provide useful anatomical context to accurately guide needles toward target locations. Registration of MRI with an initially acquired, baseline 3D US image facilitates the mapping of anatomy in MRI to intraoperative US imaging space. This work proposes a method to register a 2D US image sequence to MRI and simultaneously construct a MRI-aligned, 3D US volume to be subsequently used for real-time navigation.

METHOD AND MATERIALS

Within the registration framework, US images were simulated from MRI using a US wave propagation model that incorporated reflection, refraction, and attenuation properties. Acoustic impedances were derived from T1-weighted MR values using a non-linear mapping function with relevant values for vertebra, CSF, fat, muscle, and intervertebral disc. Simulated US was compared with each actual US image using normalized cross-correlation metric and optimized using Powell's method to compute the best corresponding slice from MRI. Registered slices were interpolated in a volumetric grid to construct the 3D volume. Experiments were performed by acquiring axial slices of a lumbar puncture phantom using a 2D, linear, 128-element array probe at 5 cm depth. For comparison, 3D US image was constructed by optically tracking the calibrated 2D US probe.

RESULTS

The error between corresponding anatomical distances between US volumes constructed from the two methods (registration vs tracking) was found to be 1.3 ± 1.2 (mean ± std) mm. Registration accuracy measured as the point-based distance between corresponding anatomical locations from MRI and US was 4.5 ± 5.9 (median ± iqr) mm. Deformation due to applied US probe pressure contributed substantially to this error and it will be incorporated to the simulation model in ongoing work to improve accuracy.

CONCLUSION

Registration between actual and simulated US images could provide a useful method to yield MR-aligned 3D US volume for navigation in spine pain procedures.

CLINICAL RELEVANCE/APPLICATION

The proposed method could provide 3D US images registered to MRI to facilitate accurate needle targeting during spine needle interventions.

SSJ21-05 Can Speed of Sound Be Better Than Conventional Elastography for Breast Characterization?

Tuesday, Nov. 28 3:40PM - 3:50PM Room: S403A

Participants
Sergio J. Sanabria, Zurich, Switzerland (*Presenter*) Nothing to Disclose
Marga B. Rominger, MD, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Corin F. Otesteanu, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Farrukh I. Sheikh, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Volker Klingmueller, Giessen, Germany (*Abstract Co-Author*) Nothing to Disclose
Orcun Goksel, PhD, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To compare a novel speed of sound (SoS) method and conventional elastography (strain ratio SR and shear wave velocity SWV) in breast with respect to tissue compression and differentiation.

METHOD AND MATERIALS

A healthy volunteer (42 yr) was repeatedly assessed with SoS and SWV at five different compression levels in order to identify non-linearity confounders. The examinations were performed in the cranio-caudal view and retromammillar segment for both non-diseased breasts. Also, five women with biopsy proven lesions (3 invasive ductal carcinoma IDC, 1 fibroadenoma FA, 1 cyst) were tested to identify differences between SoS, SR and SWV. Ultrasound examination was performed with a commercially available ultrasound system (SonixTouch, Ultrasonix, Richmond, Canada). B-mode imaging was used for lesion localization. Hand-held SoS images were generated for lesion characterization. A flat passive plexiglass reflector positioned opposite to a linear probe was used as a timing reference for the ultrasound signals transmitted through the lesions. Synthetic aperture data was acquired and average SoS values across the lesions were measured with an accuracy of <0.7%. Elastography (SWS and SR) was performed with a GE Logiq E9 machine.

RESULTS

Breast compression was 60 to 25 mm. SWV correlates with breast compression (R2>0.5) while SoS does not show a significant correlation (R2<0.2). The average SoS value was 1465 m/s (SD 7 m/s) and the average SWS value 2.5 m/s (SD 0.2 m/s). The SoS increments in the lesions were [cyst = 0.9%, FA = 0.8%, IDC [2.7-3.0%], while for SWS [cyst = 2.5 m/s, FA = 5.4 m/s, IDC = 4.1-3.95%] and SR [cyst = 1.6, FA = 5.0, IDC 2.8]. While all lesions could be correctly classified with a single SoS threshold, both SE and SWS failed to differentiate FA from IDC.

CONCLUSION

Hand-held speed of sound showed less dependency on compression than SWS and a better differentiation in an exemplary population of benign and cancerous lesions. Further studies are needed to confirm its utility.

CLINICAL RELEVANCE/APPLICATION

A hand-held SoS add-on to conventional ultrasound system provides additional information (Bulk Modulus) to conventional elastography (Young Modulus) for multi-parametric tissue characterization. SoS may reduce operator dependency and outperform conventional elastography in selected clinical scenarios. This novel technique can be implemented on a standard ultrasound machine.

SSJ21-06 Acoustic Lens-Based Photoacoustic-Ultrasound System for Noninvasive Thyroid Imaging

Vikram.Dogra54@gmail.com

CONCLUSION

A combined non-invasive PA and US imaging system, with functional and structural capability can be a potential alternate for FNAB.

Background

Among thyroid cancer screening techniques, ultrasound (US) is the most widely used modality followed by invasive fine needle aspiration biopsy (FNAB). Approximately 5% of FNAB results are inconclusive and are compromised by insufficient sampling. The US (being a structural imaging method) can depict thyroid cysts and nodules clearly but lacks the ability to differentiate between cancerous and benign nodules. We propose a hybrid multispectral photoacoustic (PA) and ultrasound imaging system for non-invasive. With the combined functional nature of PA imaging capturing physiologic changes and structural image from US image high specificity is expected. This estimate can be depicted as an image that can be used to detect, characterize, diagnose, and monitor suspect lesions in thyroid disease management.

Evaluation

The proposed PA probe consists of a light delivery system, acoustic lens and US transducers that enable real-time frontal plane imaging of the tissue. A fast Fourier-based image formation is considered for volume image formation. Axial and lateral resolution of the probe was evaluated to be 0.3 millimeters (mm) and 1.6 mm. Ex-vivo thyroid studies demonstrated high specificity greater than 96%. A circular scanning stage obtains images from multiple angles using the probe, which improves system signal to noise ratio and a fivefold improvement in lateral resolution. A polyvinylidene fluoride (PVDF) film used as a US source can provide impedance image of the tissue. Adding US imaging to PA will add value co-registering with functional information in locating the nodules.

Discussion

PA absorption image of deoxy and oxyhemoglobin shows a clear distinction between cancerous and benign. The ex-vivo studies suggest that thyroid disease classification accuracy was comparable to that of FNAB. Characterization of the proposed prototype in phantoms with human thyroid geometry are in progress. With multiple view of the target tissue a minimum detectable cancer region of 0.3 mm with high specificity is expected.

PURPOSE

The purpose of this work was to use Monte Carlo simulation techniques to examine the effects of chest CT scans performed with an organ-based tube current modulation (OBM) scheme on lung and breast doses.

METHOD AND MATERIALS

Image and raw projection data were collected for twenty-three patients (14 males, 9 females) undergoing CT chest examinations under IRB approval. These scans actually used a combination of organ based and attenuation-based modulation (XCARE + CAREDose4D, Siemens Healthineers, Forchheim, Germany). From the image data, voxelized models of chest anatomy were generated for use in a previously validated Monte Carlo (MC) simulation code; lung and glandular breast tissues were segmented from patient image data and specifically identified for the simulation. Estimates of lung and breast dose were obtained using an MDCT source model with the tube current modulation values extracted from the raw projection data. These contain precise information about the tube current values as a function of angle and table location. Lung and breast doses were tallied and normalized by scan-specific 32cm CTDIvol values based upon the average tube current across the entire scan length. Water equivalent (Dw) was used as the size metric and was calculated at the center of the scan volume for each patient. These normalized doses were then compared with previously developed estimates of breast and organ dose based on attenuation based modulation only (CAREDose4D).

RESULTS

For normalized lung dose, six patients experienced dose reduction to the lungs, while ten patients experienced an increase to breast dose, with greatest reduction being 50% and greatest increase being 114% relative to CAREDose4D chest protocol. For normalized breast dose, four patients experienced dose reduction to the breast while five patients experienced an increase to breast dose, with greatest reduction being 40% and greatest increase being 55% relative to CAREDose4D chest protocol.

CONCLUSION

The combination of organ based and attenuation based modulation may, at times, increase both lung dose and breast dose in some patients. This may be dependent on the location of the glandular breast tissue relative among other factors.

CLINICAL RELEVANCE/APPLICATION

Organ and attenuation based tube current modulation does reduce breast dose, but some patients may receive substantial dose reduction from attenuation based modulation alone.

SSJ22-02 Radiation Dose Reduction in Thin-Slice Chest CT at a Micro-Dose (mD) Level by Means of 3D Deep Neural Network Convolution (NNC)

PURPOSE

Radiation dose reduction in chest CT is highly demanded since current radiation dose is still very high for screening. Our purpose was to develop a deep-learning NNC technique to convert thin-slice mDCT to higher-dose (HD) CT volumes where noise and artifacts are significantly reduced.

METHOD AND MATERIALS

We developed a mixture of expert anatomy-specific (AS) NNC models employing volume-based neural network regression in a convolutional manner to convert thin-slice (0.5 mm) mDCT to HD-like CT volumes. We trained 3 AS NNC models with soft-gating layers with 3 anatomic areas in input lower-dose CT (10 mAs, 120 kVp, 0.37 mSv) volumes and those in "teaching" HDCT (550 mAs, 120 kVp, 34.9 mSv) volumes of an anthropomorphic chest phantom (Kyoto Kagaku, Kyoto, Japan). Through training, our NNC learned to convert lower-dose CT to volumes that look like HDCT, where noise and artifact are substantially reduced; thus, term "virtual" HD (VHD) CT. Once trained, our technology no longer requires HDCT. To determine a dose reduction rate, we acquired 5 more studies of the same phantom at different radiation doses (0.74, 1.49, 2.97, 6.21, and 10.68 mSv) by changing tube currents. Structural SIMilarity (SSIM) index was used to evaluate the image quality. For testing, we collected mD (120 kVp, 5 mAs, 0.2 mSv) and full-dose (120 kVp, 50 mAs, 2.0 mSv) thin-slice CT volumes of 50 clinical cases including 30 cases with nodules (Aquilion One, Toshiba, Japan).

RESULTS

Our VHD technology converted lower-dose CT of the testing phantom to VHDCT, improving (t-test; $P<.05$) image quality from SSIM of 0.15 to 0.77 (equivalent to 14.0 mSv), achieving 97.4% dose reduction. With our technology, the contrast-to-noise-ratio (CNR) of mDCT of clinical cases was improved from 4.1±3.9 dB to 21.5±4.9 dB which was also higher (t-test; $P<.05$) than that of "gold-standard" full-dose CT volumes (CNR: 13.4±5.1 dB). Our NNC reduced the noise and artifacts substantially while preserving anatomic structures and pathologies.

CONCLUSION

Our NNC converted thin-slice mDCT volumes of 50 clinical cases to VHDCT volumes that have higher image quality (in terms of CNR) than "gold-standard" full-dose CT volumes, achieving 90% dose reduction. Our phantom study demonstrated up to 97% dose reduction.

CLINICAL RELEVANCE/APPLICATION

Substantial reduction in radiation dose in CT by our VHD technology would potentially make micro-dose CT screening possible, and it would be beneficial to screening population.

SSJ22-03 Estimating Organ Dose from Low Dose Lung Cancer Screening CT Exams Performed with Tube Current Modulation

mmcnittgray@mednet.ucla.edu

PURPOSE

The purpose of this work was to estimate organ doses from a low-dose lung cancer screening CT exam using tube current modulation (TCM) and patient models of various sizes

METHOD AND MATERIALS

Monte Carlo simulation methods were used to estimate organ doses from a low-dose lung cancer CT screening protocol for a 64-slice CT (Definition AS64, Siemens Healthineers, Germany) that used TCM. Scanning parameters were from the AAPM's Alliance for Quality CT protocols. Data from 26 patients (14 female, 12 male) were obtained under IRB approval. For each patient, both the image data as well as the raw projection data (which contains details of the tube current modulation) were collected. Voxelized patient models were created from the image data reconstructed to full 500 mm Field of View that also had all lung, and for females the glandular breast tissue, identified. Data from the actual TCM schemes were extracted from the raw data and incorporated into the Monte Carlo simulation. The water equivalent diameter (WED) was determined by estimating the attenuation at the center of the scan volume for each patient model. Monte Carlo simulations were performed using the unique TCM scheme for each patient model. Organ doses were tallied and all dose values were normalized by both CTDIvol (32 cm phantom) and DLP for each patient. Absolute and normalized doses were reported as a function of WED for each patient model.

RESULTS

Water equivalent diameters (WED) ranged from 17.4 to 34.2 cm for the females and 14.4 to 24.5 cm for the males. CTDIvol (32 cm phantom) values ranged from 1.37 to 6.0 mGy for females and 1.25 to 2.85 for males. Monte Carlo esimated lung doses ranged from 1.03 to 4.11 mGy for females and 0.91 to 1.88 mGy for males; female breast doses ranged from 0.77 to 6.67 mGy. There is a

relationship between lung dose and WED that also indicates some difference between males (R^2= .77) and females (R^2=0.53). Breast dose also appears to have a relationship to WED (R^2 value 0.7)

CONCLUSION

This work demonstrates the ability to estimate breast and lung doses from a lung cancer screening CT exam using tube current modulation (TCM). The relationship between lung dose and patient size appears to be slightly different between males and females and warrants further investigation.

CLINICAL RELEVANCE/APPLICATION

This work describes investigations to estimate lung and breast dose from lung cancer screening CT exams that use tube current modulation.

SSJ22-04 Comparison of Four SSDE Calculation Approaches in Thoracoabdominal CT

christoph.aberle@usb.ch

PURPOSE

To evaluate SSDE (Size Specific Dose Estimate) calculations relative to a method recommended in the AAPM Report 220 using thoracoabdominal CT examinations.

METHOD AND MATERIALS

SSDE values of 112 adult thoracoabdominal exams (50 male, 62 female, BMI-range 15.8 to 39.9 kg/m2) from three CT scanners (Siemens Somatom Definition AS+, Flash and Edge) were evaluated using four calculation methods. First, the study's reference was calculated from reconstructed axial images according to the AAPM Report 220. A dedicated reconstruction with non-overlapping slices and a 500 mm field of view was used. Slice by slice, the water-equivalent diameter (WED) was calculated excluding the patient table, the CTDIvol was extracted and the SSDE was determined. The average over all slices was used as the reference SSDE. Secondly, the WED of only one slice at the center of the scan region was calculated and the SSDE was obtained using the mean CTDIvol. The third and fourth SSDE results were extracted from two commercial dose monitoring software tools (Radimetrics, Bayer HealthCare and teamplay Dose, Siemens Healthineers). The results from the dose monitoring software tools were obtained from the localizer radiographs.

RESULTS

Compared to the reference method, on average the SSDE values from the central slice method were 4% lower and the SSDE values from Radimetrics were 5% lower (1% higher) before (after) optimization of the scan region to phantom mapping in the software. The SSDE values from teamplay were 9% lower (1% higher) on average compared to the reference method before (after) optimization of scan region.

CONCLUSION

AAPM Report 220 proposes that an SSDE calculation method is compliant with a reference method if the root mean square deviation is less than 10 % relative to the reference. According to this criterion, the central slice method and the optimized teamplay and Radimetrics methods agree with the reference method.

CLINICAL RELEVANCE/APPLICATION

As standardized SSDE calculations are not yet readily available from CT scanners, comparisons of available options are needed to choose appropriate methods for accurate patient dose estimates.

SSJ22-05 Equipment Selection: Comparison of Four Different Dose Monitoring Commercial Systems - How the Choice of Different Calculation Methods Could Affect the SSDE in CT Scans of Different Body Areas

PURPOSE

The dose from a CT scan depends on both patient size and scanner radiation output. Size-specific dose estimate (SSDE) is calculated applying a correction factor based on patient's size to the CTDI value. The purpose of the study was to evaluate SSDE calculation accuracy of four different commercial Radiation Dose Index Monitoring (RDIM) software.

METHOD AND MATERIALS

Two sets of CT acquisitions (GE Discovery HD750), with and without Automatic Tube Current Modulation (ATCM), were performed on an anthropomorphic phantom positioned at the center of the scanning Field-of-View (FOV). Acquisitions were repeated after increasing or decreasing table height by 5 cm. Each set consisted of 6 acquisitions of different scanning length: chest (C) , adbomen (A), neck (N), chest+abdomen (C+A), neck+chest (N+C), head+neck+chest+abdomen (H+N+C+A). A user-developed code (Matlab, Matworks) was applied to calculate Size Specific Dose Estimate (SSDE) from Water Equivalent Diameter (WED) or Effective Diameter (eff), using the image at the center of the scanning region (SSDEc) or the average on all the axial images (SSDEm).Calculated values were compared with those registered by four commercial Radiation Dose Index Monitoring System: Radimetrics, DoseWatch, NexoDose and RDM.

RESULTS

The difference between SSDEm,WED vs SSDEm,eff and SSDEc,WED vs SSDEc,eff were within 5 % on all the scans (RMS=3.17%, max=5.1%). The difference between SSDEm,WED vs SSDEc,WED and SSDEm,eff vs SSDEc,eff were within 7 % on scan C, A and C+A (RMS=5.6%, max=9.2%) and increased on scan H+N+C+A, N and N+C (RMS=17.5%, max=31.2%) due to the diameter variation within the scanning length. The maximum difference between SSDE registered on the RDIM software was lower in C, A and C+A (RMS=15.2%, max=29.4%) and became relevant on scan H+N+C+A, N and N+C A (RMS=37.4%, max=51.7%).

CONCLUSION

Different methods of SSDE calculation are implemented by different RDIM vendor. Relevant differences were found when the scanning region comprehend anatomy with a high variation of patient attenuation (eg neck+shoulder). When comparing result from different evaluation software, the user should be aware of the calculation methods implemented and their limitation.

CLINICAL RELEVANCE/APPLICATION

Differences in SSDE arising from different calculation methods implemented on commercial dose monitoring systems should be carefully considered when comparing data in a multi-institutional framework.

SSJ22-06 Comparison of Clinical and Phantom Image Quality for Low Contrast Liver Lesions in a Prospective Multicenter CT scanner Dose Optimization Program

hugobene@gmail.com

PURPOSE

To compare diagnostic performance for low contrast liver lesions on patient and phantom images, in a prospective multicenter CT scanner dose optimization program.

METHOD AND MATERIALS

A CT scanner protocol harmonization process based on clinical indication and BMI (<25 / >25), followed by a 12% stepwise dose reduction program, was implemented in a multicenter medical imaging group (5 units, Philips Healthcare, NL). During the optimization phase, 3035 abdomen CT examinations were prospectively assessed by experienced radiologists with a "positive/negative" diagnostic image quality electronic voting tool and 33 patients who underwent a CT examination for liver tumor or cancer staging before and after optimization were graded for image quality using European image quality guidelines. In parallel, phantom (QRM™ 401 abdomen, Germany) acquisition with 2.5 (size M) and 5cm (size L) fat ring was also performed before and after dose reduction using the liver tumor follow-up protocol. A channelized hotelling model observer was used to assess the lesion detectability using the ROC paradigm with the area under the ROC curve (AUC) as figure of merit.

RESULTS

Median patient CTDIvol value decreased from 6.8 to 5.2mGy (-24%, p<0.005) and from 10.8 to 8.5mGy (-22%, p<0.005) respectively for BMI<25 and >25. For phantom images, mean CTDIvol value decreased from 8.8 to 6.3mGy (-28%) for M-sized and from 15.9 to 11.8mGy (-26%) for L-sized phantom. No negative vote for diagnostic image quality was registered and preliminary results on 33 paired patients showed no loss of image quality according to European image guidelines. Image quality phantom analysis showed a constant low contrast lesion detectability, even after a 26% dose reduction. However, an additional 12% dose reduction started impairing the detectability of 5mm lesions.

CONCLUSION

Combining clinical diagnostic image quality and phantom based analysis enable dose reduction according to the ALARA principle without impairing low contrast liver lesion detectability.

CLINICAL RELEVANCE/APPLICATION

Combining clinical image quality evaluation and phantom analysis for image quality optimization preserves diagnostic confidence and sets a low-level threshold enabling no loss of detectability of low contrast liver lesions.

cihat.eldeniz@wustl.edu

PURPOSE

The simultaneous PET/MR provides an unprecedented opportunity for motion correction. We aimed at developing an integrated MR-assisted PET motion correction method which would allow accurate PET quantification in the presence of respiratory motion. This makes it possible to detect small lesions, which would otherwise become undetectable given the blurring caused by motion. In this study, we also evaluated the performance of the proposed method using a deformable motion phantom with known ground truth.

METHOD AND MATERIALS

For tracking respiratory motion, we developed a self-navigated free breathing MR motion correction method that provides robust and fully-automated respiratory motion detection. Four spheres with FDG activity were placed in a deformable motion phantom to mimic FDG avid lesions. The diameters of the spheres were 4.5 mm, 6.75 mm, 7.5 mm and 9 mm, respectively. List mode PET data and MR motion correction data were acquired simultaneously in the presence and absence of motion. Respiratory motion was first detected using the self-navigated free breathing MR method. This MR derived motion was then used to rebin the simultaneously acquired list mode PET data. Motion-corrected and uncorrected PET images were reconstructed using the same motion-corrupted data. On the other hand, the static (no-motion) PET/MR scan was used as the ground truth for PET activity.

RESULTS

In reference to the static PET, the relative FDG activity measured in the motion uncorrected PET images were 55% (D=4.5 mm, motion range = 9.8 mm), 61% (D=6.75 mm, motion range = 10.7 mm), 75% (D=7.5 mm, motion range = 7.1 mm) and 69% (D=9 mm, motion range = 9.2 mm) for the four spheres. In contrast, the measured activity became, respectively, 95%, 99%, 96% and 96% after applying the MR assisted PET motion correction.

CONCLUSION

Depending on the size and the magnitude of motion, motion-compromised PET images can show up to 45% reduction in FDG activity. Our MR-assisted PET motion correction can recover the activity back to 95%-99% of that measured using the static data set.

CLINICAL RELEVANCE/APPLICATION

High noise and respiratory motion makes it difficult to detect small lesions in PET images. MR-assisted motion correction makes it possible to delineate lesions with significantly higher accuracy.

SSJ23-02 Faster PET Imaging: Evaluation and Optimization of PET Acquisition Overlap on both Solid State Digital PET and PMT PET in FDG and NaF PET/CT

PURPOSE

To improve patient comfort and clinical volume throughput by accelerating PET imaging using optimized PET acquisition overlaps going beyond current accepted boundaries in FDG and NaF TOF PET on both solid state digital photon counting PET (dPET) and conventional PMT PET (cPET).

METHOD AND MATERIALS

An ongoing pre-clinical (beagles) and clinical trial was initiated to investigate the feasibility of minimizing and optimizing PET acquisition overlap in axial on cPET (Gemini TF 64) and dPET (Vereos TF). Four groups of wholebody PET/CT are included: A. preclinical FDG PET (~2.8mCi), B. preclinical NaF PET (~2.8mCi), C. clinical FDG PET (~13mCi) and D. clinical research NaF PET (~3mCi). Intra-individual PET imaging was acquired on both systems under investigational overlaps of 27%, 20%, 12% and 0% besides system defaults (Gemini: 53%; Vereos: 39%). Uniformity phantoms were performed for validation. PET image quality (IQ) and SUV assessment were blinded reviewed by multiple readers.

RESULTS

4 beagles (2 FDG and 2 NaF) and 4 human subjects (2 FDG and 2 NaF) were imaged. dPET images consistently showed better IQ with enhanced contrast and more uniform background than cPET under various overlaps. FDG PET exams showed no impact on visual grades with overlaps of 27%+ for cPET and 20%+ for dPET, compared to PET using default overlaps. NaF PET exams revealed better acceptable range than FDG PET with 20%+ for cPET, and 12%+ for dPET (surprisingly, nice NaF dPET images obtained even without overlap). Reducing overlap to 27% for cPET and to 20% for dPET from default saved ~40% acq time. No significant SUV variances were found between PET using minimized overlaps and default PET for cerebellum, lung, heart, aorta, liver, fat, muscle, bone marrow, thighs and target lesions ($p>0.05$), except kidneys and bladder.

CONCLUSION

The study demonstrated through combined pre-clinical, phantom and clinical exams the feasibility of reducing PET overlaps on both solid state PET and PMT PET scanners to accelerate PET imaging for ~40% from current levels without degradation of image quality. Advantages of solid state PET being capable of enabling faster PET using less PET overlaps than PMT PET was obtained.

CLINICAL RELEVANCE/APPLICATION

Faster PET imaging has substential benifits to patient comfort and clinical volume throughput and the study examed such by optimizing PET acquisition overlaps in FDG and NaF PET on both solid state PET and PMT PET systems.

PURPOSE

Current Positron Emission Tomography (PET) scanners have a limited image resolution which is due both to the intrinsic limits set by PET physics and the design and the material used in state-of-the-art PET scanners. We present a novel 3D gamma sensor, based on pixelated CdTe, to reduce significantly the limitations coming from spatial and energy resolution.

METHOD AND MATERIALS

Each detector module has 4000 voxels (independent channels). Each voxel consists of 1mm x 1mm x 2mm of CdTe bonded to a dedicate pixel channel. The detector module is made of a stack of 10 layers. Each layer has 4 sensors glued to a flex printed circuit board (PCB). The sensor itself is a hybrid pixel CdTe detector, of size 10 mm x 10 mm x 2 mm, bonded to a dedicated pixel ASIC. The pixel ASIC is thinned down to 200um and the flex PCB is 255 um thick. Effectively, each layer has a thickness of 2mm of active material (CdTe), and 0.35mm of passive material. Each detector module has an amount of CdTe equal to 20 mm x 20 mm x 20 mm. A total of 18 of such detector modules will form a PET ring with an inner radius of 6.5 cm and an axial FOV of 2.6 cm. The full ring has 72000 independent channels. Each ASIC (of 100 channels) has one TDC with a time resolution of 1 nano-second. Each channel has its own pre-amp, shaper, discriminator, and 11 bit ADC. Each triggered voxel sends its digitized energy signal plus a time stamp. Currently, 11 out of the 18 detector modules have been assembled and tested using a Na22 source with a bias voltage of 250V/mm.

RESULTS

Overall 90% of the channels are operational. The other 10% have defects due to electronics or detector leakage current. With these working conditions, the energy resolution obtained for PET events is 2.4% at FWHM. The energy resolution for Compton events, reconstructed from two different sensors, is 3.4% at FWHM.

CONCLUSION

With a full PET ring and operating the CdTe at 500V/mm, we expect to achieve the intrinsic spatial resolution set by physics

With a full PET ring and operating the CdTe at 300V/mm, we expect to achieve the intrinsic spatial resolution set by physics, thanks to the excellent 3D detector granularity and with a negligible scattered fraction (4%) thanks to the excellent energy resolution. This translates into a possible detection of cancer lesions as small as 2mm in diameter.

CLINICAL RELEVANCE/APPLICATION

This novel PET make it possible to detector cancer lesion as small as 2mm in diameter with TNR 4:1

SSJ23-04 Evaluation of CZT Gamma Cameras for Whole-Body SPECT and Small FOV Imaging

james.hugg@kromek.com

CONCLUSION

Continual improvements in CZT detector arrays for molecular imaging, coupled with optimal collimator and image reconstruction, result in minimized dose and exam time. With CZT cost and performance improving, more clinical applications are expected.

Background

The semiconductor CdZnTe (CZT) direct-conversion gamma photon detector has been used in several molecular imaging applications, including small-animal and whole-body human SPECT, cardiac SPECT, and molecular breast imaging (MBI). We designed a modular gamma detector (4.4 cm square with 2 mm pixel pitch) and tiled it in two array sizes: a small FOV camera (8.8 cm square, 44 x 44 pixels) and a whole-body SPECT camera (39.6 cm x 52.8 cm, 198 x 264 pixels) that we mounted on a refurbished SPECT gantry for demonstration. We evaluated the performance of these gamma cameras.

Evaluation

Integration of pixelated CZT detectors with advanced ASICs and readout electronics improves system performance. We measured energy resolution of 3.0% FWHM at 140 keV, intrinsic flood field uniformity of ±0.8% integral and ±0.4% differential, system spatial resolution at 10 cm with an LEHR collimator of 6.8 mm and 7.5 mm without and with scatter, and intrinsic detector count rate performance of 1.4 M cps at 20% loss and 6.1M cps maximum observed. These metrics are significantly better than scintillator SPECT systems.

Discussion

Very good energy resolution enables better scatter rejection and image contrast, further enhanced by excellent uniformity. Smaller pixels improve partial-volume dilution and quantitation. Spatial resolution is improved, even with hexagonal-hole collimators, but registered square-hole collimators provide significantly better resolution and a boost of about 30% in sensitivity which can lower dose and/or exam time. The non-paralyzable CZT cameras count at much higher count rates, enabling new first-pass and pharmacokinetic studies. Advances in detectors, collimators, and image reconstruction have significantly improved efficiency of CZT-based molecular imaging systems and the cost of CZT detectors has steadily declined.

SSJ23-05 TV-Constrained Image Reconstruction from List-Mode TOF-PET Data

PURPOSE

We investigate an innovative image reconstruction for advanced digital time-of-flight (TOF) positron-emission tomography (PET) and demonstrate its potential for improving image quality in digital TOF PET, in terms of enhanced spatial resolution, signal-to-noise ratio, and axial coverage.

METHOD AND MATERIALS

We employ a digital SiMP TOF PET clinical scanner to collect list-mode TOF-PET data from the Jaszczak and IEC phantoms. The Jaszczak phantom contains six types of cylindrical-shaped cold rods of diameters 4.8, 6.4, 7.9, 9.5, 11.1, and 12.7 mm, whereas the IEC phantom includes 6 spheres of 10, 13, 17, 22, 28, and 37 mm diameter. The activity in the four smallest spheres is 4 times of the background, and the other two spheres have zero concentration. We developed an iterative algorithm based on Chambolle-Pock framework to reconstruct images. Images reconstructed by use of the standard ordered-subset-expectation-maximization (OSEM) algorithm are used as references. Reconstructions are evaluated visually and quantitatively. In particular, the IEC-phantom reconstructions are assessed following the instruction in NEMA NU 2-2012.

RESULTS

TOF-PET images reconstructed with the proposed algorithm exhibit appreciably lower background noise and enhanced contrast relative to that of the reference images. In particular, the reconstructions are with much improved image quality especially in regions near the axial edges where the reference images are observed to have significant artifacts. For the Jaszczak phantom, the smallest revealed cold rods reconstructed by the proposed algorithm are of 7.9mm diameter, whereas those are of 12.7 mm in the reference image. This underscores a considerable improvement on the spatial resolution in reconstructed images. For the IEC phantom, the reconstructions with the proposed algorithm reveal 7%~20% increased contrast for hot spheres, 4%~6% increased contrast for cold spheres, and 27%~46% decreased noise for background over that of the references.

CONCLUSION

The novel algorithm proposed can yield reconstructions from TOF-PET data with considerably improved spatial and contrast resolution and signal-to-noise ratio over the standard algorithms in TOF-PET imaging.

CLINICAL RELEVANCE/APPLICATION

The PET-image quality may be improved by use of advanced algorithms. The algorithm-enabled quality improvement may be of clinical implication for enhanced lesion detectability at low count statistics.

SSJ23-06 Deep Learning Enables at Least 100-fold Dose Reduction for PET Imaging

enhaog@stanford.edu

PURPOSE

Lowering injected dose in PET can reduce the risk to patients, lower imaging costs and potentially improve imaging efficiency. In addition, it may help imaging logistics when fast-decaying tracers are used. However, lowered dose adversely affects PET image quality. Previous methods typically use complicated and slow iterative reconstruction, yet still cannot yield satisfactory results at significantly low dose.

METHOD AND MATERIALS

We developed a deep network(convolutional encoder-decoder residual network) to recover PET images acquired at ultra-low-dose. This network conducts patch-to-patch regression tasks, taking a noisy low-dose PET image patch as input and outputting a high-quality patch to approximate the corresponding patch in full-dose PET. The final reconstruction is generated by concatenating and averaging overlapping patches. Using bypass connections and patch-based training, we reduced the regression task complexity and achieved robust training performance. To avoid over-fitting, we trained the network with data augmentations(~10000patches×2flips×4rotations). Brain PET-MR datasets(GE Signa 3T) were collected from 7 patients with recurrent glioblastoma(65±6 yrs, 4 males), who received 10mCi FDG. We used the full-dose reconstruction(3D-OSEM, 2 iterations and 28 subsets) as gold-standard. For input, we created low-dose images by removing counts from the listmode data, reconstructing with various dose-reduction factors(DRF). We tested on DRFs up to 200-fold, showing we can acheive satisfactory results at least with 100-fold (1% of original counts).

RESULTS

To show the method can generalize on different data/subjects, we trained the model on subsets of slices from 3 patients and evaluated on all slices which were not used for training from all 7 patients. The proposed method reduces over 50% Root-Mean-Square-Error(RMSE) and gains 7dB in Peak-Signal-Noise-Ratio(PSNR) compared with the conventional method and achieves similar Contrast-Noise-Ratio(CNR) as the gold-standard.

CONCLUSION

Using a deep learning algorithm, we can reconstruct ultra-low-dose (at least 100 fold) PET images and achieve comparable image quality as the full-dose images.

CLINICAL RELEVANCE/APPLICATION

This method could dramatically reduce the radiation dose in PET imaging: a 100-fold-low-dose reduces the effective radiation in PET imaging to a similar level as a NYC-LA flight.

PURPOSE

Cirrhotic patients (pts) may have regional variations in liver function (LF) that cannot be quantified by clinical scores based on serum liver function testing (LFT). Hepatobiliary iminodiacetic acid (SPECT-HIDA) scans map regional variations in LF. We aim to correlate HIDA with standard LFT and to evaluate its ability to predict toxicity.

METHOD AND MATERIALS

The study included pts with hepatocellular carcinoma who had a baseline SPECT-HIDA between 12/1/2012-2/28/2017. LFTs were collected at baseline, 3, and 6 months after treatment. Child-Turcotte-Pugh (CTP) and modified end-stage liver disease (MELD) scores were calculated. Pearson correlation was used to correlate HIDA and LFT. Toxicity was defined as an increase in MELD > median at 3 and 6 months (>2-point change). Stereotactic Body Radiation Therapy (SBRT) pts were analyzed separately to evaluate whether functional residual capacity (FRC HIDA; calculated as % counts receiving <15Gy * global HIDA score) predicted toxicity.

RESULTS

32 pts met inclusion criteria (SBRT=17, liver directed therapy=5, surgery=4, no therapy=6). Global HIDA correlated with CTP (r=-0.662, p=<0.001) and MELD (r=-0.690, p=<0.001) scores. Mean global HIDA was higher in CTPA than CTPB pts (3.6 vs 1.8 %/min/body surface area (BSA); p=<0.001). Mean HIDA for pts with MELD <=9 was higher than those with MELD >=10 (3.7 vs 2.0%/min/BSA; p=0.001). There was no difference in mean baseline HIDA between pts without and those with toxicity. SBRT pts without toxicity at 3 months had a higher mean global HIDA than those with toxicity (3.6 vs 2.2 %/min/BSA, p=0.025). Mean FRC HIDA in pts without toxicity at 3 months was higher than those with toxicity (2.8 vs 1.8 %/min/BSA, p=0.022). Similar trends were observed at 6 months. Of note, 8/17 SBRT pts had peritumoral defects in regional LF on baseline HIDA.

CONCLUSION

Global HIDA correlated with standard cirrhosis scoring systems. In SBRT pts, lower baseline global HIDA and FRC HIDA were associated with toxicity. If validated by a larger sample size, FRC HIDA and mapping regional variations in LF may help guide personalized SBRT.

CLINICAL RELEVANCE/APPLICATION

Global HIDA value correlates with standard cirrhosis scoring systems. If validated by a larger sample size, FRC HIDA and mapping regional LF may predict toxicity and guide personalized SBRT.

SSJ24-02 The Clinical Outcome of Stereotactic Ablative Radiotherapy for Advanced Hepatocellular Carcinoma: A Multicenter Retrospective Study

ABSTRACT

Purpose/Objective(s): To investigate the clinical outcome in patients with advanced hepatocellular carcinoma (HCC) treated with stereotactic ablative radiotherapy (SABR).Materials/Methods: Between July 2006 and June 2016, we retrospectively reviewed medical records of patients with advanced HCC treated by SABR at two medical centers. The patient eligibility criteria are as follows: (1) histologically or radiologically confirmed HCC according to AASLD (American Association for Study of Liver Diseases) criteria; (2) Karnofsky performance score =2; (3) Child-Pugh score of 5-7; and (4) Normal liver volume more than 700 mL. The treatment response was evaluated by follow-up imaging study according to RECIST (V1.1) criteria and treatment-related toxicities were scored by CTCAE (V4.03).Results: A total of 32 patients with a median Child-Pugh score of 5 (range: 5-7) were enrolled. Ten (31%) patients had tumor vascular thrombosis. The mean tumor size and mean GTV volume were 4.1 cm (range: 2.1-6.0 cm) and 22.0 mL (range: 4.5-54.3 mL), respectively. The dose scheme of SABR ranged from 24-54 Gy in 3-6 fractions (median: 45 Gy in 5 fractions). With a median follow-up duration of 13 months, the overall best treatment response rate was 46% and the median time to progression was 12 months. The 1-year local control and 1-year overall survival rate were 93% and 74%, respectively. No treatment-related toxicities above grade 2 were observed.Conclusion: SABR provides good local control and tolerable toxicity for selected patients with advanced HCC. Future prospective study is warranted to clarify the optimal patient selection, SABR dose scheme and combination of systemic drugs.

SSJ24-03 Robotic Stereotactic Body Radiation Therapy (SBRT) for Liver Metastases at a Non-Academic, Community-Based Hospital

ABSTRACT

Purpose/Objective(s): Stereotactic body radiation therapy (SBRT) has been shown to be a safe and effective option for treatment of liver metastases in both retrospective and phase I/II prospective studies. However, existing data are mostly reported by academic centers. There have been reports that advanced radiotherapy techniques for some types of cancers performed at community-based hospitals result in inferior outcomes. Our goal was to assess the implementation of this technology by studying efficacy and toxicity of SBRT on liver metastases at a non-academic, community-based hospital through retrospective database analysis.Materials/Methods: We performed an IRB approved patient registry study at a non-academic, community-based hospital. Patients had a median age of 65, KPS of at least 70 (median 90) and primary tumor controlled. All patients underwent fiducial marker placement under CT-guidance 1-2 weeks prior to planning scans. GTV was delineated using contrast enhanced CT scans, as well as fusion with PET and/or MRI scans. GTV was expanded by 5 mm to create the PTV. Treatment was delivered by image guided stereotactic robotic radiosurgery with respiratory motion tracking. Lesions were treated with 3 consecutive fractions to a median total dose of 54Gy. Overall survival, progression-free survival and local failure-free survival were estimated using Kaplan-Meier method. To investigate the relationship between tumor volume and local control, we dichotomized our data set at the mean. Log-rank statistic was used to compare local control based on gross tumor volume.Results: Between 2006 and 2016, 42 consecutively treated patients with 81 metastatic liver lesions were treated with SBRT. Median follow up was 25 months. Primary tumor sites were colon (18), lung (7), breast (3), uterine (3), renal (2), pancreas (2), and others (7). Synchronous extrahepatic disease was present in 15% of the treated lesions at the time of SBRT and 46% had prior local treatment for liver metastases. Median number of lesions treated at one time was 1 (range 1-4). Lesions had a median maximum diameter of 2.5 cm (range 0.5 cm - 9.5 cm), and a mean volume of 53 cc (0.5 cc - 363.0 cc). Kaplan-Meier estimated 1 and 2 year overall survival was 72% and 62%. Estimated 1 and 2 year progression free survival was 32% and 23%. Estimated 1 and 2 year local control was 86% and 80%. 2 year local control was worse for lesions >50 cc compared to lesions <=50 cc (62% vs 84%, p =0.04). Toxicity occurred in 26% of treatment courses and included grade 1 (n=12) (fatigue, diarrhea, nausea, skin irritation and pneumonitis) and grade 2 toxicity (n=3) (chest wall pain and vomiting with mildly elevated transaminase levels).Conclusion: These results are comparable to available published data regarding the safety and efficacy of liver metastasis SBRT on clinical trials at academic institutions. Our findings demonstrate the successful implementation of a liver metastasis SBRT program in a community hospital setting.

SSJ24-04 Assessment of Radiographic Changes after Radiotherapy for Hepatocellular Carcinoma

Tuesday, Nov. 28 3:30PM - 3:40PM Room: S104A

Participants
Onyinye D. Balogun, MD, New York, NY (*Presenter*) Nothing to Disclose

ABSTRACT

Purpose/Objective(s): Hepatocellular carcinoma (HCC) is the most frequent primary liver tumor in adults and it is the fifth most common cancer in the world. Radiotherapy is increasingly being used to treat hepatocellular malignancies. However, there are no standard imaging protocols for evaluation of tumors treated with radiotherapy. Our study reports the radiological changes noted on MRI and/or CT scan in hepatocellular cancer patients after undergoing radiation therapy to a primary tumor.Materials/Methods: CT scans and MRIs of hepatocellular cancer patients who underwent stereotactic or hypofractionated radiotherapy between 2011 and 2016 at a single institution were evaluated prior to and after radiotherapy. Eligible patients had to have at least one imaging study after radiotherapy. Variables including lesion volume, arterial enhancement with or without portal venous washout, and presence of

a pseudocapsule were evaluated.Results: Fifteen patients with radiologic studies after radiotherapy were treated between 2011 and 2016. Primary tumor size ranged from 1.2 to 16 cm. Radiotherapy was delivered in 1-15 fractions (mean 7.2 fractions). Treatment doses ranged from 800 to 5805 cGy (mean 3794 cGy). Per institutional practice, initial follow-up imaging was usually performed at approximately 1 month after treatment. CT and MRI were utilized in 7 and 8 patients, respectively, for initial follow-up evaluation. Over 70% of tumors maintained characteristics of pseudocapsule presence and arterial enhancement with portal venous washout at initial imaging and were classified as stable according to modified RECIST assessment for hepatocellular carcinoma. Of note, three patients exhibited tumor decrease within two weeks of treatment completion. Radiographic assessment is ongoing and additional endpoints will be reported.Conclusion: The findings of this study will add to the existing limited literature regarding characteristic radiation-induced changes in primary liver tumors and surrounding liver parenchyma. Together, these studies can provide a framework for the standardized assessment of tumor response after radiotherapy.

SSJ24-05 Sequencing of Chemotherapy and Radiation Therapy in the Treatment of Extrahepatic Cholangiocarcinoma and Gallbladder Carcinoma

ABSTRACT

Purpose/Objective(s): Primary malignancies of the Gallbladder and Extrahepatic biliary system (EHC-Gal) are rare. There are advantages to pre-operative chemoradiation (chemo-RT) in malignancies such as pancreatic adenocarcinoma. The objective of this study was to explore the benefit, if any, of neoadjuvant chemo-RT in patients with EHC-Gal malignancies who are not candidates for transplant, using the National Cancer Database (NCDB). We hypothesized that the use of neoadjuvant chemo-RT may improve outcomes.Materials/Methods: The NCDB was queried for patients with EHC-Gal between the years of 2006-2012. Patients without metastatic disease at the time of diagnosis, who underwent surgical resection, and received either pre-operative or post-operative chemo-RT, with radiation therapy doses between 40 Gy and 70 Gy, were included. Patients with ampulla of Vater involvement, those treated with stereotactic body radiation therapy (SBRT) or liver transplant were excluded. Baseline covariates were compared between treatment groups. Overall survival (OS) by treatment group was plotted using Kaplan-Meier methods. Univariate and multivariate Cox proportional hazards regression, incorporating inverse probability of treatment weighting (IPTW) to account for selection bias, were used to model time from diagnosis to death. The twang R package was used to calculate propensity scores and the average treatment effect of the treated (ATT) weights; the weighted estimate represents the treatment effect on the treated population. Results: Among the 561 patients meeting inclusion criteria, 34 (6%) received pre-operative chemo-RT. Among the entire cohort of 561 patients with EHC-Gal, the median age was 64 years, 47% were male, and 81% were Caucasian. Overall, 29%, 49% and 22% were clinical stage I, II, and III, respectively. Patients treated with pre-operative chemo-RT were more likely to be younger, have fewer medical comorbidities, have earlier clinical stage disease, and be treated at academic centers. Following surgical resection, patients treated with pre-operative chemo-RT had significantly higher rates of node negativity (65% vs. 34%, p Conclusion: Among a contemporary NCDB cohort of 561 patients with EHC-Gal, few patients received preoperative chemo-RT. Compared to patients treated with post-operative chemo-RT, patients treated with pre-operative chemo-RT had lower rates of positive margins and node positivity. This did not translate into a statistically significant difference in OS. This may be related to a dominant pattern of distant failure and short median survival in EHC-Gal. Further investigation into pre-operative therapy in EHC-Gal is warranted.

SSJ24-06 Does Radical Resection Obviate the Benefit of Adjuvant RT in Gallbladder Cancer?

Tuesday, Nov. 28 3:50PM - 4:00PM Room: S104A

Participants
Joseph Marascio, MD, philadelphia, PA (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

joseph.marascio@jefferson.edu

ABSTRACT

Purpose/Objective(s): Gallbladder cancer (GC) is a rare aggressive malignancy for which optimal adjuvant treatment is not well studied. Studies showing benefit to adjuvant CRT have typically included advanced T stage or node positive patients and have largely been single institution retrospective reviews or analyses of historical databases. Often in these reviews, simple cholecystectomy was the chief technique, but more recently this has been replaced by radical resection. The purpose of this study is to compare the impact of adjuvant RT in simple vs radical resection. Materials/Methods: The Surveillance, Epidemiology and End Results (SEER) database was used to identify patients diagnosed with GC between 2004 and 2013 who underwent simple or radical cholecystectomy. Patients were classified according to AJCC 6th edition and included if stage IIA, IIB or III. Patients with metastatic disease and those surviving fewer than 3 months were excluded. Overall survival (OS) was then calculated for patients who received adjuvant RT or no RT with respect to simple or radical resection. Results: For patients undergoing radical resection, 266 patients who met the above criteria were identified. 121 received adjuvant RT and 145 did not. In the adjuvant RT group the median age was 61 and staging was as follows: IIA 28.9%, IIB 65.3%, and III 5.8%. For those not receiving RT the median age was 67 and staging was as follows: IIA 41.4%, IIB 44.8%, and III 13.8%. In the adjuvant RT group the median survival was 23.4 months, 1 year OS was 87.4% (95 CI 79.6 – 92.3%) and 3 year OS was 35.3% (95 CI 25.7 – 44.9%). In those not receiving RT the median survival was 11.9 months, 1 year OS was 49.5% (95 CI 40.8 – 57.7%), and 3 year OS was 23.8% (95 CI 16.6 - 31.8%).For patients undergoing simple resection, 866 patients who met the above criteria were identified. 289 received adjuvant RT and 577 did not. In the adjuvant RT group the median age was 65 and staging was as follows: IIA 34.6%, IIB 62.3%, and III 2.8%. For those not receiving RT the median age was 72 and staging was as follows: IIA 52.5%, IIB 44%, and III 3.5%. In the adjuvant RT group the median survival was 21.1 months, 1 year OS was 75.8% (95 CI 70.3 – 80.5%) and 3 year OS was 31.3% (95 CI 25.4 – 37.3%) For those not receiving RT the median survival was 12.8 months, 1 year OS was 52.5% (95 CI 48.3 – 56.6%) and 3 year OS was 21.1% (95 CI 17.6 – 24.8%). Conclusion: In the simple resection group a significant OS benefit is seen in those

receiving adjuvant RT at 1 and 3 years. Similarly, this benefit is seen in the radical group at 1 year, however significance is lost at 3 years. These findings reflect a benefit to adjuvant RT shown in prior studies for simple resection, but also support an improved OS in those undergoing radical resection. A weakness in this review is the lack of chemotherapy data as adjuvant RT may be a surrogate for adjuvant chemotherapy. Similarly, patients of greater performance status may be more likely to be selected for adjuvant treatments.

PURPOSE

After endovascular aortic repair (EVAR) discrimination of leaking contrast media and calcifications of similar attenuation within the aneurysm sac is challenging and often requires multiple CT acquisitions. Dual contrast agent based spectral photon-counting CT (SPCCT) may provide reliable detection of endoleaks with a single CT acquisition.

METHOD AND MATERIALS

To experimentally evaluate the potential of SPCCT, an aortic phantom was in-house designed and produced. A centrally located stent lined compartment was filled with water as well as with iodine and gadolinium mimicking contrast-enhanced blood within the aortic lumen. To represent the endoleak, the adjacent compartments contained either one of the contrast agents or calcium chlorine to mimic calcifications. After data acquisition with a small field-of-view spectral photon-counting computed tomography prototype scanner with multi-energy bins, material decomposition was performed to generate iodine, gadolinium and calcium maps.

RESULTS

In a conventional CT slice, Hounsfield Units of the different compartments were similar ranging from about 145 HU up to 170 HU. Material specific maps clearly differentiate the distributions within the compartments filled with iodine, gadolinium or calcium.

CONCLUSION

A single dual contrast agent based spectral photon-counting CT scan may replace conventional CT scans in native, arterial and delayed phase to detect endoleaks of different flow rates without interference from existing calcifications after endovascular aortic repair. It is a unique feature of the dual contrast spectral photon-counting CT scan to capture different endoleak dynamics in a single scan. Additionally, a significant reduction of radiation exposure is enabled.

CLINICAL RELEVANCE/APPLICATION

Dual contrast SPCCT with material decomposition offers extended endoleak diagnostics by a single acquisition.

PURPOSE

To report the long-term result of thoracic endovascular aortic repair (TEVAR) for retrograde type A aortic dissection with the entry tear in the descending aorta.

METHOD AND MATERIALS

Medical records of thirty-one patients who underwent TEVAR for the treatment of retrograde type A aortic dissection at four institutions were retrospectively reviewed.

RESULTS

There were 30 men and one women. The mean age was 64 ± 11 years old. The entry tear was located in the descending thoracic aorta in all patients. The false lumen of the ascending thoracic aorta was patent in 12 patients (40%), while it was thrombosed in the remaining 19 patients (60%). The false lumen of the descending thoracic aorta was patent in 17(55%) patients and most of it was thrombosed in the other 14 patients (45%). TEVAR was performed in acute phase in 24 patients (77%) and in subacute phase in 7 patients (23%). Only one patient died of aortic rupture within 30 days (3%). Early aorta-related adverse events were observed in 7 patients (23%) (type Ia endoleak: 3, type II endoleak: 1, intimal injury: 1, saccular aneurysm formation in the descending aorta: 1, patent false lumen in the ascending aorta: 1) and additional interventions including surgical conversion and additional placement of stent grafts were required in four of them. The mean follow-up period was 97 ± 68 months. Although no aorta-related death was observed, five patients died during follow-up (suicide: 1, trauma: 1, pancreatic cancer: 1, pneumonia: 1, hepatocellular carcinoma: 1). Overall survival rate at 1, 5, and 10 years was 97%, 93%, and 80%, respectively. Late aorta-related adverse events were observed in 7 (27%) patients (intimal injury: 3, newly-developed type A aortic dissection: 3, dissecting abdominal aortic aneurysm: 2, left arm ischemia: 1). Aorta-related event free rate at 1, 5, and 10 years was 61%, 56%, and 56%, respectively.

CONCLUSION

TEVAR for retrograde type A aortic dissection seems promising in terms of survival rate. However, taking into consideration that aorta-related adverse event develops at a non-negligible rate, we should be careful in selecting patients.

CLINICAL RELEVANCE/APPLICATION

TEVAR is an effective treatment option for retrograde type A aortic dissection with entry tear in the descending thoracic aorta.

SSJ25-03 To Assess the Role of FDG PET/CT in Evaluating the Large Vessel Vasculitis and Disease Activity

Tuesday, Nov. 28 3:20PM - 3:30PM Room: E352

Participants
Sikandar M. Shaikh, DMRD, Hyderabad, India (*Presenter*) Nothing to Disclose

PURPOSE

To assess the value of PET-CT in the evaluating the disease activity in large vessel vasculitis .

METHOD AND MATERIALS

29 PET/CT scans were performed in 28 pts with large vessel vasculitis (giant cell arteritis, Takayasu arteritis or idiopatic aortitis). PET-CT was done after injecting FDG contrast with and without iv contrast.Vascular uptake was graded using a 4-point scale (0=no uptake, 1=less than liver, 2=similar to liver, 3=higher than liver). Grade 0-1 was negative, 2 was moderately positive and 3 was markedly positive. PET/CT was correlated with clinical indices including ITAS (Indian Takayasu Activity Score) and Kerr/National Institute of Health (Kerr/NIH), serum acute-phase reactants (ESR, C-reactive protein [CRP]) levels as well as interleukin-6 (IL-6) and the soluble IL-6 receptor (sIL-6R).

RESULTS

43% of 29 PET-CT were negative, 31% were moderately positive, and 26% were markedly positive. Further correlation was done with ESR and CRP levels. Significantly higher ESR values were observed in patients with markedly positive PET/CT (49.4 + 36.5 mm/1st h) compared with moderately positive (27+ 21 mm/1st h, p = 0.0001) and inactive scans (22.7 + 15.9 mm/1st h, p=0.0001). CRP levels were 0.8+1.0 mg/dL in pts with inactive scans, 1.3+ 2.2 mg/dL in pts with moderately positive (p=0.001) and 3.0 + 3.6 in patients with markedly positive scans (p = 0.0001). Higher levels of IL-6 resulted in patients with markedly positive scans (10.0 + 8.9 pg/ml) compared to those with inactive scans (8.1+18.5 pg/ml, p=0.013). We found no association between sIL-6R levels and vascular FDG uptake. There was a significant association between vascular FDG uptake and both ITAS and Kerr/NIH scores.

CONCLUSION

Our evaluation showed significant amount of FDG sensitivity in relation to the metabolic uptake along the vessel walls.In the clinical scenario it was helpful in evaluating borderline cases of Vasculitis where no modality shows significant sensitivity in diagnosing

CLINICAL RELEVANCE/APPLICATION

FDG PET-CT is now proven and established modality for evaluating the large cell vasculitis.

SSJ25-04 Predictors for Blood Pressure Response after Unilateral and Bilateral Stents Placement of Atherosclerotic Renal Artery Stenosis

lxyycb@sina.com

PURPOSE

To explore the difference of BP response between the unilateral and bilateral stenting, and the potential predictors for BP response.

METHOD AND MATERIALS

Retrospectively collected ARAS patients who underwent PTRAS and pre-stenting renal artery (RA) ultrasonography (US) exams in 5 years at a single institution. Patients with accessory RA and contralateral RA occultation were excluded. Baseline characteristics, including age, gender, pre-procedure BP, eGFR, and differences of bilateral US parameters (kidney length, PSV, RAR, and RI) were collected. Pre-stenting BPs and anti-hypertension medication were recorded, and were followed up at 1, 3, 6, 12 and 18 months. The BP response was classified into benefit (cure/improvement) or failure based on the guideline (2003), and the occurrence of BP benefit (study endpoint) and the time from stenting to BP benefit (month) were recorded.

RESULTS

Totally 101 ARAS patients underwent stenting were identified. After removing 14 cases with accessory RA, 9 cases with contralateral RA occultation, 12 cases without qualified data, leaving a cohort of 66 patients, including 43 (age 74.72±10.51 years, male/female 18:25) with unilateral RA stenting, and 23 (Age 69.96±13.34 years, male/female 13:10) with bilateral RA stenting. 74.4% (32/43) of unilateral stenting and 82.6% (19/23) of bilateral stenting were found BP benefit within 6 months after stenting. As in Figure 1, Log rank analysis showed no difference of BP benefit between the two groups (P=0.199). Univariate Cox analysis revealed only the bilateral PSV difference was the predictor for the BP benefit.

CONCLUSION

This study demonstrated, patients underwent unilateral and bilateral stents had similar BP response. The cure/improvement of hypertension most commonly occurred within 6 months after stenting, and higher difference of pre-stenting bilateral PSVs may be its predictor.

CLINICAL RELEVANCE/APPLICATION

The blood pressure (BP) response to unilateral and bilateral percutaneous transluminal renal angioplasty with stent placement (PTRAS) of atherosclerotic renal artery stenosis (ARAS) has not been compared.

SSJ25-05 Experimental Rabbit Study to Evaluate the Effect of Botulinum Toxin Type A Injection Into the Perirenal Arterial Space to Treat Hypertension

Tuesday, Nov. 28 3:40PM - 3:50PM Room: E352

akinagasonoda@yahoo.co.jp

PURPOSE

To develop effective renal sympathetic denervation for antihypertensive therapy, we percutaneously injected the perirenal arterial space of rabbits with botulinum toxin A (BTA).

METHOD AND MATERIALS

Our study was approved by the ethical animal laboratory committee and followed the Animal Care Guidelines of our institution. Six Japanese white rabbits (JW) and 6 Watanabe heritable hyperlipidemic rabbits (WHHL), an arterial sclerosis rabbit model, were randomly divided into two groups. Group 1 (JW, WHHL; n=3 each) was injected with 0.32 ml saline and group 2 (JW, WHHL; n=3 each) with 0.32 ml (8 units) of BTA. All injections were percutaneous and into the perivascular space surrounding the bilateral renal arteries using an ultrasound device. Before and one week- and 1-, 2-, 3-, and 4 months thereafter, their systolic blood pressure (SBP) and heart rate (HR) were measured in the right femoral artery. Significant differences ($p<0.05$) were determined with

Student's t-test.

RESULTS

No rabbits lost appetite or died due to the procedures. At one month post-injection, the SBP of botox-treated animals fell by 23.66+14.77 mmHg; in JW rabbits the difference from the baseline was not- while in WHHL rabbits it was significant ($p<0.08$ vs $p<0.05$). At 2 to 4 months post-injection, the SBP decrease between the two groups was not significantly different. There was no significant difference in the HR of both groups during 4 month.

CONCLUSION

While the percutaneous injection of BTA into the perivascular space around the bilateral renal arteries of rabbits may elicit an SBP decrease, its effectiveness duration, dose, and injection site require further study. Additional in vivo studies are needed to determine the antihypertensive effect of BTA percutaneously injected around the perirenal arterial space.

CLINICAL RELEVANCE/APPLICATION

This procedure may result in better antihypertensive therapy and facilitate new interventional radiology procedures.

SSJ25-06 Imaging Abdominal Large Vessel Vasculitis: The Diagnostic Value of T1 3D mVISTA Black Blood MRI

PURPOSE

To evaluate the diagnostic performance of a T1-3D black blood TSE (turbo-spin echo) sequence in patients with abdominal large vessel vasculitis (aLVV).

METHOD AND MATERIALS

20 patients diagnosed with aLVV according to the reference standard and 17 controls were enrolled in this single center study and subjected to 3.0 T imaging. The protocol included a pre and post gadoteric acid, free-breathing, peripheral pulse-unit triggered T1 3D modified Volumetric Isotropic TSE Acquisition (T1-mVISTA) sequence and a segmented T1 3D turbo-field-echo sequence (T1-eTHRIVE). Two independent blinded readers evaluated the aorta and its main branches on a per-segment basis for concentric wall thickening (CWT) and concentric contrast enhancement (CCE) as signs of inflammation as well as image quality (IQ), flow artefact intensity (FAI) and diagnostic confidence level (DCL), using 4-point Likert scales. Scoring results were compared between the T1-mVISTA and the T1-eTHRIVE sequence using accuracy parameters and inter-reader agreement. Additionally the mean aortic wall thickness (MAWT) was determined on post contrast T1-mVISTA images and compared between aLVV-patients and controls.

RESULTS

IQ was diagnostic in all 37 examinations. Scan time of the mVISTA sequence was 4:10 min at an average heart rate of 80 bpm. In 91.5% of 282 evaluated vessel segments IQ was rated good to excellent with absent or only minor flow artefacts in 85.4%. Inter-observer reproducibility and DCL for CCE and CWT was excellent (0.92/0.93; $P<0.001$; 3.54±0.52/3.50±0.63). Comparing the T1-mVISTA to the T1-eTHRIVE Sequence showed high correlation for the diagnostic signs of aLVV with a kappa of 0.740 for CCE and 0.702 for CWT ($P<0.001$). Using T1-eTHRIVE as reference standard resulted in in a sensitivity of 87.8%, a specificity of 83.3% and an accuracy of 85.2% of T1-mVISTA with a positive and negative predictive value of 79.6% and 90.2%. There was a significant difference in MAWT of the suprarenal and infernal aorta between aLVV-patients and controls (3.60±0.65/3.04±0.85 mm vs. 2.32±0.44/2.18±0.44 mm; $P<0.001$).

CONCLUSION

Imaging of aLVV with navigated T1-mVISTA black blood MRI is feasible, allows the detection of inflamed vessel segments and provides high IQ as well as high resolution, combined with a relatively short scan time.

CLINICAL RELEVANCE/APPLICATION

T1 3D mVISTA black blood MRI could become a valuable imaging tool for the diagnosis and follow-up of patients with aLVV.

For information about this presentation, contact:

mbeland@lifespan.org

PURPOSE

Image guided percutaneous cholecystostomy (PC) may be performed transhepatic (TH) or transperitoneal (TP). The TH approach is traditionally preferred and recommended when possible. We compared the short and long term outcomes of PC related to route of catheter placement.

METHOD AND MATERIALS

IRB approved, HIPAA compliant retrospective review of imaged guided PC was performed from 2004-2016. Search of the hospital RIS was performed using keywords including "percutaneous cholecystostomy" "gallbladder drain" and "cholecystostomy tube" and relevant procedural terminology (CPT) codes. All search results were manually reviewed to identify the cohort of 373 patients who underwent initial episode of PC placement. Radiology reports and images were reviewed to determine method and route of PC. Chart review was performed to determine clinical outcomes. Imaging studies following PC placement were reviewed when necessary to determine catheter course or complications. Differences were examined using a generalized linear model assuming a binary distribution and logit function with SAS/GLIMMIX.

RESULTS

Of the 373 patients, PC placement was performed using US in 229, US access with fluoroscopy in 129, CT in 14, fluoroscopy in 1. Trocar technique was used in 183 and seldinger in 190. 218 PC were placed TH and 153 were TP. The most common PC catheter sizes were 8 French (83), 8.5 French (151), 10 French (124), and 12 Fr (13). There was no significant difference observed between the TH and TP approach for bleeding (1.54% vs 0.91%, p=0.25), pain (2.16% vs 1.68%, p=0.85) or premature catheter dislodgement (3.15% vs. 2.61%, p=0.90). Odds of drain exchange were not different between TH (32%) and TP (24%), p=0.23. Odds of subsequent drain replacement were not different between TH (8%) and TP (10%), p=0.73. Median length of stay was 7 days for both TH and TP (p=0.96). Survival was not different (TH 1.8 years, TP 2.8 years; p=0.12).

CONCLUSION

Transperitoneal PC was not associated with increased incidence of bleeding, pain or premature catheter dislodgement. There was no significant difference between TP and TH placement for needing subsequent drain exchange, median hospital stay or survival.

CLINICAL RELEVANCE/APPLICATION

Placement of percutaneous cholecystostomy can be safely performed transhepatically or transperitoneally with similar short and long term outcomes. Choice of route should be based on the patient's anatomy.

SSJ26-02 Predictors of Clinical Outcomes of Self-Expandable Metal Stent Use to Palliate Malignant Esophagorespiratory Fistulas in 105 Patients

Tuesday, Nov. 28 3:10PM - 3:20PM Room: S402AB

kky2kkw@gmail.com

PURPOSE

to identify the predictors associated with clinical outcomes (initial and late clinical failure) and patient survival after self-expandable metal stent placement for malignant esophagorespiratory fistulas in 105 consecutive patients.

METHOD AND MATERIALS

All included patients were reviewed using logistic and Cox regression analysis.

RESULTS

Technical success was achieved in all patients. The initial clinical success rate was 78.1% (82/105; 95% confidence interval [CI], 69.3%-84.9%), and clinical success was maintained until the end of the follow-up in 47.6% (50/105; 95% CI, 38.3%-57.1%) of patients. The major complication rate was 26.7% (28/105; 95% CI, 19.1%-35.8%). A stricture length of 5-10 cm (odds ratio [OR] 0.335; 95% CI, 0.122-0.889) and stenting only in the airway (OR, 12.445; 95% CI, 1.086-284.863) were independent predictors of initial clinical failure, and stricture at the upper esophagus (OR, 3.722; 95% CI, 1.276-11.544) was an independent predictor of late clinical failure. The independent predictors of survival were fistulas opening to the pleura (hazard ratio [HR], 3.313; 95% CI, 1.142-9.605) and initial clinical failure (HR, 2.510; 95% CI, 1.490-4.228).

CONCLUSION

Self-expandable metal stent placement is safe and effective for treating malignant esophagorespiratory fistulas.

CLINICAL RELEVANCE/APPLICATION

A stricture length of 5-10 cm, stenting only in the airway, and the stricture at the upper esophagus are independent predictors of treatment failure, whereas a fistulas opening to the pleura and initial clinical failures are independent predictors of shorter survival.

SSJ26-04 Recurrent Benign Urethral Strictures Treated with Covered Retrievable Self-Expandable Metallic Stents: Long-term Outcomes over an 18-year Period

Tuesday, Nov. 28 3:30PM - 3:40PM Room: S402AB

soir09@naver.com

PURPOSE

To assess the long-term outcomes of covered retrievable self-expandable metallic stent (REMS) placement for recurrent benign urethral stricture and to compare the outcomes of three types of covered REMS.

METHOD AND MATERIALS

November 1998 to December 2016, 114 REMSs were placed in 54 men. These included 26 polyurethane (PU)-covered REMSs in 13 patients (Group A), 47 internally polytetrafluoroethylene (PTFE)-covered REMSs in 21 patients (Group B), and 41 externally PTFE-covered REMSs in 20 patients (Group C). The outcomes were analyzed and compared between the groups.

RESULTS

Overall clinical success was achieved in 14 (24%) of the 54 patients at the 5-year follow-up (Group A, 12%; Group B, 19%; Group C, 40%). The overall complication rate was 60.5%, and complication rates were significantly different between the groups ($p = 0.004$). The median maintained patency period was 108 months. In multivariate analysis, stent indwelling time was the only significant factor associated with maintained patency.

CONCLUSION

The long-term outcome of covered REMSs has not achieved the desired success rate for the standard treatment of recurrent bulbar urethral stricture. However, externally PTFE-covered REMS showed a better long-term outcome than the other studied types.

CLINICAL RELEVANCE/APPLICATION

Externally PTFE-covered REMS has low complication rate and long stent patency. Externally PTFE-covered REMS showed no tissue ingrowth and low stent migration rate. Longer stent indwelling time contributes to a high clinical success rate. Long-term outcome of covered REMSs has not achieved the desired success rate.

SSJ26-05 EW-7197-Eluting Nanofiber-covered Self-expandable Metallic Stent to Prevent Granulation Tissue

Formation in a Canine Urethral Model

Tuesday, Nov. 28 3:40PM - 3:50PM Room: S402AB

Participants
Jung-Hoon Park, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

jhparkz1125@gmail.com

PURPOSE

To evaluate an EW-7197-eluting nanofiber-covered stent (NFCS) for suppressing granulation tissue formation after stent placement in a canine urethral model.

METHOD AND MATERIALS

All experiments were approved by the committee of animal research. A total of 12 NFCSs were placed in the proximal and distal urethras of six dogs. Dogs were divided into two groups with 3 dogs each. The control stent (CS) group received NFCSs and the drug stent (DS) group received EW-7197 (1000 μg)-eluting NFCSs. All dogs were sacrificed 8 weeks after stent placement Histologic findings of the stented urethra were compared using the Mann-Whitney U test.

RESULTS

Stent placement was technically successful in all dogs without procedure-related complications. On urethrographic analysis, the mean luminal diameter was significantly larger in the DS group than in the CS group at 4 and 8 weeks after stent placement (all $p < 0.001$). On histological examination, mean thicknesses of the papillary projection, thickness of submucosal fibrosis, number of epithelial layers, and degree of collagen deposition were significantly lower in the DS group than in the CS group (all $p < 0.001$), whereas the mean degree of inflammatory cell infiltration was not significantly different ($p > 0.05$). The in vitro release study demonstrated that approximately 80% of the drug was eluted from the stents within 1 day after which the elution rate slowed and reached a plateau after 10 days.

CONCLUSION

The EW-7197-eluting NFCS is effective and safe for suppressing granulation tissue formation after stent placement in a canine urethral model.

CLINICAL RELEVANCE/APPLICATION

The direct and local therapy with EW-7197 via a covered stent is effective and safe for suppressing granulation tissue formation after stent placement in a canine urethral model.

SSJ26-06 Outcomes of Percutaneous Cholecystostomy Tube Placement in 419 Patients: A Single Institute Experience

djyoung@wustl.edu

PURPOSE

To determine proportion of patients who undergo definitive treatment of acute cholecystitis (AC), either surgical cholecystectomy or percutaneous cholecystolithotomy, following percutaneous cholecystostomy (PC).

METHOD AND MATERIALS

Retrospective study was performed with institutional review board approval, and the requirement to obtain informed consent was waived. 419 patients that underwent PC at our institution between July 2010 and September 2016 were included. Patients who underwent PC for indication other than AC were excluded from analysis. Primary outcome was definitive treatment of AC following PC, including cholecystectomy or percutaneous cholecystolithotomy. Secondary outcomes include removal of drainage catheter without further management or death with catheter in place.

RESULTS

During the study period, 377 of 419 patients underwent PC for treatment of AC (mean age, 64.5 years; range 18-100 years). Diagnosis of AC was made via sonography (51%), computed tomography (29%), or hepatobiliary scan (20%). Technical success rate of PC at our institution was 100% with few complications (major 2.4%, minor 1.6%). Following PC, 118 patients (31%) underwent definitive treatment with cholecystectomy. Sixty-one patients (16%) underwent definitive treatment with percutaneous cholecystolithotomy with removal of catheters. Seventy-four patients (20%) had their catheters removed upon resolution of cholecystitis without undergoing surgery or stone removal. Definitive treatment differed between calculous and acalculous cholecystitis groups with the former undergoing further intervention more frequently, while the acalculous group were more likely to have their drain removed without further treatment ($p<0.001$). Fifty patients (13%) died with catheters in place due to other comorbidities. Five patients (1%) still had their catheters in place at the end of the study period.

CONCLUSION

About half of patients with AC that had PC underwent subsequent treatment with surgery or percutaneous cholecystolithotomy. Percutaneous cholecystostomy remains a viable option for treatment of AC with low complication rate, and can be used as bridge to definitive therapy or as sole treatment for alleviation of symptoms associated with AC.

CLINICAL RELEVANCE/APPLICATION

PC can be used for early management of AC when plan for definitive treatment is unclear. The procedure is safe, has low complication rate, and prevents progression to sepsis in patients with AC.

PURPOSE

To compare surgical outcomes of SAVI SCOUT reflector localization (SSL) versus wire localization (WL).

METHOD AND MATERIALS

An IRB approved retrospective study was conducted. Inclusion criteria were single SSL or single WL with subsequent surgery performed by a single-surgeon (SF) to eliminate inter-operator variability. Exclusion criteria were bracketed lesions, multicentric disease and patients with neo-adjuvant chemotherapy. Tumors measuring greater than 2 cm were also excluded due to variability in neoadjuvant utilization and bracketing. Among 97 patients that underwent SSL and excised by SF from 7/2015 to 1/2017, 42 patients met the criteria. For the WL group, 42 consecutive patients were selected matched for age, size of the tumor and single WL performed from 1/2015 to 6/2015. Final surgical pathology was recorded including tumor size, histologic type, ER/PR/HER2/Ki67 status, margin status and re-excision rates. Positive and close margins were defined as tumor on ink and tumor <=1 mm from ink, respectively. Statistical analysis was performed (SPSS, v24).

RESULTS

100% (42/42) of SSL was performed prior to the day of the surgery (range 1-10 days, mean 2.8 days and median 2 days) and all were successfully excised. All patients (42/42) with WL underwent same day wire placement with successful excision. There was no significant difference in clinical-pathologic features between the SSL and WL groups (p>0.05). The mean distance [0.4 cm (range 0-1.9 cm)] between the target and SSL reflector on post localization mammogram was not statistically different than the mean distance [0.3 cm (range 0-1.3 cm)] between the target and the re-enforcement segment of the wire (p=0.45). No significant differences were present in surgical outcomes (p>0.05) including rates of re-excision (SSL, 7.1% vs. WL, 9.5%), margin positivity (SSL, 9.5% vs. WL, 7.1%), close margins (SSL 7.1% vs. WL, 11.9%) and specimen volume (SSL, 15.2 cm3 vs. WL, 16.3 cm3).

CONCLUSION

SSL is an acceptable alternative to WL with no significant differences in surgical outcomes with previously described advantages of SSL in scheduling efficiency and less patient discomfort.

CLINICAL RELEVANCE/APPLICATION

Reflector guided breast tumor localization can be done prior to the day of surgery and overcomes many of the limitations of wire localization with comparable surgical outcomes.

SSK01-02 Ultrasound Guided High Intensity Focused Ultrasound Ablation of Breast Fibroadenoma: A Pilot Study

Wednesday, Nov. 29 10:40AM - 10:50AM Room: E450A

cs3yd@virginia.edu

PURPOSE

Fibroadenoma is a common benign breast mass that can cause pain or an undesirable palpable lump. Current management includes observation, core needle biopsy, and/or surgical excision. This study evaluates the safety, feasibility, and efficacy of Ultrasound guided High Intensity Focused Ultrasound (USgHIFU) ablation for treatment of fibroadenomas. USgHIFU provides noninvasive thermal ablation of the fibroadenoma with real-time US guidance during treatment.

METHOD AND MATERIALS

Twenty women with a palpable breast fibroadenoma were enrolled in a single arm IRB and FDA approved clinical trial (IDE #G130252). Histologic confirmation of fibroadenoma on core needle biopsy was required. Patients underwent treatment utilizing the Echopulse device (Theraclion, France). All tumors had a minimum diameter >= 1 cm with volume between 0.3 cc and 10 cc. Volume calculation formula = length (mm) x width (mm) x height (mm) x π / (6 x 1000) in cc. During treatment, multiple sonications were delivered within the mass to achieve coagulative necrosis. Optimal energy delivered per sonication was established by determining the minimal setting found to produce a hyperechoic mark observed on real-time B-mode image. Energy settings were also influenced by patient tolerance. Change in tumor size, toxicity, cosmesis, and patient experience were obtained immediately after treatment and at 3, 6, and 12 months.

RESULTS

Twenty patients successfully completed therapy. Mean patient age was 35.2. Mean power/sonication = 38.3 watts. Mean number of sonications = 34.3. Pre-treatment mean tumor volume was 1.8cc (SD 1.23, Range 0.57 - 5.7). Mean reduction in volume of the fibroadenoma at 12 months was -1.12 cc (65%), SD -0.61 cc (22%), Range -2.22 to -0.31 cc (98 to 25%), p-value < 0.0001. All adverse events (AE) were grade 1 or 2. Mild pain was the most common AE. No skin burns, damage to adjacent structures, or other major toxicities were observed. On clinical exam, mass was no longer palpable in 80% of patients at 12 months. Patient satisfaction was 4.4 on a scale of 1-5 (5 = most satisfied).

CONCLUSION

USgHIFU ablation is a safe, feasible and efficacious treatment option for breast fibroadenoma. Our results are limited by the small size of our study.

CLINICAL RELEVANCE/APPLICATION

Based on the results of this pilot study, there is evidence to support a larger multi-center clinical trial.

SSK01-03 Incidence of Anaplastic Large Cell Lymphoma in Women with Silicone Breast Implants at MR Imaging

Wednesday, Nov. 29 10:50AM - 11:00AM Room: E450A

Participants
Elizabeth J. Sutton, MD, New York, NY (*Presenter*) Nothing to Disclose
Brittany Z. Dashevsky, MD,DPhil, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
Elizabeth J. Watson, MD, MPH, Springfield, MA (*Abstract Co-Author*) Nothing to Disclose
Blanca Bernard-Davila, MPH,MS, New York, NY (*Abstract Co-Author*) Nothing to Disclose
Danny F. Martinez, BSC,MSc, New York, NY (*Abstract Co-Author*) Nothing to Disclose
Elizabeth A. Morris, MD, New York, NY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To assess the incidence of benign and malignant peri-implant fluid collections and/or masses at magnetic resonance (MR) imaging among women with a history of silicone implant reconstruction.

METHOD AND MATERIALS

The institutional review board approved this HIPAA-compliant retrospective study and waived informed consent. Women were identified who (a) underwent silicone implant oncoplastic and/or cosmetic surgery and (b) underwent postoperative implant-protocol MR imaging to evaluate for rupture between 2000 and 2014. Peri-implant fluid and/or masses were measured volumetrically. A benign peri-implant fluid collection was pathologically proven or defined as showing 1 year of imaging stability and/or no clinical evidence of disease. A malignant peri-implant fluid collection was pathologically proven. Incidence of peri-implant fluid collections and/or masses and positive predictive value (PPV) were calculated on a per-patient level by using proportions and exact 95% confidence intervals (CIs).

RESULTS

In total, 1070 women with silicone implants were included (median age, 56 years; range, 26-95 years). The median time between reconstructive surgery and first MR imaging examination was 48.96 months (range, 24-53months). Of the 1070 women, 263 had more then one imaging study. Of the 1070 women, 18 (1.7%) had a peri-implant fluid and/or mass; 16 (88.9%) had adequate follow-up; only 1 of the 16 peri-implant fluid collections was malignant implant associate anaplastic large cell lymphoma, with a PPV of 6.25% (95% CI: 0.003-0.0005). The median peri-implant fluid collection was 89 cc (range, 18-450 cc).

CONCLUSION

Peri-implant fluid collections and/or masses identified at silicon implant-protocol breast MR imaging are rarely seen 24 months after reconstructive surgery. Image guided fine-needle aspiration with flow cytometry may be warranted to evaluate for implant-associated lymphoma.

CLINICAL RELEVANCE/APPLICATION

Peri-implant fluid collections and/or masses on implant-protocol breast MRI are rarely seen 24 months after surgery and the diagnostic radiologist should consider recommending ultrasound guided fine needle aspiration.

SSK01-04 Feasibility and Accuracy of Digital Breast Tomosynthesis-Guided Vacuum Assisted Breast Biopsy (DBT-VAB) for Non-Calcified Targets

Wednesday, Nov. 29 11:00AM - 11:10AM Room: E450A

Participants
Gunjan M. Senapati, MD, Boston, MA (*Presenter*) Nothing to Disclose
Sona A. Chikarmane, MD, Boston, MA (*Abstract Co-Author*) Nothing to Disclose
Christine M. Denison, MD, Boston, MA (*Abstract Co-Author*) Nothing to Disclose
Catherine S. Giess, MD, Wellesley, MA (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

gsenapati@bwh.harvard.edu

PURPOSE

To (1) determine feasibility and accuracy of DBT-VAB for non-calcified breast lesions without a sonographic correlate and (2) assess concordance of imaging and pathology findings.

METHOD AND MATERIALS

A HIPAA-compliant IRB waived retrospective review of our mammographic database between 12/11/15-8/31/16, identified 72 women with 73 non-calcified lesions on DBT who underwent attempted DBT-VAB with imaging available for review. Mammography and biopsy imaging were reviewed in consensus by three breast radiologists; imaging features and biopsy parameters were collected. Medical records were reviewed for imaging follow-up, patient characteristics, and histopathology.

RESULTS

The target lesion was sampled by DBT-VAB in 72 of 73 lesions. One biopsy was canceled because the target could not be identified at biopsy. Mean time to complete DBT-VAB was 17.3 minutes +/- 5. No major complications were reported. Findings included: 3 focal asymmetries (FA) (4%), 7 asymmetries (A) (10%), 21 masses (M) (29%) and 41 architectural distortions (AD) (57%). DBT-VAB histopathology showed invasive malignancy in 15 (21%) of 72 lesions: 1/3 FA (33%), 7/41 AD (17%), 7/21 M (33%). ADH was found in 2 (3%) of 72 lesions (both masses). 7/7 A, 2/3 FA, and 11/21 M showed benign core pathology concordant with imaging. 1/21 M had benign discordant core pathology and was malignant on excision. 34/41 (83%) AD were benign on core pathology, of which 14 (41%) were complex sclerosing lesions (CSL); 6 were excised with no upgrades. Ten of 34 (29%) AD were benign and considered concordant with imaging. The remaining 10 of 34 (29%) were benign discordant pathology at core biopsy and surgically excised; 4/10 (40%) showed CSL on final pathology. Therefore, a total of 11/72 (15%) cases were considered discordant on VAB with 1/11 (9%) malignancies on final pathology.

CONCLUSION

DBT-VAB is a quick and feasible biopsy method for targeting non-calcified mammographic lesions without a sonographic correlate. The 21% malignancy rate reaffirms biopsy is necessary for suspicious mammographic lesions occult on ultrasound. Meticulous radiology-pathology correlation is required in interpretation of DBT-VAB results, with surgical excision of discordant cases.

CLINICAL RELEVANCE/APPLICATION

DBT-VAB is a feasible biopsy method for non-calcified lesions, however, careful radiology-pathology correlation is necessary, with a low threshold to surgically excise any potentially discordant cases.

SSK01-05 Optical Coherence Tomography (OCT): A Novel Imaging Method for Ex-Vivo Breast Specimens-A Reader Feasibility Study

PURPOSE

To assess subspecialty reader sensitivity, specificity and overall accuracy to distinguish non-suspicious versus suspicious areas of

ex-vivo breast tissue using OCT images (a near-infrared based imaging technique) with histology correlation.

METHOD AND MATERIALS

This IRB exempt, HIPAA compliant study was performed on 63 surgically excised breast specimens from 35 female patients. OCT images of the specimens were performed providing micrometer resolution with tissue visualization 1-2 mm subsurface. 40 volumetric image data sets were created from the specimens for reader interpretation (16 malignant cases (8 invasive ductal carcinoma, 4 DCIS, 4 mixed IDC/DCIS) and 24 benign). 3 breast imaging fellowship trained radiologists, 2 pathologists, 2 breast surgeons and 1 non-clinical reader were first trained to interpret OCT images and then read 40 OCT data sets blinded to clinical data and corresponding histology slides. Readers were asked to distinguish non-suspicious from suspicious findings.

RESULTS

Sensitivity, specificity, PPV, NPV, and the AUC for each reader was calculated as well as averages by subspecialty. Histology was the reference standard. The overall average reader sensitivity, specificity and accuracy for all 8 readers was 80%, 87% and 0.87, respectively, Radiologists demonstrated the highest average among the disciplines, 85%, 93% and 0.94, followed by Pathologists, 79%, 90%, and 0.84, and Surgeons, 76%, 84%, and 0.82 respectively.

CONCLUSION

Multidisciplinary readers are able to distinguish suspicious from non-suspicious OCT imaging findings in ex-vivo breast tissue as confirmed by histology. These results support the potential of OCT as a real time intra-operative tool for imaging ex-vivo breast tissue. Future studies are needed to evaluate the technology in an intraoperative setting.

CLINICAL RELEVANCE/APPLICATION

Real time OCT images of ex-vivo breast tissue could be viewed intraoperatively by the surgeon to assess for suspicious tissue at the edge/margin of a specimen. Images could be exported for radiologist consultation.

SSK01-06 Use of Artificial Intelligence to Reduce Breast Biopsies

Wednesday, Nov. 29 11:20AM - 11:30AM Room: E450A

Participants
Alyssa T. Watanabe, MD, Manhattan Beach, CA (*Presenter*) Consultant, CureMetrix, Inc
Rebecca Rakow-Penner, MD, PhD, San Diego, CA (*Abstract Co-Author*) Nothing to Disclose

William G. Bradley JR, MD, PhD, La Jolla, CA (*Abstract Co-Author*) Officer, CureMetrix, nc

PURPOSE

Almost 2% of screening mammograms result in biopsy, and approximately 70% of these biopsies are benign. Decreasing the number of unnecessary biopsies would be cost effective and decrease patient anxiety about breast cancer screening. We evaluated a quantitative CAD algorithm that differentiates benign and malignant calcifications and compared these results to those of experienced radiologists in selecting cases for biopsy. The algorithm is based on a combined use of artificial intelligence (deep learning) and physics based mathematical classifiers that makes predictions of suspiciousness through quantitative scoring.

METHOD AND MATERIALS

In this IRB approved study, we performed a comparative analysis on patients' screening and diagnostic 2D mammograms where tissue was sent to biopsy based on suspicious calcifications detected by MQSA certified breast radiologists. 10,500 consecutive cases from 3 different institutions were reviewed. These images were evaluated with a quantitative CAD (qCAD) that employs deep learning (DL), a form of artificial intelligence (AI) to make predictions of suspiciousness of mammographic findings. These predictions were compared to the expert radiologists' reads. The DL embedded in the algorithm is an analytical function determined by the training datasets that mathematically define both malignant and benign calcifications.

RESULTS

Of the 391 cases sent to biopsy, 302 cases were benign and 89 malignant (including DCIS). The algorithm detected 100% of confirmed cancer cases. If biopsy recommendations had been based on the algorithm up to 56% of biopsies could have been avoided.

CONCLUSION

This CAD algorithm trained with AI can potentially reduce the number of unnecessary biopsies based on suspicious calcifications by up to 56%. The qCAD was more accurate than the radiologists at classifying breast calcifications on mammography.

CLINICAL RELEVANCE/APPLICATION

The use of artificial intelligence in mammography may be useful in reducing false positive breast biopsies and to enhance more accurate detection of breast malignancies. This is likely to lead to health savings costs as well as eliminate pain and distress for many patients.

SSK01-07 Flat Epithelial Atypia Upgrade Rate

Wednesday, Nov. 29 11:30AM - 11:40AM Room: E450A

Participants
Selina Suleman, MPH,BSC, Vancouver, BC (*Abstract Co-Author*) Nothing to Disclose
Marie Josee Cloutier, MD,FRCR, Vancouver, BC (*Presenter*) Nothing to Disclose

PURPOSE

Flat epithelial atypia (FEA) is a controversial breast lesion whose optimal management with surgical excision versus imaging follow

Flat epithelial atypia (FEA) is a controversial breast lesion whose optimal management with surgical excision versus imaging follow-up is unknown. Widespread implementation of screening mammography programs has resulted in an increased detection of FEA. This study aims to determine the likelihood of upgrade to ductal carcinoma in situ (DCIS) or invasive carcinoma in individuals diagnosed with FEA at stereotactic needle biopsy. In addition, the relationship between family history of breast cancer and likelihood of upgrade is explored.

METHOD AND MATERIALS

Stereotactic biopsies were performed primarily for the assessment of microcalcifications seen on mammography. Initially these were done with 12G core needles, but vacuum devices (10 and 9G) are now the standard. FEA diagnoses were correlated with subsequent excisional biopsy pathology results or imaging follow-up. Patients were included only if there was no concomitant diagnosis of other high-risk lesion, papillary lesion, in-situ or invasive carcinoma. Surgical pathology or follow-up imaging was obtained for 623 patients. Upgraded cases were defined as diagnosis of DCIS or invasive carcinoma at surgery. Additionally, medical charts of women diagnosed with FEA were reviewed for family history of breast cancer.

RESULTS

An upgrade rate of 1.8% (11 lesions in 623 patients; 95% CI, 1.0%-3.2%) is reported. The remaining samples (612/623) had a surgical diagnosis of FEA or ADH, lobular carcinoma in situ, a benign finding with no atypia, or stable follow-up imaging. There is no significant association between family history of breast cancer and upgrade in preliminary results (OR 1.7; 95% CI, 0.39-6.61).

CONCLUSION

The upgrade rate of FEA diagnosed at CNB or VAB at our institution was 1.8%, which is at the low end of the range reported in the literature. Each facility should audit their upgrade rate before implementing a change in practice pattern.

CLINICAL RELEVANCE/APPLICATION

These results indicate that it is reasonable at our institution to avoid surgery in favor of short-term imaging follow-up for the majority, especially when there is no family history of breast cancer.

SSK01-08 Management of Lobular Neoplasia (Atypical Lobular Hyperplasia and Lobular Carcinoma in Situ) on Core Needle Biopsy Performed for Calcifications Using Precise Radiologic-Pathologic Correlation

jean.kunjummen@emory.edu

PURPOSE

To determine if there is a difference in upgrade rate of calcified vs incidental lobular neoplasia (LN) found on core biopsy performed for evaluation of suspicious calcifications.

METHOD AND MATERIALS

The study (approved by our institutional review board) included consecutive patients who underwent core needle biopsy from December, 2009 through December, 2016 directed at suspicious calcifications with results showing LN as the highest-risk lesion. Patients with concurrent atypical ductal hyperplasia, flat epithelial atypia, radial scar, papillary lesion, phyllodes tumor, ductal carcinoma in situ (DCIS), invasive ductal carcinoma (IDC), or invasive lobular carcinoma (ILC) on core were excluded. An upgrade was defined as surgical excisional pathology showing DCIS, IDC or ILC.

RESULTS

Three hundred fifty patients underwent successful core needle breast biopsy showing LN during the study period. Of these, 80 patients had LN as the highest-risk lesion. In sixty-two patients (78%), LN was an incidental histologic finding, and the targeted calcifications were associated with variety of benign concordant entities. In 17 patients (21%), calcifications were an intrinsic part of the LN lesion. Fifteen of those 17 patients (88%) underwent surgical excision, with an upgrade rate of 27% (4/15). Of the 62 patients who had incidental, non-calcified LN, 36 underwent surgical excision, with an upgrade rate of 2.7% (1/36). One patient with incidental LN was felt to have discordant rad-path results; excision showed invasive cancer. Of those with long term follow-up rather than excision, none have developed cancer (avg. length of follow-up =28 months).

CONCLUSION

Careful radiologic-pathologic correlation is needed to determine the appropriate management of lobular neoplasia. Women with core needle biopsy for calcifications that show incidental, non-calcified LN have small rate of upgrade and may not require excisional biopsy. However, surgical excision should be offered to women who have LN associated with calcifications.

CLINICAL RELEVANCE/APPLICATION

Management of LN remains controversial with recommendations ranging from imaging follow-up to mandatory surgical excision in all cases. Our data supports close radiologic-pathologic correlation and suggests that the calcified LN in core biopsy specimens has a greater likelihood of upgrade to cancer than incidental, non-calcified LN.

SSK01-09 Utility of Ultrasonography (US) and US-guided Fine-Needle Aspiration Biopsy for Axillary Staging in Early Breast Cancer: Is the US Diagnosis for Metastatic Lymph Nodes Useful?

Wednesday, Nov. 29 11:50AM - 12:00PM Room: E450A

Participants
Hye Shin Ahn, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Sun Mi Kim, MD, PhD, Seongnam-Si, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Mijung Jang, Seongnam, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Bo La Yun, MD, Seongnam, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the accuracy of ultrasonography (US) and US-guided fine-needle aspiration biopsy (FNAB) for diagnosing metastatic invasion of the axilla in early breast carcinoma patients and to determine the usefulness of the US diagnosis for axillary staging.

METHOD AND MATERIALS

We retrospectively reviewed data on 2731 patients who were diagnosed as early breast cancer less than T2 stage from January 2006 to December 2015. All included patients underwent preoperative axillary US for axillary staging and US-guided FNAB was performed if lymph nodes showed any suspicious findings as follows: even or uneven cortical thickening, compressed fatty hilum, hypoechoic mass with loss of hilum. US and FNAB findings were compared using sentinel lymph node biopsy (SLNB) and axillary lymph node dissection (ALND) data.

RESULTS

Of 2731 patients, 446 (16.3%) showed suspicious nodes on US and underwent US-guided FNAB. Of these 446 patients, 202 (45.3%) showed positive findings, 244 (54.7%) showed negative findings on FNAB. The sensitivity, specificity, positive predictive value, and negative predictive value of US for pathologic proven metastatic lymph node were 30.4%, 88.2%, 45.3%, and 79.7%, respectively. The sensitivity, specificity, positive predictive value, and negative predictive value of US-guided FNAB were 62.4%, 93%, 88.1%, and 74.9%, respectively.

CONCLUSION

Axillary US and US-guided FNAB in early breast cancer showed relatively low rate of sensitivity. If axillary lymph nodes with suspicious US feature has been found in early breast cancer patients, axillary metastases will not be likely compared with the breast cancer patients with high tumor stage.

CLINICAL RELEVANCE/APPLICATION

In early breast cancer patients, the usefulness of axillary US for axillary staging could be lower than advanced breast cancer patients.

alejandro.rodriguezruiz@radboudumc.nl

PURPOSE

To compare the performance of a commercial deep learning computer detection system to radiologists' performance in detecting breast cancer on digital mammography (DM) images.

METHOD AND MATERIALS

Six radiologists (22 years median experience with DM, range 3-44) retrospectively reviewed 155 unilateral two-view DM exams (73 malignant and 82 negatives, of which 42 were biopsy-proven benign lesions, and 40 normal cases defined as BIRADS 1 or 2 with one year follow-up). DM exams were scored on mammography displays using standard reading conditions. For all lesions, a level of suspiciousness score was given (0 - no lesion, 1 definitely benign - 10 definitely malignant). The highest score was used as the overall exam score. A commercially available computer system based on deep learning technology (Transpara 1.2.0, ScreenPoint Medical, Nijmegen, the Netherlands) was applied to the same dataset. This multi-vendor system automatically identifies soft-tissue and calcification lesions and combines the findings of all available views into a single cancer suspiciousness score (same scale as the readers, 0-10). Analysis was performed using Dorfman-Berbaum-Metz Multiple-Reader Multiple-Case mixed model analysis of variance, both including and excluding benign lesions in the negative class. Receiver operating characteristics area under the curve (AUC) and its 95% confidence intervals were used for comparison.

RESULTS

Averaged across radiologists, AUC was 0.83 (CI: 0.76-0.90) when evaluating the whole dataset, while for the deep learning system

Averaged across radiologists, AUC was 0.83 (CI: 0.79-0.90) when evaluating the whole dataset, while for the deep learning system the AUC was 0.79 (CI: 0.72-0.86) (p=0.378). The system did not perform statistically different than any of the readers (reader AUC range: 0.77-0.87, p>0.064). When benign lesions were excluded from the analysis, AUC was 0.90 (CI: 0.85-0.96) and 0.88 (CI: 0.84-0.94) for the radiologists and the computer system (p=0.576), respectively.

CONCLUSION

For the task of detecting breast cancer in DM, the performance of a deep learning computer system is not statistically different from the average performance of 6 radiologists, even though the AUC for radiologists was still slightly higher.

CLINICAL RELEVANCE/APPLICATION

Computer systems with similar clinical performance as radiologists could be used, for instance, as double reading, to automatically discriminate normal cases, or to shorten reading time.

SSK02-03 Differentiating Between Malignant and Benign Masses at Breast US: Improving Radiologists' Diagnostic Performances Using Computer-Aided Diagnosis System Based on Deep Learning Algorithm

PURPOSE

To compare performances of computer-aided diagnosis (CAD) system based on deep learning algorithm and radiologists in differentiating between malignant and benign masses at breast ultrasound (US) and to determine whether CAD system could improve the radiologists' performances

METHOD AND MATERIALS

This prospective study was conducted with institutional review board approval. B-mode US images were obtained for 253 breast masses (173 benign, 80 malignant) in 226 concesutive women. US findings of the breast masses were retrospectively analyzed by CAD system (S-DetectTM) and four radiologists. In predicting malignancy, CAD system results were dichotomized (possibly benign vs. possibly malignant). The radiologists independently assessed the Breast Imaging Reporting and Data System (BI-RADS) final assessments for two data sets: US alone, and US with CAD system results. Final assessments of the radiologists were categorized into positive (category 4a or higher) and negative (category 3 or lower) for each data set. Diagnostic performances of CAD system and the radiologists for two data sets were compared.

RESULTS

CAD system showed significantly higher values in accuracy, specificity, and positive predictive value (PPV) ($P<0.01$), and similar sensitivity ($P>0.05$) compared to those of the three radiologists, but the differences in the corresponding values between CAD system and the one radiologist were not significant. When CAD result was added to US, the three radiologists showed significant improvement in accuracy, specificity, and PPV, without significant change in sensitivity and negative predictive value, but the one radiologist showed no significant change in diagnostic values.

CONCLUSION

Diagnostic performance of CAD system was higher than or comparable to those of raiologists in differentiating between malignant and benign masses at breast US. Using CAD system may improve the accuracy, specificity, and PPV of the raiologists without loss in sensitivity.

CLINICAL RELEVANCE/APPLICATION

CAD system based on deep learning algorithm can improve the radiologists' diagnostic performances in differentiating between malignant and benign masses at breast US.

SSK02-04 Advanced Data-Driven Imaging Biomarker for Breast Cancer Screening in Mammography

Wednesday, Nov. 29 11:00AM - 11:10AM Room: E451A

PURPOSE

Previously, we demonstrated data-driven imaging biomarker in mammography (DIB-MG; an imaging biomarker derived from large-scale mammography data by using deep learning technology) for classification of cancer and normal. Now, we assess the feasibility

of DIB-MG including cancer, normal, and benign exams and evaluate its potential for detection of malignant lesion.

METHOD AND MATERIALS

We collected 37,185 (set-A) and 7,101 (set-B) exams of 4 view digital mammograms from two institutions. For cross-institution validation, we used set-A for training DIB-MG and set-B for evaluating the trained model. Set-A consists of 1,019 cancer, 17,346 normal, and 18,820 benign exams, and set-B consists of 1,987 cancer, 2,982 normal, and 2,132 benign exams. DIB-MG is trained based on deep convolutional neural networks (CNNs). Entire training process is divided into two stages; multi-scale patch-based pre-training followed by image-based fine-tuning with semi-supervised segmentation. Total 128,960 malignant, 252,395 benign, and 200,000 normal patches were densely extracted from four scales of original images. Malignant and benign lesions were finely annotated by radiologists for patch extraction. In the image-based fine-tuning, parameters of initial convolutional layers were fixed and the rest convolutional layers were tuned based on all of 37,185 exams. During training, cancer probability of each exam is compared with the ground-truth diagnosis result, and the error between the prediction and the ground-truth label is propagated backward to optimize parameters in all layers except for the fixed one. Trained DIB-MG predicts the cancer probability of the input exam as well as a DIB map which includes the most probable locations of abnormalities.

RESULTS

AUC was 0.814. Sensitivity (specificity) according to different thresholds for the test set is: 0.764 (0.692), 0.621 (0.924), 0.549 (0.957) with respect to the thresholds 0.1, 0.3, 0.5. An exemplary DIB map is described in Fig.1.

CONCLUSION

This research showed the potential of DIB-MG as a screening tool for breast cancer through the cross-institution evaluation. Further clinical study of DIB-MG is needed for using it as a reliable screening tool for breast cancer.

CLINICAL RELEVANCE/APPLICATION

With further clinical studies, DIB-MG can be practically used as a second-reader in order to help radiologists diagnosing breast cancer and detecting malignant lesions.

SSK02-05 A Predictive Deep Learning Model to Determine the Presence of Breast Cancer on Screening and Diagnostic Mammograms

PURPOSE

Nearly one in eight U.S. women will develop breast cancer in their lifetimes. Mammography is a safe and effective screening tool; however, it suffers from high recall and biopsy rates, which are costly and traumatic to the patient. The use of deep learning has the potential to improve accuracy, thereby decreasing both the recall and biopsy rate.

METHOD AND MATERIALS

136,253 mammographic accessions corresponding to 755,945 DICOM files were extracted from the radiology picture archiving and communication system (PACS). DICOMs were filtered to include only screening and diagnostic studies and standard, non-magnification views, which resulted in 127,329 accessions corresponding to 660,989 DICOMs. 33,342 pathology reports and 93,727 BI-RADS scores were then extracted from their respective databases for ground truth labeling of DICOM images. Regular expression technique with manual validation was used to assign final pathologic diagnosis to a pilot subset of DICOM files based upon positive pathology results within one year. This was combined with BI-RADS 1, 2, and 6 cases, resulting in 4,738 cases labeled as cancer and 354,837 cases labeled as non-cancer. A deep learning model based on the Inception v3 architecture with pre-trained weights from the Imagenet dataset using the Keras API with TensorFlow backend was fine-tuned on 2,569 cancer and 5,105 non-cancer images at 299 x 299 resolution.

RESULTS

The model achieved an area under the receiver operating characteristic curve (AUC) of 0.83 when predicting on an internal test set of 200 cancer and 200 non-cancer images. Interestingly, on a subset of 50 positive and 50 negative BIRADS-2 cases, the model also achieved an AUC of 0.83, surpassing human readers. When tested on an external validation set of 2000 images with composition reflecting a more clinically accurate prevalence of cancer to non-cancer, i.e., 1% cancer and 99% non-cancer, the model achieved an AUC of 0.96.

CONCLUSION

Deep learning may be an effective tool for detecting breast cancer in mammograms, however training and validation with larger data sets is required. Results may also improve with higher resolution, however this requires modification of existing models and

increased hardware capacity.

CLINICAL RELEVANCE/APPLICATION

Deep learning in mammography has the potential to detect breast cancer using features not yet recognized by human readers, thereby improving accuracy and decreasing false positives.

SSK02-06 Automated Breast Cancer Risk Assessment from FFDM Images

PURPOSE

To automatically evaluate future breast cancer risk by computerized analysis of full-field digital mammography (FFDM) images.

METHOD AND MATERIALS

This IRB-approved study included a total of 407 GE FFDM images (12-bit dynamic range). Cases comprised 131 women who underwent screening mammography and were subsequently diagnosed with breast cancer within an average of 2.8±2.4 years. Controls comprised 276 women who did not develop breast cancer over up to 10 years of follow-up screening mammography. We extracted 99 grayscale and texture features such as Haralick and wavelet features, from patches in the CC view of the unaffected breast for cases and LCC view for controls. We applied a Bag of Visual Words method to build the histogram of image features for each breast, and used a random forest classifier to predict case or control status based on the histograms, age, race/ethnicity, menopausal status, parity and body mass index. We evaluated performance using ten-fold cross validation and computed the Area Under the ROC Curve (AUC).

RESULTS

Our method showed better discrimination between cases and controls (AUC, 0.84; 95% CI, 0.81-0.85), than other common techniques such as BIRADS (0.66; 0.62-0.74), Cumulus (0.64; 0.6-0.68), Libra (0.62; 0.55-0.65) and Volpara (0.62; 0.56-0.67). In contrast to these common methods that quantify only the absolute or percentage of dense tissue, we found that the additional image features extracted from non-dense tissue improved the AUC by 0.03 ($p<0.05$).

CONCLUSION

Our method shows promising results for risk evaluation of future breast cancer. Our novel technique is significantly better than using only area/volume/percentage of breast density, as is done by state of the art methods. Importantly, informative image features are located in both dense and non-dense breast regions.

CLINICAL RELEVANCE/APPLICATION

Our tool can automatically deliver a novel, validated imaging-based risk score to improve the accuracy and reliability of breast cancer risk prediction directly from digital screening mammography.

SSK02-07 Standard-Dose versus Synthetic Digital Mammograms: Are There Differences in Automated Measurements of Breast Parenchymal Patterns?

PURPOSE

Breast parenchymal pattern measures have demonstrated substantial potential in breast cancer risk assessment. However, as synthetic 2D mammograms (sDMs) are increasingly being used to reduce dose when screening is performed with digital breast tomosynthesis, standard-dose mammograms (DMs) that have widely been used to evaluate breast parenchymal patterns may no longer be acquired. We investigate differences in quantitative parenchymal pattern measures from DMs versus sDMs.

METHOD AND MATERIALS

We retrospectively analyzed 7365 pairs of bilateral "FOR PRESENTATION" DMs and synthetic ("C-View") images corresponding to 3698 women with negative (BI-RADS 1 or 2) routine screening evaluation. Images were acquired with a Selenia Dimensions system (Hologic Inc.) over a 4-month period at our institution for which both DMs and sDMs were available for each screening exam. For each image, 26 established parenchymal pattern descriptors were automatically estimated, including gray-level histogram, co-

occurrence, run-length, and fractal dimension texture features. Feature measurements were compared using paired Wilcoxon signed-ranks tests and Spearman correlation (r). We also compared feature correlations with automated breast percent density (PD) estimates, and evaluated the within woman intraclass feature correlation (ICC) for the two mammogram types.

RESULTS

Most features were strongly (r>0.6 for 12 features) or moderately (0.4<= r<=0.6 for 11 features) correlated between DMs and sDMs. However, all measurements were significantly different between the two mammogram types (Wilcoxon test, p<0.001). Regardless of the mammogram type, parenchymal texture measures demonstrated weak to moderate correlations with breast PD (-0.6<=r<=0.6) and strong bilateral symmetry (ICC>=0.6), with significantly increased ICC values for sDMs (average ICC = 0.80 vs average ICC = 0.67, p=0.0003).

CONCLUSION

Breast parenchymal pattern measurements extracted from sDMs are different, yet correlated with those made from DMs. Furthermore, in either mammogram type, there is an inherently strong agreement in bilateral parenchymal symmetry for the extracted texture measures capturing information complementary to the established risk factor of breast density.

CLINICAL RELEVANCE/APPLICATION

Our findings may contribute to integrating computerized parenchymal complexity analysis for breast cancer risk assessment in clinical settings where DMs may be fully replaced by synthetic mammograms.

SSK02-08 Mammographic Parenchymal Analysis with Deep Belief Network for Breast Cancer Risk Prediction

PURPOSE

To develop a quantitative mammographic parenchymal pattern (MPP) descriptor for breast cancer risk prediction using digital mammograms (DM).

METHOD AND MATERIALS

With IRB approval, we performed a matched case-control study to investigate the use of MPP for breast cancer risk prediction. We retrospectively collected data of 398 subjects including 199 paired cancer cases and cancer-free controls. The controls were frequency matched to the cases with respect to the years of screening, age, and race. The screening DMs in the year of cancer diagnosis and up to 5 years of consecutive prior screening DMs were collected for each subject. A total of 2712 CC-views were analyzed in this study. The "for processing" image was first processed by a multiscale method to enhance the fibroglandular densities and parenchymal patterns. Locations of keypoints were identified by a scale-invariant feature transform algorithm. Three ROIs were automatically localized based on the keypoint distribution and used for MPP analysis. The MPP descriptor was formed by a semi-supervised learning scheme, in which an unsupervised deep belief network (DBN) with tied weights was used as MPP feature generator. Layer-wise neurons with ReLU as activation function was first pretrained and then stacked to construct the DBN. The cross-entropy error with *L*2 norm was minimized by an optimization algorithm based on adaptive estimates of lower-order moments. A random forest was then trained to combine the MPP features and estimate the probability of cancer risk. Ten-fold cross validation was used for model selection and evaluation. ROC analysis was performed to assess the prediction accuracy.

RESULTS

The average age for cases and controls were 60.9±10.6 and 60.9±10.5, respectively. At the year of cancer diagnosis, the AUC was 0.78±0.01. The AUCs from 1-year to 5-year prior exams were 0.75±0.01, 0.70±0.01, 0.64±0.02, 0.59±0.02, and 0.61±0.02, respectively.

CONCLUSION

The MPP can differentiate cases from matched controls and the changes in MPP increased as the time approached cancer diagnosis. Our proposed MPP by machine learning shows promise for cancer risk prediction. Future work is underway to enlarge the data set and to improve the machine learning scheme.

CLINICAL RELEVANCE/APPLICATION

Our MPP analysis on screening DMs shows potential for breast cancer risk assessment and the change in risk over time, which may be useful for personalizing screening regimen and early detection.

PURPOSE

In digital mammography screening, a main concern is to reduce false recall rates. In this study, we investigate automatic identification of nuanced imaging features to distinguish mammogram images belonging to negative, recalled-benign, and positive cases, aimed to better interpret recalled images with biopsy benign results.

METHOD AND MATERIALS

A retrospective study was performed on a cohort of 1303 patients (5212 mammogram images) who underwent standard digital mammography screening (2007-2014): 552 patients were evaluated as negative in the initial screen, maintaining the cancer-free status in at least a one-year follow-up; 376 patients were recalled and eventually determined to be biopsy-proven benign based on pathology results; 375 patients were evaluated as positive for breast cancer (27% DCIS; 73% Invasive) based on pathology results. Both craniocaudal (CC) and mediolateral oblique (MLO) image views were used for all patients; for the positive cancer cases, only images of the cancer-affected breasts were included. A fully automated computerized method utilizing deep learning with a convolutional neural network was applied to distinguish between the three categories listed above (four binary-class comparisons plus one triple-class comparison). To enhance training of the deep learning network, transfer learning from a large existing imaging database was used followed by fine-tuning with the mammogram images. The receiver operating characteristic (ROC) was generated and the area under the curve (AUC) was calculated as a metric of the classification accuracy.

RESULTS

Full results of all five scenarios are shown in the figure. In all comparisons, the three categories (negative, recalled-benign, and positive) can be distinguished (AUC ranging from 0.66 to 0.81) by automatically identified mammographic imaging nuances. The identified imaging features between recalled-benign and negative are most distinguishing (AUC=0.81), followed by recalled-benign vs. positive (AUC=0.75).

CONCLUSION

Nuanced mammographic imaging features identified by automatic deep learning methods on a large imaging cohort distinguish negative, recalled-benign, and positive cases.

CLINICAL RELEVANCE/APPLICATION

Automatic learning coupled with the distinguishing mammographic imaging nuances can lead to a computerized toolkit to potentially help better interpret recalled-benign images to reduce false recalls.

PURPOSE

Coronary artery calcification degrades diagnostic accuracy on the evaluation of coronary artery stenosis. It is known that virtual monochromatic image (VMI) at high energy level using dual-energy CT (DECT) reduces blooming artifacts. The aim of our study was to evaluate the calcium blooming effect and the differences of luminal diameter in varying VMI energy using rapid kilovolt switching single-source dual-energy CT (ssDECT).

METHOD AND MATERIALS

We evaluated 45 calcified plaques in 31 patients with suspected coronary artery disease. Coronary artery calcifications were evaluated based on vessel cross-sectional images from 40 to 140 keV in both pre-contrast and contrast-enhanced coronary CT angiography (CCTA) with ssDECT. We measured the diameter of calcifications on non-contrast CT and coronary artery lumens on CCTA using the full-width half maximum method. The calcium blooming effect was evaluated on pre-contrast VMIs. The diameter of calcifications on non-contrast CT and coronary arterial lumens on CCTA in each keV were compared with that of 70 keV VMI that had an equal effective energy of 120kVp as a reference standard.

RESULTS

Only 40 keV VMI showed significantly large calcification diameter than that of 70 keV image (1.53±0.37mm vs. 1.48±0.33mm, $p<0.01$) on the pre-contrast scan. Meanwhile, the other keV images did not show significant differences in diameter compared to that of 70keV VMI. Regarding coronary artery luminal diameter, no significant differences were observed among all energy levels compared to that of 70keV VMI (40keV, 2.47±0.67mm; 50keV, 2.47±0.67mm; 60keV, 2.50±0.67mm; 70keV, 2.48±0.68mm; 80keV, 2.48±0.68mm; 90keV, 2.48±0.67mm; 100keV, 2.49±0.67mm; 110keV, 2.51±0.66mm; 120keV, 2.49±0.68mm; 130keV, 2.49±0.67mm; 140keV, 2.48±0.68mm), on CCTA (all p=N.S).

CONCLUSION

The diameter of coronary artery calcification and the luminal diameter of the coronary artery with calcified plaque would not be changed in almost all VMIs.

CLINICAL RELEVANCE/APPLICATION

The difference of VMI energy would not affect the measurement of luminal diameter of the coronary artery with calcified plaque.

SSK03-02 The Impact of Advanced Modeled Iterative Reconstruction Strength Level on the Image Quality of Calcified Coronary Segments in Coronary CT Angiography

Wednesday, Nov. 29 10:40AM - 10:50AM Room: S502AB

Participants
Yuanding Wang, Beijing, China (*Presenter*) Nothing to Disclose
Xiangying Du, MD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
Kuncheng Li, MD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To determine the value of advanced model-based iterative reconstruction (ADMIRE) on improving the image quality of coronary CT angiography (CCTA) in coronary segments with/without calcified plaques, by evaluating the image quality at different levels of ADMIRE in comparison with that at filtered back projection (FBP) on a third-generation dual source CT scanner.

METHOD AND MATERIALS

CCTA was performed on a third-generation, dual-source CT with automated tube voltage adaptation. Patients with coronary artery disease and at least one calcified segment on calcium scoring scan were enrolled. Image series were reconstructed with FBP and ADMIRE (strength levels 1 - 5), respectively. Attenuation, image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) were calculated, the volume of the calcified plaques were measurd. Subjective image quality criteria was assessed by two observers using a 5-point Likert scale.

RESULTS

Results: There were no statistically significant differences in attenuation between each ADMIRE group (strengths 1 - 5) and FBP group ($p > 0.05$). Image noise decreased significantly using ADMIRE compared with FBP and was reduced with increasing ADMIRE strength levels (maximal reduction, 45.4%, $p < 0.05$). The CNR and SNR of each ADMIRE group were significantly higher than those of FBP group, increasing with higher ADMIRE strength levels ($p < 0.05$). The volume of calcified plagues were decreased with the increasing ADMIRE strength levels($p<0.05$). Both in segments with calcified plaques and without calcification, subjective image quality was rated best at ADMIRE 4, followed by ADMIRE 5, ADMIRE 3, ADMIRE 2, ADMIRE 1, and FBP.

CONCLUSION

Image quality of CCTA can be significantly improved by the application of ADMIRE, both in coronary segments with and without calcified plaques, while the optimal image quality was achieved at iterative strength level 4.

CLINICAL RELEVANCE/APPLICATION

By increasing the image quality and decreasing the blooming artifacts, the high strength level IR technique decreases the need for unnecessary coronary catheterization or myocardial perfusion studies.

SSK03-03 Coronary Artery Enhancement for Coronary CT Angiography and Plaque Analysis: Optimization with a Test Bolus and Contrast Dilution Protocol

PURPOSE

Quantification of total coronary plaque index and coronary artery stenosis is markedly affected by attenuation levels of the coronary lumen due to partial volume averaging. Thus, achieving consistent attenuation level of the coronary artery lumen improves quantitative analysis when comparing patient studies. We studied three contrast injection protocols for coronary CT angiography (CCTA) and compared both mean levels and standard deviation of contrast enhancement.

METHOD AND MATERIALS

We evaluated a test-bolus injection protocols in comparison to a weight-based injection (body weight (BW) <60 kg: 50 mL contrast, BW >= 60 kg and BW <= 100 kg: 60 mL contrast and BW > 100 kg: 70 mL, 5 ml/sec, imaging trigger by bolus-tracking). The test bolus injection consisted of injection of 75 ml of diluted contrast (30% iopamidol 370, 4.5 ml/sec) as test bolus. The test bolus peak attenuation was used for scan timing and calculation of the angiography bolus dilution. Aortic and coronary artery attenuation was measured and compared to a pre-defined target attenuation level (375 HU at 120 kVp equivalent).

RESULTS

Overall, 119 subjects were evaluated (66% men, age 62y, BMI 29, heart rate 56/min). The test-bolus guided injection protocol achieved the coronary target attenuation successfully and consistently (mean 373±39 HU, target 375 HU, relative standard deviation (rSD) 10.5 %); inter-study variation of the test-bolus method was significantly lower than that of the body weight injection protocol (mean 362±98, rSD 27%, $p<0.0001$, also see figure). A similar trend was seen for attenuation in the ascending aorta (rSD 9.4% vs. 30% for the test bolus protocol and the body weight protocol, respectively, $p<0.0001$). The timing was optimal (highest attenuation in ascending aorta compared with left atrium or descending aorta) in 73% of cases for the test-bolus protocol compared with 27% in the body mass guided injection protocol ($p<0.0001$).

CONCLUSION

A test-bolus guided injection protocol with variable contrast dilution allowed greatly improved standardization of coronary and aortic attenuation levels for coronary CT angiography.

CLINICAL RELEVANCE/APPLICATION

Consistent coronary lumen attenuation is desirable for plaque and stenosis quantification. A test-bolus guided contrast injection achieves improved consistency in coronary lumen attenuation.

SSK03-04 Half Dose CT Coronary Calcium Score: Impact of Iterative Reconstruction

PURPOSE

To evaluate the effectiveness of Iterative Reconstruction (IR) on the coronary artery calcium scores (CACS) by using a half radiation dose CT acquisition protocol compared to standard protocol.

METHOD AND MATERIALS

Based on a power analysis, this prospective study included 57 patients without known coronary artery disease who underwent two CACS acquisition (standard and half radiation dose) with MDCT (128-slice GE-VCT Hino W/VT 2000) within the same examination, following ethical permission. The standard protocol was acquired with tube voltage of 120 KVp and tube current of 170 mA, whereas the half dose protocol was acquired with 50% reduction of mA (85 mA) and the same tube voltage. Raw data of half dose protocols were reconstructed by using IR at all strength levels available, from 10% up to 100%, every 10%. Radiation dose as well as number of plaques, Agatston score, volume and mass were calculated and compared between the two protocols by using dedicated statistical test (Medcalc v17.4, Belgium). A p value <0.05 was considered statistically significant.

RESULTS

From an original population of 57 patients we exclude 6 patients for absence of coronary plaques, thus the final population comprised 51 patients (32 men and 19 women). The mean DLP were 45.447.10 and 21.663.24 for the standard and half dose protocol ($p<0.05$), respectively. The mean Agatston score for the standard protocol was 595.82±977.09 and 19.27±19.53 plaques were identified. No significant differences for Agatston score were observed between standard protocol and half dose protocol with IR at 40 and 50% (493.35±924.31 and 498.05±959.27, $p>0.05$), whereas significant differences were observed for all the remaining IR levels (all $p<0.05$). Moreover, no significant differences were calculated for the number of plaque with IR at 40% (23.67±21.46, $p>0.05$).

CONCLUSION

Half dose acquisition protocol with IR at 40% and 50% showed reliable results in terms of Agatston score for CACS showing no significan differences with standard protocol.

CLINICAL RELEVANCE/APPLICATION

Patients can benefit of half radiation dose CACS acquisition protocol with IR at 40%, which shows comparable results in the evaluation of Agatston score and number of plaques to the standard protocol.

SSK03-05 250 Micron Resolution Photon-Counting CT: Potential for Improved Imaging of Calcified Coronary Artery Stenoses

Wednesday, Nov. 29 11:10AM - 11:20AM Room: S502AB

Participants

Amir Pourmorteza, PhD, Atlanta, GA (*Presenter*) Nothing to Disclose

PURPOSE

Coronary CT angiography using conventional CT leads to overestimation of calcified stenosis due to blooming / partial volume effects. The purpose of this study was to determine the potential utility of ultra-high resolution (UHR) (250 micron) photon-counting detector (PCD) CT using human ex-vivo hearts. We hypothesize that the increased resolution will reduce overestimation of calcified plaque stenosis when compared to (0.50 mm) standard resolution CT.

METHOD AND MATERIALS

We used a whole-body PCD CT scanner. Each PCD pixel consists of 4x4 subpixels whose photon counts are combined in standard resolution (SR) mode to create 0.50 mm isotropic pixels at isocenter. Recently, the system has been upgraded to allow 2x2 binning of subpixels making UHR CT possible with 0.25 mm isotropic pixels at isocenter. 5 human ex-vivo hearts were placed inside an anthropomorphic chest phantom and scanned in dose-matched SR and UHR modes at 140 kVp and 106 mAs. We measured the total cardiac calcium volume to evaluate the effect of higher resolution on calcium volume at a clinically used threshold of 130 HU at 140 kVp. All images were reconstructed with filtered backprojection. We assessed imaging of calcified stenosis in total of 18 coronary locations with at least semi-circumferential calcified plaques. We tested if a previously described method for inner vessel lumen detection based on the 2nd derivative of a cross-sectional Hounsfield Unit (HU) profile was able to detect a stenosed by patient coronary artery lumen.

RESULTS

Calcium volume was 10 % lower in UHR images compared with SR images (424 mm3 vs 469 mm3). Lumen detection rate was

significantly higher in UHR images compared to SR (18/18 [100%] vs. 11/18 [61%], Fisher's test P=0.0076). In addition, the detected lumen diameter was significantly larger in UHR compared to SR images (0.65 mm vs 0.60 mm, Wilcoxon P=0.02).

CONCLUSION

250 micron resolution photon-counting CT resulted in lower calcium volumes, likely reflecting less calcium blooming. It also resulted in larger lumen diameter measurements and enabled successful detection of the lumen in all calcified stenoses while standard resolution failed to depict the lumen in 39% of cases.

CLINICAL RELEVANCE/APPLICATION

One reason for false positive coronary CT angiography is calcium blooming in regions of stenosis. 250 micron photon counting CT may allow better lumen depiction of these difficult lesions.

SSK03-06 Who are the Patients Whose Coronary Artery Calcification Progresses Rapidly? According to Serial CT Measurements of Coronary Artery Calcium

PURPOSE

Coronary artery calcium (CAC) is an established surrogate marker for cardiovascular disease, but little is known about risk factors for the progression of calcium burden. This study assessed the pattern of CAC increment and risk factors for rapid CAC progression.

METHOD AND MATERIALS

515 asymptomatic adults who underwent serial CAC at least 3 times from 2004 to 2016 were included. The patients were categorized into three groups: zero CAC on all serial scans (group 1), eventual CAC formation with initially zero CAC (group 2), and increasing CAC with initial presence of CAC (group 3). Group 3 was subdivided into four groups according to the degree of slope and pattern (linear or exponential slope) of the CAC increment (Figure). Variable risk factors and blood chemistry were analyzed for the each group.

RESULTS

Group 1 (n=310, 60.2%), group 2 (n=59, 11.5%) and group 3 (n=146, 28.3%) were followed up for the mean period of 2760 days. Age, prevalence of male, hypertension, hyperlipidemia, diabetes medication, family history of ischemic heart disease, smoker, systolic and diastolic blood pressure, glucose and triglyceride were higher in the group 3 compared to the group 1 (all $p < 0.05$). There was no significant difference in any of the risk factor in between the groups with linear (n=63, 43.6%) and exponential slope (n=83, 56.8%). However, there were some risk factors that differed in between the high and low grade slopes, for both linear and exponential groups. In the linear slope group, prevalence of previous ischemic heart disease, hyperlipidemia, triglyceride, glucose, and HbA1c were higher for the group with high grade slope compared to the group with low grade slope (all $p < 0.05$). On the other hand, in the exponential slope group, initial CACS was higher for the group with high grade slope compared to the group with low grade slope ($p=0.03$).

CONCLUSION

Patients showed varying CAC progression with differing slope pattern and degree. Although there was no significant relationship of risk factors to the slope pattern (linear vs. exponential), some risk factors and initial CACS were related to the higher degree of slope of CAC progression.

CLINICAL RELEVANCE/APPLICATION

According to our study, appropriate follow up time for CAC measurement should be individualized, under consideration of each patient's risk factors as well as initial CAC score.

SSK03-07 Association between Serum Uric Acid and the Characteristics of Coronary Plaque Burden: Assessment with Coronary CT Angiography

Wednesday, Nov. 29 11:30AM - 11:40AM Room: S502AB

Participants
Ruiyi r. Tan SR, ARRT,ARRT, Beijing, China (*Presenter*) Nothing to Disclose
Qi Xiao, MD,MBA, Saint Louis, MO (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

275577014@qq.com

PURPOSE

It is controversial whether serum uric acid (UA) is an independent risk factor for cardiovascular diseases (CVD). The aim of this study was to investigate the correlation between the serum UA level and coronary plaque burden characteristics evaluated by coronary CT angiography (CCTA).

METHOD AND MATERIALS

In total, 1315 patients who underwent CCTA were divided into the hyperuricemia group and normal serum UA group according to

their serum UA level and stratified by gender. The low-attenuation plaque volume (LPV) and total plaque volume (TPV) were separately measured in each main coronary artery. The correlation of serum UA or hyperuricemia with coronary plaque burden was assessed using multivariate-adjusted logistic and linear regression analyses.

RESULTS

The TPV and LPV significantly differed between males and females ($P < 0.0001$ each). The TPV values were higher in female subjects with hyperuricemia than in subjects without hyperuricemia ($P = 0.0124$). The serum UA level significantly correlated with the TPV in both genders ($ß = 0.4231$ and $P = 0.0441$ for males and $ß = 0.4996$ and $P = 0.0149$ for females). However, the serum UA and LPV did not correlate with either gender after adjusting for multivariates.

CONCLUSION

The serum UA level was significantly associated with the coronary TPV in both genders. However, the serum UA was not associated with the LPV. We found that the serum UA may play an independent role in the pathophysiology of total plaque burden.

CLINICAL RELEVANCE/APPLICATION

We found that the serum UA plays an independent role in the pathophysiology of the total plaque burden, and we suggest controlling the serum UA level as a meaningful strategy in the management of coronary plaque burden.

SSK03-08 The Diagnosis of Coronary Plaque Stability by Multislice Computed Tomography Coronary Angiography

PURPOSE

This study was to investigate and summarize the differential characteristics of non-calcified unstable coronary plaques and stable coronary plaques using MSCT.

METHOD AND MATERIALS

Sixty patients with coronary heart disease were included in our study. 37 unstable plaques and 31 stable plaques were identified. We analyzed the plaque CT attenuation, the napkin-ring sign, napkin-ring thickness, the plaque distribution, the degree of lumen stenosis and the sensitivity, specificity, positive predictive value, negative predictive value of MSCT to identify the plaque stability. The difference and correlation between MSCT and IVUS in the diagnosis of plaque characteristic were also analyzed. All statistical analysis was done using software Stata 10.0. The difference was statistically significant if $P<0.05$.

RESULTS

The average CT value of unstable plaques (29.7±19.4 HU)was lower than stable plaques (76.4±24.8 HU)($P<0.05$),although there was some overlap. The napkin ring sign was more frequently observed in unstable group(91.9%) than stable group (22.6%) ($P<0.05$). The median thickness of napkin-ring in unstable plaques(0.7mm) was thinner than stable plaques(1.1mm)($P<0.05$). The former had more severe lumen stenosis or occlusion (70.3%)than the latter (41.9%)($P<0.05$).The plaques were mainly distributed in the left anterior descending artery in both groups. The sensitivity,specificity,positive predictive value and negative predictive value of MSCT to confirm unstable plaques were 78.4%, 77.4%,80.6% and 75% respectively, While were respectively 77.4%,78.4%, 75% and 80.6% to confirm stable plaques. MSCT and IVUS had no statistically significant difference in the diagnosis of plaque characteristic($P>0.05$),while showed a correlation in the identification of plaque stability ($P=0.00$,$r=0.5568$).

CONCLUSION

The average CT attenuation of non-calcified unstable plaques was lower than stable plaques although there was some overlap. The incidence of napkin-ring sign in unstable plaques was significantly higher than that in stable plaques; Unstable plaques had more severe lumen stenosis or occlusion than stable plaques. MSCT demonstrated a clinical significance in the identification of coronary plaque stability.

CLINICAL RELEVANCE/APPLICATION

MSCT demonstrated a clinical significance in the identification of coronary plaque stability.

SSK03-09 The Evaluation of Subclinical Coronary Atherosclerosis of Different Therapy Stages in Middle-Aged HIV (+) Chinese Adults

Wednesday, Nov. 29 11:50AM - 12:00PM Room: S502AB

Participants
Juan Huang, Zheng Zhou, China (*Presenter*) Nothing to Disclose
Yonggao Zhang, Zhengzhou, China (*Abstract Co-Author*) Nothing to Disclose

Jianbo Gao, MD, Zhengzhou, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

867864639@qq.com

PURPOSE

It is demonstrated that HIV (+) patients have a higher risk for cardiovascular disease, mainly due to HIV infection itself and medication side effect in addition to traditional risk factors. This study is aimed to determine whether the routinely long-term medication treatment using HAART has an impact on total CAC score and plaque formation.

METHOD AND MATERIALS

A total number of 120 HIV (+) patients (52 ± 4 years) was enrolled in the study, who underwent CCTA and besides, who was with normal kidney function and without the history of revascularization. According to the duration of HAART mediation treatment, the patients were divided into three groups: A (less than 2 years), B (2 to 5 years) and C (more than 5 years).

RESULTS

There were 40 patients in each group, and no significant differences in demographic data and risk factors of cardiovascular disease were found between groups. The median Agatston CCS for group A was 74 [25-75th percentile: 0-492], with a range from 0 to 4781;As for group B and group C, the median value was 79 [25-75th percentile: 0-502], with a range from 0 to 5120 and 111 [25-75th percentile: 0-532], with a range from 0 to 7320 respectively, the difference of Agatston CCS between groups were found statistically significant. The number of non-calcified plaques was 17 for group A, 29 for group B and, 33 for group C. And significant difference in the number of non-calcified plaque was also found between groups. The mean segments with plaque for different groups were 15, 23, and 27 respectively. And there was no significant difference found between groups.

CONCLUSION

It is indicated by this study that the longer duration of HAART medication therapy the patients received, the higher level of CAC score and higher incidence of non-calcified plaque would happen. However, larger sample is needed for further validation.

CLINICAL RELEVANCE/APPLICATION

The longer duration of HAART medication therapy the patients received, the higher level of CAC score and higher incidence of non-calcified plaque might happen.

gianni.dileo77@gmail.com

PURPOSE

To review the MRI safety in patients carrying a pacemaker or other ICEDs.

METHOD AND MATERIALS

A search was performed on March 2017 using MEDLINE/EMBASE for articles on the MRI safety in ICED carriers. Keywords included MRI, pacemaker, implantable cardioverter defibrillator, cardiac electronic device, safety, and adverse events (AEs). We extracted: number of patients, age, device dependency, field strength, specific absorption rate (SAR), studied body region, technical ICED parameters, and follow-up time.

RESULTS

Of 493 articles, 53 were analyzed for a total 6,237 exams in 5,394 patients. Design was prospective in 49 (4 randomized). Devices were MRI non-conditional in 32 studies (2,889 patients), conditional in 16 (1,708 patients), mixed in 5 (797 patients). Patients were device-dependent in 1 study, independent in 22, mixed in 18, and not defined in 12. Field strength was 0.2T in 1 study, 0.5T in 3, 1.5T in 45, 2T in 1, 3T in 2, mixed in 1. The studied body region was thoracic in 27 studies, non-thoracic in 16, and mixed in 10. SAR was limited in 39 studies, not limited in 5, not reported in 9. Follow up was 0-6 months in 32 studies, >6 months in 6, and not reported in 15. No fatal events occurred. Five studies reported clinically relevant AEs: atrial arrhythmias (6 patients), intolerable heating (5 patients), perforation (4 patients), lead dislodgements (3 patients), and generator failure with immediate replacement (1 patient), for a total of 19 AEs, 7 in patients with MRI conditional ICED, 9 in patients with non-conditional, and 3 in patients with an undefined ICED, for a total of 19 clinically relevant AEs. Twenty studies reported technical AEs, mainly power-on reset and battery voltage reduction. Two studies showed significant changes of atrial sensing, 4 of ventricular sensing, 3 of atrial pacing capture threshold (PCT), 4 of ventricular PCT, 6 of atrial lead impedance, 7 of ventricular lead impedance, and 9 of battery voltage.

CONCLUSION

Considering 6,237 MRI exams in 5,394 device-dependent or non-dependent carriers of conditional or non-conditional ICED, a very low rate of clinically relevant AEs was reported. The risk/benefit ratio is largely positive, also for non-conditional ICED.

CLINICAL RELEVANCE/APPLICATION

Patients carrying ICED should not be denied thoracic or nonthoracic MRI a priori, included patients with non-conditional devices. MRI may be performed safely under controlled conditions.

SSK04-02 Diagnostic Performance of Minimally Invasive Autopsy for Detection of Ischemic Heart Disease

PURPOSE

In this study we investigated the performance of minimally invasive autopsy (MIA) to diagnose ischemic heart disease in clinically deceased patients

METHOD AND MATERIALS

In 99 adult cases with written consent for conventional autopsy (CA) and MIA, diagnostic accuracy of MIA and CA was calculated for acute and chronic myocardial ischemia. MIA consisted of total-body postmortem MR (PMMR) and CT (PMCT), combined with CT-guided biopsies of myocardial lesions. PMMR and PMCT were independently read by two radiologists with expertise in cardiac radiology. Calcium score (Agatston) and ROC curve for the prediction of acute and chronic ischemia were calculated for each case. CA including macroscopy and microscopy was the gold standard.

RESULTS

CA detected 34 cases of acute ischemia. Sensitivity of PMMR for acute ischemia was 0.50 (CI: 0.33-0.67) and specificity was 0.92 (CI: 0.86-0.99). PMMR combined with biopsy improved sensitivity to 0.97 (CI: 0.91-1.00) and specificity to 0.95 (CI: 0.9-1.00). CA detected 40 cases of chronic ischemia. Sensitivity of PMMR for chronic ischemia was 0.35 (CI: 0.20-0.50) and specificity was 1.00. PMMR combined with biopsy improved sensitivity for chronic ischemia to 0.90 (CI: 0.81-0.99) but specificity was lowered to 0.75 (CI: 0.63-0.86). Calcium score was a fair predictor for chronic ischemia (AUC=0.73, $p<0.001$), but a poor predictor for acute ischemia (AUC=0.61, $p=0.073$).

CONCLUSION

MIA shows high diagnostic accuracy for detection of acute and chronic myocardial ischemia. Importantly, our results show that postmortem imaging needs to be combined with CT-guided biopsies to achieve the highest performance.

CLINICAL RELEVANCE/APPLICATION

This study shows that minimally invasive autopsy (MIA) has high diagnostic performance to detect ischemic heart disease which is a very common cause of death in clinically deceased patients.

SSK04-03 Left Bundle Branch Block: Usefulness of MRI in the Evaluation of Regional Left Ventricular Dyssynchrony and in the Detection of Previous Myocardial Infarction with Late Enhancement

Wednesday, Nov. 29 10:50AM - 11:00AM Room: S504AB

PURPOSE

Left bundle branch block (LBBB) is a common cardiac conduction abnormality diagnosed on ECG. LBBB can be a primary abnormality of the cardiac electrical conduction system or it can be secondary to other cardiogical pathologies such as myocardial infarction and cardiomyopathies. The presence of LBBB per se cannot be used as a single diagnostic criteria for the diagnosis of previous myocardial infarction. Aim of this study was to evaluate the mechanical left ventricular dyssynchrony with high temporal resolution cine MRI and to evaluate the presence of late-enhancement (LE) in order to diagnose previous myocardial infarction.

METHOD AND MATERIALS

38 patient with LBBB underwent cardiac MRI using a 1.5 T magnet (Magnetom Sonata, Siemens). The MRI protocol consisted of a left ventricular trueFISP functional study followed by Late Enhancement data sets acquired 10-15 minutes after iv administration of 0.2mmol/kg BW of extracellular Gd contrast agent. We used a segmented Inversion Recovery Turbo-FLASH sequence (TR:8ms;TE:4ms;TI:250-320ms;sl.thick:8mm). Different pattern of LE were related to the underlying pathology as stated by clinical and other diagnostic imaging features.

RESULTS

We detected a characteristic dyssynchronous ventricular contraction with septal flattening during early ventricular systole in all the patients, tenting of mitral valve apparatus in 5 pts and functional mitral regurgitation in 2 pts. In 1 pt we found the characteristic functional features of dilated cardiomyopathy with no myocardial area of LE. In 8 pts we found areas of LE (transmural in 3 pts and subendocardial in 5 pts) with typical patterns of myocardial infarction (MI). The location of MI was septal in 4 pts, infero-septal in 2 pts, lateral in 1pt, and superior in 1 pt. In 30 patients we found a reduction of the ejection fraction (75%).

CONCLUSION

Cardiac MRI is a useful diagnostic tool in the evaluation of LBBB when the assessment of ventricular dyssynerygy on echocardiography is not technically feasible and when the area of a previous myocardial infarction cannot be determined.

CLINICAL RELEVANCE/APPLICATION

MRI is a useful diagnostic tool in the evaluation of LBBB when US assessment of ventricular dyssynerygy isn't feasible and a previous possible myocardial infarction has to be determined.

SSK04-04 Utility of Native Myocardial T1 Mapping as a Diagnostic Tool for Ischemic and Non-Ischemic Cardiomyopathy

PURPOSE

Native myocardial T1 mapping measures interstitial fibrosis and provides prognostic information in patients with cardiomyopathy. We sought to determine the diagnostic utility of native T1 mapping in identifying common cardiomyopathies - ischemic (CAD), dilated cardiomyopathy (DCM), and hypertrophic cardiomyopathy (HCM) - compared with the reference standard late gadolinium enhancement (LGE).

METHOD AND MATERIALS

We enrolled consecutive adult subjects referred for CMR evaluation of ischemic or non-ischemic cardiomyopathy. CMR was performed on a 1.5T magnet using standard cine, LGE, and native T1 mapping using a modified Look-Locker inversion recovery sequence. We compared the diagnostic accuracy of native T1 mapping versus LGE of the mid septum as well as all 16 segments of the left ventricle for etiology of cardiomyopathy.

RESULTS

We evaluated 1,950 myocardial segments in 130 subjects (mean age 48±11 years, 80% male; 90 CAD, 29 DCM, 11 HCM). Mid septal T1 values were similar in CAD vs. DCM and HCM (1051±51 msec, 1064±36, 1068±22 respectively, p=0.17). T1 values in segments with fibrosis on LGE were significantly lower than segments without fibrosis, regardless of etiology (1057±65 msec with fibrosis vs. 1042±52 without fibrosis, p<.0001). T1 values were markedly reduced in CAD in segments with lipomatous metaplasia (968±17 msec). However, the diagnostic accuracy of native T1 mapping in identifying the etiology of cardiomyopathy was poor. For a threshold T1 value of < 1024 msec in any segment, the AUC for identifying CAD vs. HCM or DCM was 0.565, sensitivity 39%, specificity 78%, PPV 86%, NPV 28%). There was no association between T1 values and standard imaging indices of disease severity (ejection fraction, total myocardial scar, myocardial mass).

CONCLUSION

Compared with LGE, native T1 mapping has limited diagnostic accuracy in distinguishing between etiologies of cardiomyopathy, likely due to considerable overlap of values in CAD, DCM, and HCM. There was no association between T1 values and severity of cardiomyopathy, as measured by ejection fraction, total myocardial scar (CAD), or myocardial mass (HCM).

CLINICAL RELEVANCE/APPLICATION

Native T1 mapping is a useful tool for tissue characterization. However, its utility to distinguish between ischemic, dilated, or hypertrophic cardiomyopathies is limited.

SSK04-05 References Values of Myocardial Strain Measurement Using Cardiovascular Magnetic Resonance Tissue Tracking for Both Ventricles in Asymptomatic Asian Cohort: Association with Cardiovascular Risk Factors

holymosquito@hanmail.net

PURPOSE

To provide the reference values of myocardial deformation parameters of both ventricles using cardiovascular MR with tissue tracking (CMR-TT) in asymptomatic Asian subjects and to evaluate the association of deformation parameters and Framingham risk score (FRS).

METHOD AND MATERIALS

We enrolled 120 asymptomatic healthy adults who underwent CMR, and all subjects demonstrated normal left ventricular systolic

We enrolled 129 asymptomatic healthy adults who underwent CMR, and all subjects demonstrated normal left ventricular systolic function. We assessed the FRS of all study population. Commercial software was used to derive myocardial deformation parameters of both ventricles from short-axis cine views and apical two-, three-, and four-chamber views. The reference value of each strain parameter was determined as mean value of every individual. The linear regression analysis was performed between all strain parameters and FRS. Iota coefficient for the inter-rater agreement of strain parameters was also calculated.

RESULTS

In total 129 patients, the reference values of left ventricle (LV) were 48.90 ± 9.05 for radial, -22.30 ± 2.33 for circumferential and -19.76 ± 2.22 for longitudinal global strain. The reference values of right ventricle (RV) were 18.63 ± 6.52 for radial, -10.60 ± 3.33 for circumferential and -25.06 ± 3.01 for longitudinal global strain. The median FRS was 7 (interquartile range 4-11). The LV strain parameters were significantly associated with FRS in univariate linear regression analysis: radial strain, beta = -0.155, p = 0.002; circumferential strain, beta = 0.56, p = 0.005; longitudinal strain, beta = 0.423, p = 0.043. However, RV strain parameters were not significantly associated with FRS: radial strain, p = 0.74; circumferential strain, p = 0.76; longitudinal strain, p = 0.09. The iota coefficient of all strain parameters were 0.915 for LV (p < 0.001) and 0.715 for RV (p < 0.001), respectively.

CONCLUSION

We present the reference values of strain parameters of both ventricles in asymptomatic Asian subjects. In contrast to RV parameters, LV strain parameters assessed by CMR-TT show significant association with FRS.

CLINICAL RELEVANCE/APPLICATION

We suggest reference values of myocardial strain parameters of both LV and RV assessed by CMR-TT in asymptomatic subjects and LV strain paramters show significant association with Framingham risk scores.

SSK04-06 Cardiac Magnetic Resonance Using Late Gadolinium Enhancement Imaging and T1 Mapping Predicts Poor Outcome in Patients with Atrial Fibrillation after Catheter Ablation Therapy

PURPOSE

Success rates for ablation therapy in patients with atrial fibrillation (AF) vary widely and patient selection criteria are poorly defined. We aimed to determine the pre-procedural value of cardiac magnetic resonance (CMR) and laboratory biomarkers of fibrosis for the prediction of poor response to ablation therapy.

METHOD AND MATERIALS

Left atrial (LA) late gadolinium enhancement (LGE) and LA T1 mapping were performed during pre-procedural CMR. Patients were categorized by four different fibrosis stages based on the percentage of LA wall enhancement on LGE-CMR (Utah stages I-IV). Plasma levels of relaxin and myeloperoxidase (MPO) and serum levels of MMP-mediated cardiac specific titin (TIM) and MMP-mediated collagen type IV (C4M) were obtained prior to ablation therapy. Poor outcome was defined by the reoccurrence of AF during 1-year follow-up (90 days blanking period). Univariate and multivariate cox proportional-hazards regression was used to identify significant predictors of AF recurrence.

RESULTS

A total of 61 patients were included in this prospective study (mean age: 60.3 + 12.5 years, 65.6% male). After 1-year follow-up AF reoccurred in 20 (32.8%) of all patients. Patients with a reoccurrence of AF showed a higher mean percentage of LA wall enhancement (26.7 ± 12.5 % vs. 17.0 ± 7.7 %; P<0.001), higher LA T1 relaxation times (857 ± 112 ms vs. 747 ± 91 ms; P<0.001), and higher plasma level of relaxin (0.7 ± 1.4 pg/ml vs. 0.4 ± 0.9 pg/ml; P=0.010). No significant differences were found in plasma concentrations of MPO and serum concentrations of TIM and C4M. In a multivariate analysis, poor ablation outcome was best predicted by advanced fibrosis stage (stage III and IV) (hazard ratio 5.487; P=0.001) and higher T1 relaxation times (hazard ratio 1.007; P=0.001). Plasma relaxin was not an independent predictor of poor outcome.

CONCLUSION

Pre-procedural CMR is a valuable tool for prediction of poor response to catheter ablation therapy in patients with AF. It offers various imaging techniques for outcome prediction and might be valuable for a better patient selection prior to ablation therapy.

CLINICAL RELEVANCE/APPLICATION

Pre-procedural CMR using LGE and T1 mapping might be useful for the prediction of poor response of patients with AF undergoing ablation therapy.

SSK04-07 Association between Abdominal Adiposity and Subclinical Measures of Left-Ventricular Remodeling and Diastolic Dysfunction in Diabetics, Prediabetics and Normal Controls without History of

PURPOSE

Local, abdominal fat depots may be related to alterations in cardiac function and morphology due to a metabolic linkage, which could be further accelerated in diabetic patients. Therefore we aimed to determine their association with subtle cardiac changes and the potential interaction with hyperglycemic metabolic states.

METHOD AND MATERIALS

Subjects from the general population without history of cardiovascular disease (CVD) underwent 3 Tesla cardiac and body magnetic resonance imaging. Measures of abdominal adiposity such as hepatic proton-density fat fraction (PDFFhepatic), subcutaneous (SAT) and visceral abdominal fat (VAT) as well as established cardiac LV measures including LV remodeling index (LVCI) were derived. Associations and interactions were determined using linear regression analysis based on standard deviation normalized predictors.

RESULTS

Among 374 subjects (56.2±9.1 years, 58% males), 49 subjects had diabetes, 99 subjects had prediabetes and 226 represented normal controls. Only subtle cardiac alterations were observed (e.g. LVCI: 1.13±0.30). In multivariable analysis, VAT and PDFFhepatic were independent predictors of increased LVCI (ß=0.11 and 0.06, respectively), decreased LV end-diastolic volume (ß=-6.70 and 3.23, respectively), and LV stroke volume (ß=-3.91 and -2.20, respectively). In contrast, SAT was not associated. Hyperglycemic state or HbA1c-levels did not modify the associations between VAT or PDFF and LV measures (interaction term: all p>=0.29)

CONCLUSION

Particularly VAT, but also fatty liver are independently and incrementally associated with early LV remodeling and diastolic dysfunction in a general western population without history of CVD. Although a metabolic connection is suggestive, no interaction with the diabetic status was revealed for these important associations.

CLINICAL RELEVANCE/APPLICATION

Since LV remodeling and diastolic dysfunction is a precursor of heart failure and worse outcome, imaging-based quantification of VAT or fatty liver in patients without previous CVD could improve risk stratification and thus preventive medicine to avoid complications from heart failure in a very early state.

SSK04-08 Aortic Dimensions and Subclinical Atherosclerosis in Former National Football League Athletes

PURPOSE

To evaluate whether past participation in the National Football League (NFL) is associated with increased prevalence of ascending aortic dilation and coronary artery calcium (CAC) on cardiac CT.

METHOD AND MATERIALS

This is a retrospective, cross-sectional study of 206 former National Football League (NFL) athletes compared with 759 matched male subjects from the XXX Heart Study (XHS) older than 40 years old with body mass index >= 20 kg/m2. Mid-ascending aortic dimensions were obtained from non-contrast, multidetector cardiac-gated CT scans performed as part of a screening protocol (NFL)

or as part of the XHS. CAC scores were obtained using the Agatston method. Multivariate logistic regression was performed to evaluate predictors of aortic size > 4.0 cm, CAC>0, and CAC>100 in each cohort.

RESULTS

Compared to the control group, former NFL athletes had significantly larger ascending aortic diameters (3.8±0.5 vs. 3.4±0.4 cm; p<0.0001). A significantly higher proportion of former NFL players had an aorta of >4.0 cm (29.6% versus 8.6%, p<0.0001). After adjusting for age, race, body surface area, systolic blood pressure, history of hypertension, current smoking, diabetes, and lipid profile the former NFL players still had significantly larger ascending aortas (p<0.0001). Former NFL players were twice as likely to have an aorta > 4.0 cm after adjusting for the same parameters. CAC scores were similar in both groups as was the distribution across CAC score categories (CAC=0, 1-100, and >100).

CONCLUSION

While CAC scores are similar between former NFL athletes and controls, ascending aortic dimensions are significantly larger in former NFL athletes even after accounting for their size, age and cardiac risk factors. Whether this translates to an increased risk is unknown and requires further evaluation.

CLINICAL RELEVANCE/APPLICATION

Past exposure to the hemodynamic effects of repetitive strenuous exercise among elite athletes may have lasting effects on aortic dimensions.

SSK04-09 Diagnostic Value of Cardiac Magnetic Resonance Imaging for Cardiac Mass in Children

Wednesday, Nov. 29 11:50AM - 12:00PM Room: S504AB

oyrongzhen@163,com

PURPOSE

The aim of this study is to evaluate the diagnostic value of cardiac magnetic resonance imaging(CMR) for cardiac mass in children.

METHOD AND MATERIALS

One hundred and eleven patients who were diagnosed cardiac mass by echocardiography were recommended to perform cardiac MRI from September 2006 to August 2016. Fifty patients (34 boys and 16 girls) who underwent both cardiac MRI, echocardiography and had histopathologic results or confirmed based on clinical diagnosis were enrolled in this study. Patient age ranged from 0.2 months to 183.2 months and the median age was 44.7 months (3.7y). All MRI examinations were performed on a 1.5 T clinical MRI system. A cine balanced steady-state free procession (b-SSFP) imaging, T1and T2 weighted imaging, first-pass perfusion (resting) imaging, post gadolinium T1W and late gadolinium-enhanced imaging were included in the scanning protocol. The characteristics of cardiac masses were reviewed, and the location of cardiac mass was identified. The comparison of diagnostic accuracy between echocardiography and cardiac MR using Chi-square was made.

RESULTS

Thirty-two cases(32/50) were confirmed by histopathologic results and in which twenty-three cases were correctly diagnosed by cardiac MRI, eighteen cases(18/50) were diagnosed based on clinical evidence and in which fourteen cases were correctly diagnosed by cardiac MRI. Benign tumors accounted for 86%(43/50) and malignant tumor accounted for 14%(7/50). Cardiac mass could be located in any part of heart (chamber, wall and epicardium) and most cardiac masses located in the ventricles and outflow tracts. Accurate rate of echocardiography for cardiac mass is 100% (but no characteristic diagnosis except myxoma). Accurate rate of echocardiography for mass characteristics is 6% (3/50) and accurate rate of CMR for mass characteristics is 74% (37/50). CMR provided significantly higher accuracy of pathologic diagnoses compared to echocardiography (p <0.0001).

CONCLUSION

CMR imaging is becoming a major imaging modality for assessment of cardiac mass in children and can provide the tissue characteristics and have higher accuracy for diagnosis of cardiac mass in children.

CLINICAL RELEVANCE/APPLICATION

Cardiac mass is rare in children. The imaging modalities for it mainly include echocardiography and CMR. CMR can provide accurate characteristics and is becoming a major modality for assessment.

PURPOSE

Lung ultrasound surface wave elastography (LUSWE) may be useful for assessing interstitial lung disease (ILD) as LUSWE measures superficial lung tissue properties. We investigated surface wave speed in ILD and compared results to pulmonary function and quantitative parenchymal features.

METHOD AND MATERIALS

77 subjects with connective tissue disease and 19 healthy, never-smoking volunteers had PFTs within one year of LUSWE. All controls and 54 subjects had CT within 1 year of LUSWE. LUSWE measures are performed in seated upright at full inspiration. A 0.1s vibration at 100 Hz, 150 Hz, and 200 Hz is generated using a handheld indenter, and velocity is measured with an ultrasound probe at the same intercostal space. Bilateral upper lungs were measured anteriorly, mid-lungs laterally and lower lungs posteriorly. CALIPER (computer-aided lung informatics for pathology evaluation and rating) determined percent parenchymal interstitial abnormalities in a 15mm diameter hemisphere in CT regions studied by LUSWE. Categorical data were compared by chi square and continuous data by Wilcoxon Rank Sum.

RESULTS

The cases were significantly older ($p < 0.0001$) with a higher BMI ($p = 0.05$) and no difference in sex. Cases had lower FEV1 and FVC ($p < 0.0001$). Sonographic velocities were higher in all lung regions at all frequencies for cases, however the difference was greatest in the mid-lung at the 200Hz frequency. Median velocity in m/s was 5.84 vs 4.11 and 5.96 vs. 4.27 ($p<0.00001$) for case vs. control, left and right middle lung zones, respectively (see Table 1). LUSWE in the right mid-lung negatively correlated with FVC ($R = -0.23$, 95% CI -0.42 - -0.03) and also positively correlated with CALIPER percent ILA ($R = 0.35$, 95% CI 0.12 - 0.53). Nominal logistic regression was used in univariate analysis and found that mid-lung LUSWE at 200Hz was predictive of CT-ILD with an AUC of 0.94, $p < 0.0001$. A multivariate model including age was predictive with AUC of 0.96. For a model including right mid-lung LUSWE velocity at 200Hz, right lower %ILA, FVC and age to predict CT-ILD, the AUC approached 100.

CONCLUSION

LUSWE is a safe and noninvasive technique that may be useful for assessing the presence of ILD and correlates with function and quantitative CT.

CLINICAL RELEVANCE/APPLICATION

LUSWE could potentially be used as a screening tool to detect ILD in patients at risk without use of ionizing radiation or functional

testing.

SSK05-03 Reduced Lung Elasticity in Female Patients with Interstitial Lung Disease: Histogram Analysis and Comparison with Age, Sex-Matched Normal Controls

PURPOSE

To evaluate lung elasticity at the level of vital capacity in female patient with interstitial lung disease (ILD) using a histogram analysis by image registration of paired full inspiratory and expiratory CT scans.

METHOD AND MATERIALS

A total of 16 female patients with ILD and 8 age- and sex-matched normal controls who underwent paired CT scans at full inspiration and full expiration were included. Initially, the paired segmented CT images were aligned using surface-based affine registration. Second, landmark-based registration was sequentially performed using bronchial and pulmonary vascular landmarks (31 to 34 branching points of bronchus and peripheral pulmonary vessel for each lung) which were marked manually by one radiologist using in-house software. Then, lung attenuation-based deformable registration was applied. We obtained the x-, y-, z-axis and 3D distance of movement (mm) of each pixel for image registration between inspiration and expiration CT scans. Histogram analysis of those distances was performed in each axis. Nonparametric repeated-measures ANOVA was used for comparison and Spearman's correlation coefficient was used to assess relationships between the distance of movement and visual fibrosis score and pulmonary function test (PFT) results.

RESULTS

Mean distance error was 1.72 ± 1.32 mm in whole lung. Mean 3D distance of movement was significantly lower in the patient group (27.4 mm vs. 41.8 mm; p=.017), as well as percentile values of 3D distance of movement from 10th to 95th percentile (p<.05). Standard deviation (SD) and Entropy of 3D distance of movement were also significant lower in patient group (p=.017). When analyzed for each axis, mean, SD, entropy and 20th to 95th percentile of distance of movement were significantly lower in the patient group for y-axis (p<.05). The same trend was also observed for x- and z-axis, although not statistically significant. When compared with PFT results, forced vital capacity (FVC) showed significant positive correlation (R2=.271; p=.039) with mean 3D distance of movement.

CONCLUSION

Lung elasticity was significantly decreased in terms of absolute value and heterogeneity at the level of vital capacity in ILD patients.

CLINICAL RELEVANCE/APPLICATION

Decreased lung elasticity in ILD patients can be evaluated quantitatively by full inspiratory and expiratory CT scan, and it can be a potential biomarker of ILD with future investigation.

SSK05-04 HRCT Texture Feature Selection and Imaging Pattern Prediction of IPF using Quantum Particle Swarm Optimization

PURPOSE

Idiopathic Pulmonary Fibrosis (IPF) is a fatal lung disease with a heterogeneous natural history. Some predictive clinical models have been developed but few incorporate High-resolution Computed Tomography (HRCT) information. We propose an algorithm leveraging HRCT imaging data to build a model that predicts IPF progression at an early stage.

METHOD AND MATERIALS

We collect anonymized longitudinal serial volumetric HRCT scans from patients with IPF. Radiologists visually contoured regions of interest (ROI) and annotated lung morphology types into progression or non-progression, at the previous visits before the changes occurred. Within ROIs at baseline, 71 imaging texture features were extracted from the grid sampled voxels. Quantum particle swarm optimization (QPSO) was used to select important features, coupled with a resampling technique and random forest. In QPSO algorithm, particles iteratively search the space and communicate within swarm so that important features can be found quickly. QPSO was inspired by quantum mechanics in physics and it exhibits superior searching capabilities by using an iterative probability density function. We utilize QPSO to search the feature space and build a random forest classifier based on the QPSO selected features.

RESULTS

The algorithm yields an interpretable model with 19 texture features and achieves 77.27% sensitivity, 85.15% specificity and 83.74% accuracy at ROI level on test set in predicting progression of 6 months to 1 year follow-ups. Compared to other state-of-the-art algorithms, our approach selects a smaller feature subset, has higher prediction accuracy and achieves more balanced classification.

CONCLUSION

We propose an integrated feature selection and pattern recognition algorithm powered by QPSO that achieves superior prediction performance. The algorithm is widely extensible and has great potentials on offering IPF patients timely treatments as HRCT is inherent to the diagnosis of IPF.

CLINICAL RELEVANCE/APPLICATION

Idiopathic pulmonary fibrosis exhibits a heterogeneous natural history. We build a predictive model to anticipate disease courses and help clinicians make timely decisions.

SSK05-05 Evaluating Treatment Response in Patients with Systemic Sclerosis and Diffuse Interstitial Lung Involvement: Quantitative CT as a New Outcome Measure

mariaelena.occhipinti@unifi.it

PURPOSE

To compare semi-quantitative analysis (semi-QA) and quantitative analysis (QA) in the evaluation of treatment response in patients with interstitial lung involvement in systemic sclerosis (SS).

METHOD AND MATERIALS

31 patients with interstitial lung involvement in SS underwent functional evaluation,echocardiography and chest CT scan before and after treatment with rituximab and common anti-inflammatory drugs.Two chest radiologists evaluated the CT scans in consensus for a semi-QA by applying the international Goh score at 5 lung levels.QA was performed by CALIPER,a lung texture analysis program quantifying the relative volume of Normal, Ground-glass(GG), Reticular, and Honeycombing patterns in the whole lungs.Data obtained from semi-QA and QA were compared and correlated with clinical data (Pearson correlation, intraclass correlation coefficient, t-test). Analysis of ROC curves was performed to assess the predictability of a decline in FVC>10% or DLco>15%, commonly used to define lung disease progression.

RESULTS

Most patients (23/31,74.2%) had diffuse disease.By analyzing all 62 CT scans semi-QA and QA had a good reproducibility (ICC:0.67) for GG and only weak (ICC:0.27) for Reticular.Correlations between FVC,TLC,RV,DLco,Kco and semi-QA scores were lower (r=0.3 to 0.4) than QA scores, all statistically significant with the strongest correlations for GG or GG+Reticular and FVC (both r=-0.71).A main pulmonary artery >29mm distinguished patients with higher QA scores in GG, Reticular, GG+Reticular (p<.001),while echographic PASP did not. ΔFVC had a weak correlation with ΔDLco(r=0.4).Semi-QA scores and QA scores were not accurate in predicting a decline in FVC>10%, DLco>15%,or both combined (AUC: 0.33 to 0.70,p>0.05).

CONCLUSION

ΔFVC and ΔDLco reflect different aspects of disease progression, including impairment of volumes and diffusing capacity. QA allows an objective and reproducible evaluation of both aspects contemporary, quantifying changes in lung patterns during treatment follow-up and correlating with lung function and pulmonary hypertension better than semi-QA. QA is a promising imaging biomarker in evaluating treatment response in patients with SS to add to ΔFVC and ΔDLco, likewise recently recommended in IPF.

CLINICAL RELEVANCE/APPLICATION

QA can help multidisciplinary teams in daily practice in evaluating treatment response in SS patients with interstitial involvement.QA with its reproducibility is a promising outcome measure for RCT.

SSK05-06 Diagnostic Significance of Fibrotic CT Patterns Not Addressed in Current Guidelines

PURPOSE

A small but substantial proportion of CT scans in patients with pulmonary fibrosis cannot be classified using current guidelines. The purpose of this study was to assess the diagnostic significance of these "indeterminate" cases on CT relative to pathologic findings.

METHOD AND MATERIALS

Subjects with a multidisciplinary diagnosis of IPF, interstitial pneumonia with autoimmune features (IPAF), and hypersensitivity pneumonitis (HP); pathological data from open lung biopsy; and chest CT within one year of biopsy were included in the study. Chest CT scans were analyzed by 2 chest radiologists. Cases were classified as interstitial pneumonia (UIP), possible UIP, or inconsistent with UIP on chest CT as per guidelines. Cases which could not be confidently categorized using strict adherence to current guidelines were additionally annotated as "indeterminate" for subset analysis. Lung biopsies were read by a pathologist with expertise in the diagnosis of interstitial lung diseases.

RESULTS

CT UIP patterns were as follows: UIP (102, 39.4%), possible UIP (54, 21.0%), and inconsistent with UIP (103, 25.4%); 19 (11.9%) CT scans scored as possible UIP were also annotated as "indeterminate," mostly due to diffuse distribution in the axial and/or zonal planes. UIP, possible UIP, and inconsistent with UIP CT patterns were associated with pathological UIP in 90.2%, 81.5%, and 52.4% of subjects; respectively. Those with an "indeterminate" CT pattern showed UIP on pathology in 68.4% of cases, which was not statically different compared to the inconsistent with UIP group on CT ($p=0.198$) but was different from the CT UIP group ($p=0.010$). After exclusion of these cases, the high confidence possible UIP subset showed a UIP pattern on pathology in 88.6% of subjects, which was not statistically different compared to the UIP CT group ($p=0.784$) but did differ from the inconsistent with UIP group ($p<0.001$). The difference between pathology in the "indeterminate" and high confidence possible UIP CT patterns approached statistical significance ($p=0.069$).

CONCLUSION

There are a substantial number of cases which cannot be confidently categorized using current CT guidelines in IPF. These cases are often classified as possible UIP but differ from the high confidence cases of possible UIP in regard to their pathological UIP diagnosis.

CLINICAL RELEVANCE/APPLICATION

Our data suggests that a 4th UIP CT category may be necessary for optimal diagnosis in suspected IPF.

SSK05-07 Lung Density Analysis Using Quantitative Chest CT for Early Diagnosis of Chronic Lung Allograft Dysfunction (CLAD)

Wednesday, Nov. 29 11:30AM - 11:40AM Room: S404CD

miho.horie@uhn.ca

PURPOSE

CLAD and its sub-types, bronchiolitis obliterans syndrome (BOS) and restrictive allograft syndrome (RAS) limit long-term survival following lung transplantation (LTx). Early diagnosis may allow earlier intervention to improve ultimate prognosis. The purpose of this study was to investigate the utility of quantitative CT lung density analysis in early diagnosis of CLAD.

METHOD AND MATERIALS

A retrospective study was conducted of 82 patients having routine periodic surveillance with pulmonary function tests (PFT) and low dose CT (120kV, 25mAs) following LTx. CLAD was defined as FEV1 <80% of baseline. BOS was defined as CLAD with TLC >=90% and RAS was defined as CLAD with TLC <90%. For the CT analyses, following definitions were applied: pre-onset CT when FEV1 <=90% (pre-CLAD). Control (No-CLAD) CT was defined when FEV >90% without Tx lung complications on the latest CT. CT scans were evaluated for 30 single LTx (15 CLAD: 3 RAS and 12 BOS, 15 Control) and 52 bilateral LTx (29 CLAD:12 RAS and 17 BOS, 23 Control). The contributions of low and high-density from each lung were determined from a CT histogram. Nonparametric indices were calculated; including the right tail weight (rqw) and the left tail weight (lqw) of the CT density distribution as well as the ratio: log (rqw0.875/lqw0.125). The area under the Receiver Operating Characteristic curve (AUC) and the Mann-Whitney test were used to evaluate the significance of difference in the metric; log (rqw0.875/lqw0.125) between CLAD and No-CLAD patients before CLAD onset.

RESULTS

Comparison of single LTx: CLAD and No-CLAD, the AUC was 0.80 [95% CI: 0.62- 0.93] (Figure 1a). Bilateral LTx: RAS and No-CLAD, the AUC was 0.80 [95% CI: 0.63-0.91] (Figure 1b), and BOS and No-CLAD, the AUC was 0.78 [95% CI: 0.62-0.89] (Figure 1c). There was a statistical significance between CLAD, RAS, BOS vs No-CLAD ($P < 0.05$) for both single and bilateral LTx patients.

There was no statistical significance between single and bilateral No-CLAD, tail ratio (P=0.42).

CONCLUSION

Quantitative CT parameters derived from a lung density histogram may help early diagnosis of CLAD in patients with single and bilateral lung transplantation.

CLINICAL RELEVANCE/APPLICATION

A quantitative density metric for CLAD patients might improve early detection of CLAD. It can allow earlier intervention to influence patient management and help to improve clinical outcomes.

SSK05-08 Non-Contrast Computed Tomography in Asthmatics Shows That Sarcopenia Correlates Measured In the Paraspinous Muscle on Non-Contrast CT Is Inversely Correlated With IL-6 and Asthma Exacerbations: Results from the Severe Asthma Research Program

PURPOSE

We sought to determine if a novel imaging biomarker for sarcopenia, found on non contrast CT of the paraspinous musculature, had any relationship to interluekin-6 (IL-6) and asthma exacerbation.

METHOD AND MATERIALS

:This was an IRB approved and HIPAA compliant study involving 173 patients enrolled in the Severe Asthma Research Program. There were 21 normal volunteers, 72 non-severe asthmatics, and 79 severe asthmatics (age range 2 - 72 years). Each patient's diastolic blood pressure, BMI, total cholesterol, triglyceride levels, HDL, LDL, fasting glucose, IL-6 plasma levels, asthma exacerbation frequency and steroid dosage per day were recorded. Region-of-interest Hounsfield unit (HU) measurements were obtained in liver density (LD), trabecular density at vertebrae levels T12 and L1, and paraspinal muscle density. Kruskal-Wallis and Fisher's exact test were used ($P<0.05$) to compare groups for continuous and discrete variables, respectively.

RESULTS

. For males and females combined (and individually), patients with MetS had lower liver density than those without MetS. Severe and non-severe asthmatics had lower liver HU (p-value = 0.0097), lower trabecular HU (p-value = 0.0006), and lower paraspinal muscle HU (p-value = 0.00002) when compared with normal volunteers. Females had stronger correlations between MetS, asthma severity, and liver density than males. Steroid dosage per day did not correlate with liver density or MetS. A lower LD, lower T12 and L1 BMD, and lower PSMD was found in severe asthmatics. IL6 was strongly correlated with PSMD (Spearman r= -0.62, p< 0.0001) and moderately correlated with hepatic density (Spearman r = -0.35, p < 0.03) Ashtma exacerbations trended to be more common with progressive sarcopenia.

CONCLUSION

IL=6 is strongly correlated with PSMD. The presence of MetS was inversely related to vertebral body BMD and PSMD.. The use of inhaled or oral steroids was not found to be associated with MetS or LD, as there may not be a detectable dose-effect.

CLINICAL RELEVANCE/APPLICATION

A simple imaging biomarker for sarcopenia is now available from routine non contrast CT chest exams that is negatively correlated with IL-6. This is confirmatory evidence that the progressive deposition of intramuscular fat is detrimental to normal health and promotes an underlying increase in inflammatory cytokines.

SSK05-09 Low-dose CT Using Model Based Iterative Reconstruction at Chest Radiography Dose Levels: A Pilot Study in Patients with Cystic Fibrosis Undergoing Treatment with Ivacaftor (Kalydeco)

Wednesday, Nov. 29 11:50AM - 12:00PM Room: S404CD

PURPOSE

The purpose of this prospective feasibility study was to assess the utility of a modified low-dose CT thorax protocol reconstructed with Model Based iterative reconstruction (MBIR) for the surveillance of pulmonary disease in patients with cystic fibrosis (CF).

METHOD AND MATERIALS

Following institutional review board approval, 15 patients with CF underwent routine quarterly radiological follow-up with low-dose CT thorax for 12 months with a final low-dose CT thorax at 24 months following initiation of Ivacaftor therapy. A modified 7-section, low-dose axial CT protocol reconstructed with adaptive statistical iterative reconstruction (IR) (LD-ASIR) was used for the first 12-month quarterly studies. A modified low-dose volumetric protocol reconstructed with model-based IR (LD-MBIR) was used at 24 months. The image quality of both techniques was assessed quantitatively and qualitatively by 2 experienced readers who also quantified disease severity using a validated scoring system (Bhalla score).

RESULTS

15 patients (7 female, 8 male) with a mean age of 26.5±6.1 years of age were included in the study. No significant change was observed in mean Bhalla score over the study period (p=0.51). Body mass index and pulmonary function measures increased significantly after 1 and 2-years of treatment. LD-MBIR studies were performed at a significantly lower mean effective dose (0.09±0.01mSv) than LD-ASIR studies (0.10±0.02mSv)(p=0.02). Quantitative measures of image noise and signal-to-noise ratios did not differ significantly between each low-dose protocol. Subjective image assessment of mediastinal structures was significantly worse with the LD-MBIR studies compared to the modified LD-ASIR studies however diagnostic acceptability of lung assessment was similar in both imaging techniques.

CONCLUSION

The use of MBIR with a volumetric low-dose protocol enabled the acquisition of diagnostic quality lung CT images at a dose equivalent to that of a PA and lateral chest radiograph with the added advantage of full volumetric imaging of the entire lungs

CLINICAL RELEVANCE/APPLICATION

This LD MBIR technique provides full volumetric imaging of the lungs and allows earlier and more reliable detection of bronchiectasis, mucus plugging and other subtle findings than with chest radiography at similar radiation doses and is ideally suited for follow-up of younger patients with chronic lung conditions

PURPOSE

to prospectively compare image quality of compressed-sensing (CS) accelerated 3D MR cholangiopancreatography (MRCP) to conventional navigator-triggered (NT) 3D MRCP, in patients with pancreatobiliary disorders.

METHOD AND MATERIALS

Sixty-two patients (38 men and 24 women, median age, 56 years, range, 24-84 years) underwent 3D MRCP at 3T. Three protocols were performed in each patient: a CS-accelerated breath-hold (BH) protocol based on a prototype sequence; a CS-accelerated NT protocol based on a prototype sequence, and a conventional NT protocol. Acquisition time of each protocol was recorded. Image quality of predefined segments of the pancreatobiliary tree was rated on a 5-point scale by two radiologists independently, who were blinded to the acquisition protocols.

RESULTS

Acquisition time for the CS-BH protocol was 17 seconds, for CS-NT was 134.1±33.5 seconds, both significantly shorter than the conventional NT protocol (364.7±78.4 seconds, both $p<0.01$). Severe respiratory motion artifacts was significantly reduced with the CS- BH protocol (4.8%, compared to 11.3% and 16.1% for CS-NT and conventional NT protocol, respectively), while overall image quality of the biliary tree was higher($p<0.05$, compared to both NT protocols). However, CS-BH was less efficient in depicting pancreatic ducts. Overall image quality of the pancreatic duct was better with the CS-NT protocol ($p<0.05$, compared to CS-BH and conventional NT protocols). Acceptable or better image quality (score>=3) of the entire pancreatic duct (head, body and tail) was achieved in 90.9% patients with CS-NT, 78.2% with CS-BH, and in 83.6% with conventional NT protocol.Acceptable or better image quality for the entire pancreatobiliary tree was achieved with in 95.2% patients with CS-BH +CS-NT protocol, compared to 82.3% with the conventional NT protocol.

CONCLUSION

CS-accelerated 3D MRCP is feasible in routine patients. The protocol is time-efficient and overall image quality is superior than the conventional approach.

CLINICAL RELEVANCE/APPLICATION

CS-accelerated BH and NT 3D MRCP are both feasible in clinical routine. CS-BH-MRCP is free from respiratory movement artifacts and has better image quality for the biliary tree. CS-NT-MRCP can be used to assess pancreatic ducts, when they are not

adequately depicted with CS-BH. The combined CS-BH and CS-NT protocol achieves high success rate for imaging the entire pancreaticobiliary tree, while the acquisition time is still reduced.

SSK06-03 Evaluation of HCC Response to Locoregional Therapy: Validation of MRI-Based Response Criteria Against Explant Pathology

PURPOSE

To evaluate the performance of various magnetic resonance imaging (MRI) response criteria for the prediction of complete pathologic necrosis (CPN) of hepatocellular carcinoma (HCC) post locoregional therapy (LRT) using explant pathology as reference.

METHOD AND MATERIALS

We included 61 patients (M/F 46/15, mean age 60y) who underwent liver transplantation after LRT with transarterial chemoembolization plus radiofrequency or microwave ablation (n=56), or 90Yttrium radioembolization (n=5). MRI was performed within 90 days of liver transplantation. Three independent readers assessed the following criteria: RECIST, EASL, mRECIST, percentage of necrosis on subtraction images, and diffusion-weighted imaging (DWI) [qualitative (signal intensity) and quantitative (apparent diffusion coefficient, ADC)]. Degree of necrosis was retrospectively assessed at histopathology. Intraclass correlation coefficient (ICC) and Cohen's kappa were used to assess inter-reader agreement. Logistic regression and ROC analyses were used to determine imaging predictors of CPN. Pearson correlation was performed between imaging criteria and pathologic degree of tumor necrosis.

RESULTS

97 HCCs (mean size 2.3±1.3 cm) including 28 with CPN were evaluated. There was excellent inter-reader agreement (ICC 0.77-0.86, all methods). EASL, mRECIST, percentage of necrosis and qualitative DWI were all significant ($p<0.001$) predictors of CPN, while RECIST and ADC were not. EASL, mRECIST and percentage of necrosis performed similarly (AUCs 0.810-0.815) while the performance of qualitative DWI was lower (AUC 0.622). Image subtraction demonstrated the strongest correlation ($r=0.71-0.72$, $p<0.0001$) with pathologic degree of tumor necrosis.

CONCLUSION

EASL/mRECIST criteria and image subtraction have excellent diagnostic performance for predicting CPN in HCC treated with LRT, with image subtraction correlating best with pathologic degree of tumor necrosis. Thus, MR image subtraction is recommended for assessing HCC response to LRT.

CLINICAL RELEVANCE/APPLICATION

Image subtraction is recommended for assessing HCC response to LRT when performing MRI. RECIST and ADC should not be used for prediction of CPN.

SSK06-04 Clinical Feasibility of Implementing DCE-MRI in Routine Liver MRI Using Golden-Angle Radial Sparse Parallel MRI: Preliminary Results

Wednesday, Nov. 29 11:00AM - 11:10AM Room: E350

Participants

Jeong Min Lee, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Grant, Bayer AG; Grant, General Electric Company; Grant, Koninklijke Philips NV; Grant, STARmed Co, Ltd; Grant, RF Medical Co, Ltd; Grant, Samsung Electronics Co, Ltd; Grant, Guerbet SA; Robert Grimm, Erlangen, Germany (*Abstract Co-Author*) Employee, Siemens AG
Berthold Kiefer, PhD, Erlangen, Germany (*Abstract Co-Author*) Employee, Siemens AG
Kai Tobias Block, PhD, New York, NY (*Abstract Co-Author*) Royalties, Siemens AG
Hersh Chandarana, MD, New York, NY (*Abstract Co-Author*) Equipment support, Siemens AG; Software support, Siemens AG; Advisory Board, Siemens AG;

PURPOSE

To investigate clinical feasibility of implementing dynamic contrast enhanced magnetic resonance imaging (DCE-MRI) in routine liver MRI using Golden-angle Radial Sparse Parallel (GRASP) MRI.

METHOD AND MATERIALS

In this IRB-approved ongoing prospective study, 25 patients who were scheduled for liver biopsy or resection have been enrolled and informed consent was obtained from all patients. Liver MRI was performed using incoherent undersampling technique at 3T. A standard dose of extracellular contrast media was injected, and T1-weighted images (T1WI) were obtained using incoherent undersampling technique in free-breathing. Images were reconstructed to achieve either 13.3- or 3.3-second time resolution. On 13.3-second time resolution T1WI with respiratory gating, motion and overall image quality were assessed on four-point scale by two radiologists in consensus, and 3.3-second time resolution T1WI was analyzed using software of dual-input single compartment

model.

RESULTS

In 25 patients, motion artifact was 1.5±0.5, 2.1±0.3, 1.0±0.3 and 1.0±0.0 on pre, arterial, portal venous and delayed phase which indicated no significant motion artifact. Overall image quality was 3.9±0.6, 3.5±0.5, 3.9±0.3, and 3.8±0.4, respectively. In all patients, perfusion analysis was done successfully. After excluding one patient who was treated with chemoembolization, patients with advanced fibrosis (n=7, >=F2) showed substantially high arterial fraction (67.0±17.1%) than patients with no or early fibrosis (n=18, F0-1) who had arterial fraction of 44.7±27.6% (P<0.05).

CONCLUSION

GRASP technique allowed implementation of DCE in routine liver MRI by obtaining high time-resolution and sufficient spatial resolution.

CLINICAL RELEVANCE/APPLICATION

Implementation of DCE-MRI in routine MRI would facilitate its application for various organs and contribute to non-invasive diagnosis and monitoring by displaying hemodynamic information of lesions.

SSK06-05 An Experimental Study on the Assessment of Renal Fibrosis by Using Magnetic Resonance T1rho Imaging

Wednesday, Nov. 29 11:10AM - 11:20AM Room: E350

hugenwen@163.com

PURPOSE

To correlate magnetic resonance (MR) T1 relaxation time in the rotating frame (T1rho or T1ρ) with degree of renal fibrosis in a rat model of unilateral ureteral obstruction (UUO).

METHOD AND MATERIALS

This study was approved by the institutional animal care and use committee. UUO was created in each of 36 rats. UUO-A group with 6 rats, longitudinal T1rho value was performed before the UUO (day 0) and on days 1, 3, 5, 10, and 15 after the UUO and was followed by histopathologic analysis (one rat died on 11 days after the UUO). Six rats from UUO-B group (n = 30) were examined at each of five time points on days 0, 1, 3, 5 and 10 after the UUO. Four rats from Sham group (n = 12) were examined on days 1, 5, and 15 after UUO. Hematoxylin-eosin, Masson trichrome staining and a-smooth muscle actin (a-SMA) were performed. T1rho Sequences with Stretched adiabatic as Spin lock pulse type. Spin lock time: 1, 27, 54 ms,with 3.0T clinical MR scanner.

RESULTS

Histopathologic examination revealed typical renal fibrosis on the side with UUO. The T1rho values increased over time on the UUO side, Mean T1rho value with day 0, 1, 3, 5, 10, and 15 after the UUO were 142.23±8.69, 149.53 ±9.38, 172.53 ±13.53, 181.05 ±17.34, 216.31 ±22.64, 228.47 ±26.95ms, respectively. Sham rats were 140.28 ±7.19, 137.74 ±9.38, 138.89 ±17.76 ms, respectively. Mean T1rho value associated positively ($r = 0.868$ $P < 0.001$) with a-SMA expression level.

CONCLUSION

Our study shows that the degree of renal fibrosis was correlated with degree of increase with T1rho value in model induced by UUO.

CLINICAL RELEVANCE/APPLICATION

MR-T1rho may become a noninvasive imaging tool for the diagnosis of renal fibrosis.

SSK06-06 Histologic Characteristics of Hepatocellular Carcinoma with Irregular Rim-Like Arterial Phase Enhancement

Wednesday, Nov. 29 11:20AM - 11:30AM Room: E350

Participants
Hyungjin Rhee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Chansik An, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Hye-Young Kim, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

Young Nyun Park, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Myeong-Jin Kim, MD, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To examine the histopathologic characteristics of hepatocellular carcinoma (HCC) with irregular rim-like arterial phase enhancement, which has been reported to be associated with more aggressive tumor behavior.

METHOD AND MATERIALS

Institutional review board approved this retrospective study and waived the informed consent. Our subjects were 84 pathologically

confirmed HCCs in 84 patients who underwent curative hepatic resection after gadoxetate-enhanced magnetic resonance (MR) imaging between January 2008 and February 2013. Two abdominal radiologists independently reviewed the MR images and classified HCCs into two categories: HCC showing irregular rim-like arterial enhancement (IRE-HCC) or HCC showing hypovascularity or diffuse arterial enhancement (non-IRE-HCC). We assessed and compared their clinical and pathologic characteristics, using a representative whole-section slide of each case. Differences in disease-free survival were analyzed using the Kaplan-Meier method with the log-rank test. The chi-square, Fisher exact test, or Mann-Whitney test was used to compare the variables.

RESULTS

Of the 84 HCCs, 22 and 51 were classified as IRE-HCCs and non-IRE-HCCs by both reviewers, respectively. Classification was discordant in the remaining 11 patients. IRE-HCC showed, compared to non-IRE-HCC, poorer five-year disease-free survival after curative resection (33.6% vs. 60.3%; P = .030), more frequent microvascular invasion (91% vs. 35%). IRE-HCCs were also associated with lower microvascular density (227 vs. 437 per mm2), more frequent sinusoidal microvascular pattern (55% vs. 0%), larger necrotic area (15% vs. 0%), and larger stromal area (8.3% vs. 2.2%), suggesting more hypoxic and fibrotic microenvironment, and exhibited higher expression of immunomarkers of hypoxia (CAIX, 64% vs. 8%) and stemness (K19 protein, 27% vs. 6%). P-values were < .001 for all comparisons except for K19 (P = .018). Discordant tumors showed intermediate features between IRE-HCC and non-IRE-HCC.

CONCLUSION

Irregular rim-like arterial enhancement of HCC is associated with hypoxic and fibrotic tumor microenvironment which are related with hypoxia and stemness marker expression and poor prognosis.

CLINICAL RELEVANCE/APPLICATION

IRE-HCCs may be associated with worse clinical outcome and histopathologic features related to aggressive biologic behavior, compared to non-IRE-HCCs.

SSK06-07 Impacts of Adding Recent CT Arterial Phase Images On Diagnostic Performances of Gadoxetic Acid-Enhanced MRI in Assessment of HCC

sykim.radiology@gmail.com

PURPOSE

To investigate impacts of adding recent CT arterial phase findings on diagnostic performances of gadoxetic acid-enhanced MRI in the assessment of hepatocellular carcinoma (HCC)

METHOD AND MATERIALS

We retrospectively identified 1272 patients (1026 men, 246 women; mean age, 56.6 years) with pathologically confirmed 1490 nodules (1370 HCCs, 60 dysplastic nodules, 39 combined HCC and cholangiocarcinomas, 13 cholangiocarcinomas, 8 nodules with other pathologies) between January 2008 and December 2016 with the following inclusion criteria: patients with chronic hepatitis or liver cirrhosis who had pathologically confirmed focal hepatic lesions; who underwent both multiphase CT and gadoxetic acid-enhanced MR I within 120 days before the pathologic exams; and the size of lesions <= 3 cm. We compared the enhancement patterns on arterial phase imaging between the two imaging modalities. The sensitivity and 95% confidence interval (C.I.) for detecting arterial hyperenhancement in patients with HCCs on a per-nodule basis was compared between the MRI only analyses and the CT+MRI analyses using generalized estimated equations based on a binary logistic regression model to account for data clustering and dependency, as some patients had more than one nodules.

RESULTS

The mean time interval between MRI and CT was 16.5 days. Among the 1490 nodules, 1361 nodules (91.3 %) had the same arterial enhancement patterns both on CT and MRI. In the remaining 129 nodules (105 HCCs and seven non-HCC lesions) with the different enhancement patterns between CT and MRI, arterial hyperenhancement was detected only by CT in the majority of cases (86.8%, 112/129). The sensitivity in detecting arterial hyperenhancement in HCC was significantly improved in the CT+MRI analyses (92.4 %; 95% C.I., 90.9 to 93.7) compared to the MRI only analyses (84.7 %; 95% C.I., 82.2 to 87.0) (P<0.001).

CONCLUSION

Adding recent CT arterial phase findings can improve the detection of arterial hyperenhancement of gadoxetic acid-enhanced MRI in the evaluation of HCC.

CLINICAL RELEVANCE/APPLICATION

Arterial phase findings on recent CT images can serve a substitute for suboptimal arterial phase MR images on gadoxetic acid-enhanced MRI in the assessment of HCC.

SSK06-08 A Prospective and Long-Term Follow-Up Study of Non-Hypervascular Hypointense Nodules on the Hepatobiliary Phase of Gadoxetic Acid-Enhanced MRI

PURPOSE

To investigate the incidence of non-hypervascular hypointense nodules on the hepatobiliary phase (HBP) of gadoxetic acid-enhanced MRI and to identify the incidence of arterial hypervascular transformation and associated features in a prospective cohort with a long-term follow-up

METHOD AND MATERIALS

A prospective surveillance study included 407 cirrhosis patients at high risk for HCC who underwent one to three, biannual screening examinations with gadoxetic acid-enhanced MRI between November 2011 and August 2014. Among them, 40 patients were identified to have 63 hypovascular hypointense nodules on HBP of gadoxetic acid-enhanced MRI. Follow-up contrast-enhanced MRI and CT were reviewed to identify hypervascular transformation (median follow-up period, 45 months). Univariate and multivariable Cox proportional hazards model with robust standard errors for clustered data were used to investigate the association between arterial hypervascular transformation and clinical and imaging features with respect to nodule size, signal intensity on T1-, T2-, diffusion-weighted, portal and delayed phase images, and intratumoral fat.

RESULTS

The incidence of non-hypervascular hypointense nodules on HBP in the prospective cohort was 9.8 % (40/407). On follow-up images, the 1-, 3-, and 5-year cumulative incidences of hypervascular transformation were 6.4, 12.8, and 24.3 %, respectively. Univariate analyses revealed the size >= 1cm and hyperintensity on T1-weighted images as significant risk factors for hypervascular transformation. According to the multivariable analysis, the size >= 1cm was independently associated with hypervascularization with a hazard ratio HR of 12.6 (P=.02). The 5 year-cumulative incidence of nodules >= 1cm in size (52.5%) was more than 10 folds compared to that of nodules smaller thant 1cm (4.4%).

CONCLUSION

Our study demonstrates the incidence of non-hypervascular hypointense nodules on HBP and hypervascular transformation in a prospective cohort. Non-hypervascular hypointense nodules >= 1cm in size are strongly associated with hypervascular transformation.

CLINICAL RELEVANCE/APPLICATION

Non-hypervascular hypointense nodules on HBP >= 1cm in size should be cautiously followed up with their culmulative incidence of hypervascular transformation in mind.

SSK06-09 High-Precision Computed Diffusion Weighted Images for the Diagnosis of Hepatocellular Carcinoma

Wednesday, Nov. 29 11:50AM - 12:00PM Room: E350

PURPOSE

Diffusion-weighted images (DWI) obtained with higher b-values yield better contrast between tumor and background normal tissue. Computed DWI (c-DWI) can calculate high b-value images from DWI obtained at lower b-values. However, the image quality of c-DWI may be degraded due to mis-registration between image acquisitions with different b-values. We developed high-precision c-DWI (hc-DWI) in which mis-registration was reduced by applying non-rigid registration technique to real DWI (r-DWI) with different b values. We tested our hypothesis that hc-DWI can improve image quality in diagnosing hepatocellular carcinoma (HCC) compared to conventional c-DWI (cc-DWI).

METHOD AND MATERIALS

In 75 patients with HCCs we acquired r-DWIs with b-value at 150, 600, and 1000 s/mm2. We defined the r-DWI acquired with b = 1000 s/mm2 as standard. C-DWIs with b-value at 1500 s/mm2 were calculated with DWIs at b-values of 150 and 600 s/mm2. For generating hc-DWI we used a non-rigid image registration for avoiding mis-registration of two different b-value images and an image filter to remove abnormal values from the apparent diffusion coefficient map.Two radiologists evaluated the image quality of each DWI by consensus reading using a 3-point scale where 1 = poor (non-diagnostic), 2 = fair (diagnostic but blurred margin), 3 = good (good quality and sharp margin). They also evaluated the signal intensity of HCC using a 3-point score where 1 = not visible, 2 = discernible, and 3 = clearly visible and calculated the contrast ratio (CR) between HCC and the surrounding liver parenchyma.

RESULTS

Image quality was better with hc-DWI compared to cc-DWI ($p < 0.01$). The visual score of HCC was also better with hc-DWI compared to cc-DWI ($p < 0.01$). In addition, the CR for HCC was significantly higher in hc-DWI compared to cc-DWI (mean value: 2.6 and 2.1 for hc-DWI and cc-DWI, $p < 0.01$).

CONCLUSION

Image quality, subjective visual score, and CR of HCC was higher in hc-DWI compared to cc-DWI.

CLINICAL RELEVANCE/APPLICATION

Hc-DWI may be useful for characterization of HCC compared to cc-DWI.

PURPOSE

Assessment of KRAS mutation status is essential for prognosis assessment and for guiding treatment decisions in patients with metastatic colon cancer. This study investigates the association between quantitative tumor MRI features and KRAS mutation status in this patient population.

METHOD AND MATERIALS

In this IRB-approved retrospective study, we identified 52 patients with stage 4 colon cancer with hepatic metastases reported on abdominal MRI studies performed from 2007-2013. KRAS mutation status was ascertained from the medical record. The largest hepatic lesion was identified on the portal venous phase T1-weighted fat-suppressed post-contrast images and manually segmented. MR radiomic feature vectors were extracted from each lesion using quantitative morphological and texture analysis. Univariate logistic regression analysis was used to assess for independent contribution of 18 extracted morphological features and 32 extracted texture features to mutation status prediction. A linear support vector machine (SVM) machine learning technique was applied to the extracted imaging phenotype vector to predict tumor mutation status. The classifier was trained and tested using 10-fold cross validation to avoid overfitting. ROC analysis and the area under the curve (AUC) were used to assess classification performance.

RESULTS

60% (19/31) of patients had tumors with KRAS mutations. Tumor circularity and tumor coarseness exhibited significant differences in mean values between KRAS-wildtype and KRAS-mutated tumors ($p<0.001$ and $p=0.01$, respectively). Univariate regression revealed six features independently association with KRAS mutation status: tumor circularity ($p=0.003$), solidity ($p=0.006$), eccentricity ($p=0.03$), coarseness ($p=0.03$), shade ($p=0.01$), and GLCM matrix standard deviation ($p=0.04$). A trained SVM model that included the tumor morphologic and texture features resulted in an area under the ROC curve of 0.95.

CONCLUSION

Quantitative tumor MRI features exhibit significant association with KRAS mutation and may contribute to predicting KRAS status in colon cancer patients.

CLINICAL RELEVANCE/APPLICATION

Tumor MRI radiomic analysis may aid in non-invasively assessing tumor genetic status and may aid in informing treatment choices and personalizing therapeutic decisions in patients with colon cancer.

SSK07-03 A Deep Neural Network for Liver Volumetry in Contrast Enhanced MRI

PURPOSE

To establish a fully automated, reliable, and novel liver volumetry in contrast enhanced MRI based on deep learning algorithms.

METHOD AND MATERIALS

Data-sets of Gd-EOB-DTPA-enhanced liver MR images of 48 participants were assembled, consisting of 44 training and 4 validation cases. All imaging was performed using a clinical whole-body 3-T system (Magnetom Skyra, Siemens Healthcare). For segmentation, a T1-weighted volume-interpolated breath-hold examination (VIBE) sequences with fat suppression covering the entire liver, acquired during one breath-hold during the hepatobiliary phase (20 min after contrastinjection), was used.The current gold standard of manual liver segmentation was accepted as ground truth. Image Segmentation was performed by a resident physician with 5 years of experience in hepatobiliary imaging. Furthermore, 9 of the training images have been segmented by a second reader (5 years of experience) to determine the expert intraclass correlation coecient (ICC), dice index, and overlap. The neural network topology is loosely based on U-Net.

CONCLUSION

This study presents a fully automated liver volumetry scheme in MR imaging. It is evaluated in comparison to the gold standard manual volumetry. The neural network achieves a higher concordance with the ground truth than two expert readers agree in terms of ICC, dice index, and overlap. The results are highly competitive to current studies, in example Huynh et al. found an ICC of 0.94.

CLINICAL RELEVANCE/APPLICATION

This scheme provides an accurate automatic liver segmentation in MRI; hence it would serve as a useful tool for radiologists for treatment planning, especially for patients undergoing liver surgery.

SSK07-04 The Value of Texture Analysis on Perfusion-Weighted Magnetic Resonance Imaging for Malignancy Characterization of Hepatocellular Carcinoma

Wednesday, Nov. 29 11:00AM - 11:10AM Room: E353A

Participants
Jie Chen, Chengdu, China (*Presenter*) Nothing to Disclose
Ting Duan, Chengdu, China (*Abstract Co-Author*) Nothing to Disclose
Xin Li, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose
Bin Song, MD, Chengdu, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To explore the performance of texture analysis on perfusion-weighted magnetic resonance imaging (PW-MRI) in evaluating the malignancy of hepatocellular carcinoma (HCC).

METHOD AND MATERIALS

Thirty-one surgically confirmed HCC patients were prospectively included and examined using a 3.0 Tesla MR scanner. The perfusion data was acquired using a prototype radial stack-of-stars three-dimensional spoiled gradient echo pulse sequence with golden-angle radial sampling schemes over the course of 6.25 minutes. Post-processing of PW-MRI data was performed on an in-housed software (Omini-Kinetics, GE Healthcare) to generate the Ktrans, Kep, Ve and AUC parametric maps using the Extended Tofts liner model. Texture analysis was then performed on those parametric maps using the same software. A total of 75 texture features were calculated for each perfusion results. The Edmondson-Steiner classification of HCC were histopathologically determined. Texture parameters were correlated with the Edmondson-Steiner grade of HCC. Receiver operation characteristic (ROC) analysis of discriminating low-grades (grade 1 and 2) from high-grades (grade 3 and 4) HCC was conducted for identified texture parameters.

RESULTS

The MinIntensity of Ktrans (r=-0.433, P=0.015), Kep (r=-0.409, P=0.022) and Ve (r=-0.384, P=0.033) maps, and the MinIntensity (r=-0.451, P=0.011), skewness (r=0.623, P<0.001), kurtosis (r=0.412, P=0.021) and uniformity (r=-0.55, P=0.001) of AUC maps showed week to moderate correlations with the Edmondson-Steiner grades of HCC. The skewness and kurtosis of AUC were significantly lower in low-grades HCC than in high-grades HCC, while the uniformity of AUC were significantly higher in low-grades HCC than in high-grades HCC. The areas under the ROC curve for the skewness, kurtosis and uniformity of AUC in differentiating high-grades from los-grades HCC were 0.868, 0.789 and 0.719, respectively.

CONCLUSION

Texture features based on PW-MRI, in particular the skewness of AUC, offer a potential avenue toward preoperative evaluation of HCC malignancy.

CLINICAL RELEVANCE/APPLICATION

Texture features of perfusion imaging can reflect the intratumoral heterogeneity of blood supply and cellular density, thereby

Texture features of perfusion imaging can reflect the intratumoral heterogeneity of blood supply and cellular density, thereby providing a reliable marker of lesion's potential malignancy.

SSK07-05 Hepatocellular Carcinoma: Texture Analysis of Preoperative CT Images as a Potential Marker of Disease-Free Survival

Joon Koo Han, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To investigate the performance of CT textural analysis (CTTA) in characterizing malignancy of hepatocellular carcinoma and predicting disease-free survival (DFS).

METHOD AND MATERIALS

Institutional review board approved this retrospective study, with a waiver of informed consent. From January 2009 to January 2015, 81 patients with single HCC underwent preoperative contrast-enhanced CT with same protocol and vender. Texture features of the largest tumor cross-sectional area from portal phase liver CT images were assessed by using TexRAD software which employed a filtration-histogram technique. Mean value of positive pixels (MPP), entropy, kurtosis, skewness, and standard deviation (SD) of the pixel distribution histogram were derived from the images without filtration and with filter values corresponding to fine, medium, and coarse texture scale. The texture features were compared between groups with different histologic grade using Student's t-test and Mann-Whitney test. Kaplan-Meier analysis was performed to determine the relationship between CTTA and DFS. The Cox proportional hazards model was used to assess the independence of texture parameters from other known clinical and imaging parameters.

RESULTS

SD and MPP quantified from fine to coarse texture on CT images showed significant associations with the histologic grade ($P<.05$). Univariate analysis identified most CT texture features across the different filters - fine, medium and coarse texture scales were significant univariate markers of DFS. Also a number of known clinical and imaging parameters such as tumor size, vascular invasion, the average intensity of tumor, the level of AFP and PIVKA were significant univariate markers of DFS. A Cox regression model including all significant univariate markers identified that CTTA (fine texture scale - kurtosis: $p=0.037$, skewness: $p=0.015$), and tumor size ($P<0.001$) were independent predictors of DFS.

CONCLUSION

CTTA could act as a prognostic biomarker in HCCs and play a key complementary role as an adjunct with other known clinical and imaging markers in better risk stratification of these patients.

CLINICAL RELEVANCE/APPLICATION

CTTA is a significant marker of disease-free survival in patients with HCCs. Their role as a prognostic biomarker can be a useful adjunct to improve stratification of HCC patients.

SSK07-06 HCC Treated With 90Yttrium Radioembolization: Can Pre-Treatment and 6week Post-Treatment Volumetric ADC Histogram Measurements Predict Subsequent Tumor Response?

Bachir Taouli, MD, New York, NY (*Abstract Co-Author*) Consultant, MEDIAN Technologies ; Grant, Guerbet SA

PURPOSE

To assess the potential of volumetric ADC (vADC) histogram measurements obtained before and 6 weeks (6w) post-treatment for prediction of hepatocellular carcinoma (HCC) response to 90Yttrium radioembolization (RE).

METHOD AND MATERIALS

22 patients (M/F 15/7, mean age 65y) who underwent lobar RE (right lobe n=15; left lobe n=7) were included. All patients underwent MRI pre-treatment and 6w and 6 months (6m) after RE using a routine liver MRI protocol including DWI. Two readers assessed tumor response 6m after RE in consensus. Definition of complete tumor response, partial tumor response, stable disease, and progression of HCC lesions was based on modified RECIST criteria (mRECIST) for each index tumor. vADC histogram parameters (mean, median, mode, min, max, kurtosis and skewness) were obtained by placing regions of interest (ROIs) on the ADC map covering the whole index tumors. One reader placed the ROIs at baseline and 6w after treatment. Changes in tumor vADC (ΔvADC) histogram parameters were calculated. Data was evaluated using Mann-Whitney U test and receiver operating characteristics

analysis.

RESULTS

26 HCC lesions (mean size 3.4±2.4 cm) were assessed (18 patients with 1 tumor, 4 patients with 2 tumors). Response at 6m was as follows: complete response (CR, 8 tumors), partial response (PR, 3 tumors), stable disease (SD, 13 tumors) and progression (PD, 2 tumors). vADC mean, median, mode (1.76-1.81 vs. 1.23-1.34 x10-3 mm2/s) and ΔvADC median and ΔvADC max (30-43% vs. 2-9%) at 6w were significantly higher in CR/PR vs. SD/PD (p=0.013-0.032), while there was no significant difference at baseline. vADC mean, median, ΔvADC mean and ΔvADC max at 6w were significant predictors of CR/PR (AUC 0.752-0.788; p=0.014-0.031) and of CR (AUC 0.750-0.861; p=0.004-0.046) after RE. vADC median threshold of 1.377 x10-3 mm2/s at 6w had a sensitivity of 81.8% and a specificity of 66.7% for prediction of PR/CR and ΔvADC median threshold of 19.2% had a sensitivity of 87.5% and a specificity of 83.3% for prediction of CR.

CONCLUSION

vADC mean, median, ΔvADC mean and ΔvADC max at 6w are significant predictors of subsequent response in HCCs treated with RE, while pre-treatment vADC did not have any predictive value.

CLINICAL RELEVANCE/APPLICATION

Our results suggest that vADC histogram measurements at 6w post RE are early biomarkers and allow prediction of treatment response.

SSK07-07 Development of CT Derived Biomarker for Gastrointestinal Stromal Tumor; Comparison with FDG-PET and DWI

PURPOSE

Gastrointestinal stromal tumor (GIST) is the most common mesenchymal tumor of the gastrointestinal tract. It has been reported that 18F-Fluorodeoxyglucose-positron emission tomography (FDG-PET) and diffusion-weighted MRI (DWI) can be biomarkers to evaluate malignant potential of GIST. But considering availability of FDG-PET and DWI, development of CT derived biomarker would be valuable. The texture analysis such as fractal analysis of the medical image has been reported to be a potential biomarker for malignancies, reflecting structural heterogeneity of the tumor. The purpose of this study is to evaluate the usefulness of CT fractal analysis in preoperative assessment of malignant potential of GIST, comparing with FDG-PET and DWI.

METHOD AND MATERIALS

We retrospectively identified 43 patients (20 M / 23W; median age: 65) with GISTs who received FDG-PET, DWI, and contrast-enhanced (CE) CT before surgery. Tumor SUV and ADC were measured from FDG-PET and DWI. Regarding CT analysis, fractal analysis was applied to portal-phase CE-CT image with use of a plugin software of ImageJ (NIH), and fractal dimension (FD) of the tumor was measured. These tumor parameters were compared with the risk classification of GIST, and diagnostic values of these parameters for malignant potential of GIST were evaluated.

RESULTS

According to modified Fletcher classification, 9 patients were categorized as the high risk, and the other 34 cases were categorized as the very low or low risk (26) or the intermediate risk (8). Tumor FD of high risk group was significantly higher than that of the other risk groups (very low, low, and intermediate risk) ($P<0.05$). The areas under the ROC curves (AUCs) of tumor FD, ADC and SUV for prediction of high risk group were 0.84, 0.86 and 0.82, respectively. From this ROC curve analysis, 1.11(FD), 1.21(ADC), and 4.16(SUV) were the best cut-off value to predict the high risk GIST patients with a highest accuracy (85.7%, 71.4% and 83.3%, respectively).

CONCLUSION

Diagnostic value of CT fractal analysis for prediction of high risk GIST is comparable with FDG-PET and DWI. In terms of cost and availability, CT fractal analysis can be a most beneficial imaging biomarker for the management of GIST.

CLINICAL RELEVANCE/APPLICATION

CT fractal analysis can be a noninvasive, economical and widely applicable biomarker for preoperative risk stratification of GIST, and it would help select an optimal therapy for patients with GISTs.

SSK07-08 CT-Based Radiomic Signature Preoperatively Predicts Lymphovascular Invasion in Patients with Advanced Gastric Cancer

PURPOSE

To develop and validate a machine learning based radiomics signature for preoperative prediction of lymph vascular invasion (LVI) in patients with advanced gastric cancer (AGC).

METHOD AND MATERIALS

In this ethical-approved retrospective study, we collected a primary cohort consisting of 152 patients gathered from July 2011 to December 2013 and a time-independent validation cohort consisting of 95 patients from January 2014 to July 2015. 273 texture features were extracted from venous-phase CT of AGC. Then, we adopted minimum redundancy maximum relevance (mRMR) algorithm to reduce the feature dimension as well as identify a radiomics signature for predicting LVI. We built a support vector machine (SVM) model to yield a quantitative risk score for LVI. The classification performance of the SVM model was evaluated by univariate analysis, multivariate analysis and receiver operator characteristics (ROC) analysis in the primary cohort and validated in the time-independent validation cohort.

RESULTS

The 5-feature-based radiomics signature was an independent predictor for LVI in AGC ($P<0.001$ for both primary and validation cohorts). The radiomics signature showed strong discriminatory power for LVI prediction with an AUC of 0.764 (95% CI: 0.685-0.843; sensitivity: 0.844; specificity: 0.618) in the primary cohort. In addition, the radiomcs analysis achieved competitive generalization performance with an AUC of 0.744 (95% CI: 0.640-0.848; sensitivity: 0.818; specificity: 0.600) in validation cohort.

CONCLUSION

Machine learning by means of SVM in combination with texture features can be used to associate with the status of LVI. The radiomics signature may serve as a potential non-invasive tool for the preoperative LVI prediction in patients with AGC.

CLINICAL RELEVANCE/APPLICATION

Machine learning based radiomics signature has potential in the preoperative non-invasive prediction of lymphvascular invasion and facilitate the clinical strategy.

SSK07-09 Comparison of Current Response Criteria in Patients with HCC Treat with Targeted Therapy Using a 3D Quantitative Analysis

PURPOSE

The aim of this study was to compare existing available non-three-dimensional methods (Response Evaluation Criteria in Solid Tumors [RECIST], modified RECIST [mRECIST], European Association for Study of the Liver [EASL]) with three-dimensional (3D) quantitative methods of the index tumor as early response markers in predicting patient survival after targeted therapy.

METHOD AND MATERIALS

This study was a retrospective single-institution HIPAA-compliant. A total of 88 patients with hepatocellualr carcinoma (HCC) treated with targeted therapy was enrolled (in 76 men and 12 women; mean age, 61 years ± 7 [standard deviation] ; Range, 22-88 years). CT scans before and after targeted therapy were analyzed. Six response assessment methods (RECIST, mRECIST, EASL and 3D methods of volumetric RECIST [vRECIST], modified vRECIST [vmRECIST] and quantitative EASL [qEASL]) were used to classify all patients as responders or nonresponders by following standard guidelines for the uni- and bidimensional measurements and by using the formula for a sphere for the 3D measurements. 3D quantitative tumor assessments were performed using an in-house software prototype (3D Quantitative Imaging, MGH, USA).The Kaplan-Meier method with the log-rank test was performed for each method to evaluate its ability to help predict survival of responders and nonresponders. Uni- and multivariate Cox proportional hazard ratio models were used to identify covariates that had significant association with survival.

RESULTS

The 3D quantitative tumor assessments of vRECIST (hazard ratio,0.6; 95% confidence interval [CI]: 0.4, 1.2; P=0.03), vmRECIST (hazard ratio,0.6; 95% CI: 0.3, 0.9; P=0.04), and qEASL (hazard ratio,0.5; 95% CI: 0.3, 0.6; P=0.002) showed a significant difference in survival between responders and nonresponders groups, whereas the uni- and bidementional measurements of RECIST (hazard ratio,0.5; 95% CI: 0.3, 0.9; P=0.08), mRECIST (hazard ratio,0.6; 95% CI: 0.3, 1.0; P=0.07), and EASL(hazard ratio,0.7; 95% CI: 0.3, 0.8; P=0.06) did not show a significant difference between these groups.

CONCLUSION

Compared with the uni- and bidemensional measurements, the 3D-based imaging biomarkers vRECIST, vmRECIST and qEASL could

be used to predict patient survival early after targeted therapy.

CLINICAL RELEVANCE/APPLICATION

Volumetric quantification is sensitive to detect early change of HCC and to accurately assess treatment response.

SSK08

Gastrointestinal (Colon Cancer and CT Colonography)

PURPOSE

In a large randomized trial the overall adenoma detection rate appeared to be similar between CTC and sigmoidoscopy (FS). CTC achieved a higher detection than FS in the proximal colon, while the reverse was true for the distal colon. To assess the relationship between radiologist experience and adenoma detection rate at CTC screening.

METHOD AND MATERIALS

Post-hoc analysis of a RCT, examining the diagnostic performance of radiologists in relation with previous CTC experience. Radiologist experience was classified according to the total number of CTC performed before the trial (i.e, <200, 200-1,000, >1,000). Multilevel logistic regression was used to model the influence of reading volumes and patient characteristics on the probability to detect adenomas. Patient factors included gender, previous CRC screening, CRC family risk, and image/distension quality. Analyses were performed separately for each of the following lesions: all adenomas (ADR), distal adenomas (DADR), proximal adenomas (PADR), advanced histology (i.e. >=10-mm, villous histology or high grade dysplasia). A 6-mm cut-off was used for post-CTC referral to colonoscopy.

RESULTS

2593 CTC (1266 F; age, 58-60) were read by 7 radiologists. In detail, 1337 (51.5%), 584 (22.5%), and 672 (26.0%) were read by radiologists with reading volumes<200, 200-1000, and >1000, respectively. The average ADR, DADR and PADR were 8.0% (95% CI: 7.0-9.1%; range, 5.8-8.7%), 5.0% (95% CI:4.3-5.9%, range, 2.1-8.4%), and 5.1% (95% CI:4.2-6.3, range, 4.4-5.4%), respectively. Radiologist experience appeared to be related with DADR (OR, >1000 vs <=1000:1.49; 95% CI: 1.04-2.13), but not with PADR (OR,>1000 vs. <=1000:0.91; 95% CI:0.64-1.29). The association of radiologist experience with distal location appeared to be statistically significant also for advanced adenomas (OR,>1000 vs. <=1000, 1.73; 95% CI:1.08-2.88). In multivariate analysis, volumes>1000, male gender, excellent/good image quality and no previous colonoscopy were significantly associated with greater odds of detecting distal adenomas.

CONCLUSION

According to our data, distal adenomas, including those with advanced histology, could be missed by less experienced radiologists (<1000 CTC).

CLINICAL RELEVANCE/APPLICATION

High reading volumes, greater than 1000 CTCs, may be required to achieve high adenoma detection rates in the distal colon. Optimization of training methods is critical to ensure a consistent high-quality level at CTC screening.

SSK08-02 Effect of Iterative Model Reconstruction algorithm on Radiologist's Performance in CT Colonography

Wednesday, Nov. 29 10:40AM - 10:50AM Room: E353B

Participants

Yanbang Lian, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To assess radiation dose and image quality of CT colonography (CTC) at 100 kVp with iterative model reconstruction algorithm (IMR) at 20 mAs compared with filtered back projection (FBP) at 50 mAs.

METHOD AND MATERIALS

Thirty-two patients suspected with colon adenomatous polyp or adeno-carcinoma were enrolled in this study. All of patients underwent CTC examination at 50mAs in supine position and 20mAs with prone position with the same tube voltage at 100 kVp about two hours before fibro-colonoscope. Images were reconstructed using FBP and IMR. Two radiologists independently evaluated image quality. Qualitative image quality was assessed with a five-score scale. Image noise, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and effective radiation dose were recorded and calculated. Qualitative and quatitative values were analysed by using Wilcoxon signed rank test and the paired t test, respectively.

RESULTS

Totally 38 colon polyps or adeno-carcinoma were detected in fibro-colonoscope examination. For 20 mAs with IMR (A group) and 50 mAs with FBP (B group), there is no statistically significant difference in lesion detection (reader 1: 35/38 vs 36/38, and reader 2: 31/38 vs. 33/38, p>0.05). However, qualitative image quality scores (3.9 vs 2.5), image noise ([12.77± 0.91] HU vs. [50.04±5.45] HU), SNRs (3.13±0.28 vs. 1.02±0.20) and CNRs (81.42±6.11 vs. 19.93±1.46) were significantly superior of 20 mAs with IMR, respectively (p<0.05) . Compared with B group, radiation dose of A group decreased significantly (0.42±0.03 mSv vs. 1.07±0.12mSv).

CONCLUSION

Image quality of CTC using 20 mAs with IMR reconstruction could be comparable to 50 mAs with FBP at the same tube voltage while with no significant detection of poply, and radiation dose of the former was only 0.42 mSv, which was reduced by about 39.3%.

CLINICAL RELEVANCE/APPLICATION

This preliminary study helps to reduce the radiation dose of patients undergoing CTC examination with IMR algorithm.

SSK08-03 Feasibility of Computer-Aided CT Colonography in a Single-Position Reading

Wednesday, Nov. 29 10:50AM - 11:00AM Room: E353B

For information about this presentation, contact:

yoshida.hiro@mgh.harvard.edu

PURPOSE

To evaluate the performance of computer-aided single-position reading of full-cathartic CT colonography (CTC) in detecting polyps from patients at average or high risk of colorectal cancer.

METHOD AND MATERIALS

A total of 266 CTC cases were sampled from a multi-center CTC trial for patients at average or high risk of colorectal cancer. The patients underwent cathartic bowel preparation with 2L polyethylene glycol solution and fecal tagging by 20mL sodium diatrizoate, followed by automated CO2 insufflation. A computer-aided detection (CADe) system trained with cases independent from this study was used to review the CTC cases. Two experienced readers (>=600 CTC cases reading experience) reviewed the cases for >=6 mm lesions in supine-only reading mode, in which only the supine scans of these cases were interpreted and CADe was used as a second reader. The per-patient sensitivity and area under the receiver operating characteristic curve (AUC) were compared in the detection of adenomas and carcinomas between the unaided and CADe-aided supine-only readings, and between the CADe-aided supine-only reading and the conventional unaided dual-position reading result of the original trial.

RESULTS

There were 35 and 28 patients with 6-9 mm and >=10 mm adenomas/carcinomas, respectively. The corresponding average per-patient sensitivities (AUCs) for CADe-aided supine-only reading were 82.9% (0.89) and 90.9% (0.95), respectively, whereas those of unaided dual-position reading were 82.9% (0.88) and 92.9% (0.96), respectively. The differences of sensitivities and AUCs at each size range were not statistically significant (sensitivities: Fisher's exact test, P>0.7; AUCs: two-sided t-test, P>0.3). For 6-9 mm lesions, the per-patient sensitivity (AUC) of CADe-aided supine-only reading was 82.9% (0.89), higher than that of unaided supine-only reading of 71.4% (0.85) (sensitivity: McNemar's test, P<0.01; AUC: one-sided t-test, P<0.05).

CONCLUSION

In full-cathartic CTC, CADe-aided single-position reading yields an equally high performance in detecting adenomas and carcinomas as that of conventional supine-prone reading. In single-position reading, the use of CADe significantly improves the detection of polyps 6-9 mm in size.

CLINICAL RELEVANCE/APPLICATION

Computer-aided single-position reading has potential to allow one-position scanning in CTC, thereby effectively halving the radiation

Computer-aided single-position reading has potential to allow one-position scanning in CTC, thereby effectively halving the radiation dose and reading time of conventional dual-position reading.

SSK08-04 Dual-Energy CT Colonography Using Dual-Layer Spectral Detector Computed Tomography: Feasibility of Virtual Monochromatic Imaging for Electronic Cleansing

Wednesday, Nov. 29 11:00AM - 11:10AM Room: E353B

PURPOSE

We investigated the utility of virtual monochromatic imaging (VMI) using dual-layer spectral detector CT on the electronic cleansing in fecal-tagging CT colonography.

METHOD AND MATERIALS

This study included 30 patients who underwent fecal-tagging CT colonography performed on a novel dual-layer detector spectral CT scanner. Conventional 120-kVp images and VMI at 40-, 50-, and 60-keV were reconstructed. Quantitative image quality parameters, i.e. CT attenuation of tagged fluid and image noise, were compared and the visual image quality was scored on a four-point scale. We recorded the number of the colon segments with appropriate CT attenuation of tagged fluid (>= 300 HU) for each patient and used these data to compare the reconstructions. The performance of the electronic cleansing was also assessed semi-quantitatively using a four-point scale.

RESULTS

The mean CT attenuation of tagged fluid was significantly higher on VMI than conventional 120-kVp images. There was no significant difference in image noise among the reconstructions. The number of colon segments with appropriate CT attenuation of tagged fluid was significantly higher on VMI than conventional 120 kVp images. Significant higher score of the subjective image quality and the performance of the electronic cleansing were observed on VMI than conventional 120 kVp images.

CONCLUSION

With dual-layer spectral detector CT, the use of VMI can yield significantly better image quality of fecal-tagging CT colonography and improve the performance of the electronic cleansing.

CLINICAL RELEVANCE/APPLICATION

VMI using dual-layer spectral detector CT can improve image quality of fecal-tagging CT colonography and provide more accurate diagnostic information.

SSK08-05 Inter-Observer Agreement Using a Coding System for Reporting Virtual Colonoscopy

Wednesday, Nov. 29 11:10AM - 11:20AM Room: E353B

Participants
Stephen Sammut, MBChB, Stoke-on-Trent, United Kingdom (*Presenter*) Nothing to Disclose
Vincent Leung, MBCHB, Stoke-on-Trent, United Kingdom (*Abstract Co-Author*) Nothing to Disclose
Nicola J. Cook, MBChB, Stoke-on-Trent, United Kingdom (*Abstract Co-Author*) Nothing to Disclose
Paul Clarke, Stoke-on-Trent, United Kingdom (*Abstract Co-Author*) Nothing to Disclose
Ingrid Britton, MBBS, FRCR, Stoke On Trent, United Kingdom (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

A coding system is utilised at our UK institution for reporting virtual colonoscopy/CT colonography (CTC) examinations. The C coding refers to the intra-colonic findings, whereas the E coding refers to extra-colonic findings, both on a scale from 1 to 5. The purpose of this study was to validate the coding system by assessing the inter-observer variability of two independent readers using the same coding system to summarise the CTC findings.

METHOD AND MATERIALS

A retrospective study was performed of all CTCs in our University Teaching Hospitals NHS Trust in the UK, which performs the largest number of examinations at any single institution throughout Europe, over a 3 month period (01/07/16 - 30/09/16). Our standard practice is for each study to be read initially by an advanced practitioner radiographer with a final report issued by a consultant radiologist. The report coding issued by the different readers was analysed and compared.

RESULTS

626 CTCs (mean age 69 years) were selected for inclusion. 57 studies were excluded either as they were not coded, not read by a radiographer prior to consultant report or rated as an inadequate study by either reader. The percentage agreement between radiographer findings and radiologist report was 92.3% for C coding and 50.6% for E coding. Interobserver agreement Kappa statistic was calculated to be 0.77 (95% CI 0.703-0.830) for C coding and 0.27 (95% CI 0.206-0.324) for E coding.

CONCLUSION

There is high inter-observer agreement between medical and non-medical readers for C coding suggesting it is a precise and easy to follow method of classifying colonic findings. The greater variability for E coding may be due to difficulty in classifying extra-

colonic findings but also reflective of the skill set between the two types of readers.

CLINICAL RELEVANCE/APPLICATION

The use of a report scoring system highlights important CTC findings so that the clinical teams can expedite arrangement of the appropriate further management and if necessary multi-disciplinary team discussion. The study shows that our scoring system is easy to use and demonstrates high inter-observer agreement for the intr-colonic findings, which is required for the system to be valid.

SSK08-06 Assessment of the Neoadjuvant Chemoradiation Outcomes in Patients with Clinical T1/T2 Rectal Cancer Using the MRI Tumor Regression Grade

Wednesday, Nov. 29 11:20AM - 11:30AM Room: E353B

Participants
Heejin Bae, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Joonseok Lim, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To analyze magnetic resonance imaging (MRI) tumor regression grade (mrTRG) for predicting the outcomes after the neoadjuvant chemoradiation in patients with clinical T1/T2 rectal cancer.

METHOD AND MATERIALS

Between 2012 and 2016, we retrospectively registered 39 patients with clinical T1/T2 rectal cancer who had undertaken either the total mesorectal excision (TME) or local excision after the neoadjuvant chemoradiation. Initial rectal MRI was analyzed to determine the mural involvement of the primary tumor (partial or transmural involvement) and both initial and post-treatment rectal MRI were reviwed for mrTRG. Surgical pathologic assessment including Mandard grade was used to evaluate the tumor regression after the neoadjuvant treatment and Mandard grade 1 was considered as pathologic complete response (pCR). Associations of mrTRG and the degree of mural involvement with Mandard grade and pathologic T stage (pT) were analyzed.

RESULTS

Out of 39 patients, 20 patients had mrTRG 1 and 19 patients had mrTRG 2-4 (mrTRG2=11, mrTRG3=6, mrTRG4=2). Sixty-five percent (13/20) of mrTRG 1 patients showed pCR, and this positive predictive value of mrTRG 1 was higher than observed pCR rate (18/39, 46.2%). The odds of accomplishing pCR were 5.2 times higher for mrTRG 1 than they were for mrTRG 2-4 (95% confidence interval (CI): 1.3 - 20.5, p=0.019). Univariate analysis of the degree of mural involvement indicated that the difference in probability of pCR did not reach the significance (odds ratio (OR)=1.1, 95% CI=0.3-3.9, p=0.882). Ninety percent (18/20) of mrTRG 1 patients had early stage cancer (pT0, pTis and pT1) after the preoperative chemoradiation. Univariate analysis demonstrated that mrTRG1 group was significantly more likely to have early stage cancer than was mrTRG2-4 group (OR=8.1, 95% CI=1.5-45.1, p=0.017), while the OR of partial involvement of the primary tumor was not statistically significant (OR=3.6, 95% CI=0.8-16.3, p=0.103).

CONCLUSION

mrTRG 1 can be used as a supportive factor to predict the complete response after the neoadjuvant chemoradiation in patients with clinical T1/T2 rectal cancer. Moreover, mrTRG seem to deduce pathologic early stage rectal cancer which can be the candidate for local excision rather than TME.

CLINICAL RELEVANCE/APPLICATION

mrTRG can be a supportive tool to predict the complete response and to identify pathologic early stage cancer after the neoadjuvant chemoradiation in clinical T1/T2 rectal cancer patients.

SSK08-07 Influence of Iterative Reconstruction and Slice Thickness on Texture Analysis

Wednesday, Nov. 29 11:30AM - 11:40AM Room: E353B

mathilde.wagner@aphp.fr

PURPOSE

To assess the variability of texture analysis parameters on CT scans depending on the iterative reconstruction technique and the slice thickness.

METHOD AND MATERIALS

To date, ten patients (M/F=4/6, mean age 71 yo) with liver metastases were retrospectively included in this study (1 patient with a GIST, 1 patient with a pancreatic cancer, 8 patients with a colorectal cancer). All patients had a CT-scan at a portal venous phase after injection of Iomeron 350, using a Philips system (ICT256). The standard reconstruction parameters included an iDose4 reconstruction with a 2 mm-slice thickness. Four additional reconstructions were performed: iDose4 with 1 and 5 mm-slice thickness, and iDose2 and 6 with a 2 mm-slice thickness. Using LIFEx software v3.0, a region of interest (ROI) was drawn by one radiologist, on one of the reconstruction. The ROI contained the largest diameter of the liver metastases (max 5 lesions /patient, lesion diameter > 1cm). The ROI was copied and pasted on the images from other reconstructions. Mean, standard deviation, skewness, kurtosis and entropy of each ROI were obtained. Variability between iterative reconstructions and slice thicknesses was

assessed using coefficient of variation (CV), and Bland and Altman limits of agreement (BALA) (percentage of difference).

RESULTS

Forty-eight liver metastases were analyzed. Between iterative reconstructions, all the parameters, except skewness, had a good reproducibility (CV<8%). The mean was the less variable parameter with a CV<1% and BALA thinner than [-4.38%;2.36%], while skewness was the less reproducible parameter with a CV of 25.5% and BALA until [-135.3%;48.18%]. For all texture parameters, the variability was higher between slice thicknesses than between iterative reconstructions, but still acceptable for all parameters (CV<18%) except for skewness. Skewness had a very low reproducibility between slice thicknesses with a CV of 954% and BALA until [-846.5%;1103%].

CONCLUSION

Texture parameters, mostly skewness, show some variability depending on the iterative reconstruction and moreover on the slice thickness.

CLINICAL RELEVANCE/APPLICATION

Texture analysis is a more and more used method, especially for tumor follow-up and assessment of treatment response. Variability related to the CT acquisition parameters needs to be taken into account to avoid incorrect conclusion.

SSK08-08 Changes in the Diagnostic Accuracy of Radiologists and Residents for Rectal Cancer Staging by using Diffusion Weighted Imaging

PURPOSE

To analyze the influence of Diffusion Weighted Imaging (DWI) on the diagnostic accuracy for the staging of Rectal Cancer (RC), regional lymph nodes (LN) and primary tumor (T) in Radiologists with different degree of expertize

METHOD AND MATERIALS

The study included 50 patients with Magnetic Resonance Imaging (MRI) for RC staging, all with same technique (1.5 T) and later total mesorectal excision. Initial diagnosis (32) and post-neoadyuvancy cases (28, MRI after treatment) were included (ID and PN respectively). The histological stage was used as Gold Standard. 10 Radiologist reviewed individually all cases, blinded to any data but the presence of RC: 3 experienced in RC staging (ER); 3 experienced in other areas (NER); and 4 Residents (RR). Each reading had 2 phases: 1st analyzing just T2 and T2 High Definition sequences (T2HD); after a month washout period, 2nd reading with DWI and T2HD. The staging followed AJCC 7th ed. guidelines. Malignant LN were defined as heterogeneous internal signal/irregular borders. The results were pooled by experience groups for statistical analysis. Area under ROC curves were used to determine accuracy of positive LN, stage greater than I and T greater tan 2. Also, ponderated Kappa with respect to the histological results. All calculations were made in the different reviews and then made again after spliting them into ID and PN patients groups.

RESULTS

Due to their length the results have been summarized in the attached charts. Differences after use of DWI (increase/decrease) in group accuracy and Kappa regarding Gold Standard are shown.

CONCLUSION

There is a significant decrease of accuracy for local and N staging in all Radiologists with the use of DWI (also present in Kappas), more uniform in the experienced ones but for local stage in PN cases. Residents' accuracy for N highly increase in ID cases, while decreasing in PN. This could be due to a better detection of the LN, but with difficult interpretation of the changes secondary to treatment. On the contrary, all Radiologists show an increase in accuracy for T stage with DWI in ID cases (also PN in experienced ones), while decreasing in the rest. This could be due to a decrease in the overstaging of desmoplastic reaction or fibrosis in PN, with difficult interpretation of the latter for unexperienced ones.

CLINICAL RELEVANCE/APPLICATION

DWI could be functioning as a confounding factor in RC, especially in N and global staging.

SSK08-09 Role of CT-Colonography for Detection and Characterization of Synchronous Proximal Colonic Lesions in Patients with Stenosing Colorectal Cancer

PURPOSE

To evaluate the clinical usefulness of CT Colonography (CTC) immediately after incomplete Optical Colonoscopy (OC) for occlusive colorectal cáncer (CCR), in the detection of synchronous carcinomas and advanced adenomas and their impact in the management of patients.

METHOD AND MATERIALS

Posterior to incomplete OC,165 patients (mean age of 71 years) with occlusive colonic carcinoma underwent subsequent CTC. 135 patients had distal CRC and 29 proximal. Experienced radiologists prospectively analyzed the presence of syncronous carcinomas and colorectal polys. 164 patients underwent colorectal resection. We retrospectively analyzed the surgical outcome and the follow-up of patients.

RESULTS

Seventeen syncronous tumors were detected in 11 patients (6,6%). Eight in the proximal and nine in distal colon. Eigth patients had only one synchronous tumor and three patients had several tumors (2, 3 and 4 synchronous carcinomas, respectively). Nineteen polypoid lesions > 2 cm were detected in 10 patients, seventeen were tubulo-villous adenomas with high-grade displasia and two were tubulo-villous adenomas with low-grade displasia. Twenty one patient (12.72%) had pediculated and sesil polyps in the remainig colorectum not explored in the OC, that required OC and exeresis between 1 and 6 months after surgery. After CTC, surgeons modified initial surgical plan in 22 patients (13,3%) and the follow-up in 25 patients (15,15%). 13 patients with obstructive cancer couldnt be correctly assesed, 8 because of defficient colonic distension and 5 due to great amount of feces. Gross lesions were discharged, nevertheless we recommended vigilance during surgical procedure and posterior.

CONCLUSION

Detection of all synchronous CRC and adenomatous polys, before surgery is very important, as the number and location of tumors may affect the surgical procedure and the subsequent management of patients. In our series, CTC changed surgical management and surveillance in 47 patients (28,45%). CTC is a technically robust and the most practical method to evaluate the colon proximal to an occlusive cancer, even in patients with metallic stent placement in acute neoplastic colonic obstruction.

CLINICAL RELEVANCE/APPLICATION

This exhibit exposes the use of CT-Colonography to evaluate all the colon in obstructing colorectal cancers with incomplete Optical Colonoscopy and their ability to detect synchronous cancers and advanced adenomas.

PURPOSE

The development and validation of multi-parametric MRI (mp-MRI) for prostate cancer (CaP) diagnosis relies on comparisons with histopathology (HP) and accurate spatial alignment is critical. In this study, we develop and evaluate a new system that combines patient-specific molds and ex vivo MRI of the resected prostate to align in vivo (InV) MRI, ex vivo (ExV) MRI, and whole-mount (WM) HP in CaP patients.

METHOD AND MATERIALS

Patients who underwent radical prostatectomy were studied. InV-MRI was obtained prior to surgery (mean = 77 days) at 3 T (Trio/Verio/Skyra/Prisma, Siemens) using an external array and an endorectal coil. The protocol included 3D T2w MRI, on which the prostate was contoured in 3D to print a patient-specific mold before surgery. Within 30 min after surgery, the fresh whole prostate specimen was placed in a patient-specific mold and underwent ExV-MRI at 3 T (Prisma, Siemens) using a knee coil. The protocol included high-resolution T2w MRI to evaluate spatial alignment with in vivo 3D T2w MRI and WM slides. Immediately afterwards, the prostate was sectioned in the mold along slits (4.5-mm steps) to create WM slides. InV-MRI was registered to ExV-MRI using a mutual information based rigid 3D algorithm. A non-rigid algorithm was used to register WM slides to ExV and InV MRI. A radiologist matched 2D slice locations and annotated corresponding non-cancerous landmarks on all three image sets. The WM to ExV-MRI slice offset error was recorded. In the matched slices, 2D target registration error (TRE) between the landmarks was calculated.

RESULTS

In all patients (N=10, mean 64.7 years, mean PSA 6.17 ng/ml), ExV-MRI was successfully completed (mean time 116 min). The mold and ExV-MRI had no adverse impact on WM HP. The mean slice offset error was 1.36 mm (<1.5-mm MRI slice thickness). Mean 2D TRE was (mean±SD): 1.9±1.1 mm for InV vs. ExV MRI, 1.6±0.9 mm for WM vs. ExV MRI, and 2.1±1.4 mm for WM vs. InV MRI.

CONCLUSION

We have successfully integrated the new system with our clinical workflow to achieve excellent spatial alignment among InV-MRI, ExV-MRI, and WM slides with 2D TRE of 1-2 mm. This can enable MRI-WM comparisons and integrated research in CaP.

CLINICAL RELEVANCE/APPLICATION

The new system achieves excellent spatial alignment among in vivo MRI, ex vivo MRI, and whole-mount histopathology for integrated research in prostate cancer.

SSK09-02 An Objective Tool for Diagnosing Prostate Cancer and Benign Prostatic Hyperplasia: Radiomics Features Extracted from Diffusion-Weighted Imaging

Wednesday, Nov. 29 10:40AM - 10:50AM Room: E450B

Participants
Chen Lihua, Dalian, China (*Presenter*) Nothing to Disclose
Ailian Liu, MD, Dalian, China (*Abstract Co-Author*) Nothing to Disclose
Yan Guo, Shenyang, China (*Abstract Co-Author*) Nothing to Disclose
Xin Li, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose
Dan Guo, Dalian, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the usefulness of radiomics features indistinguishing prostate cancer (PCa) from benign prostatic hyperplasia (BPH) based on diffusion-weighted imaging (DWI) sequence without subjective factors.

METHOD AND MATERIALS

This retrospective study was approved by local IRB, and written informed consent was waived. 200patientswere enrolled followed by surgery or biopsy within one month in this study(100 were PCa and 100 were BPH)High-throughput extraction and analysis of the radiomics features based on DWI included five procedures: 1) 2D region of interest (ROI) was sketched along the edge of the whole prostate at the slice with the maximum diameter of the lesion by a 3-year experienced radiologist.2) 396 radiomics features, including size and shape based-features, histogram, GLCM as well as GLRLM texture features were automatically generated from A.K.(Analysis-Kinetics, GE Healthcare). 3) Feature reduction was conducted based on Kruskal-Wallis test and auto-correlation analysis with $|r|>0.9$ using R.4)90 PCa and 90 BPH selected randomly in 200 patients were used for supervise Model-learning using Logistic Regression. 5)10 PCa and 10 BPH were used and compared with pathologic diagnosis and receiver operating characteristics (ROC) were used to assess the efficiency of model.

RESULTS

K-W test showed that 233 radiomic parameters had significant difference between PCa and BPH groups, auto-correlationanalysis reduced them into 47 potential predictors which used for diagnostic model building. The area under the curve (AUC) of Logisticregression model in discriminating the two groups was 0.894, sensitivity and specificity were respectively 92.2% and 86.7%, with 85% diagnosis accuracy rate.

CONCLUSION

Radiomics features of DWI performed well indistinguishing PCa from BPH, which could help objectively and quantitatively evaluate tumor heterogeneity, and have prospect of being an independent &non-invasive efficient diagnostictool.

CLINICAL RELEVANCE/APPLICATION

Compared with traditional manual method, Radiomics features not only could lighten the visual fatigue for radiologist but also raise the precision of diagnosis.

SSK09-03 Diagnosing Prostate Cancer through Non-Invasive Estimation of Prostate Tissue Composition Using Hybrid Multidimensional MRI

aritrick@uchicago.edu

PURPOSE

This study proposes to use Hybrid Multidimensional MRI (HM-MRI) to measures the change in ADC and T2 as a function of TE and *b*-value, respectively. This interdependence is used as a source of information about the underlying tissue microstructure. Specifically, we analyzed HM-MRI data to identify signal contribution from epithelial, stromal and luminal compartments in each image voxel. We evaluated whether this compartmental analysis can distinguish prostate cancer (PCa) from normal tissue.

METHOD AND MATERIALS

Patients (n=21) with confirmed PCa underwent preoperative 3T MRI. Axial images using HM-MRI were acquired with TE = 47, 75, 100 ms and *b*-values of 0, 750, 1500 s/mm2, resulting in a 3×3 array of data associated with each voxel. Volumes of tissue components- stroma, epithelium and lumen were calculated by fitting the hybrid data to a three compartment signal model, with distinct ADC and T2 associated with each compartment. Volume fractions, and conventional ADC and T2 were measured for ROIs on sites of prostatectomy verified malignancy (n=28) and normal tissue (n=71). ROC analysis was used to evaluate the performance of various parameters in differentiating PCa from benign tissue.

RESULTS

HM-MRI data from PCa showed significantly increased fractional volumes of epithelium (48.8±9.2 vs 23.2±7.1%) and reduced lumen (14.0±5.2 vs 26.4±14.1%), stroma (37.2±9.1 vs 50.5±15.7%), ADC (0.86±0.18 vs 1.30±0.23μm2/ms) and T2 (76.3±22.9 vs

104.2±47.1ms) as compared to normal tissue. These trends and values measured by HM-MRI are similar to those reported in previous histological studies. The volume fractions of epithelium (0.65), stroma (-0.44) and lumen (-0.39) show significantly higher Spearman correlation coefficient with Gleason score as compared to T2 (-0.29) and ADC (-0.32). Area under the ROC curve was highest for epithelium (0.99), followed by lumen (0.80), stroma (0.79) and T2 (0.71).

CONCLUSION

Fractional volumes of prostatic lumen, stroma, and epithelium change significantly when cancer is present. These parameters can be measured non-invasively using HM-MRI and these novel quantitative parameters have the potential to improve PCa diagnosis and determine the aggressiveness of PCa.

CLINICAL RELEVANCE/APPLICATION

Prostate tissue composition estimated non-invasively using HM-MRI has better diagnostic accuracy of detecting PCa compared to conventional T2 and ADC values.

PURPOSE

The purpose of our study was to retrospectively evaluate and categorize temporal changes in MRI appearances of the prostate in patients who underwent focal therapy with MRI follow up.

METHOD AND MATERIALS

The Institutional Review Board approved this retrospective study and waived the requirement for informed consent. Forty-two patients (median age 61; 48-76 years) with low-to-intermediate-risk, clinically organ-confined prostate cancer underwent focal ablation therapy from 2009 through 2014. Two radiologists reviewed post-treatment MRIs (n=88) and categorized imaging features blinded to the time interval between the focal therapy and the follow-up MRI. Inter-reader agreement was assessed (kappa) and generalized linear regression was used to examine associations between imaging feature being present/absent and days between ablation and MRI.

RESULTS

Inter-reader agreement on MRI features ranged from fair to substantial. The presence of edema on MRI was found at the shortest median time interval after ablation (15-22d; $p<0.001$), followed by rim enhancement of the ablation zone (18-23d), a hypointense rim around the ablation zone on T2-weighted images (49-54d) and the presence of an appreciable ablation cavity (49-55d; all $p<0.05$). The formation of a T2-hypointense scar (446-461d) and enhancement of the ablation zone/scar (216-610d) were found to be present on later MRI scans for one reader.

CONCLUSION

The MRI appearance of the prostate after focal ablation changes substantially over time. Identification of temporal patterns in the appearance of imaging features should help radiologists distinguish normal MRI findings from possible recurrence and reduce image interpretation variability and errors when assessing post-therapeutic scans.

CLINICAL RELEVANCE/APPLICATION

The identification of distinct imaging features on prostate MRI after ablation with distinct temporal patterns allows for a more consistent language among radiologists and could reduce variability and errors when assessing post-therapeutic scans.

SSK09-05 Multiplexed Sensitivity-Encoding (MUSE) Reconstructed Multi-Shot Diffusion Weighted Imaging in Patients with Prostate Cancer: Preliminary Study on Image Quality and Apparent Diffusion Coefficient

PURPOSE

Multiplexed Sensitivity-Encoding (MUSE) is a new reconstruction algorithm for multi-shot diffusion weighted image (msDWI) without using navigator echo to correct motion-induced phase error. The purpose of this study was to prospectively evaluate the image quality and apparent diffusion coefficient (ADC) of high-spatial resolution msDWI reconstructed with MUSE in patients suspected with prostate cancer.

METHOD AND MATERIALS

Fifteen consecutive patients clinically suspected with prostatic cancer (median 72 years old, range 55 - 80) underwent 3-T MR imaging using T2 weighted image, single-shot DWI (ssDWI; matrix, 96 x 96) and MUSE-reconstructed msDWI (matrix, 192 x 192) acquired with 4-shot interleaved echo-planar imaging. Both DWI were acquired with FOV of 22 cm, thickness of 4 mm, and b-value of 50 and 800 mm2/s. ADC maps were constructed for both DWI. Two radiologists blindly and independently assessed the image quality of DWI (b = 50, 800) and ADC map by comparing ssDWI and msDWI on image noise, anatomic delineation, distortion, artifact, and overall image quality with a 5-point scale. ADC values were measured in transitional and peripheral zone (TZ and PZ). Wilcoxon rank-sum test, kappa coefficient and paired t test was used to compare the score, inter-observer concordances and ADC value.

RESULTS

The scores of anatomic delineation of msDWI (b = 50, 800) and msADC map were significantly better than a single-shot image, and the scores of image noise were significantly worse for multi-shot image by 2 radiologists ($p < .05$, respectively). The score of overall image quality of msDWI (b = 50) was significantly better than ssDWI by 2 radiologists ($p = .001$, for both), but there were no significant differences for DWI (b = 800) and ADC map. Distortion and artifact were not significantly different between msDWI and ssDWI. The inter-observer concordances were poor to good (k = .074 - .770). ADC values of msDWI and ssDWI were not significantly different for TZ and PZ ($p = 0.47$ and 0.70).

CONCLUSION

The msDWI reconstructed with MUSE and its ADC map significantly improved anatomical delineation of the prostate, although the technique increased image noise. ADC values were not significantly different between ssDWI and msDWI.

CLINICAL RELEVANCE/APPLICATION

Evaluation of the prostate can be improved with high-spatial resolution msDWI reconstructed with MUSE, which is a promising technique for the detection and diagnosis of prostate cancer.

SSK09-06 Radiomics on Contrast-Free Bi-Parametric MRI Achieves Improves Prediction of Significant Prostate Cancer Compared to Clinical PI-RADS Version 2 Interpretation

PURPOSE

To apply radiomics and machine learning (ML) to PI-RADS version 2 lesions and assess whether radiomics alone or the addition of radiomics improves predictive performance.

METHOD AND MATERIALS

In 194 consecutive patients examined on a 3T MRI system 253 PIRADSv2 lesions were identified and manually segmented on ADC/b-value of 1500 s/mm2 and T2-weighted images (segP). Patient were subsequently undergoing MRI-TRUS fusion biopsy with median 23 systematic cores and 4 targeted cores per lesion. In addition, on the basis of the biopsy results, retrospective PI-RADS assessment (PIRADSv2R) and manual lesions segmentation of the MR index lesion was performed manually by an experienced radiologist (segR). A total of 1073 quantitative radiomics features [including first-order, volume shape features, and texture features] were automatically extracted. The prediction of clinically significant Cancer (csPC) (GS 3+4 and 4+3 or higher) by PIRADSv2 assessment was compared to different ML approaches to integrate radiomics data (random forest, parameter normalization, training on segP/segR). Performance was assessed using bootstrap. The number of biopsies spared was assessed on a lesion and patient level.

RESULTS

A cut-off >=3 for PIRADSv2 was used. Radiomics Models were evaluated at the PIRADSv2 sensitivity, which was 96-97% in all cases. On a per-lesion basis PIRADSv2 achieved a specificity of 20% compared to 39% for the best ML model (RF trained using segR at PIRADSv2R cut-off of 4 including normalization, for GS4+3 prediction), which would have saved 42.3 biopsies. On a per-patient basis the model increased specificity from 23% to 37% which would have saved 23 patients a biopsy. Excluding the transitional zone, specificity increased from 41% to 52% for lesions, saving 11.2 biopsies and from 48% to 59% for patients saving

14.2 biopsies for GS3+4 prediction. Figure 1 demonstrates improved performance of the best ML model over PI-RADSv2, especially in the important high sensitivity range.

CONCLUSION

Radiomics and ML improve predictive performance compared to PI-RADS version 2 when applied to clinically selected lesions. The potential of radiomics to support clinical decision making is shown. Our results motivate the evaluation of this approach in larger and prospective cohorts.

CLINICAL RELEVANCE/APPLICATION

The potential application of the addition of radiomics to the clinical evaluation of PI-RADS lesions should be evaluated in a prospective setting.

SSK09-07 Towards Improved Gleason Score Prediction Using 18F-FACBC (Fluciclovine) PET and MRI: Evaluation of Advanced Post-Processing Methods Using Machine Learning

Wednesday, Nov. 29 11:30AM - 11:40AM Room: E450B

Awards
Trainee Research Prize - Resident

Heikki R. Minn, MD, PhD, Turku, Finland (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the potential of advanced post-processing methods for 18F-FACBC (Fluciclovine) PET and MRI in the characterization of prostate cancer.

METHOD AND MATERIALS

Twenty one patients with histologically confirmed prostate cancer (PCa) scheduled for robotic-assisted prostatectomy underwent PET/CT immediately after injection of 369 ±10 MBq 18F-FACBC followed by PET/MRI (ClinicalTrials.gov Identifier: NCT02002455). MRI of PET/MRI consisted of T2-weighted imaging (T2w), two separate diffusion weighted imaging (DWI) acquisitions, second order rotating frame (RAFF) imaging, and T2 mapping. A separate 3T mpMRI consisting of T2w, three DWI acquisitions, proton magnetic resonance spectroscopy (1H-MRS) and dynamic contrast enhanced (DCE) imaging was acquired within a week of the PET scans. DWI was post-processed using kurtosis (ADCk, K), mono- (ADCm), and biexponential functions (f, Dp, Df) while Logan plots were used to calculate volume of distribution (VT). Logistic Regression with l2 normalization and leave-pair out cross validation (LPOCV) based area under the curve (AUC) values were used to estimate the potential of the quantitative parameters and their combination to predict Gleason score group (3+3 vs >3+3). Recursive feature elimination technique in the cross-validation loop was applied to exclude the bias of the model performance. In total, 16 unique PET (Vt, SUV) and MRI derived quantitative parameters were evaluated. Whole mount prostatectomy sections were used as "ground true".

RESULTS

The RAFF, monoexponential and kurtosis derived parameters had LPOCV AUC in the range of 0.72 to 0.82 while the corresponding value for VT was 0.85. T2 mapping, 1H-MRS ((choline+creatine)/citrate)) and DCE-MRI (Ktrans, Ve) derived parameters had the lowest LPOCV AUC in the range of 0.33 to 0.60. Most frequently selected parameters in each round of the cross-validation were VT, ADCk (0-2000 s/mm2, 12 b values), ADCm (0-1500 s/mm2, 2 b values), ADCm (0-500 s/mm2, 5 values), and K (0-2000 s/mm2, 12 b values) which demonstrated LPOCV AUC of 0.91.

CONCLUSION

Quantitative models using DWI and RAFF derived parameters led to improved PCa characterization. The added value of 18F-FACBC PET appears to be limited.

CLINICAL RELEVANCE/APPLICATION

18F-FACBC (Fluciclovine) PET has a power to predict Gleason score but adds little value to DWI and RAFF derived parameters.

SSK09-08 Computer-Aided Diagnosis for Prostate Cancer Detection in Multiparametric MRI: Influence on Reader Performance

PURPOSE

To determine the interaction between computer-aided diagnosis (CAD) and readers with varying levels of experience in the interpretation of multiparametric prostate MR imaging with PIRADS v2.

METHOD AND MATERIALS

The institutional review board waived the need for informed consent. 64 patients (PCa=35; nonPCa=29) who were suspected of PCa and underwent mpMRI with subsequent biopsy or prostatectomy within 3 months were involved in this retrospective study. 6 readers were divided into 3 groups according to their experience in prostate imaging. Unknown the pathologic diagnosis, readers were asked to detect up to 3 lesions and graded 1-5 score according to PI-RADS v2 separately first without CAD and subsequently with CAD. Interreader agreement was assessed. According to histologic-radiologic correlation, the effect of CAD was evaluated by using ROC curve and Z test on patients and lesions basis. Wilcoxon signed ranks test were used to compare the diagnostic time and confidence with and without CAD. Furthermore, the requirement for CAD was also evaluated.

RESULTS

the AUC of stand-alone CAD was 0.918±0.036, and the spearman correlation coefficient between predictive values and PI-RADS scores was 0.706(P<0.01). Based on lesions, the AUCs of 6 readers were improved from 0.697-0.868 to 0.778-0.921 and the improvements were better than patient basis analysis. While the difference wasn't significant(P>0.05). Among 3 groups, the difference of AUCs between less experienced and experienced readers was significant without CAD, while with CAD, the difference was not significant. Besides, the interreader agreement and diagnostic confidence was improved significantly with CAD assisted. The rates of requirement for CAD were rising with reader's experience reduce. The average interpretation time of each case required an additional 0.8 minutes.

CONCLUSION

Integrating CAD into PCa mpMRI diagnostic process as a second reader, the performance of less experienced readers could be improved and similar with experienced readers. Additionally, with the reducing of experience, the requirement for CAD was rising.

CLINICAL RELEVANCE/APPLICATION

The CAD assisted can significantly improve the performance of less experienced readers in prostate mpMRI interpretation, and much better in lesion detection and evaluation than it in patient, which indicate that CAD could be a promising method for detecting a target lesions for prostate biopsy.

SSK09-09 Detection of MRI "Index Lesion" with mpMRI-TRUS Fusion-Targeted Prostate Biopsy: Does it Correspond to Histopathology?

PURPOSE

To determine the histopathological correspondence of MRI "index lesion" between multiparametric magnetic resonance imaging (mpMRI)/Transrectal ultrasonography (TRUS) fusion biopsy and radical prostatectomy.

METHOD AND MATERIALS

Institutional review board approval; Informed consent was obtained from all individual participants included in the study. This prospective study has been performed on a cohort of 142 biopsy naive patients aged 45-76 years, with elevated PSA level, recruited from October 2015. Diagnostic 3T MRI was performed and the index lesion is identified as being the one with the highest PI-RADS v.2 score and 1-3 additional "potential lesion" with a lower PI-RADS (v.2) and/or smaller volume are defined as 'Non Index lesion'. A maximum of 2-3 biopsies per lesion have been carried out and pathologic results acquired. Patients found to be positive undergo radical prostatectomy.

RESULTS

Prostate cancer was detected in 142/142 patients with a cancer detection rate being 100%. MR index lesion and the pathology report show a 100% correspondence concerning the lesion dimensions. MR/TRUS guided biopsy and the pathology report show a 86% correspondence with a relative risk of 0.94 and a p value <0.01, concerning Gleason Score Determination; and a 72% correspondence with a relative risk of 0.69 a p value <0.01, concerning the highest Gleason Score. Missed lesions on MRI proved to be low risk , Gleason Score 6 area, with a volume < 0.5 cc, which can be defined as «Insignificant» disease, with a negative predictive value (NPV) equal to 95-98%.

CONCLUSION

MRI/TRUS fusion biopsy shows a good correlation between "MRI index lesion" and definitive histopathological diagnosis on radical prostatectomy, in terms of dimensions, histological aggressiveness and highest Gleason Score of the pathology report.

CLINICAL RELEVANCE/APPLICATION

Among the new approaches to prostate biopsy, MR Imaging-Transrectal US Fusion has the potential to significantly increase the detection of csPCA.

ferrero.andrea@mayo.edu

PURPOSE

In dual-energy CT (DECT) a threshold in the ratio between the average CT number within the stone from a low kV and a high kV image is generally used to differentiate stone types. This approach has demonstrated near 100% accuracy in separating uric acid (UA) from non-uric acid (NUA) stones, however it has failed to yield acceptable performance in separating NUA subtypes, such as calcium oxalate and apatite stones. In this study, we investigated a probabilistic approach that replaced discrete classification of stone mineral composition with a likelihood estimation.

METHOD AND MATERIALS

Patients with a DECT scan of the abdomen followed by an ex vivo analysis of the removed stone were retrospectively evaluated with IRB approval. Of these, only the cases with pure stones (i.e. >90% purity) were included in the study. Each stone was segmented using automated in-house software, and histograms of the distribution of CT number ratios for each stone were generated. Each histogram was compared to simulated histograms for 5 mineral compositions: uric acid (UA), cystine (CYS), struvite (STR), calcium oxalate / brushite (COM/COD/BRU) and apatite (APA). The likelihood of each mineral composition was computed as the overlap of the area between each histogram. The most likely mineral composition was compared to the conventional, threshold based approach currently used in clinical practice. Accuracy for the two methods was computed as the percentage of patient cases whose stone was correctly classified, using the ex vivo composition analysis as reference.

RESULTS

228 patients were retrospectively identified. 112 patients that had a pure stone (as determined ex vivo through infrared spectroscopy) of at least 10 mm3 were included in the study. The threshold-based method correctly classified 70% of the stones, whereas the probabilistic method correctly classified 73% - 88% if the two most likely compositions were considered. Of note is that the average confidence for the correct cases was 65%, whereas it was below 50% for the incorrect cases.

CONCLUSION

A probabilistic approach that provides an estimation of composition likelihood has been shown to more accurately characterize renal stones compared to threshold-based methods.

CLINICAL RELEVANCE/APPLICATION

The proposed method would increase clinician confidence in the in vivo determination of urinary stone composition using DECT,

appropriately identifying cases where the assessment is more uncertain.

SSK10-03 Characterization of Small (<4 cm) Focal Renal Lesions: Diagnostic Accuracy of Spectral Analysis using Single-Phase Contrast-enhanced Dual-energy CT

Wednesday, Nov. 29 10:50AM - 11:00AM Room: N228

Participants
Bhavik N. Patel, MD,MBA, Stanford, CA (*Presenter*) Consultant, General Electric Company; Research support, General Electric Company
Kingshuk Choudhury, PhD, Durham, NC (*Abstract Co-Author*) Nothing to Disclose
Rendon C. Nelson, MD, Durham, NC (*Abstract Co-Author*) Research Consultant, General Electric Company; Research Consultant, Nemoto Kyorindo, Ltd; Consultant, VoxelMetrix, LLC; Co-owner, VoxelMetrix, LLC; Advisory Board, Bracco Group; Advisory Board, Guerbet, SA; Research grant, Nemoto Kyorindo, Ltd; Speaker Bureau, Bracco Group; Royalties, Wolters Kluwer nv
Daniele Marin, MD, Durham, NC (*Abstract Co-Author*) Research support, Siemens AG

PURPOSE

To determine whether single-phase contrast-enhanced dual-energy quantitative spectral analysis improves the accuracy of diagnosis for small (< 4.0 cm) renal lesions, compared to conventional single-energy attenuation measurements.

CONCLUSION

Single-phase contrast-enhanced dual-energy quantitative spectral analysis significantly improves the specificity for characterization of small (< 4.0 cm) renal lesions, compared to conventional single-energy attenuation measurements.

CLINICAL RELEVANCE/APPLICATION

Single-phase contrast enhanced dual energy quantitative spectral analysis can reliably characterize small renal lesions thereby reducing the need for additional subsequent dedicated renal lesion evaluation protocol imaging.

SSK10-04 Analysis of Dual Energy Spectral CT and Pathological Grading of Clear Cell Renal Cell Carcinoma

Wednesday, Nov. 29 11:00AM - 11:10AM Room: N228

Participants
Jinyan Wei, Lanzhou, China (*Presenter*) Nothing to Disclose
Junlin Zhou, Lanzhou, China (*Abstract Co-Author*) Nothing to Disclose

weijinyan501@163.com

PURPOSE

To discuss the dual energy spectral CT imaging features of the pathological grading of clear cell renal cell carcinoma (ccRCC) and the correlation between spectral CT imaging features and pathology.

METHOD AND MATERIALS

We performed retrospective analyses of 62 patients with confirmed diagnosis of ccRCC. All patients underwent non-enhanced CT and dual-phase(cortex phase, CP and parenchyma phase, PP) contrast-enhanced CT with dual energy spectral mode. The subjects were pathologically divided into two groups: low-grade group (Fuhrman 1/2) and high-grade group (Fuhrman 3/4). The CT value of each lesion was measured on the monochromatic image of 70keV; the normalized iodine concentrations (NIC) and the slope of spectrum curve were calculated.The qualitative morphological parameters, including tumor shape, calcification, pseudocapsule, necrosis, and enhancement mode were compared between the two groups.

RESULTS

The CT value, NIC, and the mean slope of the low-grade group were higher than that of the high-grade group during CP(P=0.001, P=0.043, P<0.001, respectively). The CT did not differ significantly during PP(P=0.134); however, the NIC and mean slope varied considerably in the low grade than the high-grade group (P=0.048, P=0.017, respectively). The CT threshold value, NIC, and slope had high sensitivity and specificity in differentiating well-differentiated ccRCC from the poorly differentiated.The tumor shape, pseudocapsule, and necrosis differed significantly between the two groups (P<0.01).

CONCLUSION

Dual energy spectral CT with the quantitative analysis of iodine concentration and qualitative analysis of morphological characteristics increase the accuracy of diagnosing pathological grading of ccRCC.

CLINICAL RELEVANCE/APPLICATION

Clinnical relevance/application Dual energy spectral CT with the analysis of iodine concentration and the correlation between spectral CT imaging features and pathology may help increase the accuracy in differentiating the pathological grading of ccRCC

SSK10-05 Impact of Noise-Optimized Virtual Monoenergetic Dual-Energy Computed Tomography on Image Quality in Patients With Renal Cell Carcinoma

simartin@outlook.com

PURPOSE

To perform a quantitative and qualitative image analysis of noise-optimized virtual monoenergetic images (VMI+) in patients with renal cell carcinoma (RCC) undergoing dual-energy computed tomography (DECT).

METHOD AND MATERIALS

Fifty-two patients (33 men; 61.5±13.6 years) with RCC underwent contrast-enhanced DECT during the corticomedullary and nephrogenic phase of renal enhancement. DECT datasets were reconstructed with standard linearly-blended (M_0.6) as well as traditional virtual monoenergetic (VMI) and VMI+ algorithms in 10-keV increments from 40 to 100 keV. Contrast-to-noise (CNR) and tumor-to-cortex ratios for corticomedullary- and nephrogenic-phase images were objectively measured. Subjective image quality and RCC delineation were evaluated by three radiologists.

RESULTS

Greatest CNR values were found for 40-keV VMI+ series in both corticomedullary- (8.9±4.9) and nephrogenic-phase (7.1±4.6) images and were significantly higher compared to all other reconstructions (P<0.001). Furthermore, tumor-to-cortex ratios were highest for 40-keV nephrogenic-phase VMI+ (2.1±3.5; P<=0.016), followed by 50-keV and 60-keV VMI+ (2.0±3.2 and 1.8±2.8, respectively). Qualitative image quality scored highest for 50-keV VMI+ series in corticomedullary-phase reconstructions and 60-keV in nephrogenic-phase reconstructions (P<=0.031). Highest scores for lesion delineation were assigned for 40-keV VMI+ reconstructions (P<=0.074).

CONCLUSION

Low-keV VMI+ reconstructions lead to improved image quality and lesion delineation of corticomedullary- and nephrogenic-phase DECT datasets in patients with RCC.

CLINICAL RELEVANCE/APPLICATION

In summary, our results demonstrate that the noise-optimized VMI+ algorithm substantially improves subjective and objective image quality of abdominal DECT examinations in patients with RCC compared to traditional VMI and standard linearly-blended images. Furthermore, low-keV VMI+ reconstructions have the potential to improve delineation of RCC lesions

SSK10-06 Dual-Source Single-Energy Multidetector CT Urography with Multiple Radiation Exposures within the Same Patient: Comparison of Full-Dose and Half-Dose Images Reconstructed with FBP and Half-Dose Images with SAFIRE

Wednesday, Nov. 29 11:20AM - 11:30AM Room: N228

Participants
See Hyung Kim, Daegu, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Donghyeon Kim, Daegu, Korea, Republic Of (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

kseehdr@dsmc.or.kr

PURPOSE

To prospectively compare image quality and lesion confidence of CTU images acquired at FBP with 100% radiation dose with those of CTU images simultaneously acquired at FBP and SAFIRE-3 with 100% and 50% radiation dose in patients with high risk for urothelial carcinomas.

METHOD AND MATERIALS

The institutional review board approved the study with written informed patient consent. 150 patients underwent CTU examinations using a dual-source single-energy scanner. Data from both tubes were reconstructed with FBP, and data from the primary tube only were reconstructed with SAFIRE. Seven radiologists subjectively assessed image quality and lesion confidence for 1200 total datasets. Nonparametric methods for cluster data were used to estimate the areas under the receiver operating characteristic curves (AUCs) for variance methods on the basis of a noninferiority margin of 0.05.

RESULTS

Mean AUCs of image quality in SAFIRE-3 at 25% radiation dose was significantly lower than those of FBP at 100% radiation dose (all P <0.05). The mean AUCs for the presence of lesion were 0.907 and 0.894 for FBP at 100% and 50% radiation doses, and 0.900 and 0.799 for SAFIRE-3 at 50% and 25% radiation doses. However, SAFIRE-3 at 25% radiation dose was significantly inferior to FBP at 100% radiation dose.

CONCLUSION

CTU images acquired at SAFIRE-3 with 25% radiation dose were inferior to those of FBP with 100% radiation dose for image quality and confidence for the presence of lesion, regardless of the radiologists' experience.

CLINICAL RELEVANCE/APPLICATION

CTU images acquired at SAFIRE-3 with 25% radiation dose were inferior to those of FBP with 100% radiation dose for image quality

and confidence for the presence of lesion, regardless of the radiologists' experience.

SSK10-07 The Application Value of Spectral CT Imaging in Distinguishing Renal Cell Carcinoma and Renal Angiomyolipomas

416725386@qq.com

PURPOSE

To assess the value of dual-energy spectral CT imaging in differentiating renal cell carcinoma (RCC) from Renal Angiomyolipomas (RAML).

METHOD AND MATERIALS

53 patients with suspected renal tumors who underwent plain and contrast-enhanced CT in cortical phase and medulla phase with dual-energy Spectral imaging mode were retrospectively analyzed. There were 31 cases of RCC and 22 cases of RAML. Images were analyzed on an AW4.6 workstation with GSI Viewer software to measure the effective-Z and fat concentration for lesions with the plain scan, CT values in 70keV images and iodine concentration (IC) in the cortical and medulla phases for lesions. The iodine concentration was normalized to that of the aorta to obtain normalized iodine concentration (NIC), and the difference of NIC between medulla and cortical phases was calculated. The above quantitative parameters from lesions were compared using independent sample t test, and ROC analysis was used to evaluate their diagnosis efficiency in differentiating RCC from RAML.

RESULTS

The Effective-Z, fat concentration, NIC in cortical phase, medulla phase, NIC difference, CT value in cortical phase and medulla phase for RCC were 7.60±0.13, -143.03±32.75g/L, 0.64±0.13, 0.49±0.15, 0.14±0.18, 116.53±14.29HU, 94.8±12.34HU, respectively; while the corresponding values for RAML were 7.74±0.11, -103.24±9.84 g/L, 0.50±0.88, 0.58±0.12, -0.08±0.13, 96.47±18.46HU, 105.58±14.14HU, respectively. The differences for these parameters between the two lesion types were statistically significant (all $p<0.05$). Using the threshold value of -112.8g/L for the fat concentration in ROC analysis, one would obtain a sensitivity of 90.9% and specificity of 77.4% for differentiating RCC from RAML and the area under the curve was 0.89.

CONCLUSION

The parameters obtained in dual-energy spectral CT scans demonstrated appreciable clinical values for differentiating RCC from RAML, with the fat concentration providing the highest diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

Dual-energy spectral CT is a promising method in differentiate RCC from RAML.

SSK10-08 Does Dual Energy CT Have the Ability to Differentiate Benign vs Malignant Ovarian Tumors?

Wednesday, Nov. 29 11:40AM - 11:50AM Room: N228

Awards

steven.w.zheng@uth.tmc.edu

PURPOSE

To assess the ability of dual energy CT (DECT) to distinguish benign from malignant ovarian tumors (OT).

METHOD AND MATERIALS

Following approval of the institutional-review-board, institutional database was mined for treatment naïve patients who underwent primary cytoreduction for OT. 35 patients were included in the study. 17 patients had high grade, 8 had low grade, and 10 had benign tumors. Age, gender pathological diagnosis following surgical resection and tumor grade was documented. Advanced processing using the Advantage Work (AW) station was performed on the preoperative dual energy CT scan. ROIs were drawn on the ovarian mass on the AW. Pixel level data of the tumor was recorded for different energy levels 50 keV, 70 keV and 120 keV. The effective-Z (atomic number) amount of water and iodine present in the ovarian mass was recorded. Kruskal;Wallis test was used to compare the differences between three types of OT. All tests were two;sided and $p < 0.05$ were considered statistically significant.

RESULTS

Patients with high grade OTs were older than those with the low grade and the benign OTs ($p = 0.02$). High grade OT had higher

Hounsfield values than low grade and benign OT at 50 keV (p = 0.001), 70 keV (p = 0.0006), 120 keV (p = 0.0009), and higher amount of water g/cm3 (p < 0.005). Benign OT had significantly lower atomic number (p = 0.002) and amount of iodine g/cm3 (p = 0.002) compared to malignant OT.

CONCLUSION

Dual energy CT has the potential to distinguish between high grade, low grade and benign ovarian tumors. Given the small sample size, future trials may be helpful in confirming our findings.

CLINICAL RELEVANCE/APPLICATION

DECT has the potential to differentiate between benign and malignant tumors and may be helpful in avoiding unneccessary surgery.

PURPOSE

To assess non-inferiority of novel dual layer spectral detector CT (SDCT) technology in comparison to dual source dual energy CT (dsDECT) in discriminating between uric acid (UA) and non-UA stones

METHOD AND MATERIALS

In this phantom study, 57 surgically extracted urinary calculi were placed in individual tubes within a cylindrical phantom in a water bath. CT images were obtained at 1 mm slice thickness and 0.5 mm intervals on a prototype SDCT scanner (IQon, Philips Healthcare), and second and third generation dsDECT scanners (Somatom Flash and Force, Siemens Healthcare) under matched scan parameters. For SDCT data, effective Z images and virtual monoenergetic images (40, 62, 92, 100, and 200 keV) were created. For SDCT data, 3D growing region segmentation tool using custom pyOsirix software was used to segment each stone on the various reconstructions for pixel by pixel analysis. Median virtual monoenergetic ratios (VMR) of 40/200, 62/92, and 62/100 (chosen as VMR theoretically yielding best spectral separation, equivalent of 100/140Sn, and 100/150Sn kVp ratios used in dsDECT) and effective Z (Zeff) values for each stone were recorded. For dsDECT data, dual energy ratio (DER) for each stone was recorded from vendor specific post-processing software (Syngo Via) using the Kidney Stones Application. The clinical reference standard of x-ray diffraction analysis was used to assess non-inferiority. Pearson's correlation coefficient was calculated to assess correlation between the 3 VMRs and 2 DERs.

RESULTS

6 pure UA, 47 pure calcium based, 1 pure cystine, and 3 mixed struvite stones were scanned. All pure UA stones were correctly separated from non-UA stones using SDCT and dsDECT. For UA stones, median VMR was 0.95-0.99, Zeff 7.2, DER 1.00-1.02. For non-UA stones, median VMR was 1.65-4.1, Zeff 10.76, and DER 1.54-1.69. VMR ratio 40/200 provided the greatest difference between UA and non-UA stones. There was excellent correlation between the 3 VMRs and DERs (Pearson's correlation coefficient 0.89-0.94, p<.0001). More variability was noted using Zeff.

CONCLUSION

SDCT spectral reconstructions demonstrate similar performance to dsDECT in discriminating UA from non-UA stones in a phantom model.

CLINICAL RELEVANCE/APPLICATION

Uric acid stones may be differentiated from non uric acid stones using novel dual layer spectral detector CT technology in a phantom model.

PURPOSE

Cancer treatment has recently undergone a dramatic shift toward personalized care, with new therapies significantly prolonging life, often in the setting of advanced disease. The imaging of treatment response and toxicity has dramatically changed with the advent of molecular targeted agents and immune modulating drugs. Despite these changes, there are currently no specific guidelines regarding the teaching of cancer-imaging to radiology residents. This study surveyed radiology chief residents (CRs) and program directors (PDs) to determine the current state of cancer-imaging teaching in residency.

METHOD AND MATERIALS

An IRB-exempt survey was provided to CRs and PDs at the Association of University Radiologists (AUR) meeting in 2014. Survey results were summarized using frequency and percentages. Chi-square tests and Fisher's exact test were used for statistical analysis.

RESULTS

102 CRs and 64 PDs responded. Most respondents were from university-based residency programs (80% of CRs, 70% of PDs) and most reported program size >30 residents (64% of CRs, 44% of PDs). Most CRs and PDs report incorporation of cancer imaging into residency education by body part (70% and 75%, respectively), with very few having a dedicated cancer-imaging block (6% and 8%, respectively). While most CRs report 6 or more cancer-imaging lectures annually (69%), fewer than half have dedicated lectures on treatment response, side effects and genomics (43%, 37% and 34%, respectively). Just over half of CRs and PDs would like a dedicated, standardized cancer-imaging curriculum added to the ABR residency curriculum guidelines (52% and 57%, respectively). CRs that had lectures on treatment response were significantly more likely to want added curricula (P=.0053).

CONCLUSION

Despite radiologists' integral role in cancer care, most residencies do not currently incorporate dedicated cancer-imaging teaching blocks, with curricula lacking in topics such as cancer treatment response, side effects and genomics.

CLINICAL RELEVANCE/APPLICATION

Despite dramatic advances in cancer treatment, cancer-imaging education may be lagging behind; radiology residencies must adapt to include dedicated cancer-imaging teaching, in order to ensure imagers remain essential members of the oncologic team.

SSK11-02 Medicolegal Issues in Radiology Training

Wednesday, Nov. 29 10:40AM - 10:50AM Room: S105AB

Participants
Sarvenaz Pourjabbar, MD, New Haven, CT (*Presenter*) Nothing to Disclose
Amir Imanzadeh, MD, Shelton, CT (*Abstract Co-Author*) Nothing to Disclose
Jonathan Mezrich, MD, New Haven, CT (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

sarvenaz.pourjabbar@yale.edu

PURPOSE

Radiologists comprise approximately 3.6% of US physicians while ranked 6th in medicolegal claims. Studies suggest that by age of 60, 50% of radiologists will be sued at least once. Given this inevitability, it is surprising how little attention is paid to teaching of medicolegal and malpractice issues during training and practice. Most trainees emerge from residency with only a vague notion of the medicolegal issues inherent in radiology, and it is hypothesized that most radiologists would benefit from additional training on these topics.

METHOD AND MATERIALS

All the radiology attending, trainees and alumni in our tertiary care 1500-bed teaching hospital were surveyed via an electronic questionnaire. Respondents were surveyed on their overall knowledge of job-related medicolegal issues and willingness to receive additional education. The survey also included two real life medicolegal scenarios and the radiologists were asked to choose the most likely result.

RESULTS

A 9-item questionnaire was sent to total of 332 trainees, attending and alumni. There were 104 responses constituting a response rate of 31% (104/332) from 60% (62/104) academic and 40%(42/104) private practice radiologists, F:M 29:75. Only 36% of the respondents were aware that by age of 60, half of them would be involved in at least one lawsuit. All knew the most common causes of malpractice claims in the United States, however, only one-third were aware of available resources offered by ACR. 80% never received training on medicolegal issues during residency and 97% believed that additional education would be useful; 87% showed willingness to attend post-residency medicolegal CME courses. All the residents believed that medicolegal lectures should be included in the didactics.

CONCLUSION

There is a dearth of knowledge among radiologists on job-related medicolegal topics, and radiologists are willing to acquire additional training in the form of targeted didactic sessions for trainees or CME for the graduates. This survey suggests that, at a minimum, incorporating additional medicolegal topics into the non-interpretive skills curriculum of residents would be well received.

CLINICAL RELEVANCE/APPLICATION

As medicolegal issues are numerous in radiology this topic should be of interest to all radiologists in active practice.

PURPOSE

Education is an important component of any successful and sustainable radiology program, which warrants continuous and methodical improvement. However, there is often a lack of structured radiology training in countries with limited resources. In addition to clinical teaching, which can only be provided in person, sharing of educational material is feasible nearly everywhere around the world. While utilizing publicly accessible materials from the internet is one option to supplement learning, we hypothesized that participating remotely in lectures provided by a well-established training program with a more structured didactic system may provide additional benefits to all, especially as outreach to less resourced establishments within developing countries. The purpose of this study was to assess whether live streaming of educational resident lectures to a partner program in a developing country can have an impact on radiology training and patient care.

RESULTS

The pre-survey demonstrated that 80% of the residents stated they currently have educational lectures once a week or less. 90% believe that live-streamed lectures could be useful for their daily work and case spectrum, 65% percent believe there will be an immediate impact on local patient care, while 35% percent believe there will be no immediate impact, but potential long-term impact. Areas of particular interest included Musculoskeletal radiology, Neuroradiology, Chest Imaging, and Breast Imaging. After implementation of the lecture-sharing program, preliminary feedback from 13 residents demonstrated that 100% of residents thought the lectures have assisted them in learning radiology and 53% of them felt that they were exposed to new material.

CONCLUSION

Lecture sharing as an initiative to improve education in resource limited settings has substantial potential to impact radiology training programs and has proven beneficial during this outreach project. The future goal is to stream at least one lecture per week use follow-up surveys to continually assess any improvement in learning habits, local didactic culture and eventually patient care. As the project progresses, the frequency of streamed lectures will be increased and the program will be expanded to other partner-

institutions in other developing countries. Long-term impact on examination performance will be studied annually to assess any change in overall performance of trainees, which could be attributed to lecture sharing. Ultimately, maintaining a robust relationship is the most important goal, which would facilitate residents' access to a stored lecture database and also facilitate developing direct resident exchange programs between countries.

METHODS

Twenty residents from a radiology residency program in the country of Jamaica, were surveyed about their interests in participating in streamed lectures from our institution. Survey questions included gathering information about their current learning tools and resources, their current lecture system and logistics of participating in lectures remotely. Members of our institutional faculty were also surveyed about willingness to participate and feasibility of this concept. The current lecture infrastructure was expanded to include remote communication capabilities, which included using a web conferencing software platform. A preset link was generated for access to the sessions and this was distributed in advance to the residents after they signed applicable waivers. After implementation of the project, residents were surveyed to assess impression of the lecture system.

PURPOSE

Improve radiology recruitment efforts by identifying what factors influence medical students' choice of radiology and what factors correlate with job and career satisfaction.

METHOD AND MATERIALS

An IRB-exempted online survey was distributed to United States radiology residents by email between December 7, 2016 and March 31, 2017. Respondents identified what aspect of radiology was most appealing during medical school and what experience was most influential in choosing radiology. Respondents also completed visual analog scale measures of career choice satisfaction and current job satisfaction. Descriptive statistics were performed to evaluate relative factor importance. Analysis of variance with post hoc Tukey honest significance difference test was performed to compare career and job satisfaction scores across factors.

RESULTS

A total of 488 radiology residents (age 30.8 ± 3.2 years; 358 male, 129 female, 1 non-responder; 144 PGY1, 123 PGY2, 103 PGY3, 118 PGY4) responded. Respondents were most drawn to the intellectual component (n=187, 38%), imaging component (n=100, 20%), procedure component (n=96, 20%), and potential lifestyle (n=69, 14%) of radiology. Individuals were most influenced by radiology clerkship reading room shadowing (n=143, 29%), radiologist mentor (n=98, 20%), non-radiology clerkship imaging exposure (n=77, 16%), and radiology clerkship interventions exposure (n=75, 15%). Residents who chose radiology primarily for potential lifestyle recorded less career satisfaction and less job satisfaction than residents who chose radiology for its intellectual (p=0.00005 and 0.0004) and imaging (p=0.00002 and 0.0003) components. There was no significant relationship of influential experiences with career or job satisfaction.

CONCLUSION

Effective recruitment of medical students into radiology may best be achieved by radiology clerkships that emphasize the intellectual and imaging components of radiology through reading room shadowing and exposure to interventions. Those who choose radiology for potential lifestyle appear less likely to have job and career satisfaction, at least during residency.

CLINICAL RELEVANCE/APPLICATION

Optimal recruitment of medical students into radiology may be achievable through radiology clerkships that emphasize the intellectual and imaging components of radiology.

SSK11-06 Development, Implementation, and Evaluation of a Medical Student Radiology Elective

Wednesday, Nov. 29 11:20AM - 11:30AM Room: S105AB

Participants
Natasha Larocque, MD, Hamilton, ON (*Presenter*) Nothing to Disclose
Stefanie Y. Lee, MD,FRCPC, Hamilton, ON (*Abstract Co-Author*) Nothing to Disclose
Sandra Monteiro, PhD, Hamilton, ON (*Abstract Co-Author*) Nothing to Disclose
Karen Finlay, MD, Burlington, ON (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

natasha.larocque@medportal.ca

PURPOSE

To re-structure a medical student Radiology elective based on the results of a needs assessment and to prospectively evaluate implemented interventions.

METHOD AND MATERIALS

An online retrospective survey was sent to medical students who completed a Radiology elective during the 2015 calendar year. Students were asked to evaluate current and potential elective activities using dichotomous, ranking, and 5-point Likert scale questions (5=excellent, 4=very good, 3=good, 2=fair, 1=poor). The Salant-Dillman survey protocol was used to maximize response rate. Based on these results, three new interventions were piloted: a more structured schedule, bi-weekly resident-led medical student rounds and the creation of a medical student case bank. These changes were implemented from July 1- December 31, 2016 and were prospectively assessed using the same methodology as the needs assessment. Responses were analyzed using descriptive statistics and t-tests.

RESULTS

Response rate for both the needs assessment and prospective survey was good (62% and 90%). In the needs assessment, mean score for overall elective experience was 3.4/5 (SD=1.08) and self-rated knowledge gained was 3.4/5 (SD=0.99). The highest rated educational activities were: working with residents (mean=4.1/5, SD=1.24) and attending resident rounds/self-study time (mean=3.6/5, SD=1.11/1.26). Prospective evaluation of the three interventions showed an increased score for overall elective experience of 4.24/5 (SD=0.90, p=0.022) and for perceived knowledge gained (mean=3.76/5, SD=0.83, p=0.11). The resident-led rounds and case bank were the highest rated activities students encountered in the new elective with scores of 4.87/5 (SD=0.35) and 4.67/5 (SD=0.49) respectively.

CONCLUSION

This study describes the successful re-structuring of a medical student Radiology elective with improved scores in student satisfaction and knowledge gained.

CLINICAL RELEVANCE/APPLICATION

These results are important to medical educators and may facilitate the creation of higher quality electives for medical students.

SSK11-07 Resident Perception of the Use of Peer Teachers for Hands-On Ultrasound Training

Wednesday, Nov. 29 11:30AM - 11:40AM Room: S105AB

Participants
Netanel Berko, MD, Bronx, NY (*Presenter*) Nothing to Disclose
Mordecai Koenigsberg, MD, Flushing, NY (*Abstract Co-Author*) Nothing to Disclose
Thomas G. Hoffman, RT,BS, Bronx, NY (*Abstract Co-Author*) Nothing to Disclose
Beverly A. Thornhill, MD, Bronx, NY (*Abstract Co-Author*) Nothing to Disclose
E. Stephen Amis JR, MD, Bronx, NY (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

Netanel.Berko@uphs.upenn.edu

PURPOSE

To determine resident perceptions of the use of peer teachers for hands-on radiology resident education.

METHOD AND MATERIALS

Hands-on musculoskeletal and abdominal ultrasound scanning workshops were designed for radiology residents. Prior to the workshops several senior residents received three hours of training, and then served as instructors ("peer teachers") during the workshops. During the workshops, demonstrations were performed by an attending radiologist or senior sonographer, followed by small-group hands-on scanning led by the peer teachers. Following the workshops resident participants and peer teachers completed surveys with 5-point Likert scale statements regarding their experience. Median scores and interquartile ranges (IQR, 25-75%) were calculated.

RESULTS

40 residents from all years of training and 9 senior resident peer teachers participated in 6 workshops. Participants thought that peer teachers were effective (median score 5, IQR 4-5), would like to be taught by peer teachers again (5, 4-5) and were interested in serving as peer teachers (4, 3-5). Peer teachers highly rated the overall experience (5, 5-5), were interested in serving as peer teachers again (5, 5-5), and found peer teaching enjoyable (5, 5-5). Peer teachers felt comfortable with the material (4, 4-5) and were able to answer most questions posed to them (4, 3-5). Peer teaching resulted in increased understanding of ultrasound technique and anatomy (5, 5-5). 78% of peer teachers thought that 3 hours of training was sufficient, while all thought that group size (3-4 residents per small group) was appropriate.

CONCLUSION

Use of peer teachers for hands-on ultrasound training is viewed extremely positively by resident participants and peer teachers. Residents found peer teaching educational, enjoyable and highly rated the overall experience. Both resident participants and peer teachers were interested in participating in peer teaching again. A ratio of 1 peer teacher for 3-4 trainees is appropriate for effectively teaching ultrasound scanning technique, and approximately 3 hours of peer teacher training is required.

CLINICAL RELEVANCE/APPLICATION

Peer teaching is viewed extremely positively by residents and can play a role in hands-on training of radiology residents.

SSK11-08 Procedural Training in Radiology Residency: Variability in the Use of Simulation

Wednesday, Nov. 29 11:40AM - 11:50AM Room: S105AB

smatalon@partners.org

PURPOSE

Increased attention to quality and safety has cast doubt on the classic "see one, do one" model of procedural training. Many have proposed simulation training as an additional teaching tool in procedural training. This study surveyed radiology residents to determine if and how simulation-based training is being utilized during residency.

METHOD AND MATERIALS

An IRB-exempt online survey was distributed to current radiology residents in the United States by e-mail. Survey results were summarized using frequency and percentages. Chi-square tests were used for statistical analysis where appropriate.

RESULTS

353 residents completed the survey. Thirty-seven percent (n=129/353) of residents have not participated in procedure simulation (37%, n=129/353). Of the residents who have used simulation, most did not do so until after having already performed procedures on patients (59%, n=132/223). Vascular/interventional (VIR) radiology is the most common subspecialty in which residents get hands-on exposure to procedures (96%, n=336/352), but only 26% (n=57/222) reported procedural simulation use in VIR. Simulation was most commonly utilized by breast and abdominal divisions (n=97/222, 44%, and n=95/222, 42%, respectively). The presence of a dedicated simulation center was reported by over half of residents (56%, n=196/353) and was associated with prior simulation experience (P=.007). Simulation training was associated with higher comfort levels in performing procedures (P<.001).

CONCLUSION

Although procedural simulation training is associated with higher comfort levels in performing procedures, there is variable use in radiology resident training and its use may not be currently optimized. Results suggest the need to increase procedural simulation use throughout US residencies, including earlier introduction to simulation during residency, particularly within the vascular/interventional division.

CLINICAL RELEVANCE/APPLICATION

Simulation training is associated with higher resident comfort levels in performing procedures, but its use is variable in resident training and increased use may benefit both resident training and ultimately, patient care.

SSK11-09 Integrating Simulated Clinical Decision Support at the Point-of-Order into Physician Assistant Students' Radiology Curriculum

mwillis@bcm.edu

PURPOSE

Improving appropriateness of imaging is a national focus, including imaging requested by advanced practice providers (Hughes et al, JAMA Intern Med 2015;175(1):101-107). Given our experience in this arena, we engaged leadership from our physician assistant program to innovate the radiology education curriculum. We introduced a cutting-edge clinical tool (ACR Select) through an education simulation portal. In an era of evolving decision support for medical providers, this simulation portal exposes future ordering providers to evidence-based medicine and clinical decision support.

METHOD AND MATERIALS

We utilized an education portal integrated with ACRSelect to allow learners to simulate ordering imaging studies with clinical decision support. Learners received instant feedback during their simulation. Our program utilized a hybrid classroom experience. The learners met with key members of our radiology team in a traditional classroom before and after the simulation education. Assessment was via a pre/post-assessment a qualitative survey.

RESULTS

In 2015, sixteen students completed both tests, and on average, showed a gain of 11% from one test to the next. A paired t-test between students' pre- and posttest scores was statistically significant - $t(15)=4.664$, $p<0.001$, with a large effect size (Cohen's $d = 1.166$). In 2016, the module cases were updated and refined. The test items were accordingly updated. Thus, comparisons cannot be made directly between the two groups. However, similar to the 2015 cohort, the 2016 cohort, also had about an 11% increase from pre- to posttest, which was a statistically significant average content knowledge gain $t(17)=3.4436$, $p=0.003$, with a

large effect size (Cohen's d = 0.812).

CONCLUSION

The role of advanced practice providers is expected to expand within our evolving health care system. Their radiology curricula need to empower these future providers to request the "right test at the right time". Evidence-based, simulated ordering of imaging exams with integrated clinical decision support is a promising resource. This web-based platform is easily scalable which enhances the potential to have a broad and meaningful impact on medical education.

CLINICAL RELEVANCE/APPLICATION

Given the challenges of our current health care situation and national trends in medicine, it is imperative that we find more efficient and effective mechanisms to better educate and prepare medical providers for the future.

PURPOSE

The aim of this study was to investigate whether cathepsin activity can be utilized as a novel biomarker for presence and inflammatory status of giant cell arteritis (GCA).

METHOD AND MATERIALS

Biopsy specimen of the temporal artery from patients (n=91, average age: 74 years) with a suspected giant cell arteritis were partially subjected to immunohistological analyses of the expression of Cathepsin K, L and B. The enzymatic activity of the specimen was assessed in n=61 cases with a fluorometric essay sensitive to cathepsin K. Ex vivo fluorescence imaging using a pan-cathepsin activatable fluorescent imaging agent was performed in n=45 temporal artery biopsy specimen and in n=13 segments of the internal thoracic artery from non-vasculitis patients (control group) undergoing cardiac bypass surgery. Cathepsin-based methods were compared to standard clinical diagnostics, serology, presurgical MRI and routine histology.

RESULTS

The clinical reference diagnosis revealed n=18 negative cases, n=45 positive cases and n=28 cases with inconclusive results. Immunohistochemistry (Figure) showed significantly increased ($p<0.001$) expression of cathepsins B, K and L in patients diagnosed with GCA versus negative diagnoses. GCA positive biopsy specimen also had significantly increased cathepsin activity compared to negative biopsy specimen ($p<0.01$) and compared to control arteries from bypass surgery ($p<0.05$) as determined by ex vivo fluorescent imaging. Supporting a pathogenic role for cathepsin K, tissue lysates showed increased Cathepsin K enzymatic activity ($p<0.001$). The ex vivo fluorescent signal moderately but significantly correlated with cathepsin K activity ($R^2=0.63$, $p<0.001$), and strongly with the histological scores of all cathepsin stainings (Cathepsin B: $R^2=0.74$; Cathepsin K: $R^2=0.72$; Cathepsin L: $R^2=0.76$; $p<0.001$).

CONCLUSION

These in vitro findings demonstrate that cathepsins can be utilized as an immunohistological and imaging biomarker for the diagnosis of GCA.

CLINICAL RELEVANCE/APPLICATION

Cathepsins possibly offer a translational approach towards in vivo fluorescent imaging for the non-surgical diagnosis of GCA.

SSK12-02 Comparison of Different Semi-quantitative Approaches for the Diagnosis of Graft Infection after Thoracic or Abdominal Aortic Repair Using [F-18]-FDG PET/CT

Wednesday, Nov. 29 10:40AM - 10:50AM Room: S504CD

Participants
Ingo Einspieler, Munich, Germany (*Presenter*) Nothing to Disclose
Victor Mergen, Munich, Germany (*Abstract Co-Author*) Nothing to Disclose
Heiko Wendorff, Munich, Germany (*Abstract Co-Author*) Nothing to Disclose
Markus Schwaiger, MD, Munich, Germany (*Abstract Co-Author*) Research Grant, Siemens AG; Speaker, Siemens AG
Mona Mustafa, Munich, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The aim of this study was the evaluation and comparison of different semiquantitative parameters for the diagnosis of graft infection after thoracic or abdominal aortic repair applying [18F]fluorodeoxyglucose (FDG) positron emission tomography (PET)/computed tomography (CT).

METHOD AND MATERIALS

50 patients who underwent [18F]-FDG PET/CT for suspected aortic graft infection were retrospectively analysed. Besides, 13 oncological patients with aortic repair but without graft infection were included in the analysis. Maximum standardized uptake values (SUVmax) were obtained for all patients and different graft to background ratios were calculated. The diagnostic accuracy of SUVmax and different target-to-background ratios (TBRs) was assessed by receiver-operating-characteristic (ROC) analysis. Overall, 8 different background regions were defined and analysed (blood pool activity within the left cardiac ventricle, 4 different aortic segments, the vena cava and the pulmonary trunk as well as FDG wall uptake in non inflammatory aortic segments). A combination of clinical follow-up, imaging (including PET/CT) and/or microbiological/histopathological results, if available, served as the standard of reference for the final diagnosis.

RESULTS

28 infected and 35 uninfected grafts were identified. SUVmax was the most powerful predictor for the diagnosis of graft infection according to the ROC analysis (area under the curve: 0.978, CI: 0.904-0.999). ROC analysis suggested an SUVmax cut off value of >4.48 to differentiate between infected and non-infected grafts ($p<0.0001$). Notably, there was no substantial difference between SUVmax and other semiquantitative approaches (TBR) according to the area under the curve.

CONCLUSION

Semiquantitative approaches and in particular SUVmax provide a good reference to assess graft infection after thoracic or abdominal aortic repair and may increase the diagnostic accuracy of [18F]-FDG-PET/CT in the setting of suspected graft infection.

CLINICAL RELEVANCE/APPLICATION

[18F]-FDG-PET/CT is increasingly used in the setting of suspected aortic graft infection. However, data is limited with respect to different semiquantitative approaches for the diagnosis of graft infection. According to our results, SUV max showed the best performance to differentiate between infected and non-infected grafts and may increase the diagnostic accuracy of [18F]-FDG-PET/CT.

SSK12-03 Ultrasound-detectable O2 Microbubbles Generated from Catalase-Containing Silica Nanoshells (CSNs) in Determining Infected from Non-infected Fluid Collections in Humans

Wednesday, Nov. 29 10:50AM - 11:00AM Room: S504CD

Participants
Christopher D. Malone, MD, San Diego, CA (*Abstract Co-Author*) Nothing to Disclose
David T. Fetzer, MD, Dallas, TX (*Presenter*) Nothing to Disclose
Jacques Lux, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose
Robert F. Mattrey, MD, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

cmalone05@gmail.com

PURPOSE

Elevated levels of hydrogen peroxide (H2O2) play a key role in neutrophil oxidative defense against infection. Catalase-containing silica nanoshells (CSNs) are novel nanoparticles that generate oxygen microbubbles (O2 MBs) in the presence of elevated levels of H2O2. We aim to determine whether ultrasound detectable O2 MBs produced by CSNs can distinguish infected from non-infected fluid collections drained from patients.

METHOD AND MATERIALS

During this HIPAA-compliant, IRB-approved study, 52 human fluid samples were collected from clinically-required, image-guided percutaneous drainage procedures. Each sample was placed in a 3 mL transfer pipette imbedded in a tissue mimicking agarose/corn starch holder. Both the holder and the face of a Siemens Sequoia 512; 15L8-S linear transducer were submerged and mechanically held in a 37 °C water bath. CSNs were added to the fluid samples while imaging in real-time using the CPS microbubble-only imaging technique. Production of detectable MBs was graded subjectively as negative (not infected), or mild, moderate, or marked (infected) by a single observer blinded to all clinical data. The truth standard was culture results performed by the Microbiology laboratory. Performance characteristics including ROC curves were calculated.

RESULTS

Presence of MB formation to distinguish infected from non-infected fluids was 84% sensitive and 72% specific, and offered positive and negative predictive values of 64% and 89%, respectively. The area under the ROC curve (AUC) was 0.79. All nine false positive cases were peritoneal fluid collections, which could be indicative oxidative stress rather than infection.

CONCLUSION

The presence of elevated H2O2 recognized by MB formation in the presence of CSNs is sensitive in distinguishing infected from non-infected fluids with a relatively high negative predictive value. CSNs may offer a novel point of care method at the time of

percutaneous drainage, potentially obviating placement of drains in otherwise sterile collections to minimize risk of colonization and secondary infection.

CLINICAL RELEVANCE/APPLICATION

CSN technology can be administered through a needle or potentially incorporated on existing needles/catheters, functioning as a point of care device during percutaneous drainage or aspiration.

SSK12-04 Utility of F18 FDG PET/CT in Evaluation of Pyrexia of Unknown Origin

Wednesday, Nov. 29 11:00AM - 11:10AM Room: S504CD

Participants
Rasika Kabnurkar, MBBS,MD, Thane, India (*Presenter*) Nothing to Disclose
Namrata Tuteja, MBBS, Mumbai, India (*Abstract Co-Author*) Nothing to Disclose
M.l Rokade, MD, Thane, India (*Abstract Co-Author*) Nothing to Disclose
Nikhil Kamat, MD, Thane, India (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Pyrexia of Unknown Origin (PUO) often poses diagnostic challenge. Timely diagnosis helps in guiding appropriate treatment. The aim of this retrospective study was to asses the contribution of Fluorine-18 Fluorodeoxyglucose (18F-FDG) Positron Emission Tomography /Computed Tomography (PET/CT) in the diagnostic evaluation of PUO.

METHOD AND MATERIALS

46 consecutive patients of PUO (23 men and 23 females, Age Range: 5 to 75 years) referred for 18F-FDG PET/CT between December 2015 to March 2017 were evaluated. Biopsy confirmation was available in 12 patients. Remaining patients underwent biochemical, microbiological, clinical and imaging follow up.

RESULTS

FDG PET/CT identified hypermetabolic foci in 42 patients (91.30%). Out of these, 14/42 patients revealed non-specific FDG uptake which did not contribute to final diagnosis. No abnormal focal FDG uptake was seen in 4 patients. No pathological disease was diagnosed in these 18 patients on subsequent work-up and were afebrile on follow up. Among the definite positive scans in 66.67% patients(28/42), various etiologies identified were as follows: A) Infectious etiology (n=15) including tuberculous lymphadenitis(7/15),septic arthritis (1/15), otitis media (1/15), acute hepatitis (1/15), infected prosthesis (2/15), spondylodiskitis (2/15), gluteal pyogenic abscess(1/15); B) Inflammatory etiology (n=10) such as Interstitial lung disease (2/10), Inflammatory mesenteric lymphadenopathy (2/10), Synovitis (2/10), Polymyositis and Dermatomyositis (2/10)Vasculitis (2/10); C) Malignancy (n=3) in colon carcinoma, adrenocortical carcinoma of lung, liver metastases from unknown primary.

CONCLUSION

18F-FDG PET/CT has a useful role in identification of pathological focus in PUO. Negative FDG PET/CT scan reliably rules out focal etiologies for PUO. Further prospective studies are warranted for confirmation.

CLINICAL RELEVANCE/APPLICATION

18F-FDG PET/CT has higher sensitivity to identify occult pathologies in PUO.

SSK12-05 Ultra-small Superparamagnetic Iron Oxide Nanoparticle as a Surrogate Marker of Aortic Wall Inflammation Following Radiation Therapy for Pancreatic Cancer

PURPOSE

Radiation therapy for cancer can lead to atherosclerosis by inducing inflammatory changes in the vascular wall. Though atherosclerotic changes can be seen with CT and MRI techniques, it is difficult to quantitatively measure inflammation on CT and MR imaging studies. The purpose of this study was to assess the use of ferumoxytol- an ultrasmall superparamagnetic iron oxide nanoparticle, as a surrogate marker of vessel wall inflammation secondary to radiation therapy in pancreatic cancer patients in comparison with healthy volunteers.

METHOD AND MATERIALS

MRI of upper abdomen (T1, T2, multi-echo T2*-weighted imaging) was performed on 3T magnet before and 48 hours after intravenous administration of ferumoxytol in pancreatic cancer patients who underwent radiation therapy (n=8) and healthy volunteers (n=8). R2* value was obtained by drawing regions of interest (ROIs) outlining the aortic wall directly on the T2* medic image and subsequently transposed to the R2* image using Amira software (Version 5.3.2, FEI, Bordeaux, France). The change in R2* values was analyzed by student's t-test.

RESULTS

The average change in R2* value of the pancreatic cancer patients was determined to be 216.18 1/ms. The average change R2*

value of the control patients was determined to be 54.67 1/ms. This indicates that the pancreatic cancer patients following radiation therapy had a greater uptake of ferumoxytol (p=0.0082) in their aortic wall.

CONCLUSION

Ferumoxytol can offer a non invasive, quantitative assessment of vascular inflammation following radiation therapy in cancer patients.

CLINICAL RELEVANCE/APPLICATION

Radiation therapy induced atherosclerosis could potentially be diagnosed earlier on due to its inflammatory nature. Ferumoxytol enhanced MRI offers a novel, radiation-free imaging marker of inflammation, would augment risk stratification, inform therapeutic decisions, and allow safe, robust, and quantitative monitoring of therapy-mediated changes.

SSK12-06 Anti-Inflammatory Therapeutic Effects in Swine Acute Ileitis: Longitudinal Monitoring with Ultrasound Molecular Imaging

willmann@stanford.edu

PURPOSE

Ultrasound molecular imaging (USMI) using P- and E-selectin targeted microbubbles (MBselectin) has been shown to accurately quantify inflammation at molecular level in rodent and swine models of inflammatory bowel disease (IBD). This study aimed to assess whether USMI allows longitudinal monitoring of anti-inflammatory treatments in a swine model of IBD.

METHOD AND MATERIALS

Fourteen female swine with acute terminal ileitis induced by TNBS/ethanol solution at day 0 were randomized into 1) an anti-inflammatory treatment group (n=8 with meloxicam at 0.25mg/kg and prednisone at 0.5mg/kg; oral or intravenous, twice daily) and 2) a control group (n=6 without treatment). USMI was performed with a clinical machine (Acuson Sequoia 512; 15L8W, 7MHz; Siemens) after intravenous injection of MBselectin (5x108/kg). Three bowel segments per swine were imaged each at baseline, day 1, 3 and 6 after inflammation induction. Imaging signal was quantified as the difference between pre- and post-destructive signal intensity with VueBox software (Bracco) and normalized to day 1. At day 6 after imaging, scanned ileal segments were analyzed ex vivo for expression level of P-selectin using immunofluorescence staining.

RESULTS

Background USMI signals at baseline day 0 were not significantly different (P=0.09) between the two groups. At day 1, USMI signals significantly (P<0.05) increased in both groups and were not significantly different (P=0.9) between both groups. At day 3, signals significantly (P=0.02 vs. day 1) decreased in the treatment group, while it remained high in controls (P=0.25) and was significantly higher (P=0.001) compared to the treatment group. At day 6, signals further decreased in the treatment group; signals also dropped in controls due to known spontaneous decrease of inflammation in this model, but it remained significantly higher (P=0.046) compared to the treatment group. Immunofluorescence staining demonstrated significantly (P=0.004) higher P-selectin expression level in control versus treated ileum.

CONCLUSION

Dual-selectin targeted USMI allows longitudinal monitoring of anti-inflammatory treatment effects in a swine model of acute ileitis.

CLINICAL RELEVANCE/APPLICATION

This study paves the way for clinical translation of this radiation-free technique for monitoring IBD in patients.

SSK12-07 Sepsis of Unknown Origin: A Role of 18F-FDG-PET/MRI in Immunocompromised Patients

PURPOSE

To evaluate a diagnostic value of the PET/MRI in detection of cause of the septic state in patients with immunodeficiency

METHOD AND MATERIALS

There were performed 20 18F-FDG-PET/MRI examinations in patients including two children (the age 7-69 year, 13 females, 8

males) who suffered from signs of sepsis, and the cause was remained unclear after routine examinations. The procedures were performed using integrated PET/MRI system after application of the 18F-FDG with the dose of 2.5 MBq/kg. The examinations had to be performed under general anesthesia in 5 patients. The imaging protocol contained gradient echo T1 (VIBE) and T2 STIR sequences before application of the gadolinium contrast. The application of macrocyclic gadolinium containing contrast agent was used with the dose of 0.1 mmol/kg in those patients in whom the renal impairment was not present. PET data acquisition took 4 minutes in each position. When the suspected inflammation of the brain or spine was suspicious, the targeted imaging was performed. The imaging findings were compared with microbiology investigations or histological assessments

RESULTS

There were eleven patients immunocompromised after therapy of the hemato-oncological disease, four patients with advanced diabetes, three patients on long-term dialysis and two patients with congenital impairment of cellular immunity. The cause of the septic state was found in 90% of all cases. There were found seven cases of musculoskeletal infections caused by Staphylococcus (5), Enterococcus sp. (1), and Pseudomonas (1) infections. In four patients were found central nervous system infections including one patient with granulomatous inflammation of unknown agens and one patient with Toxoplasma meningitis. Other single causes included lung aspergillosis, abdominal Salmonella abscess, mycobacterial lymphadenitis. In three patients, the recurrent hematological malignancy was found, the disseminated renal cell carcinoma was found in one patient. The cause of septic state remained undetected in two patients. The results of imaging trigger therapy in 16 patients.

CONCLUSION

18F-FDG-PET/MRI could play an important role in detection of the cause of septic state in immunocompromised patients and in the therapy decisions.

CLINICAL RELEVANCE/APPLICATION

The advantage of the combination of PET and MRI lies especially in the detection of central nervous system and musculoskeletal infections.

SSK12-08 MRI Detection of Brain Abscesses and Monitoring of Antibiotic Treatment Using Endogenous Bacterial CEST Contrast

Wednesday, Nov. 29 11:40AM - 11:50AM Room: S504CD

jliu142@jhmi.edu

PURPOSE

To develop an endogenous CEST MR imaging strategy to detect bacterial infections and to monitor their antibiotic treatment in deep organs, and to evaluate it in a preclinical animal model.

METHOD AND MATERIALS

Brain abscesses were developed by stereotactically injecting 6x106 *S. aureus* in the brains of F344 rats (3 mm left, 2 mm anterior of Bregma). After well circumscribed lesions were formed on ~ 9 days [1], rats received the ampicillin treatment at a daily dose of 30 mg/kg (*i.p.*) twice a day for 10 days. A F98 brain tumor model was established by injecting 5x104 F98-luc cells (3 mm right, 2 mm anterior of Bregma). MRI assessments were conducted before, 4 days and 10 days after the treatment. CEST MRI weighted images were acquired using a 3-sec CW pulse (B1= 1 and 3 μT) according to previously published methods [2].

RESULTS

As shown in Fig.1A, endogenous CEST contrast at 2.6 ppm allowed the *in vitro* MRI detection of three types of gram positive bacteria (*C. novyi-NT* [2], *S. aureus* and *S. epidermidis*) with slightly differing CEST patterns, as well as the *in vivo* visualization of brain abscesses formed by *S. aureus* (Fig.1C). Currently, differentiation of bacterial infection and brain tumors remains a formidable clinical challenge. In CEST MRI, while both type lesions showed higher CEST contrast than brain parenchyma, bacteria and tumors cells showed different CEST-dependence on the B1 strengths used for RF irradiation in CEST, likely attributed to the difference in cell composition and metabolism, which was utilized to differentiate them successfully (Figs. E-H). Finally, we investigated the longitudinal CEST signal changes during antibiotic treatment. As shown in Figs. I&J, CEST signal decreased markedly in the animals receiving amoxicillin treatment and, in contrast, remained constantly in the control group.

CONCLUSION

The endogenous CEST contrast of bacteria cells enables the direct and specific MRI assessment of bacterial infections of *S. aureus* in animal models. Moreover, this method allows non-invasive monitoring of bacteria responses to antibiotic treatments. References (1) Flaris, N. A.; Hickey, W. F. Am J Pathol 1992, 141, 1299-307. (2) Liu, G., et al. Magn. Reson. Med. 2013, 70, 1690-8.

CLINICAL RELEVANCE/APPLICATION

Endogenous CEST MRI contrast of bacterial cells provides a new clinically compatible imaging strategy for the diagnosis and treatment monitoring of bacterial infections in deep-seated organs.

SSK12-09 Developing a Novel Paramagnetic Fluorinated Nanoemulsion for Sensitive Imaging of Inflammation by Fluorine-19 Magnetic Resonance Imaging

PURPOSE

Imaging of macrophages holds tremendous promise to address a variety of unmet diagnostic needs, such as imaging of cancer, cardiovascular disease, inflammatory disease, or tracking cells in vivo. 19F MRI of inflammation has emerged as an approach to locate macrophages using exogenous 19F probes in a highly specific and quantitative manner. We propose a novel nanoemulsion (NE) imaging probe for sensitive imaging of inflammation in vivo.

METHOD AND MATERIALS

We designed and synthesized a highly stable hexadentate chelating agent for iron (III). The structure of this complex was confirmed by NMR and x-ray crystallography. We added the iron (III) complex to perfluorooctyl bromide (PFOB) to form paramagnetic PFOB (P-PFOB) NE. (PFOB has been used previously in the clinic as a 19F tracer.) The NE was formed using high shear microfluidization to yield a monodispersed oil-in-water NE. Relaxation time 19F NMR measurements (9.4 T and 3 T) and in vitro cell apoptosis assays where used to characterize the nanoemulsion. Inflammation was induced in a murine model via a subcutaneous plug of Matrigel mixed with lipopolysaccharide in the neck. NE was subsequently injected intravenously and 11.7 T MRI data were acquired 24 h later using 2D chemical shift imaging (CSI).

RESULTS

Addition of Fe3+ chelate to PFOB dramatically enhanced 19F MRI detection sensitivity by reducing the 19F T1 by an order of magnitude. T1 values at 3 T are reduced from 1266 ms (PFOB) to 199 ms (P-PFOB, [Fe3+]= 3.5 mM) with minimal T2 line broadening; the effect diminishes at higher fields. In vitro cell assays confirmed viability of NE-labeled macrophages. Upon intravenous injection of P-PFOB NE, accumulation of the agent in the Matrigel plug was observed by 19F MRI, corresponding to the inflammation site. A linear [Fe3+]-dependent chemical shift was also observed in the PFOB fluorine peaks, which enables simultaneous tracking of various subtypes of cells via CSI.

CONCLUSION

We developed P-PFOB, capable of forming NE, with enhanced 19F MRI detection sensitivity over PFOB. By shortening T1, more signal averaging in a given scan time is possible. P-PFOB can also serve as a chemical shift agent for tracking various subtypes of immune cells.

CLINICAL RELEVANCE/APPLICATION

P-PFOB NE is a novel 19F MRI probe with greatly enhanced sensitivity for imaging inflammation and can be used to track various subtypes of immune cells in vivo.

alessandro.napoli@uniroma1.it

PURPOSE

To determine the clinical impact of CT-guided Pulsed Radiofrequency in the management of patients with acute or sub-acute neuro-radicular pain from lumbar disc herniation, refractory to usual therapeutic strategies.

METHOD AND MATERIALS

Patients were eligible for this single-center prospective study if they presented acute or sub-acute neuro-radicular low back pain (EMG confirmed), refractory to usual treatments (drugs and injections), and if they could safely undergo Pulsed Radiofrequency procedure. Treatment was performed using a 22-20 G needle-electrode with probe tip directed to the symptomatic DRG under CT guidance; E-pulsed radiofrequency (Cosman G4) was administered for 10 min at 45V with constant local temperature of 42°C. Clinical evaluation was conducted with Visual Analogue Scale (VAS), Owestry Disability Index (ODI) and Roland-Morris (RM) score for quality of life assessment; all questionnaires were obtained at baseline and at 1-week, 1-month and 3-month follow-up. Analyses were performed on a per-protocol basis.

RESULTS

Over a 3-year period, 80 patients were treated with Pulsed RadiofrequencyMedian VAS scores decreased from 7.8 at baseline to 3.5 at 1week after treatment, to 2.6 at 1 month and 1.3 at 3 months; median ODI scores decreased from 78.0 at baseline to 12.5 at 1 week, to 6.0 at 1 month and 5.5 at 3 months; RM score decreased from 16 at baseline to 3 at 1 month and 1.5 at 3 months ($p<0.001$). Overall, 90.0% of patients reached a 0 VAS score within the first month after treatment; 97.5% of patients had a decrease of at least 20 points in ODI score in the same interval. There were 6 patients considered partial responders that required a second PRF session.

CONCLUSION

CT-guided Pulsed Radiofrequency has shown to be a minimally invasive, effective and repeatable percutaneous treatment option for patients with acute or sub-acute neuro-radicular low back pain.

CLINICAL RELEVANCE/APPLICATION

the results of this study are superior to those reported from literature for usual care strategies and injections and may avoid surgery for a substantial number of patients with sciatic disc compression.

SSK13-02 Effects of Allogeneic Human Chondrocytes Expressing TGF-ß1 (TG-C) On Structural Progression of MRI Features Of Knee Osteoarthritis: A Randomized Clinical Trial

guermazi@bu.edu

PURPOSE

To determine effects of allogeneic human chondrocytes expressing TGF-ß1 (TG-C) on structural progression of MRI features of knee osteoarthritis over a 1 year period.

METHOD AND MATERIALS

This phase II randomized controlled trial of TG-C included patients with moderate to advanced osteoarthritis. Patients were randomized to receive an intraarticular 3:1 mixture of non-transduced allogeneic human chondrocytes and TG-C or placebo. 3T MRI was acquired for all patients at baseline and follow-up (3, 6 and 12 months). MRIs were assessed using the WORMS system including cartilage damage, bone marrow lesions (BMLs), meniscal damage/extrusion, Hoffa-, effusion-synovitis, and osteophytes. Analyses were performed on a whole knee level, compartmental level, and subregional level. Binary logistic regression with Generalized Estimating Equation was used to compare risks of progression, adjusting for baseline age and gender. Mann-Whitney-Wilcoxon tests were used to assess differences for continuous variables.

RESULTS

57 Patients were included in the TG-C group and 29 in the placebo group. At 12 months, knees in the TG-C group showed less progression of cartilage damage compared to placebo on a whole knee level (34.6% vs. 47.9%; adjusted RR 0.7, 95%CI [0.5-1.1], p=0.077). Less progression of Hoffa-synovitis and effusion-synovitis was observed in the TG-C group compared to placebo (9.6% vs. 21.1%, adjusted RR 0.5, 95%CI [0.2,1.2], p=0.115). No statistically significant differences were seen for BMLs, meniscal damage and osteophytes.

CONCLUSION

Intraarticular treatment with TG-C showed fewer patients in the treated group with progression in structural OA features and other MRI-defined inflammatory markers such as Hoffa-synovitis and effusion-synovitis. However, no differences were observed in regard to progression of BMLs and meniscal damage, or hypertrophic osteophyte formation.

CLINICAL RELEVANCE/APPLICATION

Intraarticular treatment with TG-C may potentially show benefits on delayed progression of cartilage damage and MRI markers of inflammation in osteoarthritis.

SSK13-03 MR Guided High Intensity Focused Ultrasound (MRgFUS) for the Treatment of Oligometastatic Prostate Cancer Bone Metastasis: Can Soundwaves Downstage Cancer Spread?

Wednesday, Nov. 29 10:50AM - 11:00AM Room: E353C

Participants
Carola Palla, MD , Rome, Italy (*Presenter*) Nothing to Disclose
Alessandro Napoli, MD, Rome, Italy (*Abstract Co-Author*) Nothing to Disclose
Cristina Marrocchio, Rome, Italy (*Abstract Co-Author*) Nothing to Disclose
Lorenzo Chiurchioni, Rome, Italy (*Abstract Co-Author*) Nothing to Disclose
Fabrizio Andrani, MD , Roma, Italy (*Abstract Co-Author*) Nothing to Disclose
Carlo Catalano, MD, Rome, Italy (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

With improvements in diagnostic modalities such as functional imaging, oligometastatic prostate cancer is being diagnosed with greater frequency than ever before. Our aim was to determine MRgFUS ability to downstage patients with oligometastatic bone disease with single session of non-invasive metastasis-directed therapy.

METHOD AND MATERIALS

The study was designed with intention-to-treat metastatic bone lesions. Patients were enrolled if they had accessible bone metastasis and could safely undergo MRgFUS (InSightec, Israel). Baseline measurable characteristics included dynamic contrast enhanced MRI study (Gd-BOPTA, Bracco; GE 750 3T magnet) with semiquantitative perfusion analysis, PSA level (ng/ml) and choline PET (SUV). Measurable variables were obtained at treatment time, 3 months, 12 months and 24 months follow-up.

RESULTS

18 patients fulfilled the inclusion criteria and safely underwent MRgFUS procedure of metastatic bone ablations. Lesions were located in the pelvis (11), scapula (3) and long bones (4). At baseline all lesions showed a significant DCE perfusion (highly vascular) with mean perfusion reduction of 88% at 3 months follow-up (CI: 100-50; $p<0.001$) stable at subsequent follow-up scans. Similarly PSA levels decreased from a mean baseline of 19 (ng/ml) to 7.1, 2.9 and 2.1, at 3-12 and 24 moths respectively. SUV values showed similar trend with reduction from baseline (mean 8.9 to 3.0, 2.3 and 1.7: $p<0.001$). In all patients single MRgFUS session was appropriate without any major or minor adverse events reported.

CONCLUSION

MRgFUS is a totally non-invasive procedure that can obtain nearly complete bone ablation in patients with oligometastatic prostate disease. The technique features a radiation-free approach that can be of incremental value in long-survivor subset on oncological patients, significantly reducing risk of toxic effects.

CLINICAL RELEVANCE/APPLICATION

MRgFUS could be routinely introduced as a treatment option for oligometastatic bone disease non responding to conventional treatment.

SSK13-04 Image-guided Spine Injections: Paradoxical Particle Formation of Ropivacaine and Non-Particulate Dexamethasone Poses a Risk for Spinal Cord Infarction Events

Wednesday, Nov. 29 11:00AM - 11:10AM Room: E353C

Participants
Brandon Childers, MD, Baltimore, MD (*Presenter*) Nothing to Disclose
Il Minn, Baltimore, MD (*Abstract Co-Author*) Nothing to Disclose
Jace Jones, Baltimore, MD (*Abstract Co-Author*) Nothing to Disclose
Maureen Kane, Baltimore, MD (*Abstract Co-Author*) Nothing to Disclose
Jan Fritz, MD, Baltimore, MD (*Abstract Co-Author*) Research Grant, Siemens AG; Scientific Advisor, Siemens AG; Scientific Advisor, Alexion Pharmaceuticals, Inc; Speaker, Siemens AG

PURPOSE

Image-guided epidural steroid injections are frequently performed radiologic procedures using local anesthetics and steroids. Because particulate steroids can embolize into the arterial system and cause rare cord infarction events, non-particulate steroids are now recommended. However, we have observed paradoxical particulation when mixing the non-particulate steroid dexamethasone and the local anesthetic ropivacaine, posing a risk for cord infarction events despite using recommended non-particulate injectables. Therefore, we investigated the occurrence of particulation between different local anesthetics and non-particulate dexamethasone formulations, as well as the mechanism of action.

METHOD AND MATERIALS

We evaluated clinically relevant dilution series (1:1 - 1:10) of commercially available ropivacaine (2), lidocaine (2) and bupivacaine (1) formulations mixed with three different commercially available dexamethasone formulations. The outcome variables were the pH of the native drugs and mixtures as well as the presence of precipitation using macroscopic inspection and microscopic photography. Mass spectroscopy was used to analyze the composition of ropivacaine-dexamethasone precipitate.

RESULTS

The pH of the native formulations and mixtures were acidic for ropivacaine, and near neutral for bupivacaine, lidocaine, and dexamethasone. All mixtures were pH neutral. Both ropivacaine formulations demonstrated particulation at all concentrations when combined with two dexamethasone formulations, whereas only minimal particulation occurred at concentrations of 1:1-2 of ropivacaine and the third dexamethasone formulation. Bupivacaine showed minimal, wall-adherent crystal formation with only one dexamethasone formulation at concentrations of 1:1-2. Lidocaine did not form any particles. Mass spectroscopy identified the particles as pure ropivacaine precipitate.

CONCLUSION

Ropivicaine precipitates out of solution and forms particles when combined with dexamethasone, owing to a change from acidic to neutral pH. However, the degree of particulation varies based upon the commercially-available formulations, suggesting that other factors may also play a role.

CLINICAL RELEVANCE/APPLICATION

The combination of non-particulate ropivacaine and non-particulate dexamethasone formulations should be avoided when performing epidural steroid injections to prevent particle formation and minimize the risk of embolic cord infarction events.

SSK13-05 Greater Occipital Nerve Infiltration under MR Guidance: Feasibility Study and Preliminary Results

Wednesday, Nov. 29 11:10AM - 11:20AM Room: E353C

Participants

Stephan Chabardes, Grenoble, France (*Abstract Co-Author*) Nothing to Disclose
Alexandre Krainik, MD, PhD, Grenoble Cedex, France (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To assess the feasibility of greater occipital nerve (GON) intermediate site infiltration with MRI guidance

METHOD AND MATERIALS

Eleven consecutive patients suffering from chronic refractory cranio-facial pain who underwent 16 GON infiltrations between November 2016 and January 2017 were included in this prospective study. All of the procedures were performed on an outpatient basis in the research facility of our institution, equipped with a widebore 1.5T scanner. The fatty space between inferior obliquus and semispinalis muscles at C1-C2 level was defined as the infiltration target. Technical success was defined as the ability to accurately inject the products in the pre-defined target, assessed by post procedure axial and sagittal proton density weigthed sequences. Clinical success was defined as a 50% pain decrease at one month follow up.

RESULTS

Technical success as defined above was 100%. GON was depicted in 6 of 11 cases on planning MRI sequences. Mean duration of procedure was 22.5 minutes (range-16-41). Clinical success as previously defined was obtained in 7 of 11 included patients (63.6%) with a mean self reported improvement of 78%.

CONCLUSION

Interventional MR guidance for GON infiltration is a feasible technique offering similar results to an already established effective procedure. It may appear as a useful tool in specific populations, such as young patients and repeat infiltrations, and should be considered in these settings.

CLINICAL RELEVANCE/APPLICATION

• MR guidance for GON infiltration is a feasible technique • Preliminary results are in agreement with other guidance modalities • MR guidance may be seen as a useful tool in specific populations

SSK13-06 Cementoplasty of Pelvic Bone Metastases: Lesion Filling and Other Factors Influencing the Therapeutic Response

Wednesday, Nov. 29 11:20AM - 11:30AM Room: E353C

Participants
Thomas Moser, MD, Montreal, QC (*Presenter*) Nothing to Disclose
Marta Onate Miranda, MD, Madrid, Spain (*Abstract Co-Author*) Nothing to Disclose
Katia Achour, MD, Laval, QC (*Abstract Co-Author*) Nothing to Disclose
Veronique Freire II, MD, Montreal, QC (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

thomas.moser@umontreal.ca

PURPOSE

To determine the parameters likely to influence the therapeutic response in cementoplasty of pelvic metastases.

METHOD AND MATERIALS

We retrospectively reviewed a series of pelvic bone cementoplasties performed for symptomatic metastatic involvement in the last 7 years. In addition to demographics, primary tumor and associated treatments, we collected information on the lesion treated: localization, dimensions, cortical destruction graded 0-6, soft tissue mass and pathological fracture; and procedural information: number of needles, cement volume, filling percentage and extra-osseous leakage. The pain scores were evaluated on a visual analog scale before treatment and at the 1 month follow-up visit.

RESULTS

We included 44 procedures in 40 patients (21 females and 19 males, mean age 63 years). The primary tumor was lung (n = 15), breast (n = 9), kidney (n = 7), thyroid (n = 2) or other (n = 7). There were 38 osteolytic and 6 mixed lesions. Localization was acetabular (n = 30), iliac (n = 11) or sacral (n = 3). The maximal lesion diameter was on average 43 mm. The cortical destruction was on average 2.4 / 6 with soft tissue extension in 7/35 and pathological fracture in 7/35. The number of needles was one in 32/44, two in 10/44 and three in 2/44. The volume of cement injected was on average 10 ml with an average filling of 55%. A cement leak was minimal in 11/44, moderate in 9/44. Pain relief was observed in 74% of patients with an average score of 84/100 before the procedure and 46/100 after. The pain relief did not appear correlated to lesion volume (p = 0.2), presence of pathological fracture (p = 0.3), soft tissue extension (p = 0.21), filling percentage (p =0,42), cement leak (p = 0,26), or previous radiation therapy (p = 0,8).

CONCLUSION

Cementoplasty of pelvic bone metastases provides pain relief in a majority of patients. The lesion filling can be optimized by injection through multiple needles but this parameter does not appear correlated with the therapeutic response.

CLINICAL RELEVANCE/APPLICATION

Cementoplasty is a valuable adjunct in the management of symptomatic pelvic bone metastases.

SSK13-07 Hip Steroid/Anesthetic Injections: Is there an Increased Incidence of Hip Osteoarthritis Progression, Femoral Head Osteonecrosis and Collapse?

Wednesday, Nov. 29 11:30AM - 11:40AM Room: E353C

For information about this presentation, contact:

cychang@mgh.harvard.edu

PURPOSE

To evaluate incidence of osteoarthritis progression, femoral head osteonecrosis and articular surface collapse in hip steroid/anesthetic injection patients.

METHOD AND MATERIALS

Our study was IRB-approved and HIPAA compliant. A total of 123 hip steroid/anesthetic(40 mg triamcinolone, 4 mL 0.5%

preservative free ropivicaine) injections were performed from 01/2014 to 07/2015. Inclusion criterion was follow-up radiography of the native hip 3-9 months after the injection. Two musculoskeletal radiologists performed retrospective, blinded reviews of the pre- and post-injection radiography of hip injection patients (HIPs) and 2 demographic and follow-up duration matched control groups: 1, patients undergoing hip x-rays without injection; 2, glenohumeral joint injection patients. Groups were compared with Fisher exact test.

RESULTS

There were 102 HIPs (age 65 ± 13 (range 19-92) years; 62 F, 40 M; 41 L, 61 R), who were followed for 26 ± 10 (12-66) weeks. For Reader 1, 38/102 (37%) of HIPs had increased osteoarthritis after steroid injection, compared with 27/102 (26%) of hip controls and 14/44 (32%) of shoulder injection patients. For Reader 2, 42/102 (41%) of HIPs had increased osteoarthritis after steroid injection, compared with 20/102 (20%) of hip controls and 10/44 (23%) of shoulder injection patients. There was no significant difference between these groups (P>0.05). For Reader 1, 24/102 (24%) of HIPs had new osteonecrosis and 15/102 (15%) had new collapse after the steroid injection, compared with 9/102 (9%) and 4/102 (4%) of hip controls and 2/44 (5%) and 1/44 (2%) of shoulder injection patients. There was significantly more osteonecrosis and collapse in HIPs, compared with hip controls (P=0.001 and 0.01) and shoulder injection patients (P = 0.005 and 0.04). For Reader 2, 22/102 (22%) of HIPs had new osteonecrosis and 17/102 (17%) had new collapse after the steroid injection, compared with 9/102 (9%) and 4/102 (4%) of hip controls and 2/44 (5%) and 1/44 (2%) of shoulder injection patients. There was significantly more osteonecrosis and collapse in HIPs, compared with hip controls (P=0.01 and 0.01) and shoulder injection patients (P = 0.03 and 0.005).

CONCLUSION

Hip injection patients have a greater incidence of osteonecrosis and collapse compared with hip controls and shoulder injection patients.

CLINICAL RELEVANCE/APPLICATION

Further evaluation of hip injectates and the injection population is warranted, given these findings.

SSK13-08 MRI-Guided High Intensity Focused Ultrasound: A New First-Line Technique in the Treatment of Osteoid Osteoma?

roberto.scipione@uniroma1.it

PURPOSE

to demonstrate that completely non-invasive radiation-free ablation of osteoid osteoma with MRI-guided high intensity focused ultrasound (MRgFUS) is a safe, effective and durable treatment option.

METHOD AND MATERIALS

Patients with typical clinical and radiological diagnostic findings of osteoid osteoma (non-vertebral), suitable for MRgFUS and anaesthesia, were enrolled in this dual-centre prospective observational study. Vertebral locations were excluded as considered inaccessible. MrgFUS was performed using InSightec ExAblate 2100 system. Safety (rate of complications), clinical effectiveness (Visual Analogue Scale [VAS] pain score reduction) and durability (stability of results over time) of MRgFUS were evaluated as primary outcomes; tumour control (nidus ablation) at dynamic contrast enhanced MR imaging (Discovery 750, GE; Gd-BOPTA, Bracco) was considered as secondary outcome. All patients underwent a minimum follow-up period of 4 years.

RESULTS

Out of 50 subjects screened for recruitment, 45 were enrolled and submitted to MRgFUS. No treatment-related complications were observed. A complete and durable response was achieved in 80% of cases. Median VAS pain score dropped from 8 (IQR 7-9) to 0 at 1-week, and at all subsequent follow-up check points (1 month, 6, 12, 24, 36 and 48 months). Scores evaluating interference of pain with sleep, physical and daily activities showed similar improvement after treatment. Among subjects with partial response (20%), 4 received a second treatment (3 with CT-guided Radiofrequency Ablation, 1 with MRgFUS), and 5 did not need any other treatment. All re-treated patients achieved 0 VAS score. Overall, 87% of patients after MRgFUS treatment reached and maintained a stable 0 VAS score during follow-up. At 3-year MRI osteoid osteoma showed no vascularization in 32/42 patients (76%) treated with MRgFUS alone.

CONCLUSION

MRgFUS is a safe, effective and durable option in the treatment of non-spinal osteoid osteoma.

CLINICAL RELEVANCE/APPLICATION

This technique provides relevant advantages in the treatment of this impairing disease affecting mostly young population: no ionizing radiation, no incisions or needles, and, so far, no complications. Our results support the role of MRgFUS as first-line treatment option for accessible osteoid osteoma.

SSK13-09 Imaging and Clinical Risk Factor Correlation with Rate of Conversion to Surgery Following Fluoroscopically Guided Facet Cyst Rupture

Wednesday, Nov. 29 11:50AM - 12:00PM Room: E353C

PURPOSE

Facet cysts may be encountered at magnetic resonance imaging (MRI) in patients with back pain and radicular symptoms. The purpose of this study was to evaluate the conversion rate to surgery following cyst rupture, and to assess associated clinical, imaging and procedural variables.

METHOD AND MATERIALS

A retrospective review was completed of all patients who underwent fluoroscopically guided facet cyst rupture through access of the inferior facet recess from 2000-2016. Primary outcome was conversion to surgery. Secondary outcomes included clinical, MRI, and procedural variables possibly associated with conversion. Clinical variables included sex, age, # of comorbidities, symptoms (pain, motor, sensory), pain laterality, and if pain involved the leg, back or both. MRI variables included cyst size, shape, internal signal, rim signal, spine level, laterality, spondylolisthesis, canal or lateral recess stenosis, presence of facet fluid +/- unilateral vs. bilateral, bone edema and erosion. Procedural variables included cyst opacification, successful epidural rupture and pre vs. post procedure pain.

RESULTS

49 patients met the inclusion criteria. 4 were excluded because they had either no clinical notes or no MRI available for review. 13/45 (29%) of patients converted to surgery. Successful epidural rupture was observed fluoroscopically in 33/45 (73%), of whom 7/33 (21%) converted to surgery. No epidural rupture was seen in 12/45 (27%), of whom 6/12 (50%) converted to surgery. The average interval to surgery was 95 days and average follow up was 889 days after cyst rupture. Of the clinical, imaging and procedural variables evaluated, only the number of comorbidities was significantly associated with conversion to surgery ($p = 0.03$).

CONCLUSION

Facet cysts have been recognized as a cause of spinal stenosis. Fluoroscopically guided facet cyst rupture may be attempted prior to surgery, though 29% our patients eventually required surgery. No significant correlation was found between facet cyst features at MRI and conversion rate to surgery to aid in determining which patients may be benefit from intervention.

CLINICAL RELEVANCE/APPLICATION

Fluoroscopic guided facet cyst rupture is a minimally invasive procedure worth attempting in symptomatic patients as it has a high rate of technical success, with most patients avoiding surgery.

PURPOSE

To develop image processing algorithms and visualization tools to assist with the interpretation of molecular breast imaging (MBI).

METHOD AND MATERIALS

MBI images were first denoised using a state-of-the-art denoising pipeline. The pipeline consists of a variance stabilization step, followed by noise suppression using the block-matching 3D (BM3D) filter. Optimal denoising parameters were defined based on a subset of cases; a graphical user interface allows for dynamic adjustment of the sharpness and noise by the reader. The visualization software includes a computer-aided diagnosis (CAD) feature, which searches for bright regions on the denoised image and automatically highlights their positions for further investigation. To assist the translation between MBI and digital mammography (DM), a registration algorithm is used to determine an affine algebraic transformation that maps coordinates from the MBI images into coordinates on the DM images. The transformation can be used to highlight a region on the DM image based on a user selected location on an MBI image. Alternatively, the MBI may be fused with the corresponding DM images and displayed similar to PET CT images. A software prototype was implemented using MATLAB and evaluated using 18 patient cases.

RESULTS

The denoising algorithm improved the visualization of lesions with subtle uptake by suppressing noise with minimal signal smoothing. The CAD was capable of identifying areas of increased uptake in faint lesions. In this small test set, all lesions were marked; false-positive marks at the chest wall were noted in a minority of cases. The MBI registration resulted in good matches between MBI and DM images, based upon visual inspection of anatomic landmarks.

CONCLUSION

We have developed image processing algorithms and visualization tools for improving the interpretation of MBI images. It is important that MBI is combined with current technologies, such as DM and tomosynthesis, to improve the detection and characterization of lesions.

CLINICAL RELEVANCE/APPLICATION

Denoising may offer the potential to reduce MBI radiation dose and imaging time and increase tumor detectability. By co-registering MBI and DM images, ambiguities between the modalities are reduced, offering the potential to reduce false positive findings.

SSK14-02 Supine Breast PET-MR Imaging in a Whole-Body Approach: How Good is it Compared to Dedicated Breast PET MR Imaging

PURPOSE

To evaluate the detection rate of breast tumor in supine breast MRI and supine breast 18F-FDG PET/MRI compared to diagnostic breast MRI and diagnostic breast 18F-FDG PET/MRI.

METHOD AND MATERIALS

A total of 32 patients (31 women, 1 man, mean age 38 years) with histopathologically confirmed breast cancer were included in this study. Each patient underwent a whole-body 18F-FDG PET/MR examination including dedicated diagnostic breast imaging in prone position and subsequently a whole-body MRI in supine position. We analysed the diagnostic performance of (1) dedicated prone breast MRI, (2) dedicated prone breast 18F-FDG PET/MRI (3) supine breast MRI and (4) supine breast 18F-FDG PET/MRI derived from a whole-body staging examination, on a per-patient and per-lesion basis.

RESULTS

Dedicated prone breast MRI and dedicated prone breast 18F-FDG PET/MRI correctly identified all 32 patients with breast cancer (100%). Supine breast MRI correctly identified 28/32 patients (87.5%), while supine breast 18F-FDG PET/MRI correctly identified 29/32 patients (90%). Based on the reference standard a total of 51 lesions were included for analysis. In both dedicated breast imaging examinations all lesions (100%) were identified with 2 additional false-positive findings. Supine breast MR imaging identified 36/51 lesions (70%) with 5 additional false-positive findings and supine breast 18F-FDG PET/MRI identified 40/51 lesions (78%) with 6 additional false-positive findings. The mean SUVmax for lesions in prone 18F-FDG PET/MRI was 3.4 and 4.2 in supine 18F-FDG PET/MRI.

CONCLUSION

Dedicated breast imaging in prone positioning with or without 18F-FDG information is superior to examinations in supine position. While 18F-FDG information did not improve the diagnostic value of dedicated prone breast MRI, adding 18F-FDG information to supine breast examination led to an increase of tumor detection but also of false positive findings.

CLINICAL RELEVANCE/APPLICATION

Dedicated prone breast (PET)MRI is superior to supine breast imaging, as supine breast (PET)MR imaging identifies less tumor lesions and elicits an increase of false-positive findings leading to potentially harmful biopsies.

SSK14-03 Correlation of Bone Marrow Fat Fraction Content using T1 Dixon and Changes in FDG with PET/MR in Breast Cancer Patients with Bone Metastases

Wednesday, Nov. 29 10:50AM - 11:00AM Room: S505AB

PURPOSE

Bone metastases replace the normal fat of bone marrow which can easily be imaged with Dixon sequence. However, there is a lack of quantitative evaluation in the literature. We utilized Dixon sequence with FDG PET/MR to determine if change in fat content correlated with change in metabolic activity and if it could be used to assess treatment response.

METHOD AND MATERIALS

We retrospectively identified 7 females with osseous metastases from breast cancer who had pre- and post-treatment FDG PET/MR scans. Regions of interest were drawn around metastases on coronal T1 Dixon fat only images. Fat fraction of each lesion was measured using the ratio of signal intensity of metastases to signal intensity of the patient's normal psoas muscle as well as normal vertebral body. Change in fat fraction was then compared with change in PET SUV of each lesion.

RESULTS

32 bone metastases were identified on PET/MR scans in 7 females with breast cancer. 63% (n=20) of the lesions were in the spine, 22% (n=7) in the pelvis, and 15% (n=5) in the extremities. The average time between studies was 6 months. From pre-treatment

to post-treatment study, 25 lesions increased in FDG activity and 7 lesions decreased in FDG activity. 89% (22/25) of lesions with increasing metabolic activity demonstrated a decrease in fat fraction, with an overall average change in fat fraction of -56%. To the contrary, lesions with decreasing metabolic activity had an average change of +153% in fat fraction. A Wilcoxon rank-sum test revealed a significant difference in the change of fat fraction between the two groups with a p-value of 0.01. A Pearson correlation test between the percent change in SUV and change in fat fraction of each lesion revealed an r-value of -0.3. More specifically, 100% (7/7) of pelvic and 85% (11/13) of vertebral lesions with increased metabolic activity demonstrated a decrease in fat fraction.

CONCLUSION

Quantitative analysis of bone metastases in breast cancer patients reveals that fat fraction of lesions increases with significance as metastases improve and vice versa. However, a strong negative linear correlation did not exist between changes in metabolism and changes in fat fraction.

CLINICAL RELEVANCE/APPLICATION

Many breast cancer patients present in the late stages with osseous metastases. Measuring quantitative fat fraction changes in lesions can help follow up treatment response in bone metastases, especially when PET imaging is not available.

SSK14-04 Quantitative Evaluation of Metabolic Tumor Burden in Molecular Subtypes of Primary Breast Cancer with FDG PET/CT

Wednesday, Nov. 29 11:00AM - 11:10AM Room: S505AB

PURPOSE

To quantitatively evaluate volume-based metabolic tumor burden including metabolic tumor volume and total lesion glycolysis in different molecular subtypes of breast cancer and to compare the total lesion glycolysis before and after normalizing for lean body mass on 18F-FDG PET/CT.

METHOD AND MATERIALS

This study involved 99 female patients who were pathologically diagnosed with primary breast cancer and 18F-FDG PET/CT were performed before any therapy. The patients were divided into 4 subtypes including Luminal A, Luminal B, ERBB2+ and Basal-like according to the immunohistochemistry results. Metabolic tumor volume (MTV) and total lesion glycolysis (TLG) before and after correction for lean body mass (LBM) were achieved and compared. Correlations between metabolic tumor burden and the expression level of Ki-67 and p53 were analyzed. Diagnostic performance of volume-based metabolic parameters was evaluated using the receiver operating characteristic curve.

RESULTS

Group differences of the total lesion glycolysis were found between each molecular subtype of breast cancer, with the highest value in the subtype of Basal-like but there was no significant difference in metabolic tumor volume in subtypes of breast cancer. Values of total lesion glycolysis before and after correction for LBM were highly associated and significant reduction was found after correction of LBM for all subtypes of breast cancer. TLG after correction for LBM showed more close correlations with the expression level of Ki-67 and it presented higher diagnostic ability in identifying patients of Basal-like from those of non-Basal-like than that before correction.

CONCLUSION

Metabolic tumor burden could reflect the metabolic differences and predict prognosis of different molecular subtypes of breast cancer, especially total lesion glycolysis after correction for LBM. It could be used to help with differentiating patients in the subtype of Basal-like.

CLINICAL RELEVANCE/APPLICATION

Metabolic tumor burden is superior to daily used SUV and could comprehensively reflect the metabolic differences and predict prognosis of different molecular subtypes of breast cancer,

SSK14-05 Relationship between SUV Max and Gene Expression in FDG-PET/CT in Invasive Ductal Breast Cancer

Wednesday, Nov. 29 11:10AM - 11:20AM Room: S505AB

Charles.intenzo@jefferson.edu

PURPOSE

To compare 18FDG uptake within invasive ductal breast carcinoma (IDC) with estrogen and progesterone receptor status, as well as epidermal growth factor (HER-2) gene expression.

METHOD AND MATERIALS

Over a 5-year interval, a total of 142 women with IDC, 1 cm or larger, underwent PET/CT imaging for staging purposes. From histopathology reports, all estrogen receptor (ER) and progesterone receptor (PR) status results were collected, as well as results of the human epidermal growth receptor 2 (HER-2) gene expression status. Four patient subgroups were formed. Group A (N=43) were ER negative/PR negative/HER-2 negative (i.e. 'triple negative'), group B (N=50) were ER positive/PR positive/HER-2 negative, group C (N=45) were ER positive/PR positive/HER-2 positive, group D (N=9) consisted of any other combination.

RESULTS

The triple-negative tumors had the highest SUV Max, ranging from 2.24 to 26.7, with a mean of 14.69. The ER positive/PR positive/HER-2 positive had the lowest SUV Max, ranging from 0.85-6.86, with a mean of 3.85.

CONCLUSION

As expected, triple negative IDC, as the most aggressive, demonstrated the highest glucose comsumption rate. By contrast, those tumors with combined estrogen, progesterone and HER-2 receptor activity demonstrates the lowest glucose consumption.

CLINICAL RELEVANCE/APPLICATION

There is a direct correlation between hormone and HER-2 receptor status and 18FDG uptake in invasive ductal breast cancers.

SSK14-06 A Patient-Centered Quality Initiative: Stepwise Modification of Departmental Protocol Culminating in a Single Periareolar Radiotracer Injection with Equally Effective Sentinel Node Detection While Reducing Procedural Pain

Wednesday, Nov. 29 11:20AM - 11:30AM Room: S505AB

Awards
Student Travel Stipend Award

Participants
Janice Thai, MD, Staten Island, NY (*Presenter*) Nothing to Disclose
Michael Shamis, MD, Staten Island, NY (*Abstract Co-Author*) Nothing to Disclose
Ami Gokli, MD, Staten Island, NY (*Abstract Co-Author*) Nothing to Disclose
Arnold Brenner, DO, Staten Island, NY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the effectiveness of multiple technical modifications of technique in performing preoperative axillary sentinel lymph node (SLN) mapping in breast cancer patients, with the endpoints of nodal detection sensitivity and perceived procedural pain.

METHOD AND MATERIALS

A superficial injection of radiotracer 99Tc- ultra-filtered sulfur colloid was used. Stepwise optimization of this technique resulted in a standardized injection protocol with a tracer dose of 1 mCi, administered through a single periareolar intradermal injection of 0.1 mL using a TB syringe and a 26G needle. Additional modification included the use of benzocaine topical anesthetic spray. Over a 6 year period (2011 - 2017), the number of periareolar injections performed was reduced stepwise from 4 injection sites to 1 injection site and this final refinement was analyzed for SLN detection sensitivity and perceived pain, using our institutional pain scale ranging from 0-10.

RESULTS

682 women with invasive breast cancer who underwent consecutive preoperative axillary SLN mapping were included (mean age 63, range 31-90). Laterality of breast injection site included 263 in the right breast, 287 in the left breast and 132 in bilateral breasts. Axillary SLN was visualized with detection sensitivity of 100%. In women who had 4 injection sites in a unilateral breast or 8 injections in bilateral breasts (n= 180), the mean reported pain score was 4.6 (range 0-10). Women with 3 injection sites in a unilateral breast or 6 injections in bilateral breasts (n= 214) and 2 injection sites in a unilateral breast or 4 injections in bilateral breasts (n= 196) have a mean reported pain score of 3.7 and 3.2, respectively (range 0-10). Women who had only 1 injection in a unilateral breast or 2 injections in bilateral breasts (n= 92) reported a mean pain score of 2.4 (range 0-8). A decrease in the number of injection sites from 4 to 1 reduced the mean pain score by 48% (p-value < 0.0001).

CONCLUSION

Multiple sequential technical modifications culminating in a single periareolar injection technique for axillary SLN mapping reduces periprocedural pain while maintaining 100% SLN detection sensitivity.

CLINICAL RELEVANCE/APPLICATION

A stepwise modification of technique resulting in a single periareolar intradermal injection reduces periprocedural pain while maintaining 100% axillary sentinel lymph node detection sensitivity.

SSK14-07 Value of Intratumoral Metabolic Heterogeneity and Quantitative 18F-FDG PET/CT Parameters to Predict Prognosis in Patients with Cervical Cancer

Wednesday, Nov. 29 11:30AM - 11:40AM Room: S505AB

Participants
Daniella F. Pinho, MD, Dallas, TX (*Presenter*) Nothing to Disclose
Brent King, MD, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose
Rathan M. Subramaniam, MD, PhD, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

daniella.pinho@utsouthwestern.edu

PURPOSE

To evaluate the impact of intratumoral metabolic heterogeneity and quantitative FDG PET/CT parameters for predicting patient outcomes in cervical cancer.

METHOD AND MATERIALS

This ongoing IRB and HIPPA complaint retrospective study included a total of 120 patients with biopsy proven squamous cell carcinoma of the cervix who had a FDG PET/CT for initial staging. Automated gradient-based segmentation method was used to assess the primary tumor standardized uptake value maximum and peak (SUV max and SUV peak), metabolic tumor volume (MTV) and metabolic intratumoral heterogeneity index, calculated as the area under cumulative SUV-volume histograms (AUC-CSH), with lower AUC-CSH indexes corresponding to higher degrees of tumor heterogeneity. Patient's demographics and tumor staging were also collected. Median follow up time was 27.5 months. Overall survival (OS) and progression free survival (PFS) were calculated using multivariate cox proportion hazard regression model and log-rank (Mantel-Cox) test to generate Kaplan-Meier survival plots.

RESULTS

The patients' mean age was 54.4 ± 13.1 years and there were 27 patients with stage I, 53 with stage II, 23 with stage III and 17 with stage IV disease. Median survival was 74.9 months. Thirty three patients died and 82 were alive (for 5 patient no information on survival available). Higher MTV was significantly associated with reduced OS in the multivariate analysis for every 10 mL increase in volume (HR=1.084, 95% CI=1.036-1.134, p=0.0005). Higher AUC-CSH (lower tumor heterogeneity) was significantly associated with increased PFS in the multivariate analysis for every 1000 increase in the area under the curve (HR=0.679, 95% CI=0.468-0.968, p=0.042). Kaplan-Meier survival analysis using the median value for MTV (74.7 mL) significantly predicted OS (HR = 2.839; 95% CI =1.33-6.02; p=0.0045) and using median value for AUC-CSH of 5602 significantly predicted PFS (HR = 0.469; 95% CI =0.226-0.973; p=0.03).

CONCLUSION

MTV segmented by gradient method is significantly associated with overall survival and tumor heterogeneity is associated with progression free survival for patients with cervical cancer.

CLINICAL RELEVANCE/APPLICATION

FDG PET/CT quantitative parameters can provide prognostic information on initial staging scan, potentially leading to a more personalized approach for patient's treatment.

SSK14-08 18F-FDG PET/MRI vs MRI Alone in Whole-Body Staging of Seventy-One Patients with Suspected Recurrent Gynecologic Pelvic Cancers

Wednesday, Nov. 29 11:40AM - 11:50AM Room: S505AB

Participants
Lino Sawicki, MD, Dusseldorf, Germany (*Presenter*) Nothing to Disclose
Julian Kirchner, Dusseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Johannes Grueneisen, Essen, Germany (*Abstract Co-Author*) Nothing to Disclose
Verena Ruhlmann, Essen, Germany (*Abstract Co-Author*) Nothing to Disclose
Gerald Antoch, MD, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Lale Umutlu, MD, Essen, Germany (*Abstract Co-Author*) Consultant, Bayer AG

PURPOSE

To evaluate the diagnostic performance of whole-body 18F-fluordesoxyglucose positron emission tomography/magnetic resonance imaging (18F-FDG PET/MRI) for whole-body staging of suspected recurrent gynecologic pelvic cancer in comparison with whole-body MRI alone.

METHOD AND MATERIALS

Seventy-one consecutive female patients (54 ± 13 years) with suspected recurrence of cervical (32), ovarian (26), endometrial (7), vulvar (4), and vaginal (2) cancer prospectively underwent whole-body PET/MRI including a diagnostic contrast-enhanced MRI protocol. PET/MRI and MRI datasets were separately evaluated regarding lesion count, localization, categorization (benign/malignant), and diagnostic confidence (4-point scale; 0 - 3) by two radiologists. The reference standard was based on histopathological results and follow-up imaging. Proportions of lesions rated correctly were compared on a per-patient and per-lesion basis using McNemar's chi2 test. Differences in diagnostic confidence were assessed by Wilcoxon test.

RESULTS

Fifty-five patients had cancer recurrence. PET/MRI and MRI alone correctly identified 55/55 (100 %) and 46/55 (83.6 %) patients with cancer recurrence, respectively. A total of 241 lesions were described on the reference standard, including 181 malignant and 60 benign lesions. PET/MRI detected all 241 lesions, whereas only 186/241 lesions (77.2 %) were detectable on MRI alone. PET/MRI provided correct identification of all 181 malignant lesions. Instead, MRI alone correctly identified only 126/181 (69.6 %) malignant lesions, which was significantly less compared with PET/MRI ($p < 0.001$). PET/MRI offered significantly higher diagnostic confidence in the categorization of malignant lesions compared with MRI alone ($p < 0.001$).

CONCLUSION

PET/MRI demonstrates excellent diagnostic performance and outperforms MRI alone in staging of patients with suspected recurrent gynecologic pelvic cancers.

CLINICAL RELEVANCE/APPLICATION

PET/MRI enables exact assessment of recurrence of female pelvic malignancies and should be considered a valuable alternative for whole-body staging of patients with suspected recurrent disease.

SSK14-09 First-in-Human Biodistribution and Dosimetry of In-111/Y-90-FF-21101: A Radioimmunotherapeutic Agent Targeting P-cadherin

PURPOSE

To assess the human biodistribution and dosimetry of 111In/90Y-FF-21101, a human-mouse chimeric monoclonal antibody directed against P-cadherin, encoded by CDH3 gene-overexpressing solid tumors.

METHOD AND MATERIALS

Ten patients (4 male, 6 female) in a first-in-human dose-escalation (5, 10, 15, 20, 25 mCi/m2 <= 60 mCi) 90Y-FF-21101 clinical trial, underwent a 5 mCi 111In-FF-21101 pre-treatment dosimetry study. Whole-body planar (WB) scans were acquired at 0.25, 4, 24, 72 and 144 h on a Siemens Symbia S camera. A two-bed SPECT scan was acquired at 24-h, calibrated with a 10 ml vial containing 50 µCi of 111In, to compute organ absolute activity. (A CT scan was acquired on a General Electric 750 HD scanner for SPECT attenuation correction and fusion.) Blood samples were collected at 0.5, 1, 2, 4, 24, 72 and 144 h, for estimating marrow dose. Time-activity curves (TACs) were generated from two-dimensional regions of interest drawn on the WB images around the heart contents, lungs, liver, spleen, kidneys, testes and total body. Three-dimensional volumes of interest for the lungs, liver, spleen and kidneys were defined on the SPECT/CT images, to activity-correct planar TACs and estimate organ masses for the dosimetric analysis. Source organ and marrow 111In and 90Y residence times derived from TAC exponential fits were entered into OLINDA/EXM v1.1 for dose calculation (mSv/MBq), with mass correction for liver, kidneys, spleen and lungs. Tumor uptake was assessed qualitatively.

RESULTS

The five highest mSv/MBq for 111In were: spleen (M:2.55,F:2.66); kidneys (M:0.77,F:0.76); testes (M:0.62) and liver (F:0.64); liver (M:0.62) and lungs (F:0.52); and pancreas (M:0.57,F:0.47); and for 90Y were: spleen (M:23.4,F:28.5); testes (M:8.56) and kidneys (F:6.42); kidneys (M:6.48) and lungs (F:5.09); liver (M:4.34,F:4.66); and lungs (M:4.12) and heart wall (F:2.66). Tumor uptake was visualized in 6 of 10 patients; with the highest uptake seen in tumors of epithelial origin, including metastatic vaginal, ovarian and colon carcinomas, and liposarcoma, consistent with anti-P-cadherin targeting.

CONCLUSION

FF-21101 exhibits favorable biodistribution and dosimetry, enhancing its attractiveness as an imaging and therapeutic agent targeting P-cadherin overexpression.

CLINICAL RELEVANCE/APPLICATION

FF-21101 demonstrates P-cadherin targeting and favorable biodistribution, and thus may be a viable radioimmunotherapeutic agent for P-cadherin-overexpressing cancers.

PURPOSE

Malignant cerebellar edema (MCE) is a life-threatening complication after acute cerebellar stroke. The aim of this study was to identify imaging predictors for the occurrence of MCE using multiparametric CT including whole-brain CT perfusion (WB-CTP).

METHOD AND MATERIALS

We selected all subjects with cerebellar WB-CTP perfusion deficit and follow-up-confirmed infarction from a cohort of 3,254 consecutive patients who underwent multiparametric CT. Follow-up imaging was assessed for the presence (MCE+) or absence (MCE-) of MCE, measured using an established 10-point scale by Jauss et al., of which scores >=4 are considered malignant. Posterior-circulation-Acute-Stroke-Prognosis-Early-CT-Score (pc-ASPECTS) was determined to assess ischemic changes on non-contrast CT (NCCT), CT angiography (CTA), and on parametric WB-CTP maps (cerebral blood flow, CBF; cerebral blood volume, CBV; mean transit time, MTT; time to drain, TTD). The volumes of CBF, CBV, MTT, and TTD deficits were quantified. Chi-square, Mann-Whitney-U tests and receiver operating characteristics (ROC) analyses were performed.

RESULTS

Fifty-one patients were included. 42 patients (82.4%) were categorized as MCE- and 9 (17.6%) as MCE+. MCE+ patients had larger CBF, CBV, MTT and TTD deficit volumes (each with $p<0.001$) and showed significantly lower median pc-ASPECTS assessed using WB-CTP (CBF: 5 vs. 8; CBV: 8 vs. 9; MTT: 5 vs. 8; TTD: 5 vs. 8; each with $p<0.001$) compared to MCE- patients, while median pc-ASPECTS on NCCT was not significantly different (9 vs. 10, $p=0.097$). ROC analyses for MCE yielded the largest area-under-the-curve (AUC) values for CBF (0.984), followed by CBV deficit volumes (0.972) and pc-ASPECTS on CBF (0.949), whereas pc-ASPECTS on NCCT (0.664) and CTA (0.699) provided less diagnostic value. Regarding mortality, ROC analyses revealed the highest AUC values for pc-ASPECTS CBV (0.853) and CBV deficit volume (0.837), and the lowest AUC values for pc-ASPECTS on NCCT (0.610) and CTA (0.643).

CONCLUSION

WB-CTP provides added diagnostic value regarding the prognosis of MCE occurrence and clinical outcome after cerebellar stroke compared to NCCT and CTA.

CLINICAL RELEVANCE/APPLICATION

WB-CTP performed in acute cerebellar stroke has the potential to impact clinical decision making based on an early identification of patients that are at high risk of developing MCE.

SSK15-02 Utility of Serial and Ancillary Neuroimaging in Assessment of Suspected Hypertensive Hemorrhage

PURPOSE

To assess the utility of serial and ancillary neuroimaging in the work-up of primary intracerebral hemorrhage involving characteristic hypertensive regions, including basal ganglia, thalamic, pontine and cerebellar hemorrhages. Lobar hemorrhages were included in the study, although these are more classically seen with cerebral amyloid angiopathy in non-hypertensive patients.

METHOD AND MATERIALS

This IRB-approved study retrospectively reviewed hypertensive patients presenting to the emergency room or transferred from an outside facility with imaging findings of primary intracerebral hemorrhage from October 2013 - October 2015. Patients were excluded if they had known CNS malignancy. Age, admitting systolic blood pressure, the location of bleed, and findings from follow-up imaging were recorded.

RESULTS

A total of 135 patients were identified, of which 73.6% (98/135) and 51.9% (70/135) had follow-up CTA/MRA or MRI, respectively. Sites of involvement included basal ganglia (42.9%, 56), thalamic (24.4%, 36), lobar (20%, 27), and the remaining within the brainstem or cerebellum. Of patients who underwent ancillary imaging, CTA/MRA revealed a vascular abnormality in a single patient, an arteriovenous malformation within the cerebellum. MRI also revealed a vascular abnormality in a single patient, vasculitis resulting in lobar hemorrhage. All remaining follow-up imaging reviewed was negative for additional pathology. With regards to location, all cases of basal ganglia and thalamic hemorrhages were consistent with hypertensive hemorrhage only.

CONCLUSION

In the setting of hypertension, ancillary imaging for basal ganglia and thalamic hemorrhages did not reveal alternative etiologies. In the absence of initial findings to warrant operative management, serial CT imaging in otherwise clinically stable patients did not result in findings warranting a change in management.

CLINICAL RELEVANCE/APPLICATION

In the absence of clinical concerns and findings on initial imaging, there is low utility in ancillary and serial neuroimaging for primary intracerebral hemorrhage involving the basal ganglia and thalamus in patients presenting with hypertension.

SSK15-03 The Ischemic Penumbra Assessment Using 3D ASL at Different Post Labeling Delays in Patients with Unilateral Middle Cerebral Artery Severe Stenosis or Occlusion

PURPOSE

To evaluate ischemic penumbra (IP) using three-dimensional pseudo continuous arterial spin labeling (3D pCASL) at PLD of 1.5 s and 2.5 s in patients with ischemic cerebrovascular disease.

METHOD AND MATERIALS

Twenty-six patients (mean age, 60±12 years; 16 men and 10 females) with unilateral middle cerebral artery (MCA) severe stenosis or occlusion were enrolled into the present study, underwent MRI scan especially 3D pCASL with PLDs of 1.5s and 2.5s and DWI. The IP was first observed according to mismatched CBF-DWI region. The mean CBF (CBF1.5 vs. CBF2.5, mL/100g per minute) values and the mean area (mm2) of IP were measured at PLDs of 1.5s and 2.5s. Comparisons of the mean CBF values and the mean IP area between the two PLDs were analyzed using paired T test. Compared with the positive detection rate of IP by Chi-square test.

RESULTS

The detection rate of IP increased at the PLD of 1.5s (21/26, 80.77%) than 2.5s (6/26, 23.08%) (P=0.000). The mean CBF1.5 and CBF2.5 values of IP were 12.32±1.66 vs.18.84±1.44 (P=0.002). The mean IP area was also significantly widened at the PLD of 1.5s (4273.17±611.17) than 2.5s (1074.50±955.32, P=0.01).

CONCLUSION

IP detection and areas result from different PLD using 3D ASL and DWI in patients with ischemic cerebrovascular disease. The higher detection, decreased CBF and wider region of IP are present at the PLD of 1.5s.

CLINICAL RELEVANCE/APPLICATION

It is necessary to consider the different PLDs to assess IP by 3D pCASL in ischemic cerebrovascular disease.

SSK15-04 Early Identification of Tissue at Risk of Infarction after Acute Ischemic Stroke Using Convolutional Neural Networks

PURPOSE

Early identification of potentially salvageable tissue after acute ischemic stroke (AIS) is increasingly being used to guide treatment decisions. Deep learning algorithms, e.g. convolutional neural networks (CNN), have been employed for chronic stroke lesion segmentation. We investigated the utility of CNN algorithms for predicting tissue infarction on follow-up MRI based on acute DWI and PWI MRI.

METHOD AND MATERIALS

The study included 50 AIS patients not treated with reperfusion therapy with DWI and PWI acquired <12h from the time when patients were last known to be well. Patients were also required to have follow-up (F/U) imaging performed >= 4 days after stroke. Apparent diffusion coefficient maps, T2WI, isotropic DWI, MTT, and Tmax were used as covariates to train a CNN (5-fold cross validation). The CNN was trained via the open source framework DeepMedic using the default architecture. The CNN segmentation maps were evaluated for each patient individually. Performance metrics were based on Dice score, sensitivity, and precision.

RESULTS

The CNN prediction of F/U lesions resulted in a mean±SD Dice score of 42%±26%, sensitivity 39%±27% and precision 60%±30%. The CNN resulted in fair results for lesion volumes >= 10ml, however it underperformed for smaller lesions <10 mL (Dice score 24%±20%, Sensitivity 25%±25%, Precision 38%±30%). Visual inspection showed compelling results for large lesions (Figure). The lesion size group analysis and the correlations of lesion volumes revealed that performance was dependent on lesion extent.

CONCLUSION

Our results showed that CNN can be used to combine acute multiparametric MRI for predicting tissue infarction on F/U, which hold especially true for large lesions. Although the CNN performed best for large lesion volumes, the focus of many early decision-making for AIS patients is whether or not the patient is at high risk of infarct growth. Therefore, CNN algorithms that can identify which patients will experience large infarct volumes without intervention hold promise for guiding AIS treatment decision strategies on an individual patient basis.

CLINICAL RELEVANCE/APPLICATION

Convolutional neural networks can be used to combine acute multiparametric MRI to predict follow-up tissue infarction with high accuracy, and therefore has potential for guiding treatment decisions on an individual patient basis.

SSK15-05 Regional Detection of Hemorrhagic Transformation using Kernel Spectral Regression and a Neural Network on Multi-modal MRI for Acute Ischemic Stroke

Wednesday, Nov. 29 11:10AM - 11:20AM Room: N226

PURPOSE

Hyperperfusion detected on arterial spin labeling (ASL) cerebral blood flow (CBF) images acquired after acute ischemic stroke (AIS) onset has been shown to be significantly associated with development of intracerebral hemorrhage. The purpose of this study was to develop a machine model for the voxel-based detection of tissue at risk for hemorrhagic transformation (HT) given multiple MRI modalities as input.

METHOD AND MATERIALS

The present study utilized routine clinical MRI and ASL image data acquired from 67 AIS patients shortly after endovascular therapy or clot retrieval. A novel regional cuboid sampling framework was developed for machine learning training, in which local cuboids were extracted from the CBF map, DWI, FLAIR, and T2 TSE before being matched with GRE-based manually drawn bleed groundtruth delineations. Kernel spectral regression (KSR) uses the information in the eigenvectors of the graph representation to reveal low dimensional structure in high dimensional data. After determining optimal kernel input parameters with KSR, we built a two-layer feed-forward neural network with 10 neurons in the sigmoid hidden layer and trained with scaled conjugate gradient backpropagation to classify cuboid inputs into likelihood of HT.

RESULTS

The proposed multimodal regional framework reached an accuracy of 80.59 ± 3% in detecting hemorrhage with KSR on our dataset (better than any single image modality alone); while a simple voxel-based prediction was 72.80 ± 5% accurate. Using the neural network training, the framework reached an improved accuracy of 95.1% ± 0.6%. Figure 1 shows a few predictive images based on the probabilities determined by the neural network. One can appreciate how the regions with high likelihood of hemorrhage determined by machine learning match well with the manually drawn regions in the reference GRE map.

CONCLUSION

Machine learning using kernel spectral regression or neural networks in particular can provide more accurate detection of tissues at risk for HT. Although CBF can inform AIS patient clinical outcome, the addition of multi-modal MRI data into the regional cuboid framework substantially improves the voxel-based HT detection accuracy.

CLINICAL RELEVANCE/APPLICATION

The proposed multi-modal regional framework for HT detection can improve stroke physicians' utilization of perfusion data in AIS treatment planning and monitoring.

SSK15-06 The Detectability of Forward Projected Model-Based Iterative Reconstruction for Low Contrast Lesions: Acute Cerebral Infarction-Phantom Study

Wednesday, Nov. 29 11:20AM - 11:30AM Room: N226

PURPOSE

Low-contrast areas in acute cerebral infarction are often difficult to be detected by computed tomography (CT) despite use of hybrid iterative reconstruction techniques such as adaptive iterative dose reduction 3D (AIDR 3D, Toshiba Medical Systems). Forward projected model-based Iterative Reconstruction SoluTion (FIRST, Toshiba Medical Systems), a novel iterative reconstruction technique, can strongly reduce noise and beam hardening artifact and improve spatial resolution. We compared the detectability of low contrast lesions on AIDR 3D- and FIRST images using a head phantom including simulated acute cerebral infarction.

METHOD AND MATERIALS

We developed dedicated head phantoms including simulated acute cerebral infarction using a 3D printer (Agilista 3200, Keyence). This study included 36 images of various models of acute cerebral infarction and 24 images of normal brain model. Half of these images were reconstructed with AIDR 3D and the rest were reconstructed with FIRST. Two radiologists separately specified the location of the low-contrast lesions in which subtle contrast between the gray and white matter diappeared. They rated the probability of the presence using an analog confidence scale. For the evaluation ROC analysis was performed. Statistical difference between AIDR 3D and FIRST was tested by DeLong's method.

RESULTS

ROC analysis showed that the difference between AIDR 3D (reader1: Az- value 0.773, reader2: Az- value 0.706) and FIRST (reader1: Az- value 0.935, reader2: Az- value 0.880) was significant in favour of FIRST (p = 0.037, 0.041, respectively).

CONCLUSION

Our study demonstrates a significant advantage of FIRST in the detection of low contrast lesions compared with AIDR 3D, one of the conventional iterative reconstruction techniques.

CLINICAL RELEVANCE/APPLICATION

FIRST may improve detectability of low contrast lesions in acute cerebral infarction.

SSK15-07 Intra-Arterial Thrombectomy in Patients with Cervical Dissections in the MR CLEAN Trial: A Descriptive Analysis

Wednesday, Nov. 29 11:30AM - 11:40AM Room: N226

Participants
Kars Compagne, BSC, Rotterdam, Netherlands (*Abstract Co-Author*) Nothing to Disclose
Olvert A. Berkhemer, MD, Amsterdam, Netherlands (*Abstract Co-Author*) Nothing to Disclose
Ad Van Es, Rotterdam, Netherlands (*Abstract Co-Author*) Nothing to Disclose
Aad Van Der Lugt, MD, PhD, Rotterdam, Netherlands (*Abstract Co-Author*) Research Grant, Stryker Corporation; Research Grant, General Electric Company
Bart J. Emmer, MD, Leiden, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

Several treatment strategies have been proposed in patients presenting with acute stroke and an extracranial dissection of the internal carotid artery (ICA). The aim of this study is to describe the outcome and variation of treatment strategies in intra-arterial thrombectomy (IAT) in patients with dissection of extracranial ICA and a proximal intracranial occlusion.

METHOD AND MATERIALS

Data (n=500) of the randomized controlled MR CLEAN trial on the effectiveness of IAT were analyzed. Carotid dissection was identified on CTA scans at baseline. Primary outcome was a favorable functional outcome defined as an modified Rankin Scale (mRS) score of <=2. Secondary outcomes were mRS <=3 and serious adverse events (SAE).

RESULTS

Carotid dissection was identified in 24 patients (21 male; median age 50.5)of which 15 in IAT group and 9 in non-IAT group. No differences at baseline NIHSS (p 0.74) and collateral score (p 0.29) was observed. In two patients stent placement was performed during IAT. A good functional outcome was observed at 7 (47%) in the IAT group versus 1 patient (11%) but was not statistically different (p 0.18). With respect to secondary outcomes, mRS <=3 and SAE were significantly different in favor of IAT (resp. p 0.03 and 0.04).

CONCLUSION

IAT is feasible in patients with extracranial dissections of the ICA and good outcomes have also been observed without carotid stenting.

CLINICAL RELEVANCE/APPLICATION

Carotid dissection is not a reason the withhold IAT in acute stroke patients.

SSK15-08 Diagnostic Accuracy of 3D black blood MRI with High Resolution T1 SPACE in the Evaluation of Intracranial Arterial Thrombosis

Wednesday, Nov. 29 11:40AM - 11:50AM Room: N226

PURPOSE

3D black blood (BB) MRI using a T1 sampling perfection with application-optimized contrast using different flip angle evolutions (SPACE) sequence allows high resolution, vessel wall imaging to evaluate the intracranial arterial wall and its associated pathologies. We investigated the diagnostic features and accuracy of 3D BB MRI in the detection of arterial thrombosis.

METHOD AND MATERIALS

We retrospectively identified fifteen patients with intracranial arterial thrombosis that underwent 3D BBMRI with non-enhanced and contrast enhanced high resolution T1 SPACE sequences. 3D BBMRI findings were evaluated by 2 independent neuro-radiologists blinded to all other angiographic studies, conventional MRI sequences, and clinical indications for imaging. Nineteen total intracranial vessel segments per patient were evaluated and graded on a three-point scale (grade 0-2) [Table] for intraluminal TI SPACE hyperintensity and contrast enhancement. Images were considered positive for arterial thrombosis when focal intraluminal T1 SPACE hyper-intense signal and/or enhancement on 3D BBMRI was graded as 1 or 2. Arterial occlusion was confirmed by digital subtraction angiography (DSA) or computed tomographic angiography (CTA). In limited cases (n=4) without DSA/CTA availability, susceptibility weighted imaging (SWI) in combination with time of flight (TOF) MR angiography (MRA) confirmed the diagnosis of complete vessel occlusion.

RESULTS

Fifteen patients with 18 intracranial arterial occlusions were studied. Fair inter-observer agreement for intraluminal T1 SPACE hyperintensity (Kappa = 0.50) and excellent inter-observer agreement for contrast enhancement (Kappa = 0.84) was noted. The sensitivity and specificity for intracranial arterial thrombosis of intraluminal T1 hyperintensity was 88.89% and 100% respectively and that of contrast enhancement was 94.45% and 100% respectively, taking Observer 1 as gold standard and Observer 2 as test when both partial and clear visualization (combined grades 1 and 2) suggested vessel thrombosis/occlusion.

CONCLUSION

3D BBMRI with T1 SPACE imaging is a valuable sensitive and specific technique for the evaluation of intracranial arterial thrombosis.

CLINICAL RELEVANCE/APPLICATION

This technique provides an adjunctive mechanism to confidently diagnose complete arterial occlusions in the setting of low resolution conventional MRI findings and absent flow enhancement on TOF-MRA imaging prone to overestimation.

SSK15-09 Actionable Vascular and Other Incidental Findings on CTA in Patients Undergoing Acute Stroke Intervention: Findings in 225 Patients

ritikanesa@gmail.com

PURPOSE

The detection and appropriate management of incidental findings is an important part of any clinical radiology practice. The intricate anatomy covered by CTAs of the head and neck coupled with the time pressures of acute stroke diagnosis creates an environment for missing important unrelated findings. The purpose of our study was to document incidental findings on CTA in 225 patients undergoing acute stroke intervention.

METHOD AND MATERIALS

Under IRB approval and HIPAA compliance, 225 CTAs of the head and neck in patients undergoing acute stroke intervention from 2011-2016 were reviewed for important incidental findings. Average patient age was 65 (range 16-95 years). Findings were separated into vascular (mainly aneurysms) and non-vascular entities (such as tumor and infection), with results tabulated.

RESULTS

There were 19 vascular and 31 non-vascular important incidental findings. Intracranial aneurysms were the most common vascular finding, with 18 aneurysms present in 16 patients (7% of patients). All aneurysms were unknown prior to imaging, with average size of 5mm(range of 2-10mm). 5 malignancies, most of which were unknown, included 2 lung cancers and an erosive nasopharyngeal skull base tumor. 2 patients with malignancy had pathologic cervical spine fractures. Critical pulmonary findings included 3 malpositioned endotracheal tubes in their right main stem bronchus, and 1 moderate pneumothorax. 6 patients had pulmonary edema, and 3 had pneumonia.

CONCLUSION

Providing fast and accurate diagnosis of acute large vessel occlusion on CTA is essential for good stroke outcomes. However, important and even urgent findings are surprisingly frequent in this patient population, and should be looked for with equal fervor.

CLINICAL RELEVANCE/APPLICATION

CTAs of the head and neck in patients undergoing acute stroke intervention harbor important and urgent findings with surprising frequency, and should not be overlooked even in this time-sensitive clinical scenario.

PURPOSE

The purpose of our study was to compare the results of interictal EEG and structural MRI with ASL-MRI findings in patients with epilepsy in the peri-ictal period and inter-ictal period and try to localize the epileptogenic zone.

METHOD AND MATERIALS

Two groups of patients were selected. The first group consisted of 21 patients having seizure episode in the hospital premises (selected randomly as per availability of MRI machine at time of seizure) who underwent structural MRI with an additional ASL sequence in the peri-ictal period (arbitrarily fixed at 2 hours from seizure onset). The patients also underwent an inter-ictal scalp EEG. The second group included 30 patients with refractory seizures who underwent inter-ictal structural MRI with additional ASL sequence (selected randomly from out-patient referrals for MRI from a dedicated seizure clinic). Inter-ictal scalp EEG was also performed for these patients. Hyperperfusion or hypoperfusion was recorded and localized to the hemisphere and if possible the anatomical lobe.

RESULTS

In the 'peri-ictal' group, 'structural MRI positive' patients had 87.5% concordance of ASL findings with the structural MRI abnormalities (50% showed localization to ipsilateral hemisphere -partial concordance, and an additional 37.5% to ipsilateral lobe and the hemisphere -complete concordance) whereas the 'structural MRI negative' patients had 71.3% concordance between ASL and structural MRI findings (57% having complete concordance and an additional 14.3% showing partial concordance). In the 'inter-ictal' group, 'structural MRI positive' patients showed 75% concordance between ASL and structural MRI findings (50% complete concordance and 25% partial concordance) and 'structural MRI negative' patients had a 78.5% concordance between ASL and structural MRI findings (71.4% complete concordance and additional 7.1% partial concordance).

CONCLUSION

Perfusion abnormalities are intricately linked with seizures in both inter-ictal and peri-ictal phase with localized hyperperfusion being the most frequent pattern in peri-ictal and hypoperfusion predominating in the inter-ictal phase.

CLINICAL RELEVANCE/APPLICATION

ASL imaging can be a promising complementary imaging tool and can be contributory to the clinical scenario irrespective of the time of imaging, including in follow-up imaging and in increasing confidence in lesion localization for possible surgical work-up.

SSK16-02 Multi-Regional Volumetric Patterns are Associated with Post-Surgical Outcomes in Patients with Medically Refractory Temporal Lobe Epilepsy

PURPOSE

To investigate patterns of regional pre-operative volumetric differences that may be associated with post-operative outcome using lasso regression analysis (LRA) in patients with medically refractory temporal lobe epilepsy (TLE) who underwent anterior temporal lobectomy (ATL).

METHOD AND MATERIALS

69 subjects with TLE treated with ATL are classified as either seizure-free (ILAE 1-2) or as having continued seizures (ILAE 3-6) postoperatively. Preoperative T1-weighted MRI were analyzed for volumetric measurements. LRA was performed to identify groups of regions associated with postoperative outcomes and results were cross-validated to quantify the selected model's ability to predict outcome classification. A sub-group of patients with pathology proven mesial temporal sclerosis (MTS) was analyzed in a similar manner (n=26).

RESULTS

LRA identified smaller volumes in the contralateral occipital lobe as being associated with the seizure-free group ($p = 0.0179$); cross-validation revealed sensitivity of 0.27 and specificity of 0.77 in correctly identifying patients with continued postoperative seizures. In the sub-group of patients with MTS, LRA selected the contralateral occipital lobe, ipsilateral hippocampus, ipsilateral caudate, contralateral cerebellum, and contralateral frontal lobe in the model associated with postoperative outcomes ($p<0.001$). Cross-validation yielded better results in the more focused sub-group (sensitivity = 0.7, specificity=0.81). Hippocampal volumes alone were not significantly different between the seizure-free and continued seizures groups in either analysis.

CONCLUSION

LRA identified temporal and extra-temporal regions associated with postoperative seizure outcome. The model selected by LRA was more descriptive and more robust in cross-validation when limited to subjects identified by a single pathology such as MTS indicating that the underlying pathology should be accounted for in such analyses. Involvement of extra-temporal regions may be related to extra-temporal seizure activity, chronic sequela of anti-epileptic drug usage and/or history of frequency/severity and generalization of seizures.

CLINICAL RELEVANCE/APPLICATION

Approximately 40% of patients who undergo temporal lobectomy for TLE may continue to experience seizures postoperatively. Thus, further stratification of potential surgical candidates using pre-operative data may improve outcomes.

SSK16-03 The Clinical Impact of Emergency CT Brain Scan in Seizure

Wednesday, Nov. 29 10:50AM - 11:00AM Room: N229

Participants
Bodo P. Kress, MD, Frankfurt, Germany (*Presenter*) Research Grant, Guerbet SA; Research Grant, Bayer AG
Eduardo Lazo-Gonzalez, Heidelberg, Germany (*Abstract Co-Author*) Nothing to Disclose
Uta Meyding, Frankfurt, Germany (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

Kress.bodo@khnw.de

PURPOSE

Does emergency CT brain in patients with seizures have an immediate clinical impact?

METHOD AND MATERIALS

In a retrospective analysis we evaluated 1785 CT brain scans performed between 2006 and 2013 in patients after seizures. The indication for this exam has been to exclude pathological lesions being focus of seizures or being caused by seizures. Study design and protocol has been approved by our local ethic comitee (S071/2017).

RESULTS

1088 male, 697 female, average age 58 years. In 173 (9,6%) patients the CT scan revealed a significant pathological finding. In 104 (5%) patients a either tumorous or metastatic lesion was found, in 62 (3,5%) hemorrhages (subdural, epidural, parenchymal or subarachnoidal) and in 14 (0,7%) signs of a subacute infarct. 1 patient revealed signs of a acute hydrocephalus. All patients with infarcts were outside the lysis time window or time window for thrombectomy. No patient with tumorous or metastatic lesion needed immediate treatment. 6 (0,3%) of 62 patient with hemorrhage were transfered for immediate treatment. All 6 patients had clinical symptoms additionally to seizures such as clinical history of acute headache, midface fracture, hypertension (>220mmHg). No patient with isolated clinical symptom of seizure needed emergency treatment.

CONCLUSION

In this study no CT scan revealed pathological findings with immediate clinical impact if patient had only clinical history of seizure. It should be discussed whether patient with additional clinical symptoms such as acute headache, severe head trauma or hypertension need CT scan in the acute setting and whether the other patients -taken to the ward for surveillance- are evaluated only by MR scan in between 24 hours.

CLINICAL RELEVANCE/APPLICATION

Retrospective design is ia limitation, however all other studies published in the literature evaluated less than 200 exams (while we evaluated 1785), therefore this is the study with by far the biggest number of cases.

SSK16-04 Abnormality of Cerebral White Matter Microstructure in Children with New-Onset, Untreated Idiopathic Generalized Epilepsy

Wednesday, Nov. 29 11:00AM - 11:10AM Room: N229

qiulihuah@gmail.com

PURPOSE

Epilepsy, as one of the most prevalent, noncommunicable neurologic conditions and a significant cause of disability and mortality, affects approximately 70 million people worldwide. Microstructural change of idiopathic generalized epilepsies (IGE) has been widely reported in children and adult patients. However, previous studies were focused on the chronic patients with antiepileptic drugs. This study aims at using the diffusion tensor imaging (DTI) technique to investigate the microstructural abnormalities of white matter in children with new-onset, untreated IGE.

METHOD AND MATERIALS

A total of 45 IGE patients (age range: 5-18 years, males: females=26:19) and 32 healthy controls (age range: 5-18 years, males: females=21:11) were included in our present study. Voxel-based analysis was used to compare the differences of DTI metrics including fractional anisotropy (FA) and mean diffusivity (MD) between patients and controls. Pearson correlation analysis was used to investigate the relationships between altered DTI metrics and clinical parameters.

RESULTS

After multiple comparison correction using family-wise error method, only the parameter of mean diffusivity (MD) showed significant decrease in the left paracentral lobule, right precuneus and right superior parietal lobule (SPL) in IGE patients compared to healthy controls. Increased factional anisotropy (FA) was found in the deep white matter of bilateral prefrontal lobe in IGE patients at a less conservative level using AlphaSim correction. There was no correlation between the altered diffusion parameters and the clinical measures.

CONCLUSION

Our study demonstrated microstructural impairments in children with new-onset, untreated IGE and that the MD might be more sensitive to detect the microstructural changes in the early stage of IGE than FA. Furthermore, the increased FA and decreased MD in the IGE group might suggest an initiating or compensatory mechanism prior to cognitive decline in IGE patients. Longitudinal studies are needed to clarify the maturational and seizure-related nature of these alterations of brain anatomy, their potential progression over the course of illness in IGE patients, and the potential impact of therapeutic intervention on these processes.

CLINICAL RELEVANCE/APPLICATION

Microstructural abnormalities exist from the very beginning of IGE and MD may be more affected than FA in the initial stage of children with IGE.

SSK16-05 Utility of MRI Brain Epilepsy Protocol in New Onset Seizures: How is it Different in Developing Countries?

Wednesday, Nov. 29 11:10AM - 11:20AM Room: N229

Participants
Janardhana Ponnatapura Satyanarayana, MBBS,MD, Bangalore, India (*Presenter*) Nothing to Disclose
Avisha Singla, Bangalore, India (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

PSJANARDHAN@YAHOO.COM

PURPOSE

1. To evaluate the diagnostic efficacy of a standard MRI of the brain in patients with first onset seizures. 2. To identify whether there is an increase in the diagnostic yield with the addition of high-resolution sequences with a dedicated seizure protocol. 3. To compare the diagnostic yields of MRI and EEG individually and in combination.

METHOD AND MATERIALS

Patients presenting with a history of first onset seizures who underwent MRI of the brain and EEG. Totally 129 cases were studied for a period of 18 months. Chi square test of significance ($p<0.005$) was used to test for the difference in proportion. The correlation between MRI brain and EEG was studied using McNemer test. All the patients underwent both standard protocol and dedicated epilepsy protocol MRI brain scanning on 1.5T within seven days from the onset of seizures. A routine electroencephalogram is recorded from the scalp electrodes obtained three days before or after the MRI and as soon as practical after presentation with the index seizure, preferably within 48 hours.

RESULTS

The diagnostic yield of MRI in detecting epileptogenic lesion was 47% in our study. Among the potentially epileptogenic lesion, infection and inflammation was most common 17 (28%). Of the 59 patients with potential epileptogenic lesions in our study, 37 (63%) epileptogenic lesions were detected using "standard protocol" MRI and remaining 22 (37%) lesions were detected using "dedicated epilepsy protocol" MRI. Of the epileptogenic lesions, all 11 patients (100%) with hippocampal sclerosis were detected by using "epilepsy protocol" MRI which would have been missed if only "standard protocol" MRI was done. Patients who presented with focal-onset seizures (27) had a higher proportion of potentially epileptogenic lesions 22 (81%) compared with the patients with generalized clonic tonic seizures. There were 22 patients (18%) with an abnormality on both MRI and EEG. So, abnormal MRI and

EEG were concordant in18% of patients in our study.

CONCLUSION

A dedicated epilepsy protocol MRI should be done in all patients who presents with first-onset seizures. MRI in first-onset seizure patients allows the identification of a lesion and earlier consideration of epilepsy surgery especially in patients presenting with focal-onset seizures.

CLINICAL RELEVANCE/APPLICATION

A dedicated epilepsy protocol MRI should be done in all patients who presents with first-onset seizures.

SSK16-06 PET-MRI Value in Detecting 'Occult' Anterior-Inferior Temporal Lobe Encephaloceles in Medically Refractory Focal Temporal Lobe Epilepsy

Wednesday, Nov. 29 11:20AM - 11:30AM Room: N229

Participants
Karl N. Krecke, MD, Rochester, MN (*Presenter*) Nothing to Disclose
Robert J. Witte, MD, Rochester, MN (*Abstract Co-Author*) Nothing to Disclose
Robert E. Watson JR, MD, PhD, Rochester, MN (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Temporal lobe anterior-inferior encephaloceles are increasingly recognized as a surgically amenable cause of adult medically-refractory temporal lobe epilepsy. The anatomic defect on MRI exam can be quite subtle and these lesions are frequently overlooked for multiple years and exams. Two such cases led to a review of our PET-MRI experience in imaging-occult medically refractory focal epilepsy.

METHOD AND MATERIALS

PET-MRI has been part of our epilepsy imaging armament since December 2015. A PET-MRI database was created that included patients with refractory focal epilepsy that were considered non-lesional, based on prior MRI exams. The PET-MRI exams were reviewed without knowledge of the specific clinical history or signs and symptoms with a goal of identifying additional cases of anterior inferior temporal lobe encephalocele. Separately, we collected demographic and clinical data from the medical record including age of seizure onset, semiology, EEG and interpretation of prior imaging exams.

RESULTS

Sixty-eight patients were catalogued in our epilepsy PET-MRI database including examinations through March 31, 2017. Four patients were identified with anterior-inferior temporal lobe encepahlocele. Two patients had been identified through clinical evaluation for epilepsy surgery and two additional patients were identified though this retrospective review. The key PET-MRI findings were 1. Decreased FDG uptake in anterior temporal lobe, ipsilateral to the clinical region of concern, 2. FDG activity extending beyond the expected confines of the middle cranial fossa and sphenoid wing, 3. MRI findings of CSF or brain extending into a defect in sphenoid wing, unrecognized on prior exams. Demographic items include: 3 female patients (75%), age: mn= 28 (15-43 range), age from seizure onset mn=9 years (3-18 range). The three female patients demonstrated MRI findings of incranial hypertension or dural ectasia.

CONCLUSION

PET-MRI can be useful as a next-step in evaluation of medically refractory focal temporal lobe epilepsy, particularly in the surgical candidate. Anterior-inferior temporal lobe encephalocele, as a cause of refractory epilepsy, is unusual but a combination of co-localizable findings can identify patients who may benefit from a focal resection.

CLINICAL RELEVANCE/APPLICATION

Temporal lobe encephalocele is emerging as an important, surgically amenable cause of epilepsy. PET-MRI can help with detection.

SSK16-07 Hippocampal Sclerosis with Negative MR Findings: Diagnostic Usefulness of Subfield Volumetric Analysis

Wednesday, Nov. 29 11:30AM - 11:40AM Room: N229

Participants
Hiromi Masaki, MD, Kitakyushu, Japan (*Presenter*) Nothing to Disclose
Shingo Kakeda, MD, Kitakyushu, Japan (*Abstract Co-Author*) Nothing to Disclose
Koichiro Sugimoto, MD, Kitakyushu, Japan (*Abstract Co-Author*) Nothing to Disclose

Yukunori Korogi, MD, PhD, Kitakyushu, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

In previous studies, up to 15% of the patients with diagnosis of hippocampal sclerosis (HS) showed normal findings on conventional MRI (neg-MR). Recently, subfield volumetry of hippocampus (SVH) using the open-source automatic segmentation software has been utilized. Our aims were; (a) to study the volume changes of the hippocampal subfields in HS patients using SVH, and (b) to determine the diagnostic accuracy of the SVH for the HS patients with neg-MR.

METHOD AND MATERIALS

We assessed 46 unilateral HS patients and 54 controls; all HS cases had histopathologic confirmation by surgery. Two neuroradiologists divided the HS patients into two groups based on the presence (pos-MR, n=26) or absence (neg-MR, n=20) of following MR findings at the affected hippocampus; reduced volume or increased T2 signal. For SVH analysis, 3D-volume T1-weighted images were processed with FreeSurfer (ver.5.3, ver.6.0) in all patients and controls. The ratio to total intracranial volume were calculated for each subfield and compared among the two groups. The diagnostic accuracy (AUC) were calculated using cutoff values for the hippocampal subfield volumes that were obtained in a ROC analysis.

RESULTS

In the pos-MR group, 8 of 9 subfields at the affected side (CA1, CA3, CA4-DG, fimbria, hippocampal-amygdala transitional area, presubiculum, hippocampal tail, and subiculum) were significantly smaller than in the controls. In the neg-MR group, however, only 2 of 9 subfields (CA3 and CA4-DG) were significantly smaller than in the controls. The diagnostic accuracy of the discrimination of the HS patients with neg-MR was better for the SVH based on the volumes of CA3 and CA4-DG (AUC: 0.719) than for the volume of the whole hippocampus (AUC: 0.614).

CONCLUSION

In the MR-negative HS patients, the subfield volumetry detected the localized atrophy within CA3 and CA4-DG, and showed better diagnostic performance than the whole hippocampal volume.

CLINICAL RELEVANCE/APPLICATION

In the mesial temporal epilepsy patients with normal findings on conventional MRI, SVH may be used not only for the diagnosis of HS but also for the assessment of its histopathologic subtypes.

SSK16-08 Longitudinal Functional Connectivity of Language Networks in Surgical Epilepsy Patients: Preliminary Results

olivia.foesleitner@muv.ac.at

PURPOSE

Investigating the reorganization of language networks in temporal lobe epilepsy (TLE) patients with task-based functional MRI (fMRI) before and after selective amygdalohippocampectomy or anterior temporal lobectomy (ATLR).

METHOD AND MATERIALS

Eighteen TLE patients (8 left TLE, 10 right TLE) performed task-based fMRI using a verb generation and a semantic paradigm before and after neurosurgery (9 ATLR; mean age at surgery: 38y, range: 26-53y). Mean time between surgery and postoperative scan was 14.9 months (range: 3-44m). Neuropathology revealed hippocampal sclerosis in 13 patients, focal cortical dysplasia in 4 patients and ganglioglioma in one patient. Ten healthy right-handed subjects underwent the same fMRI protocol on the same 3T scanner (mean age: 38y, range: 31-49y). FMRI activation maps and functional connectivity (FC) were analyzed on SPM12 for intra- and intergroup comparisons ($p<0.005$ uncorr.).

RESULTS

Compared to controls, patients showed decreased FC ipsilateral to their epileptogenic focus before and after surgery. In comparison to scans before surgery, postoperative left TLE patients had markedly decreased FC involving the left TL with particularly less connections to the right frontal lobe, stronger connections were visible including the residual left posterior TL and the right TL. In postsurgical right TLE, inter- and intrahemispheric FC to the right TL was decreased with only few stronger postsurgical connections exclusively found in the left hemisphere.

CONCLUSION

Task-based fMRI functional connectivity analysis visualizes extensive language related reorganization processes in TLE patients following surgery. Patterns of reorganization in language FC differ between left- and right-sided TLE with more extensive changes in left TLE patients.

CLINICAL RELEVANCE/APPLICATION

Temporal lobe epilepsy (TLE) surgery triggers widespread changes of language-related functional connectivity (FC). FC analysis allows us to link specific clinical deficits with certain neuroanatomical and imaging substrates. This will help to optimize surgical approaches and minimize postoperative language deficits in individual TLE patients.

SSK16-09 DTI-Derived Textural Features Can Improve Detectability of Epileptogenic Tubers in Tuberous Sclerosis Complex

Wednesday, Nov. 29 11:50AM - 12:00PM Room: N229

Participants
Hajime Yokota, MD, Los Angeles, CA (*Presenter*) Nothing to Disclose
Yoko Hirata, Los Angeles, CA (*Abstract Co-Author*) Nothing to Disclose

Iren Orosz, MD,PhD, Los Angeles, CA (*Abstract Co-Author*) Nothing to Disclose
Noriko Salamon, MD, Los Angeles, CA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Diffusion tensor imaging (DTI)-derived quantitative values such as maximum apparent diffusion coefficient (ADC) were reported as predictors of epileptogenic tubers in tuberous sclerosis complex (TSC). Texture of tubers, volume and location were also known predictors of epileptogenicity. The purpose of this study was to document detectability of texture analysis for DTI, which can combine the information of DTI and textural heterogeneity.

METHOD AND MATERIALS

Twenty-five consecutive studies involving 23 patients were involved in this study. Epileptogenic tubers were characterized using video-encephalographyEEG, structural MRI, FDG-PET, magnetoencephalography, magnetic source imaging (MSI) and intraoperative electro-corticography. A total of 558 tubers, 32 epileptogenic and 526 nonepileptogenic, were identified. The volume of interest (VOI) of tubers was drawn on an ADC map based using T2-weighted and FLAIR images. The original VOI was inflated to include 4-mm-thick ring-shaped tissues surrounding the tuber. Histogram- and 3-dimentional 13-direction gray-level co-occurrence matrix (GLCM)-based textural features were extracted from the VOIs using ADC, fractional anisotropy, axial diffusivity and radial diffusivity maps. Mann-Whitney U-test with false discovery rate control was used to compare the features. The diagnostic model was constructed with an elastic net model to avoid overfitting. The model was compared with known predictors using receiver operating characteristic analysis and DeLong test.

RESULTS

A total of 122 features was derived from each VOI. There were no significant difference in features derived from the original VOI between epileptogenic vs non epileptogenic tubers. By contrast, 32 of 122 features showed significant differences on the inflated VOI. The diagnostic model was significantly better than the ROC curves of maximum ADC, volume and location (area under curve = 0.75 vs. 0.67 and 0.55; P = 0.042 and 0.001). The model did not significantly surpass tuber volume (0.75 vs. 0.71, P = 0.119).

CONCLUSION

Texture analysis using inflated VOI showed improved diagnostic performance to differentiate between epileptogenic and nonepileptogenic tubers. The VOI within the tuber was not useful for DTI-based texture analysis.

CLINICAL RELEVANCE/APPLICATION

DTI-derived texture analysis with VOI including perituber tissue can improve detectability of epileptogenic tubers in tuberous sclerosis complex.

nmickevicius@mcw.edu

PURPOSE

The purpose of the present work is to accelerate pseudo steady-state free-precession magnetic resonance fingerprinting (pSSFP-MRF) T1 and T2 mapping sequences with simultaneous multislice (SMS) imaging methods.

METHOD AND MATERIALS

Controlled aliasing (CAIPI) techniques are useful for improving the image quality from SMS acquisitions. For multi-shot non-Cartesian k-space trajectories, as is the case for most MRF acquisitions, CAIPI takes the form of modulating the phase of one or more SMS slices relative to the others from readout-to-readout. This is usually accomplished by means of RF phase cycling. An underlying assumption of the pSSFP-MRF method, however, is that all slices experience a sign change of RF phase in consecutive excitations, thus prohibiting the use of RF phase cycled CAIPI. Gradient blips along the slice-selection axis allow similar CAIPI phase modulation without the use of RF phase patterns. This work employs a blipped-CAIPI acquisition with a radial trajectory for pSSFP-MRF. The SMS pSSFP-MRF sequence was implemented on a Siemens 3T scanner. The gradient blips were applied to induce a phase difference of pi/2 between two simultaneously excited slices. The sign of the gradient blip changed in each subsequent spoke which rotates with the golden angle of ~111.246 degrees. A total of 881 spokes were acquired in approximately 5 seconds. To reconstruct images of each slice, the conjugate of the blip-induced phase of the slice-of-interest was added to each spoke. A dictionary was simulated, and T1 and T2 maps were reconstructed using the low rank (R=5) alternating direction method of multipliers (ADMM) technique. The brain of a glioblastoma patient who consented to be a part of an institutional review board approved study was scanned.

RESULTS

The T1 and T2 maps of two simultaneously excited slices are shown in the figure. Total acquisition time was 5 seconds. No slice-leakage is apparent. The relaxation times outside of the tumor agree with literature values for healthy brain tissue. Lengthened T1 and T2 values can be seen within the lesion.

CONCLUSION

A blipped radial CAIPI pSSFP-MRF sequence permits rapid T1 and T2 mapping for use in disease diagnosis, treatment planning, and response assessment.

CLINICAL RELEVANCE/APPLICATION

This work aims to further push the acceleration of pSSFP magnetic resonance fingerprinting scans to aid in the clinical adoption of fully quantitative imaging protocols.

SSK17-02 First Clinical Assessment of kT-Points Dynamic RF Shimming on Abdominal DCE-MRI in a Commercial 3T MRI Scanner

PURPOSE

The 'B1 artefact' is an important challenge for abdominal MRI at 3T. Our aim was to assess excitation homogeneity and image quality achieved in the liver by kT-points pulses, compared to patient-tailored static RF-shimming.

METHOD AND MATERIALS

The prototypical non-selective kT-points pulse design was compared with patient-tailored static RF shimming for 3D breath-hold liver DCE-MRI on a product dual-transmit MAGNETOM Skyra MRI (Siemens Healthcare). 50 consecutive patients referred for liver MRI at a single institute were included in this IRB-approved study. Quantitative analysis was carried out via simulation to estimate flip angle homogeneity. Signal homogeneity, T1 contrast, enhancement quality, structure details and global degree of trust provided by each technique were qualitatively assessed on a 4-level scale (0 to 3) by 2 radiologists on in vivo pre-injection and late-phase images from 20 acquisitions selected from the pool. An exact matched-pairs one-tailed Wilcoxon signed-rank test was used to compare the methods.

RESULTS

Average excitation inhomogeneity was significantly reduced with kT-points compared to static RF-shimming (mean flip angle error ± standard deviation: 8.5±1.5% vs 20.4±9.8% respectively; $p<0.0001$). The worst case (heavy ascites) was 13.0% (kT-points) vs 54.9% (RF-shim). KT-points qualitative grades were higher for all criteria. Global image quality was significantly higher for kT-points than for RF-shimming (mean grade ± standard deviation: 2.3±0.5 vs 1.9±0.6; $p=0.008$). One subject's examination was judged unusable (0/3 for all criteria) with RF-shim by one reader and none with kT-points. 85% of kT-points acquisitions were graded at least 2/3, compared to only 55% in the static RF-shim case.

CONCLUSION

KT-points significantly reduce excitation inhomogeneity both quantitatively and qualitatively, especially in patients with ascites and prone to 'B1 artefact'.

CLINICAL RELEVANCE/APPLICATION

Proper excitation homogeneity is crucial to take advantage of the high signal-to-noise ratio available at 3T. KT-points improve 3T MRI for abdominal imaging of all patients.

SSK17-03 Multi-Compartmental Analysis Using a Fast Multi-Echo TSE Sequence for Prostate Cancer Diagnosis

PURPOSE

Prostate tissue has three major histological components: stroma, glandular lumen and epithelial cells. These volume fractions change when cancer is present. This study evaluates the feasibility of measuring the volume fractions of these compartments quantitatively in normal prostate and prostate cancer (PCa) using multi-compartment T2 decay modeling. A fast multi-echo TSE T2 MRI (k-t-T2) was applied to obtain high resolution T2 maps in clinically feasible scan time. Signal contributions from the three compartments were compared with pathological slices as a gold standard.

METHOD AND MATERIALS

k-t-T2 data were acquired on 17 patients on Philips 3T Achieva scanner; this method uses k-space under sampling for image acquisition to accelerate the scan. TR=3.1-10s; 32 echoes; ΔTE=12ms (TE=24-396ms); 1.0x1.0x3 mm3 in-plane resolution, scan time=4.5-9.6min. Regions of-interest (ROIs) including PCa (n=28) and normal prostate (n=43) were identified through histologic and MRI consensus review. Voxel-based three compartment analysis was used to extract the epithelial, lumen and stromal volume fractions, and T2 value of each compartment, in each ROI. Kruskall-Wallis test and Welch two sample t-test were used to evaluated the statistical significance between ROI groups. Spearman correlation coefficient was calculated between the image features and ROI-specific Gleason scores (GS).

RESULTS

ROI based analysis results showed the volume fraction of epithelium (50±12% vs. 37±10%) and lumen (11±6% vs. 21±7%) are

significantly different between PCa and normal prostate (p<0.01). There is no significant difference in stromal volume fraction (39±9% vs. 41±8%) between PCa and normal prostate (p>0.5). The volume fractions measured by MRI are close to those reported in previous histological studies. The volume fractions of epithelial cells and lumen are strongly correlated with GS (ρ =0.53; -0.41, p<0.05). Epithelial volume fraction in PCa correlates better with GS compared to T2 values (ρ=-0.41, p=0.02).

CONCLUSION

Multi-echo k-t-T2 sequence is feasible in clinical setting. Volume fractions obtained from three compartment model fitting of spin echo signal decay sampled at multiple TE's may help to characterize prostate lesions and may be sensitive to Gleason grade.

CLINICAL RELEVANCE/APPLICATION

New features extracted from multi-echo TSE images are more sensitive to prostate cancer and Gleason score than T2 values alone which may improve prostate cancer diagnosis.

PURPOSE

To compare difference of readout segmented diffusion weighted imaging (RS-EPI) and single shot echo planar imaging (SS-EPI) on image quality with ultra-high b value for prostate cancer detection.

METHOD AND MATERIALS

37 patients with prostate disease who underwent both RS-EPI and SS-EPI were enrolled in this study. All data were collected on a MAGNETOM Skyra 3T MR scanner (Siemens AG, Erlangen, Germany) with the b value of 0,1000,2000,3000s/mm2. The image quality including lesions clarity, anatomical distortion, image sharpness, detail display based on diffusion weighted imaging (DWI) were classified according to Likert score into 1 to 5 grade.(Grade 1 : cannot be used for diagnosis; Grade 2: poor; Grade 3: acceptable; Grade 4: good; Grade 5: very good.) All the images were analyzed by two experienced radiologists blinded to any clinical information as well as MR sequence information. The classification was provided from two radiologists separately. The signal-to-noise ratio (SNR), and contrast ratio, and contrast to noise ratio (CNR) were also measured on workstations by the radiologist.

RESULTS

The scores concluded by the two radiologists have good consistency, Kappa value>0.80. The image quality including lesions clarity, anatomical distortion, image sharpness, detail display obtained from RS-EPI sequences were higher than those obtained from SS-EPI regardless of 1000,2000,3000s/mm2 (P<0.001). The signal-to-noise ratio (SNR), and contrast ratio, and contrast to noise ratio (CNR) measured on RS-EPI sequences were also higher than those measured on SS-EPI (P<0.001) (table1).

CONCLUSION

Compared with the SS-EPI sequence, ultra high b value RS-EPI sequence significantly improves the image quality, which is more conducive to the detection of prostate lesions.

CLINICAL RELEVANCE/APPLICATION

Compared with the SS-EPI sequence, ultra high b value RS-EPI sequence significantly improves the image quality, which is more conducive to the detection of prostate lesions.

SSK17-05 Magnetic Resonance Water-Fat Separation using Deep Machine Learning

Wednesday, Nov. 29 11:10AM - 11:20AM Room: S404AB

Participants
James W. Goldfarb, PhD, Roslyn, NY (*Presenter*) Nothing to Disclose

PURPOSE

The goal of this study was to develop, train and evaluate a convolutional neural network for decomposition of cardiovascular MR images into separate water and fat images with additional calculation of R2* and off-resonance.

METHOD AND MATERIALS

1204 cardiac images in multiple anatomical orientations from 90 imaging sessions acquired at 1.5T using a dark blood double inversion recovery multiple spoiled gradient-echo sequence (TR=20ms; 12 TEs=2.4-15.5ms (1.2ms spacing), bipolar gradient acquisition) were included in this study. This included 15 acute myocardial infarction (MI), 24 sub-acute MI, 34 chronic MI subjects and 17 normal subjects. Water-fat separation was initially performed with a conventional model based technique providing water, fat, R2* and off-resonance images for deep learning training. A U-Net convolutional neural network (CNN) was used for deep learning. The input to the CNN was 24 real and imaginary images from 12 TEs. The output of the CNN was four images (water, fat, R2* and off-resonance). The implementation was done using open source software written in Python v2.7 with the TensorFlow v1.1 and Keras v2.0 machine learning libraries. Training on 900 (x12 echo-times) complex images with 50 epochs was performed using the Adam optimizer with Nestrov momentum. Water and fat images from the data not used for training (n=304) were predicted using the trained CNN. Water-fat fraction images were constructed for both the conventional and deep learning approaches.

RESULTS

Water-fat separation performed well across all image slice orientations. Signal-to-noise was better in the deep learning images when compared to conventional images, $p<0.001$. Fine details were preserved in the deep learning images when compared to conventional images. There was an excellent correlation ($R2=0.97$, $p<0.001$) between the conventional and deep learning fat fraction measurements. Multiple pathologies were visualized with deep learning, including fatty metaplasia (Fig 1a) and intramyocardial hemorrhage (IMH) Fig 1b.

CONCLUSION

Deep learning is a robust, efficient, feasible method for water-fat separation. After the learning phase, utilization is computationally efficient and can make use of echoes with bipolar gradients.

CLINICAL RELEVANCE/APPLICATION

Deep machine learning can provide fat suppressed images and quantitative fat fraction maps with R2* and off-resonance corrections in challenging situations such as cardiovascular imaging.

SSK17-06 Analysis of Different Image Registration Algorithms for Fourier Decomposition MRI in Functional Lung Imaging

Wednesday, Nov. 29 11:20AM - 11:30AM Room: S404AB

Participants
Alexandra Ljimani, MD, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Rotem S. Lanzman, MD, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Gerald Antoch, MD, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Hans-Jorg Wittsack, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Julian Kirchner, Dusseldorf, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate different image registration algorithms for Fourier decomposition MRI (FD-MRI) in functional lung imaging in healthy subjects.

METHOD AND MATERIALS

Fifteen healthy volunteers (mean age 33.0±10.1 years) were examined on a 1.5 T whole-body MR-scanner (Magnetom Avanto, Siemens AG) with a non-contrast enhanced 2D-TrueFISP pulse sequence in coronal view (TR/TE 2.06/0.89 ms, acquisition time 180 ms/image, 250 images). No ECG or respiratory triggering was used. Three different image registration algorithms (fMRLung 3.0, Siemens Corporate Research; diffeomorphism based ANTs by Avants et al. NeuroImage 2011; Elastix by Staring et al. Medical Physics 2007) were used to compensate the spatial variation of the lung structure. Quality control for the image registration was performed by quotient images (ΔQ) and dice similarity coefficient (ΔD). The impact of the used registration algorithms on the calculated perfusion and ventilation values by Fourier decomposition method was evaluated.

RESULTS

The average time for motion correction by the different image registration algorithms were for fMRILung 1.0±1.6 min, ANTs 38±13.5 min and Elastix 5.9±1.3 h, respectively. No significant ($p>0.05$) difference in the quality of the motion correction provided by different image registration algorithms (ΔQ fMRILung 0.12, ANTs 0.11, Elastix 0.11; ΔD fMRILung 0.06, ANTs 0.07, Elastix 0.06) occurred. Further no significant difference of the calculated ventilation and perfusion values between the different registration algorithms ($p>0.05$) were determined. The calculated ventilation values were 119±12 for fMRILung, 110±14 for ANTs and 118±12 ml/min/100 ml for Elastix, respectively. The perfusion values for fMRILung, ANTs and Elastix were 156±41, 166±46 and 185±66 ml/min/100 ml, respectively.

CONCLUSION

The mandatory motion correction for the calculation of perfusion and ventilation images by FD-MRI is possible with different image registration algorithms without significant influence on the quality of the motion correction or changes of the calculated functional lung values. fMRILung 3.0 (Siemens Corporate Research) provides the fastest way of motion correction.

CLINICAL RELEVANCE/APPLICATION

Motion correction for FD-MRI is possible with different image registration algorithms without loss of accuracy of perfusion and ventilation results.

SSK17-07 MRI Quantitative Quality Control and Calibrated Measurement with DTI and Reference Fluid Phantom Novel Phantom for Quantitate Assessment of DTI Inters Canner Variability

CONCLUSION

Current DTI scanning has substantial systematic error, distorting measurement and impairing clinical diagnostic stability. Phantom calibration can quantify such errors and may provide a means for a correction factor to reduce variability across scanners.

Background

We used a novel DTI and isotropic fluid phantom funded by the Chronic Effects of Neurotrauma Consortium, VA, DoD & NIH QIBA programs to provide "ground truth" reference measurement and quality assurance metrics.

Evaluation

The phantom contains anisotropic diffusion components of hollow textiles termed Taxons (axon-shaped tubes, 12-µm inner diameter diffusion chambers) arranged in water-filled bundles of > 100,000. To quantify loss of tract integrity and size, we created tracts with densities of 12.5%- 100% and tract cross-sections of 4-100 mm2. The phantom includes 32 NIST reference fluids (T1, T2, PD, ADC) for isotropic reference metric correction. We imaged on 11 scanners (1.5T and 3T, Siemens, GE & Phillips) with head coils 12-64 channels. Scans detected tracts with high spatial detail at all sizes (average correlation of FA to tract density r=0.992). We found tight repeat measurements, with small changes between scans on the same magnet within a few weeks. However, substantial (35%) inter-scanner systematic error/biases in measurements of FA were seen, greatly exceeding presumed effect size of TBI-induced FA change and 2.85 times the variance within scanner. We applied a reference measurement correction by estimating scanner-specific systematic error on one scan and applying that correction to a second scan weeks later to calculate calibrated FA relative to the mean cross-scanner FA to reference density metrics. The correction reduced the across-scanner spread error by 94%.

Discussion

The phantom provides a reliable and reproducible method to determine degree to which DTI scans on a MR scanner differ from a reference standard that simulates the microstructure of brain white matter. The phantom also allows a means to determine the degree to which DTI scans from multiple scanners differ from one another and, potentially, a method to correct for inter-scanner differences.

SSK17-08 A Quality Improvement (QI) Initiative to Evaluate MR QA Training Strategies for MR Technologists to Enable Them to Undertake Quality Assurance (QA) Testing in MRI

PURPOSE

The American College of Radiology (ACR) standard recommends that quality assurance (QA) testing of MR systems is the responsibility of both technologists and medical physicists to ensure efficient scanner performance. However, in the Kingdom of Saudi Arabia (KSA), meeting this standard is challenging due to a shortage of medical physicists, variable MR-specific education amongst technologists, and difficulties in achieving standardisation across centres providing MR imaging services. These factors have contributed to low compliance with recommendations for the performance of MR QA tests. This study explored the development of an education-based Quality Improvement (QI) initiative to enable MR technologists across multiple clinical sites to consistently perform MR system QA testing. The authors aimed to develop an educational tool to provide MR QA training to technologists enabling them to undertake this activity in their departments.

RESULTS

There was 95% agreement between the expert-determined and technologist-determined MR QA test results. Interview findings revealed that all technologists reported that the test methods presented in the training video were clear and logical, and enabled them to perform practical QA testing of their scanner. 12% of technologist participants (n=1) acknowledged some difficulty positioning the QA phantom, and 50% (n=4) indicated challenges interpreting the test pattern appearances due to the inherent subjectivity of the low contrast detectability QA test. All participants indicated that their experience of MR QA training was positive, using expressions such as "I enjoyed it", "It was a positive experience", and "very good experience", "It showed me what I can do with the right training". Technologists indicated they had learned a new skill to help them improve the quality of the MR imaging service they provide, and were willing to continue undertaking QA testing, seeing this as one way to expand their professional role.

CONCLUSION

With the ongoing shortage of medical physicists in KSA and other countries, the training video introduced as a QI initiative

With the ongoing shortage of medical physicists in KSA and other countries, the training video introduced as a QI initiative demonstrated the effectiveness of an appropriately designed educational resource combining both technical information and practical skills demonstration. The ease of access and display means that this educational tool can readily be made available to MR technologists across multiple centres in KSA, as a strategy to prevent a shortage in expert personnel limiting the implementation of practices to optimise MR service quality. The broader application of the methods applied during this education-based QI is apparent.

METHODS

Educational Tool Design: A training video was designed to demonstrate MR QA test methods and provide background explanatory information. sing a focus group discussion framework, the research team, comprising two medical physicists and four MR technologists, reached consensus regarding the essential content and presentation format, drawing on ACR MR QA guidelines and the expertise of group members. Based on ACR recommendations, the method for the following QA tests was planned: central frequency, geometric accuracy, high-contrast spatial resolution, low-contrast detectability, image intensity uniformity and signal-to-noise ratio (SNR). Each test was broken down into logical steps which included: MR QA phantom design features, set-up and positioning, pulse sequence and parameters and use of MR images to provide numerical indicators of MR system performance. The performance of these steps by the research team members for each QA test was videoed in sequential order to make it easy for the MR technologists to follow the test method. Editing of the video footage and overlay of audio content was performed by a videographer in consultation with the research team. Educational Tool Evaluation: MR technologists (n=8) in one public (n=4) and one semi-public (n=4) hospital in KSA evaluated the QA training video. Technologists were given supervised access to this resource for two 30-minute sessions per day over one week. A supporting booklet outlining the test methods was also provided. On completion of the educational intervention, each technologist was asked to implement the QA test process in their MRI department for a three-month period by individually conducting weekly QA testing on the MR scanner and documenting the images and numerical results for each test. These findings were compared to images and values independently determined for the same QA tests on each MR scanner as performed by an expert in MR QA following the methodology outlined in the training video. Face-to-face semi-structured interviews were conducted with each technologist to ascertain their opinion regarding the effectiveness of the QA training video and their experiences undertaking the QA tests.

guanboch@usc.edu

CONCLUSION

We proposed a 3D real-time microwave monitoring method and synthetically validated it for interstitial thermal therapy monitoring. We will further validate on animal models before moving to clinical trials. With this intraoperative temperature monitoring, radiologists will be able to more selectively target tumors, extend the application of thermal ablation to new therapeutic areas, and reduce surgery time.

Background

Thermal ablation is a minimally invasive surgery that is gaining increasing popularity as first-line therapy for soft-tissue tumors. However, its application has been limited by inadequate thermal image guidance. Fiber optic sensors measure temperature only at their tips. B-mode ultrasound is limited to 2D. MRI is not available within the operating room and adds 30-40 minutes to surgery time. To address these challenges, we have developed a microwave monitoring system that can intraoperatively provide a 3D real-time temperature map. The system consists of a multi-antenna imaging cavity, where microwave measurements are collected with a network-analyzer-based measurement system. The data is processed with a differential inverse scattering algorithm, which generates real-time 3D temperature images through a mapping between tissue dielectric change and temperature. In our prior work, the system has been experimentally validated using laboratory phantoms heated with an ablation probe.

Evaluation

To synthetically test the monitoring of the ablation process in the case of brain tumor treated with thermal therapy, we derived a 3D dielectric brain phantom from MRI and simulated the heating of the target region with a multi-physics model of an interstitial ablation probe. In the test, the target region is heated from 37 °C to 70 °C, and 3D temperature maps are generated throughout the procedure.

Discussion

Sample validation results are shown in the figure attached. The 3D temperature maps can be generated as fast as 1 frame/second, provide a resolution of 1 cm, and can track temperature change as small as 1 °C. To further improve temperature accuracy, the mapping model between dielectric and temperature change is currently being refined with empirical studies using *in vitro* tissue samples.

PURPOSE

To assess the effect of ATVS on the applied tube voltage, tube current, image quality and radiation exposure across four scanners from two vendors.

METHOD AND MATERIALS

In this IRB approved study, 341 subjects (age: 58 ± 17 years) underwent abdominopelvic CT exams with ATVS technique set at a reference value of 120kVp on four recently introduced CT platforms. kV assist: Revolution CT, GEHC (Group A, n=90); CarekV: Somatom Definition Flash, Siemens (group B, n=16), Somatom Definition Force, Siemens (group C n=82) and Somatom Definition Edge, Siemens (group D n=153). Subjects were categorized based on body weight (<150lb, 151-200lb, >201lb). Images were reconstructed using ASIR-V 40% for group A, SAFIRE 3 for groups B and D, and ADMIRE A3 for group C. In 86 additional subjects, 100 kVp was selected as reference for ATVS (Group E; Revolution CT). Applied scan parameters (tube voltage and mean tube current) and radiation dose (SSDE) were compared for all body weight categories among the groups; ANOVA was performed.

RESULTS

There was no significant difference in body weight among subjects in groups A-E within each category ($p>0.05$). Across all groups and weight categories, low tube voltage (<120 kVp) was selected in 48% of exams (165/341). 5% of exams (19/341) were scanned using 90kVp (<200lb). Majority of low kVp scans were performed in subjects <200lb (147/165). Low kVp was selected in 21.6% of subjects (18/83) >201lb. Highest number of low kVp acquisitions were found in Group D (70%) followed by group C (61%) and Group B (31%). Only 3.3% of exams (3/90) in group A (all <200lb) were performed using 100kVp. However, 86% of exams (74/86) were acquired at 100 kVp in group E. SSDE (mGy) was 12.9 ± 3.3 in group A, 10.9 ± 2.4 in group B, 11.5 ± 3 in group C, 11.2 ± 3.2 in group D, and 7.7 ± 2.2 in group E ($p<0.01$).

CONCLUSION

The kVp selection with ATVS not only depends on body composition but on the reference kVp setting and tube current capacity. Using reference of 120kVp, careKV (Siemens) selected low kVp in 31-70% of exams. Using a reference of 100kVp on kV assist (GE), low kVp selection increased to 86% of exams independently of the body weight.

CLINICAL RELEVANCE/APPLICATION

Due to higher image contrast and lower radiation dose, clinical practice is drifting towards low kVp CT acquisitions. Knowledge of ATVS software selection of kV options can facilitate implementation in clinical practice without degrading image quality or CT workflow.

SSK18-02 Automatic Mapping of CT scan Locations on Computational Human Phantoms for Accurate Organ Dose Estimations for a Large Number of Patients

Wednesday, Nov. 29 10:40AM - 10:50AM Room: S503AB

Participants

choonsik.lee@nih.gov

PURPOSE

Using Monte Carlo simulations of CT scanners and computational human phantoms, there are several computational solutions available for organ dose estimation from CT. Although most scan parameters can be extracted from DICOM, it is still necessary to manually map the scan locations of patients on phantoms which may cause significant dose difference for organs near the scan boundaries. We developed a method to automate the mapping process and applied it to organ dose estimation for 60 chest CT patients.

METHOD AND MATERIALS

We generated a two-dimensional antero-posterior projection image of the skeleton from given patient CT images. We compared the patient skeleton image with a pre-generated skeleton image from a reference whole body phantom from the top of the head to the bottom of the feet with 1 cm increment to find the best Dice matching score. The mapping algorithm was tested for five partial torso CT sets (22 image sets from the top clavicle with 20 cm scan length with 2 cm increment for each patient) simulated using five full torso CT sets. Illustrative organ doses were calculated for 60 chest CT patients using the algorithm combined with an in-house CT dose calculator. Automatic mapping algorithm-based organ doses were compared with the data based on the scan location manually mapped by experienced medical physicists.

RESULTS

Comparison of the scan location of simulated partial torso CT with the values of automatically-mapped location in phantoms showed very good agreement (less than 10%) with the Dice score of 57% on average. The automatic detection of the scan location took about a minute per CT. The illustrative organ dose for 60 chest CT patients showed significant difference up to 5-fold for some organs located atnthe scan boundaries across the 60 patients. The organ doses from the automati. Mapping algorithm agreed within 5% with the values calculated from manual mapping of scan locations.

CONCLUSION

Our method will provide faster and more accurate organ dose estimation compared to existing approaches in cases requiring organ dose for a large number of patients such as patient dose monitoring, clinical trials, and epidemiological studies.

CLINICAL RELEVANCE/APPLICATION

The new methods we developed in this study will provide with more accurate patient-specific organ doses, which will help radiologists and patients to better understand the health impact of CT scans.

SSK18-03 A Personal Organ Dose Archive System for Patient Safety in Radiotherapy

Wednesday, Nov. 29 10:50AM - 11:00AM Room: S503AB

Participants
Ying Liang, PhD, New Haven, CT (*Presenter*) Nothing to Disclose

ying.liang@yale.edu

PURPOSE

Although state-of-the-art radiotherapy techniques have improved local tumor control over the years, normal tissue complication is still of concern in the clinic. Estimation of normal tissue doses depend primarily on treatment planning system (TPS). However, leakage and scatter doses, imaging doses and doses to non-contoured organs are not well considered by modern TPS. In this work, we aim to develop a personal organ dose archive (PODA) system for individual patients undergoing radiotherapy to track doses of all relevant organs from all radiation events.

METHOD AND MATERIALS

CT images, contours and treatment parameters are exported and extracted from TPS via DICOM format. Deformable image registration and dose mapping are performed with MIM with 3D volumetric imaging. GPU-based Monte Carlo dose engine is used for super-fast 3D dose calculation in patient anatomy. A SQLite database is deployed to manage the data registration and inquiry.

RESULTS

Our PODA system includes four parts: (1) DICOM library; (2) PODA database; (3) GPU-based Monte Carlo dose engine; (4) functional modules. DICOM library hierarchically stores all the raw data for each individual patient. PODA database organizes and manages the general information of all patients. GPU-base dose engine computes organ doses and outputs to PODA database for each event involving ionizing radiation. Major functional modules include Update Organ Dose, Report & Alert and Database Backup & Recovery. The four components work together to track patient organ doses on a daily basis. A proactive early warning is issued if organ dose will exceed pre-set dose criteria by prediction.

CONCLUSION

We have developed a PODA system that can be used to track and accumulate each patient's organ doses associated with the use of sophisticated treatment technologies and image-guidance procedures in modern radiotherapy.

CLINICAL RELEVANCE/APPLICATION

With PODA we can provide an important safety mechanism to help prevent irreversible radiation damage to normal tissues and provide a comprehensive organ dose database to help clinicians make informed decisions for individual patients including pre and

post care management.

SSK18-04 Comparison of Image Quality and Radiation Dose of Female Chest CT Using Organ Dose Modulation with Different Detector Coverage on 16cm Wide-detector CT

liyanan976@163.com

PURPOSE

To evaluate the impact of two different detector coverages (80mm and 40mm) on image quality and radiation dose of the female chest CT using organ dose modulation (ODM).

METHOD AND MATERIALS

Forty female patients undergoing chest CT with clinical justifications were prospectively and randomly assigned to two groups: Group A (n=20) with 80mm detector coverage and pitch 0.992:1; Group B (n=20) with40mm detector coverage and pitch 0.984:1. Both groups used the 0.5s rotation speed and the SmartmA and ODM technique for the breasts. The standard deviation (SD) in the aortic arch, carina, and inferior pulmonary vein in both the anterior and posterior lungs were measured. Image quality was evaluated by two experienced radiologists using a 5-point scoring system. The tube current in different directions (A/L/P/R) were recorded from mA Table. The CTDIvol and DLP values were recorded from dose report and effective dose calculated. The above parameters for the two groups were analyzed using SPSS 20.0.

RESULTS

There was no difference in the anatomic coverage between the two groups (258.75 ±27.85mm vs. 253.00 ±24.51mm). However, Group B with 4mm collimation had lower tube current in all four directions and reduced over-scan range than Group A (29.50±0.60mm vs. 59.40±7.47mm, P<0.05), resulting in 25% lower radiation dose in Group B compared with Group A (0.74±0.13mSv vs. 0.99±0.33mSv). . The ODM feature worked in both groups, and the tube current in the anterior was lower than that in the posterior in both groups (P<0.05), and produced about 30% radiation reduction for the breasts in both groups. There was no significant difference in SD for the aortic arch, carina, and inferior pulmonary vein level between the two groups. The image quality of two group were judged to be clinically acceptable. There was no significant difference in subjective image quality grading (p>0.05) with excellent agreement between the two radiologists (Kappa=0.77, P<0.001).

CONCLUSION

The use of helical scan with 40mm collimation and ODM chest CT ensures good image quality with 25% reduced radiation dose, compared with chest CT that uses helical scan with 80mm collimation and ODM.

CLINICAL RELEVANCE/APPLICATION

The use of helical scan with 40mm collimation and ODM chest CT can dramatically reduce radiation dose while maintaining image quality compared with helical scan with 80mm collimation and ODM.

SSK18-05 Efficacy of Organ Dose Modulation and Metal Artifact Reduction Techniques on Reducing Exposed Radiation Dose on Abdominopelvic Computed Tomography Scans With Metal Hip Prosthesis

Wednesday, Nov. 29 11:10AM - 11:20AM Room: S503AB

Participants
Ok Kyu Song, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Yong Eun Chung, MD, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

songokkyu@yuhs.ac

PURPOSE

To evaluate the effect of metal hip prosthesis on exposed radiation dose and assess the efficacy of organ dose modulatation (ODM) and metal artifact reduction (MAR) protocols on dose reduction.

METHOD AND MATERIALS

Six patients with history of total hip arthroplasty who had both preoperative and postoperative abdominopelvic CT scans using an identical protocol were selected and their preoperative and postoperative CT dose index (CTDI, mGy) were compared. An anthropomorphic phantom was scanned with and without bilateral metal prostheses and exposed surface and deep doses (mGy) at pelvic and extrapelvic cavities were measured using nanoDot dosimetry system. Finally, exposed radiation doses using reference scans, ODM, and two MAR protocols (GSI32 and GSI3; CTDI equivalent to reference scan without and with metal prosthesis respectively) in pelvic and extrapelvic cavities were compared.

RESULTS

Among six patients, the mean CTDI (mGy) increased by 18.1% after metal hip prosthesis implantation (p=0.028, Preoperative CTDI: 8.64±2.47, Postoperative CTDI 10.20±3.51). On phantom experiment, adding unilateral or bilateral metal prosthesis in pelvis increased CTDI (mGy) by 14.4% and 30.5% respectively. The tube currents were also increased in pelvic cavity but the metal hip

prosthesis had no effect on the tube currents of extrapelvic area. The utilization of MAR and ODM protocols decreased both the surface and the deep organ doses in pelvis. GSI32 showed the most significant dose reduction in the deep pelvic cavity followed by GSI3 and ODM. However, MAR (GSI32, GSI3) protocols increased radiation doses in extrapelvic cavity compared to the reference scan. ODM showed significant reduction of both the surface and deep organ doses in the extrapelvic cavity.

CONCLUSION

Metal hip prosthesis implantation increased exposed radiation doses in abdominopelvic CT scans. MAR protocol can be utilized to reduce the exposed radiation doses in pelvic cavity while improving image quality. When MAR protocol is not applicable, ODM is an alternative protocol that can be utilized to reduce exposed radiation doses of both pelvic and extrapelvic cavities.

CLINICAL RELEVANCE/APPLICATION

Metal artifact reduction and organ dose modulation techniques reduce radiation doses in patients with metal prosthesis implantation.

SSK18-06 Impact of Adjusting the Pulmonary-Embolism CT-protocol on Female Fertility Preservation by Reducing the Radiation Exposure of the Ovaries

Wednesday, Nov. 29 11:20AM - 11:30AM Room: S503AB

PURPOSE

To assess in female patients undergoing a clinical pulmonary-embolism CT-protocol the relative and absolute reduction of the radiation exposure on the gonads by using a modified protocol that imposes a caudal imaging limit of the costodiaphragmatic recesses, in lieu of the common imaging window which also captures the supraadrenal glands. Cumulative exposure to radiation remains a concern due to the rising maternal age at primigravida, and the often unavailable exposure during emergencies such as suspected pulmonary embolisms.

METHOD AND MATERIALS

Thirty non-pregnant female patients with suspected pulmonary embolism underwent a contrast enhanced CT of the chest on a 3rd generation dual source CT (SOMATOM Force, Siemens Healthcare) in single-energy mode with automatic tube voltage selection and tube current modulation. Organ dose of the ovaries was automatically calculated using a commercial dose tracking software (Radimetrics, Bayer Schering). Full assessability of the thoracic cavity was assured with the modified imaging window, although incidental findings of e.g. suprarenal growths were precluded.

RESULTS

Median age of the patients analyzed in the retrospective study was 35 years [17 - 42]. The median equivalent dose of the gonads was 0.031 [0.009 - 0.190] mSv for the adapted (shrunk imaging window) and for the non-adapted protocol (typical size imaging window) 0.060 [0.013 - 0.266] mSv. The reduction in radiation dose was statistically significant ($p<0.0001$). The mean absolute difference in the ovarial radiation dose amounted to 0.041 ± 0.031 mSv, corresponding to a relative reduction in gonadic exposure of 43.8%.

CONCLUSION

For female patients prior to menopause in general, and their subgroup with a history of suspected pulmonary embolisms and thus repeated thoracic CT imaging specifically, an adaption of the CT protocol as outlined conveys a significant cumulative reduction of the radiation exposure on the ovaries.

CLINICAL RELEVANCE/APPLICATION

Shortening the scan range of pulmonary CTA positively affects the ovarian radiation exposure, important in pre-menopausal women undergoing repetitive scans.

SSK18-07 CT-Guided Periradicular Infiltration Therapy: How IR and Protocol Modifications Contribute to Achieving Ultra-Low-Dose

PURPOSE

To evaluate robustness and safety of ultra-low-dose protocols for CT-guided periradicular infiltration of the cervical and lumbosacral spine on a CT scanner with iterative reconstruction software.

METHOD AND MATERIALS

This retrospective study included a total of 366 patients who underwent periradicular infiltration therapy of the cervical (n=191) and lumbar (n=175) spine. Respective study group (90 each cervical and lumbosacral) was treated on a new CT scanner with a new intervention protocol using an iterative reconstruction algorithm. Spot scanning was implemented for planning purposes and a basic low setup of 80 kV (cervical) or 100 kV (lumbosacral) and 5 mAs was established during intermittent fluoroscopy. The comparison group comprised 101 (cervical) and 85 (lumbosacral) prior interventions on a scanner without iterative reconstruction software. Dose-length product, number of acquisitions, pain reduction on a numeric analogue scale and protocol changes to achieve a safe intervention were recorded.

RESULTS

Median DLP for the whole intervention was 24.3 mGy*cm in the cervical and 49.3 mGy*cm in the lumbosacral comparison group towards 1.8 mGy*cm in the cervical and 3.2 in the lumbosacral study group. Pain reduction was median -2 in all the cervical and lumbosacral study and comparison group. Raise of the tube current-time product by 5 mAs was needed in 5 patients of the cervical and 3 patients in the lumbosacral study group.

CONCLUSION

Implementation of a new ultra-low-dose intervention protocol resulted in a reduction of dose by 92.6% (cervical) and 64.0% (lumbosacral) without limitation of safety and pain relief.

CLINICAL RELEVANCE/APPLICATION

Dose reduction in CT imaging is of relevant interest from patients and physicians perspective. Changes of the scanner parameters and implementation of IR can significantly reduce overall dose also of interventional procedures. This dose reduction does not impact the procedure itself nor the outcome as seen in periradicular infiltration.

SSK18-08 Prospective Evaluation of Ultra-Low Dose Enhanced Abdominal Computed Tomography (MDCT) Using 100 kV with Tin Filter as Spectral Shaping: Effect on Radiation Dose Reduction and Image Quality with a Third-Generation Dual-Source CT System

PURPOSE

The purpose of this prospective study was to investigate the radiation dose exposure and image quality of enhanced abdominopelvic single-energy MDCT using a tin filter at 100Kv tube voltage in comparison to the standard enhanced acquisition.

METHOD AND MATERIALS

110 medium size oncologic patients (BMI:25±3.2kg/m2) over 60 years old (mean age:73.2±10.2 years) referred for an enhanced abdominopelvic MDCT examination underwent in addition to our conventional protocol an ultralow dose acquisition with tin filter (TF) in portal venous phase. Our institutional ethical committee reviewed and approved our investigation. The examinations were performed in single energy helical mode with a third-generation dual-source CT (Somatom Force). Both standard acquisition (SP) with an automatic individually-adapted kV (90-110) and tin filter (TP) (100 Sn kV/300mAs) were acquired with automatic milliamperage modulation and identical length of coverage, pitch, reconstructed slice thickness of 2mm, acquisition time and ADMIRE strength : 4. Radiation dose was recorded as dose-length product (DLP), volume CT index (CTDIvol). Effective dose (ED) was calculated. Subjective image quality was evaluated on a 5-grade scale by two blinded independent radiologists and interobserver agreement was calculated. Objective image quality was calculated by signal-to-noise ratio (SNR). The attenuation with standard deviation in liver and psoas muscle were assessed.

RESULTS

Radiation dose was reduced by 82-84% withTF compared to SP (DLP : 290±12.0 vs 49.6± 3.2 mGy.cm; p<0.0006, CTDIvol:1.32±0.36 vs 7.25±1.64 mGy; p<0.0001, ED : 4.93±0.2 vs 0.84±0.1 mSv ; p<0.0005). The image quality was rated as excellent for both (4.5 for TF, 5 for SP) with an excellent interobserver agreement (Kappa =0.87). All abnormalities discovered on SP were identified on TF. SNR was not significantly different with TF in liver (9.53±0.9 vs 8.10±1.1; p : 0.08) or psoas (6.03±1.5 vs 5.46±0.2 ; p : 0.06), respectively. Attenuation values were slightly lower with TF (91±14HU vs 102±12HU, 52±16HU vs 65±10HU; p= 0.06) for liver and psoas muscle, respectively

CONCLUSION

An ultralow radiation dose (ED<1mSv) for abdominopelvic CT is achieved using a tin filtration as spectral shaping at 100 kV without

degradation of image quality and diagnosis confidence in medium size patients.

CLINICAL RELEVANCE/APPLICATION

The TF acquisition should be proposed for enhanced abdominal CT follow up examinations in oncologic patients.

SSK18-09 Reducing Variability of Radiation Doses in CT

CONCLUSION

Significant decrease of variance in head, chest, and abd/pelvis CT was achieved using a combination of standardizing protocols across the network and implementing advanced software that effectively managed radiation dose.

Background

While reducing radiation is an important goal, also important in the management of radiation dose is ensuring consistency in the amount of radiation administered for each type of study. Being able to consistently administer the same dose everytime a study is performed is the hallmark of high quality in radiation management. We implemented an approach to reducing variance in CT dose by standardizing protocols and employing software at the scanner to provide consistency across the network.

Evaluation

We measured variance of dose administered to head, chest, and abd/pelvis CT in two periods. The first period is pre-intervention: 1/1/13-7/31/14. We then measured the period after intervention: 1/1/16-12/31/16. Statistical analysis for differences in variability of radiation dose pre- and post-intervention used Bartlett's test. Pre-intervention dose and SD: head CT (n= 12,002): 26.4 CTDI with SD of 4.3; chest CT (n=3,149): 8.6 CTDI with SD of 5.2; abd/pelvic CT (n=9833) :12.5 CTDI with SD of 5.2. Post-intervention dose and SD: head CT (n=13,274): 20.1 CTDIvol with SD of 3.4; chest CT (n=3,746): 5.4 CTDI with SD of 2.7; abd/pelvis Ts (n=12,121): 7.7 CTDI with SD 3.3. Post intervention SD was significantly decreased for all studies ($p<0.001$).

Discussion

Our approach to reducing variability in radiation CT was a multifaceted approach: 1. Establishing the Radiation Dose Optimization Committee, 2. Standardizing Protocols, and 3. Implementing scanner software which reduces variance of dose. We implemented software in scanners that increases tube current to a lesser degree than would be obtained by hold noise constant. The software increases tube current for increasing diameter size at a rate less than would be needed to hold noise constant. Thus for larger patients,allowing for controlled increase in dose to improve signal to noise yet also accepting more noise allowed for better dose management avoiding exponential increase in radiation that occurs with conventional dose modulation.

ABSTRACT

Purpose/Objective(s): Cancer survivors often experience psychological stress, with impact on quality of life (QOL) and mortality. Better understanding the heterogeneity in individuals' psychological adjustment to cancer diagnosis and treatment may help identify valid screening practices for those most in need of psychosocial support. The specific aim of the current study investigates the role of psychological state prior to treatment on the course of QOL during radiotherapy for localized non-metastatic prostate cancer. We hypothesized inverse correlations between depression and QOL. We also categorized participants in three groups based on depressive symptoms (i.e., minimal, mild, moderate+) and hypothesized a significant between group difference in QOL as measured pre-, mid-, and post-treatment.Materials/Methods: The PHQ-9 assessed depression. We grouped participants into Minimal (n=22), Mild (n=8), and Moderate or higher (n=6) depression groups based on PHQ-9 score. The FACT-P assessed QOL, including physical, social, emotional, and functional well-being. Our total sample (N=41) had mean age of 68 (range 54-81) and education of 15.5 years (range 10-20). Most participants (33; 80%) identified as European-American. There were no between-group differences in age, education, or ethnic identity. Repeated measures ANOVA assessed effects of group and time. Associations of variables of interest were also assessed by Pearson's correlation coefficients.Results: Significant inverse correlations were observed between depression and QOL pre-treatment (p p p F (1,33)=16.49, ppConclusion: These analyses reflect strong inverse correlations between degree of depressive symptoms and QOL pre-, mid-, and post-treatment. Investigating subgroups based on extent of depressive symptoms was also illuminating in that QOL characteristics of the "moderate or higher" group were distinct from the other two groups, which did not significantly differ from one another. Indeed, a "mild" degree of depression may not be unexpected in inherently distressing circumstances. These findings support the conclusion that there may be a useful clinical cutoff on the PHQ-9 (e.g., mild vs. moderate) for triggering psychosocial support or other intervention. We are of course limited by small samples in our subgroups and these findings can therefore be considered preliminary. Future directions include investigation into other potential contributors to QOL changes, as well as investigation of these factors in other disease or treatment groups.

SSK19-04 Stereotactic Body Radiation Therapy (SBRT): A Strategy to Reduce Disparities in African American Men with Localized Prostate Cancer?

Wednesday, Nov. 29 11:00AM - 11:10AM Room: S104A

Participants
Robert Dess, MD, Ann Arbor, MI (*Presenter*) Nothing to Disclose

ABSTRACT

Purpose/Objective(s): Prostate cancer (PCa) is the most common cancer in men, and African-Americans (AA) consistently have inferior outcomes compared to Caucasians (C). Technological advances that improve access to care may be one strategy to address this disparity. Stereotactic Body Radiation Therapy (SBRT) is a convenient, non-invasive course, typically involving 5 treatments over a few weeks. In a large cohort with prospectively collected health-related quality of life (HRQOL) data, we sought to explore early efficacy and HRQOL differences between men who self-report as AA compared to C race.Materials/Methods: Between 2008 and 2014, 752 consecutive men were treated with localized, node negative prostate cancer per an institutional protocol. Inclusion criteria for the present study included men with low and intermediate risk PCa treated with SBRT with or without androgen deprivation therapy (ADT). Prospective HRQOL data in the urinary, bowel, sexual and vitality domains were collected via the Expanded Prostate Cancer Index Composite (EPIC)-26 form along with other baseline demographics (Charlson comorbidity,

Anticoagulation use, Partner status, Diabetes (DM), Hypertension, Dyslipidemia, and Coronary artery disease). Cox multivariable analyses (MVA) were utilized to compare 5-year biochemical progression-free survival (bPFS) and 2 year HRQOL between AAs and Cs. Results: The median follow-up was 4.1 years. Of the 510 men who met eligibility criteria, 53% (n=270) were C, 40% (n=202) AA, and 7% (n=38) other. The cohort included 33% low, 38% favorable intermediate (Fav-Int), and 29% unfavorable intermediate (Unfav-Int) risk men, and rates were similar between AAs and Cs (p=0.44). AAs were younger at diagnosis (67 vs 70, p0.05). AA were less likely to report partners (70% vs 82%, p=0.04) or depression (0% vs 10%, pConclusion: In a prospectively followed cohort, tumor control and HRQOL were similar across low and intermediate risk men treated with prostate SBRT, even when adjusting for baseline differences. Long term follow-up is needed to confirm these promising results.

SSK19-05 Patient Safety in Radiation Oncology Departments in Spain: Preliminary Results of the First National Survey

ABSTRACT

Purpose/Objective(s): To analyze the current status of the patient's safety culture and programs among the radiation oncology departments is Spain through a national survey.Materials/Methods: The survey was targeted to 98 heads of radiation oncology departments, both public and private. Each of them received a questionnaire and the responses were utilized to explore the study aim. Twenty five questions were asked on the following topics: Existence of a patient safety commission in his hospital and participation in the same of someone of the department; If someone in the department has tasks related to patient safety; Existence of maps of processes, risks and a risk probability scale; Check lists employment, Existence of a quality assurance program with indicators to measure the quality of each phase of the radiotherapy process, and when it was last updated; Performance of any external quality control audit; Existence of an anonymous and easy-access system of events notification; Number of adverse events reported in the last 12 months; Organization of regular meetings on issues related to patient safety; Existence of specific actions aimed at improving patient safety; Degree of implementation of the safety culture in its department and, finally, His opinion on the development and implementation by the Spanish Society of Radiation Oncology of an anonymous national system of notification of errors and incidents.Results: At present, 70 questionnaires have been received (participation rate 71.4%). Although 74% of the hospitals have a patient safety commission, only in 59% a radiation oncology staff is a member. In 70.3% of the departments some member has tasks related to patient safety. In the 88.8% there is a map of processes and in 40.7% a map of risks. In 85.1% check lists are used. In 100% of the departments there is a quality assurance program. In 66.6% some adverse effects were reported in the last year. Finally, almost all (96,2%) of the department's heads who responded agreed on the development and implementation by the Spanish Society of Radiation Oncology of an anonymous national system of notification of adverse events.Conclusion: The preliminary results of the survey show that, despite the fact that important work is being done on quality and of patient safety, there is still significant scope for improvement. Collection of questionnaires continues, and the final results will be presented and the final results will be presented when a participation rate of more than 80% has been achieved.

SSK19-07 Cost Effectiveness Analysis of Utilizing 3D Printer Technology to Create Bolus for Radiotherapy: An Institutional Experience

Wednesday, Nov. 29 11:30AM - 11:40AM Room: S104A

Participants
Ankur Sharma, MD , Winnipeg, MB (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

asharma5@cancercare.mb.ca

ABSTRACT

Purpose/Objective(s): At our institution, 3D printer technology is utilized in the radiation oncology department for constructing custom bolus. Bolus created using this innovative approach produces a more accurate fit in areas with complex skin contours and reduces air gap when compared to conventional bolus. It is also more convenient for patients and radiation therapists (RTs). As the use of 3D printing technology is expected to increase drastically in radiation oncology, we set out to perform a cost effectiveness analysis and report our findings. Materials/Methods: For the calendar year of 2014, patients who could have potentially had a bolus created using 3D printer technology at our institution were identified. Treatment sites included: sarcoma, anal canal, skin using orthovoltage energy and skin using electrons. Surveys were sent to 5 RTs to estimate the average time required to fabricate and set up a bolus using the conventional technique. Staff time required when using the 3D printer technique was estimated by an experienced physicist. Labour costs were determined for RTs, physicists and machinists, taking into account staff salary and labour hours. Cost of running and maintaining one linear accelerator and one orthovoltage unit was calculated. Cost of material required for 3D printer technique using polylactic acid (PLA) and cost of material using conventional technique was determined. Using the above information, total annual fabrication cost was calculated for both techniques. Total annual set up time was also calculated for both techniques. Potential annual cost savings were determined by subtracting the total annual cost of using the 3D printing method from the total annual cost of using the conventional method. Results: A total of 318 patients received 3204 fractions of radiotherapy. Cost of running the linear accelerator was $2.64/minute and $0.73/ minute for the orthovoltage unit. The cost of PLA was .07/cm3 and .11/cm3 for conventional bolus material. Taking into account the cost of our existing 3D printer, total annual accessory fabrication cost was $18,878.00 using the conventional method and $12,249.21 using 3D printer technology. Annual set up cost using conventional bolus was $71, 054.54, compared to $27,453.00 using 3D printer technology. When the two techniques were compared, potential annual cost saving were $47,678.53.Conclusion: This analysis, although not perfect, shows that by utilizing a simple consumer

grade 3D printer to create bolus for radiotherapy treatments, there can be substantial cost savings of just under $50,000.00 annually. When combined with the fact that 3D printed bolus provides a more accurate fit to the skin surface, provides equivalent or superior dosimetrics and adds patient and staff convenience, its usage is bound to become more common in radiation oncology departments. We recommend that utilization of 3D printer technology to create bolus for radiotherapy should become the new standard of care.

SSK19-08 Treatment Time Analysis of Radiotherapy for Breast Cancer Patients Treated with LINAC

Wednesday, Nov. 29 11:40AM - 11:50AM Room: S104A

Participants
Mei Suet Wong, Hong Kong, Hong Kong (*Presenter*) Nothing to Disclose

Michelle.wong@hksh.com

ABSTRACT

Purpose/Objective(s): To analyze setup time, beam on time and total treatment time of the radiotherapy treatment of breast cancer patients for case scheduling optimization, thus improving the machine throughput and the efficiency of treatment process Materials/Methods: In this study, breast treatment techniques of tangential opposing fields (2F), tangential opposing plus anterior SCF fields (3F) and tangential opposing fields with active breathing control (ABC) were considered. The total numbers of fraction in each case were 15-25. A customized table was used for recording setup time, beam on time and total treatment time for each patient. For 2F, 41 patients with 750 fractions were marked. For 3F, 8 patients with 163 fractions were marked. For ABC, 4 patients with 78 fractions were marked.The mean of setup time (TS), beam on time (TB) and total treatment time (TTx) for all fractions were calculated and compared among 2F, 3F and ABC techniques.To investigate treatment duration variability throughout the course of treatment, the mean of TS, TB and TTx of each fraction were also calculated and analyzed.One-way ANOVA was used in this study. Results: Mean (mins) TSTBTTx2F5.85.010.83F6.66.513.1ABC11.37.618.9The TS, TB and TTx among the three techniques were significantly different (pS between 2F and 3F due to similar setup procedures. In particular, the mean TS (11.3min) and hence TTx (18.9min) were much longer when using ABC technique. ABC device was needed to setup for controlling patient's respiratory motion which increased the total treatment time significantly.For treatment duration variability, the TTx for the first fraction was almost the double of overall fraction average regardless of the technique being used (190%, 208% and 217% for 2F, 3F and ABC respectively). It was due to setup verification performed during first treatment. For 2F and 3F, the TTxs in each fraction starting from second treatment were similar which the means were within 9-11mins. For ABC, the means TTxs of 2nd to 4th fractions were within 23-25mins which were still 30% longer than the average. This suggests 4 fractions were needed for patients to adapt the ABC setting and give stable performance throughout the remaining treatment course. The re-setup rate was low (3%) and only 0.3% patients felt uncomfortable and prolonged the treatment.Conclusion: Our current routine treatment time slot for 2F and 3F is 15mins while 30mins for the first fraction. For ABC, 45mins and 30mins are for first fraction and subsequent fractions respectively. This study suggested that the treatment duration of 2F for each fraction is 10mins and 20mins for first fraction. For 3F, it keeps 15mins as the average and 30mins for the first fraction. As for ABC, 40mins is suggested for the first fraction and 25mins for 2nd to 4th fractions while 20mins for the remaining fractions. The suggested case arrangement is expected to maximize the effective machine occupancy and hence the throughput.

SSK19-09 A Pilot Study to Evaluate a Newly-Developed Needs Assessment Tool for Improving Radiotherapy and General Oncology Management in Nigeria

Wednesday, Nov. 29 11:50AM - 12:00PM Room: S104A

Participants
Chika Nwachukwu, Stanford, CA (*Presenter*) Nothing to Disclose

ABSTRACT

Purpose/Objective(s): Cancer mortality in low- and middle-income countries are rising at a rapid rate, especially in countries where screening programs are scarce and resources are limited. Fragmented infrastructure, as well as limited human resources hinder access to appropriate cancer care in these regions. The purpose of this study is to develop a tool that assesses the gaps in cancer care, with emphasis on radiotherapy infrastructure, personnel skill level, and barriers to accessing treatment.Materials/Methods: Stanford University has developed a detailed needs assessment tool, in collaboration with the American Cancer Society (ACS) and Clinton Health Access Initiative (CHAI). This tool will be tested in a cross sectional study at two teaching hospitals in Nigeria. Using this newly developed cancer assessment instrument, semi-structured interviews and onsite visits will be conducted to assess gaps in cancer care including radiotherapy infrastructure. Lastly, in collaboration with key hospital personnel, the results of this study will be used to finalize the assessment tool to ensure the local cancer care needs are adequately addressed. Results: The two hospitals sites, Ahmadu Bello University Teaching Hospital (ABUTH) and Lagos University Teaching Hospital (LUTH), were identified by the Nigerian ministry of health as two sites to be developed into comprehensive cancer centers. Both centers currently have chemotherapy delivery capacity, radiotherapy capacity (including linear accelerators, linacs), and are staffed by radiation oncologists, medical oncologists, and a small set of non-specialist clinical staff. Stanford experts have been paired with collaborators at ABUTH and LUTH. The needs assessment tool has two main components, a cancer assessment section and a human capacity section. The cancer assessment section has 6 broad areas ranging from summary and health status of the population to cancer specific needs. The different specialist from LUTH and ABUTH will complete the tool. There are 100 cancer specific needs questions, 20 of which focus directly on radiotherapy. The radiotherapy issues addressed include the demographics of patients receiving treatment (palliative or curative intent), referral patterns for patients, and barriers to care, such as cost of treatment. Furthermore, the tool assesses radiation treatment capacity to include availability of linacs, cobalt machines, brachytherapy machines and their functional capacities. Finally, the human resource section has 20 broad questions, many of which are applicable to radiotherapy staff, ranging from continuing education to the availability of staff, their respective roles, as well as their work flow. Conclusion: The completion of the needs assessment will take place during the site visit at the end of February. The results of the tool will be reported to identify actionable ways to improve cancer care, including the utilization of radiation in this setting.

sanjay.bansal@albertahealthservices.ca

PURPOSE

Non-variceal gastrointestinal bleeding (NVGIB) is a common cause of hospitalization. In patients who have failed endoscopic therapy trans-arterial embolization (TAE) is considered the treatment of choice. The primary objective of this study is to perform a detailed systematic review and meta analysis of the current literature to assess (1) the success of TAE in controlling NVGIB, and (2) evaluate the mortality and morbidity rates post-TAE in patients for whom endoscopy has failed to control NVGIB.

METHOD AND MATERIALS

A search strategy was developed for EMBASE and Medline related to embolization and gastrointestinal bleeding using appropriate exploded medical subheading terms and keywords. Studies included were those examining patients presenting with a NVGIB whose bleeding could not be controlled with endoscopic intervention and subsequently were treated with TAE. The primary outcomes will be all-cause mortality and re-bleeding rates. These will be combined using a random-effects meta-analysis if sufficient data is extracted. Secondary outcomes will include length of hospitalization.

RESULTS

The search yielded 5624 articles from EMBASE and 2874 from Medline. After eliminating duplicates a total of 6421 were identified for further screening. Application of inclusion and exclusion criteria left a final total of 46 articles to be included in the study. Technical success was 97%. 24.65% of patients had bleeding within 30 days of TAE. 12.7% of patients required surgery after TAE. 30 day mortality post embolization was 22.8%. Bowel necrosis occurred in 3% of patients.

CONCLUSION

TAE in the setting of NVGIB, in which endoscopy has failed to control bleeding, is almost always successful acheiving cessation of contrast extravasation. 30 day re-bleed and mortality are high, however this may be confounded by pre-existing comorbidities and clinical instability of patients prior to undergoing embolization. Subgroup analysis will help to delineate this.

CLINICAL RELEVANCE/APPLICATION

In patients with NVGIB that is refractory to endoscopic therapy TAE should be strongly considered as an alternative to surgery as a second option. This is especially true in patients with multiple comorbidities, and/or patients that are clinically unstable, as they are high risk surgical candidates.

SSK20-02 Prostatic Artery Embolization: Identifying the Anatomical Variations in Origin of the Prostatic Artery and Predicting the Best Tube Angle Projection to Visualize its Origin Using Three Dimensional Contrast-enhanced MR Angiography

Wednesday, Nov. 29 10:40AM - 10:50AM Room: E351

Participants
Nagy N. Naguib, MD, MSc, Frankfurt Am Main, Germany (*Presenter*) Nothing to Disclose
Nour-Eldin A. Nour-Eldin, MD,PhD, Frankfurt Am Main, Germany (*Abstract Co-Author*) Nothing to Disclose
Tatjana Gruber-Rouh, Frankfurt Am Main, Germany (*Abstract Co-Author*) Nothing to Disclose

Thomas J. Vogl, MD, PhD, Frankfurt, Germany (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

nagynnn@yahoo.com

PURPOSE

To evaluate the ability of Three Dimensional Contrast Enhanced MR Angiography (3D-CE-MRA) in identifying the origin of the prostatic artery (PA) and predicting the best tube angle projection for its visualization before prostatic artery embolization (PAE) in an attempt to find a standard angle for its visualization during intervention

METHOD AND MATERIALS

Pre-embolization CE-MRA studies from 28 males (mean age 66.54 years) were retrospectively evaluated by two radiologists in consensus. Studies were done using a 3 Tesla MRI unit and 3D images were reconstructed using Syngo Vessel View Application. The PA was identified by tracing its course from the prostate back to its origin. Then the 3D figure was rotated in all directions to obtain the best visualization angle of the origin without overlap from other arteries

RESULTS

Of the studied 56 internal iliac arteries (IIA) the PA was detected in 80.1% (n=45); unilaterally in 17.9% (n=5 patients) and bilaterally in 71.4% (n=20 patients). It originated directly from the anterior division of the IIA in 57.78% (n=26), indirectly from the anterior division with a common trunk with other arteries in 13.33% (n=6, 3 with middle rectal, 2 with superior vesical and 1 with internal pudendal) and from different branches in 28.89% (n=13, 8 from internal pudendal, 3 from obturator and 2 from inferior gluteal). For the right PA (detected in 21 patients) the angle projection required for visualizing its origin ranged from 43° left to 45° right (mean 6.33° right +/- 30.4°). Additional cephalocaudal angulation was required in 66.67% (n=14) with angle ranging between 3° and 23° caudal (mean 11.79° caudal +/- 6.69°). For the left PA (detected in 24 patients) the angle projection required for visualizing its origin ranged from 45° left to 37° right (mean 16.04° left +/- 31.49°). Additional cephalocaudal angulation was required in 37.5% (n=9) with an angle ranging between 4° and 23° caudal (mean 13.67° caudal +/- 7.98°)

CONCLUSION

3D-CE-MRA can detect the origin of the PA before PAE and can predict the best tube angle projection to visualize it. There is no standard angle to visualize the origin that can be generally recommended; instead the angle should be individually tailored.

CLINICAL RELEVANCE/APPLICATION

3D-CE-MRA can identify the origin of the PA and predict the best tube angle projection to visualize it before PAE. The preplanning can reduce the need for searching for the origin using radiation during the procedure.

SSK20-03 Prostatic Arterial Embolization with Polyvinyl Alcohol Electrospun Nanofibers in a Canine Model of Benign Prostatic Hyperplasia (BPH): A Preliminary Study

Wednesday, Nov. 29 10:50AM - 11:00AM Room: E351

Participants
Basen Li, Wuhan, China (*Presenter*) Nothing to Disclose
Liang Wang, MD, PhD, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose
Zhaoyan Feng, MD, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose

libasen@sina.com

PURPOSE

To explore the safety, feasibility and efficacy of embolization with polyvinyl alcohol (PVA) electrospun nanofibers in a canine model of benign prostatic hyperplasia (BPH).

METHOD AND MATERIALS

Five adult male beagle dogs (Beagle A, Beagle B, Beagle C, Beagle D, Beagle E) were included in this study. All beagle dogs were randomly numbered.The beagle dogs were castrated by an urologist. Intramuscular Benzylpenicillin (1,600,000 IU) was injected daily for three days to prevent infection. After one month, 2.5 mg/kg of TP were injected intramuscularly daily for 3 months. All beagle dogs underwent 3T MRI. The prostatic volume (PV) of all dogs was measured on MRI before and at 3 months after initiation of hormone administration. PAE was performed with superselective catheterization of the prostatic artery on each side through a femoral artery puncture after 3 months of TP therapy. Embolization was performed with the use of homemade 150-200 μm polyvinyl alcohol (PVA) electrospun nanofibers. All dogs was sacrificed 1 week, 1 month, 3 months, 6 months and 6 months after PAE, respectively. Histopathologic study was performed by the urologic pathologist.

RESULTS

The canine BPH model was successfully established in all dogs. The mean PV increased significantly after 3 months of hormone administration. DSA clearly depicted of the prostatic arteries after 3 months of hormone administration. PAE was successfully performed in all dogs. No serious PAE-related complication was observed during and after the procedure. In all five dogs, no significant abnormalities were found. Under the microscope, the PVA electrospun nanofibers in blood vessels with no spillover , mild inflammation in the prostate was found in Beagle A 1 week after PAE. The prostate of Beagle B 1 month after PAE showed cystic changes, atrophied gland, decreased inflammatory cells, more fibroblasts, focal hemosiderin deposition, and no evidence of neocapillarization. The parenchyma around the cavity showed atrophy under the microscope. In addition, focal hemosiderin deposition, scattered inflammatory cell infiltration, and fibrosis were found. Remnants of the glandular hyperplasia and embolic particles in blood vessels of the gland were present.

CONCLUSION

PAE with PVA electrospun nanofibers in a canine model of BPH is feasible, effective and safe.

CLINICAL RELEVANCE/APPLICATION

PVA electrospun nanofibers can be used in PAE

SSK20-04 Long-Term Clinical Outcomes and Re-Intervention Rates of Uterine Artery Embolization (UAE) For Symptomatic Fibroids or Adenomyosis: Five-Year Results

Wednesday, Nov. 29 11:00AM - 11:10AM Room: E351

jkyoon87@yuhs.ac

PURPOSE

To retrospectively investigate reintervention rates in patients treated with uterine artery embolization (UAE) for symptomatic fibroids or adenomyosis and to elucidate predictive factors for reintervention.

METHOD AND MATERIALS

Between March 2011 and February 2012, 124 patients who underwent UAE were categorized into fibroid group (n=92, 73.6%) or into adenomyosis group with or without fibroids (n=32, 26.4%). Five-year follow-up telephone survey was done to assess reintervention rates. Potential predictive factors for reintervention such as age, body mass index (BMI), as well as three-month follow-up magnetic resonance imaging (MRI) outcomes were analyzed.

RESULTS

Response rate to the telephone survey was 73.4 % (91/124, 67 fibroid and 24 adenomyosis). Technical success was achieved in all patients (100%). Overall reintervention rate was 11.0%, with seven patients in the fibroid group (10.4%) and three patients in the adenomyosis group (12.5%). Subgroup analysis of 15 adenomyosis patients without fibroids (i.e., pure adenomyosis) revealed three reintervention cases (3/15, 20.0%). Reinterventions in the fibroid group were myomectomy (n=5) and hysterectomy (n=2). Among 56 patients with available follow-up MRI, 54 (96.4%) had complete necrosis of the predominant fibroids. One patient with cervical leiomyoma had treatment failure resulting in hysterectomy. Reinterventions in the adenomyosis group were hysterectomy (n=2) and myomectomy (n=1). 13 out of 15 follow-up MRIs of adenomyosis patients with or without adenomyosis (86.6%) demonstrated complete necrosis, resulting in one case of hysterectomy. One of two adenomyosis patients without necrosis (1/15, 13.3%) underwent hysterectomy. In the adenomyosis group, there was a trend towards lower reintervention rate in patients with complete necrosis than in those without necrosis, but without statistical significance.

CONCLUSION

Reintervention rates in fibroid and adenomyosis groups at five years were 10.4% and 12.5%, respectively. Low reintervention and high clinical success rates strengthen the potential of UAE as a viable first line treatment for symptomatic fibroid or adenomyosis.

CLINICAL RELEVANCE/APPLICATION

Uterine artery embolization(UAE) has strong potential as first line treatment for adenomyosis with or without fibroids with low reintervention rate and high clinical success rate.

SSK20-05 Refinements of Preoperative Portal Vein Embolization Using Ethylene-Vinyl Alcohol Copolymer: A Pilot Study

maxime.ronot@aphp.fr

PURPOSE

To evaluate the safety profile and the added value ethylene-vinyl alcohol copolymer (Onyx) injection for selective embolisation of specific portal branches during of preoperative portal vein embolisation (PVE).

METHOD AND MATERIALS

From 2008 to 2011, 110 PVE procedures were performed in our hospital in patients with small future liver remnants (FLR). Under general anaesthesia, PVE was achieved with injection of a mixture of n-butyl-cyanoacrylate (Histoacryl) and iodised oil (Lipiodol) using a 5-F catheter. At the operator's discretion, small portal branches with a great risk of embolic agent migration were embolised with Onyx through a 2.4-F microcatheter. CT volumetry of the FLR was performed before and 4-6 weeks after PVE. Clinical outcome was assessed on medical records.

RESULTS

Twenty-eight patients (median age, 57±17 years) underwent PVE with Histoacryl-Lipiodol and additional Onyx during 29 procedures. The indications for Onyx were embolisation of segment IV (n=21), early bifurcation of portal branches in S6 and S8 (n=5) and PVE in a one-year-old girl with cystic mesenchymal hamartomas. All targeted portal branches were successfully embolised with Onyx and no major complication was observed. Related-procedure adverse events included a self-limited subcapsular haematoma (3%) and two small pieces of glue migration without thrombosis (7%). CT volumetry showed a mean FLR hypertrophy of 64±28%. Hepatectomy was performed in 25 patients (89%) and cancelled in three patients, due to tumour progression (n=2) or insufficient FLR volume (n=1).

CONCLUSION

PVE with complementary Onyx before liver resection is safe and feasible, and helps to occlude small portal branches that are not accessible with conventional embolic materials.

CLINICAL RELEVANCE/APPLICATION

PVE with complementary Onyx before liver resection is safe and feasible, and helps to occlude small portal branches that are not accessible with conventional embolic materials.

SSK20-06 Emergency Out of Hours Endovascular Hemorrhage Control Procedures: Evolution of Caseload, Casemix and Clinical Outcome between 2009 and 2014

PURPOSE

Demand for emergency OOH EVHC procedures is increasing. The most dramatic and urgent cases are those in which IR undertake minimally invasive EHCPs where surgery is physiologically undersirable or technically challenging. We analyzed the changing caseload, casemix and 30-day mortality for emergency OOH EVHC procedures performed in 2009 and 2014 with hopes to inform service design, training and clinical decision making.

METHOD AND MATERIALS

The setting was four centers providing OOH IR services for a population of 3 million. Data related to all OOH EVHC done in 2009 and 2014 were analyzed, including mortality within 30 days of the index procedure. Procedures were categorised by site and etiology of hemorrhage and by whether or not a therapeutic intervention was actually performed.

RESULTS

Between 2009 and 2014: 1. The annual total caseload increased by 40% from 93 to 130 procedures ($P<0.05$), a per capita increase in caseload from 3.1 to 4.3 per 100,000 population 2. The number of therapeutic procedures increased by 34% from 84 to 113 3. Changes in casemix included significant increases in numbers of lower gastrointestinal (GI), non-surgical iatrogenic etiologies and spontaneous hemorrhage 4. The number of upper GI cases and postoperative bleeding was unchanged 5. The number of post-partum haemorrhage (PPH) cases was significantly reduced 6. 30-day mortality significantly increased from 9% to 18% ($P< 0.05$) 7. Patients in the 2014 cohort were significantly older, mean age (range) 60.6 years (19-94) vs. 52.3 (19-91), ($P<0.05$)

CONCLUSION

Increasing demand for emergency OOH EHVC procedures was accompanied by increased caseload of lower GI, non-surgical iatrogenic and spontaneous hemorrhage, with fewer PPH cases. Speculation on reasons for changes creates interesting discussion points. The older patients in the 2014 cohort suggests that the observed increase in mortality rate is likely attributable to changing referral thresholds (e.g. more patients with co-morbidities and/or in greater physiological distress). Identifying these trends facilitates service design, effective training and clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

Analysis of changing caseload and casemix of out-of-hours (OOH) endovascular hemorrhage control (EVHC) procedures facilitates efficient service design, effective training and informed clinical decision-making

SSK20-07 Stent Graft Implantation in Visceral Arteries in Acute Life-Threatening Hemorrhage after Upper Abdominal Surgery: Technical Results and Clinical Outcome

Wednesday, Nov. 29 11:30AM - 11:40AM Room: E351

PURPOSE

Vascular erosion of the major visceral arteries (e.g. hepatic artery) due to leaking of pancreatic or jejunal anastomses is a rare but severe complication after upper abdominal surgery, leading to life-threatening delayed intraabdominal bleeding. Due to multiple risk factors and comorbidities, surgery is not always possible, making an interventional approach desireable. However, in major visceral arteries like the hepatic or superior mesenteric artery, vessel patency has to be preserved to prevent organ necrosis; thus a stent graft has to be implanted. The purpose of the present study was to analyze technical and clinical outcome after heparin-bonded stent graft placement to treat acute hemorrhage of the visceral arteries after surgery.

METHOD AND MATERIALS

A retrospective analysis of 22 male and 7 female patients (mean age: 66 years) who underwent heparin-bonded stent graft placement for the treatment of post surgical bleeding between 2009 and 2016 was performed. An explorative data analysis concerning technical success, complications as well as short term survival (<30 days) and long term survival (<90 days) was performed.

RESULTS

Successful stent graft placement and vessel reconstruction could be achieved in 24 of all 29 patients (83%). Surgical conversion was necessary in five patients. Periinterventional complications could be observed in six patients (vasospasms: n=4; pseudoaneurysm perforation: n=1; reversible stent occlusion: n=1). In 13 patients, a total of 14 stent graft related complications could be observed after the intervention (re-bleeding: n=7; stent graft occlusion: n=7), access related complications were observed in three patients. Short term survival was 76% (n=22) and long term survival was 41% (n=12), with most causes of death related to the underlying surgical complication.

CONCLUSION

Endovascular treatment of post-surgical bleeding using heparin-bonded stent grafts is a feasible treatment option with a high technical success rate. However, multiple risk factors and comorbidities in this specific patient cohort lead to a high complication rate and a comparably low long term survival rate.

CLINICAL RELEVANCE/APPLICATION

In patients with delayed intraabdominal bleeding after surgery, endovascular treatment using heparin-bonded stent grafts is a possible treatment option with a high technical success rate.

SSK20-08 Unenhanced MRI of the Pulmonary Vasculature Allows for Detection of Pulmonary AV-Malformations (PAVM) in Patients with Hereditary Hemorrhagic Telangiectasia (HHT / Osler's Disease)

Guenther K. Schneider, MD, PhD, Homburg, Germany (*Abstract Co-Author*) Research Grant, Siemens AG; Speakers Bureau, Siemens AG; Speakers Bureau, Bracco Group; Research Grant, Bracco Group;

PURPOSE

To compare the detection rate of pulmonary AV-Malformations (PAVMs) in Gd-enhanced MR angiography with unenhanced MR imaging techniques in patients with hereditary hemorrhagic telangiectasia (HHT).

METHOD AND MATERIALS

During this retrospective Study 122 patients with HHT underwent a total of 188 MR examinations between 01/2011 and 12/2015. The patients' age varied from 11 to 83 years (mean 48 years). Each examination included a non contrast enhanced SPACE (3D TSE-sequence/ TR 4.733 ms/ TE 101 ms/ FLIP 150°) and a contrast enhanced 3D GRE MRI sequence (TR 2,87ms/ TE 1,07 ms/ FLIP 25°, 0.1 mmol/kg BW MultiHance). Both examinations were read by two experienced radiologists and the number of detected AV-Malformations was reported in agreement for each examination. The contrast enhanced images were always read first and after an blanking interval of 6 weeks, the SPACE was read by the same radiologists; blinded to the results of the first reading. In cases in which therapy was required, catheter angiography was used as a gold standard and in all other cases CE-MRA served as the gold standard. A paired t-test was utilized for statistical evaluation.

RESULTS

4 Examinations had to be excluded due to respiratory artifacts in both sequences. 60 AV-malformations requiring therapy were reported in 35 patients. Using contrast enhanced images, an overall significantly higher number of AV-malformations was detected (166 vs. 96, p<0.001) but none of the AV-malformations requiring therapy (supporting vessel larger than 2 mm) were missed using the unenhanced SPACE sequence.

CONCLUSION

By using a SPACE sequence, the detection of clinical relevant pulmonary AV-malformations in patients with HHT can be safely performed in patients with contraindications for i.v. contrast medium (e.g. pregnancy).

CLINICAL RELEVANCE/APPLICATION

In patients with HHT it is important to find clinically relevant pulmonary AV-malformations, and using the SPACE sequence these can be found even in Patients with contraindications to contrast enhanced MRI.

SSK20-09 High Temporal Resolution Dynamic CE MRA in Detection of Reperfused Pulmonary Arteriovenos Malformations (PAVMs) in HHT-Patients

dr.guenther.schneider@uks.eu

PURPOSE

The recommended treatment of PAVMs in HHT patients (Hereditary Hemorrhagic Telangiectasia / Osler disease) is catheter embolization either with coils or by the use of vascular plugs. Although immediate post-interventional imaging may show complete success of embolization therapy, reperfusion may occur due to opening of collateral vessels or reperfusion of the embolized vessel itself. The aim of our study was to evaluate time-resolved contrast-enhanced MR-Angiography for detection of reperfused PAVM.

METHOD AND MATERIALS

65 patients in which treatment of PAVMs by means of platinum coil embolization or implantation of Amplatzer vascular plugs was performed, underwent follow-up studies for detection of reperfused PAVM by contrast enhanced MRA. First, a time-resolved MRA-study was performed with injection of a small contrast medium bolus (0.025 mmol/kg BW (Gd-BOPTA) MultiHance, Bracco). The temporal resolution of the sequence was 3 sec / dataset with a total number of 72 slices. Thereafter a high resolution CE MRA (0.075 mmol/kg BW MultiHance) with a timing based on the findings from the time resolved study was performed. Images were evaluated regarding enhancement of the draining vein. Recanalization was diagnosed when a simultaneous enhancement of feeding artery and draining vein or aneurysm sac was observed on dynamic CE MRA.

RESULTS

Time-resolved MR-Angiography was technically adequate in 61 of 65 cases. In 26 out of the 61 patients diagnosis of 32 reperfused PAVMs was made. In those cases in which diagnosis of reperfused PAVM was unclear on high resolution images, evaluation of the enhancement kinetics of the draining vein on dynamic CE MRA was used for diagnosis and could confirm 14 reperfused PAVM. All reperfused PAVM diagnosed on CE MRA were confirmed by DSA and underwent reembolization.

CONCLUSION

Time resolved contrast-enhanced MR-Angiography is a helpful adjunct to standard high resolution anatomic imaging, allowing for the evaluation of the enhancement kinetics of the draining vein as an indicator of recanalization of PAVM. Compared with CT imaging of embolized PAVM, this is an important advantage of CE MRA.

CLINICAL RELEVANCE/APPLICATION

Reperfusion of PAVM can occur in up to 20 percent of cases and early detection is mandatory to avoid complications. Dynamic CE MRA directly depicts early enhancement of the draining vein as a sign of reperfusion and thus gives important information not gained in conventional acquisitions.

MSRO43-02 Identifying Radiation Induced Brain Abnormalities in Adult Survivors of Pediatric Brain Tumor from "Normal-Appearing" MRI Using a Machine Learning Approach

Wednesday, Nov. 29 1:40PM - 1:50PM Room: S103CD

Participants
Leonardo Tang, Atlanta, GA (*Abstract Co-Author*) Nothing to Disclose

Hui Mao, PhD, Atlanta, GA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Radiation treatment may cause long-term adverse effects on brain tissue and cognitive function in pediatric brain tumor patients. The aim of this study is to use machine learning methods to search and extract the possible radiation induced abnormalities from the MRI data of a patient cohort, and further to characterize radiation-induced neurodegenerative effects on white and gray matters.

METHOD AND MATERIALS

14 adult survivors of pediatric brain tumors (with median radiation dose of 5400 cGy) who undergone extensive radiation treatment (RT) and demographically matched healthy controls (mean age: 22.7 ± 4.5 vs. 22.9 ± 4.3, $p>0.05$) were enrolled in the study. MPRAGE images used in this study were acquired with TR/TE = 2250/4ms, slice thickness = 1 mm, FOV = 256 mm2. All MRI data were preprocessed based the scheme shown in Figure 1 using the Statistical Parametric Mapping (SPM12) software package. Machine learning analysis was conducted using the Pattern Recognition for Neuroimaging Toolbox (PRoNTo) and run on GM and WM separately. The data were mean-centered and a Gaussian Processes Regression (GPR) model was defined using age as the dependent variable and the similarity matrix of imaging data as the independent variables.

RESULTS

The GPR model successfully differentiated the RT and controls with diagnostic accuracy of 100% in both white matter and gray matter analysis. Figure 2 shows the weighted display indicating the specific regions in WM and GM exhibiting the abnormalities in RT subjects comparing to the controls, which contribute to this classification of RT and control. In weighted display in WM, frontal lobe WM (i.e., anterior corpus callosum) contributes to the largest difference between RT and control (deep blue area), which is consistent with our previous results based on the analysis of diffusion tensor images (Wang, et al, 2015, PLOS One). However, in weighted display in GM, there is no specific region that exhibits the difference or contributes to the classification

CONCLUSION

Machine learning based method and model for predicting radiation induced neurodegenerative effect on adult survivor of brain tumor patient led to the successful identification of the abnormal regions in the brain of RT patients using just T1 weighted MPRAGE.

CLINICAL RELEVANCE/APPLICATION

Further development and application of this approach will enable integrated use of machine-learning assisted radiological assessment of treatment effect.

MSRO43-03 Profiling Myxofibrosarcoma: Patient and Disease Characteristics as Well as Clinical Outcomes at a Major Tertiary Care Cancer Center

ABSTRACT

Purpose/Objective(s): Formerly known as a myxoid variant of malignant fibrous histiocytoma (MFH), myxofibrosarcomas occupy their own niche in the World Health Organization classification in the category of fibroblastic and myofibroblastic tumors. With a predisposition for the elderly, they possess a high post treatment local recurrence rate. We take a close look at this soft tissue sarcoma subtype to highlight the incidence as well as outcomes at our large teaching hospital. Materials/Methods: A retrospective chart review was first undertaken to identify myxofibrosarcoma patients over a 10 years span from 1/2005 to 1/2015 with follow up data through to 2/2017 to guarantee at least 2 years of post-treatment data from a pool of aggregated soft tissue sarcoma tumors. Information was gathered via Electronic Medical Records, paper charts and communication with peripheral facilities and family physicians' offices. Sole inclusion criterion was histologic disease confirmation in patients aged = 18. A comprehensive literature review was also undertaken to determine current developments for this histology. Overall survival was analyzed using Kaplan-Meier methodology. Results: Thirty nine patients meeting selection criterion were selected from a total of 968 entries. With a largely male incidence (61.5%), the most common presenting symptom was a painless mass (95%). Median age was 62 years with a median follow up of 45 months. Commonest occurrence was in the extremities and superficial trunk (82%) with a median tumor size of 9.5 cm. Grade 2 disease at 41% was followed by 20.5% for both Grade 1 and 3 diseases according to the FNLCC (Federation Nationale des Centres de Lutte Contre le Cancer) system. Median pre-treatment hemoglobin post diagnosis was 12.8 g/dL. Curative intent treatment was offered in 87% of cases; with surgery in 92% of cases, being the primary modality of treatment. Radiation therapy (median fractionation of 50 Gy in 25 fractions) and chemotherapy were provided in 74% and 18% of cases respectively, primarily in an adjuvant setting for curative intent patients.Post-surgical margins were positive in 22% of patients and lymphovascular invasion identified in only 2 cases. Median time from diagnosis to initiation of primary treatment was 30 days with median time from radiotherapy start to end being 35 days. Sixty percent of curative intent patients receiving radiation had Three-dimensional Conformal Radiotherapy (3D-CRT) planning.Stage distribution by incidence was: Stage I 18%, Stage II 49%, Stage III 21% and Stage IV 10%. Thirty six percent of patients had a recurrence or disease progression with only 4 having a local component. Of the 11 patients who had a recurrence, 8 were stage II and 3 were stage III. Overall, three and five year overall survival estimates were 70% and 67% respectively.Conclusion: Treatment outcomes for myxofibrosarcoma remain relatively good at our large tertiary cancer centre. More research is required to identify strategies in enhancing both locoregional and systemic control.

MSRO43-04 Local Control in Pediatric Adolescent Meningiomas Treated with Proton Radiotherapy

Wednesday, Nov. 29 2:00PM - 2:10PM Room: S103CD

Participants

anne.sailer@my.rfums.org

ABSTRACT

Purpose/Objective(s): Pediatric meningiomas comprise less than 5% of pediatric CNS tumors. Limited pediatric data indicate that extent of surgical resection and tumor grade are strong prognostic factors for relapse free survival, but little data exists on the efficacy of radiotherapy in pediatric meningioma. Here we report the outcomes of pediatric meningioma patients treated with proton radiotherapy (PRT), which was used to minimize late effects of treatment. Materials/Methods: Eighteen patients were treated with PRT from 2005-2015 at our institution. Histologic WHO grade distribution was as follows: seven grade I, (38.8%, one with atypical features); 10 grade II (55.6 %), one grade III (5.6%). Fifteen patients had gross disease at the initiation of PRT. Three patients (with grade II or III tumors) had no visible disease at the time of PRT. The median PRT dose was 54 GyE, delivered in 1.8 GyE fractions (range, 50.4-63.4 GyE). The radiographic response of gross tumor was measured by a change in tumor volume after PRT. Clinical outcome including disease control and toxicities were reviewed and graded according to CTCAE v4.0.Results: The median follow-up time was 4.0 years with an estimated 5-year DFS and Local control rate of 100%. However one patient died from causes unrelated to disease or treatment. Eight of 15 pts with gross disease at PRT (53.3%) had decreased tumor size after PRT treatment; six (33.3%) had stable disease; and one was lost to follow up. Sequelae from treatment were minor and affected 8 of 17 patients and include: Moyamoya disease (5.6%; successfully treated), chronic headaches (18.7%), occasional grade 1-2 headaches (16.7%), radiation retinopathy (5.6%), and central endocrine deficit (11.1%). Patients who experienced hearing loss, vision loss, or seizures after PRT had these conditions at baseline prior to PRT. The mean CTV volume for patients with and without late toxicities was 41.8 cc (6.7–107.7) vs. 46.9 cc (1.7-157.4). Tumor location in the anterior cranial fossa, sphenoid wing, and optic canal were correlated with late side effects compared with other intracranial regions. Tumors near the cavernous sinus, the circle of Willis, or optic nerves were associated with the most co-morbidities at baseline.Conclusion: PRT is both safe and effective in treating pediatric meningioma. Further follow up is needed to determine if gross residual disease at the time of radiation diminishes disease control. Tumor location was more correlated with side effects than target volume.

MSRO43-05 Early Experience with Unidirectional Planar Brachytherapy for IORT of Abdominal Malignancies

ABSTRACT

Purpose/Objective(s): Recently, an innovative unidirectional Pd-103 low-dose-rate brachytherapy device, CivaSheet (CivaTech Durham, NC) has been developed as a promising IORT tool. The purpose of this study is to report our initial clinical experience using this new IORT technology to boost the tumor bed after preoperative radiotherapy and resection of abdominal malignancies. The positional stability of device following its placement is investigated using sequential post-implant CT scans.Materials/Methods: The CivaTech IORT was utilized to boost the tumor bed after resection of abdominal malignancies in two patients (recurrent retroperitoneal liposarcoma and recurrent gastric adenocarcinoma, respectively). Prior to surgery each patient underwent a CT simulation for IORT boost dosimetry planning. PTV predicted for high risk recurrence after resection were delineated via a joint effort between the radiation oncologist and the surgeon. Eclipse Treatment Planning System (Varian, Palo Alto, CA) was used for dosimetry planning. For patient 1, a 5 x 15 cm2 (108 dots, 0.8 U/dot) sheet was chosen, to prescribe 25 Gy to at least 90% of the PTV. For patient 2, a 5x10 cm2(66 dots, 0.62 U/dot) was chosen to prescribe 26 Gy to at least 90% of the PTV. Each patient underwent a successful resection of intra-abdominal malignancy. Since the Pd-103 radioactive dots are held in a spatial matrix (8 mm spacing) by a bio-absorbable membrane, with a 6 weeks onset to absorption, the positional stability of the device was investigated using post implant sequential CT scans. Dosimetric evaluation was done on CT scans acquired at specific time intervals. Results: The CivaSheet was successfully placed over the tumor bed PTV with its gold face up, which spares any normal tissue structures on top from high dose irradiation. Absorbable stitches were used to secure the device. The CivaSheet placement added 10-12 min of operative time. Postoperative recovery was uneventful for both patients. Patient 1 had CT scans at 2.5 weeks (Pd-103 T1/2 = 17 days) and 3 months post implant. Patient 2 had CT scans at 1 week and 6 weeks post implant. For both patients, all seeds were detected in the tumor bed, without regional or distant migration. A slight trend toward seed clustering was noticed on the 3 months scan for patient 1, but not on the 6 weeks scan for patient 2. PTV dosimetric coverage analysis showed D90 =25.5 Gy (102% Rx) and 29 Gy (116% of Rx) for the two post implant CT scans for patient 1. For patient 2 D90=26 Gy (100% Rx) and 28 Gy (108% Rx) was shown for the two post implant CT scans. No patient experienced complications related to CivsSheet placement or its postoperative presence.Conclusion: We found that the unidirectional CivaTech planar brachytherapy device is safe, suitable and versatile for the treatment of abdominal malignancies. CT dosimetry demonstrated no significant device movement or seed migration, while PTV coverage was well maintained up to 3 months post implant.

PURPOSE

To assess the potential implications of the United States Preventive Services Task Force (USPSTF) for women ages 40-49 in the United States.

METHOD AND MATERIALS

This is an IRB exempt study based on a literature review of multiple factors related to breast cancer screening. Based on the US consensus data, we determined the total number of women between ages 40-49. A Monte Carlo simulation model was tailored to fit our study design, specifically to assess the potential impact of USPSTF guidelines on cost and mortality. We randomized the patients into two groups: A) annual screening starting at age 40 per traditional guidelines vs. B) annual screening starting at age 50 per USPSTF guidelines. Data points from large randomized control trials and the literature were utilized as parameters in our model to predict mortality events, and biopsy events (core biopsy, fine-needle-aspiration). These parameters included: absolute morality A) 0.29% B) 0.36%, medical costs of metastatic breast cancer: $120,000, cost per mammogram: $75, and various procedure parameters for fine-needle aspiration and core biopsy. Cost analysis did not include indirect societal and nonmedical costs related to loss of life in a relatively young cohort. Differences in mortality and overall cost were assessed using a two-sided Student's t test.

RESULTS

We determined the cohort size of women ages 40-49 from the US census data to be approximately 20 million. Using our model, we ran our simulation on a cohort of 20 million patients. In the traditional screening group there were 29342 deaths. This was significantly higher compared to the USPSTF non-screening group, which had 36222 deaths ($p < .001$). In the traditional screened group the average cost per patient was $622. This was higher compared to the USPSTF non-screening group average cost of $438 ($p < .001$).

CONCLUSION

The USPSTF guidelines result in increased mortality for non-screened patients between ages 40-49. The higher average cost per patient in the screened group however may not be clinically significant, when societal and nonmedical mortality costs are taken into account.

CLINICAL RELEVANCE/APPLICATION

Breast cancer screening remains a controversial topic and further work is needed to help patients and clinicians understand new guideline implications on patients between ages 40-49.

SSM01-02 Screening Mammography Audit Metrics Differ Depending on the Reference Standard Used: Systematic Performance Underestimation and a Solution

PURPOSE

Cancer detection rate (CDR), an important screening mammography audit metric, can be determined using two different reference standards: (1) biopsy results (CDR_B)-widely used by U.S. practices or (2) registry-match (CDR_R)-used in published benchmarks. The purpose of this study was to determine CDR performance based on these two reference standards, which are both available in our practice, and to develop a conversion algorithm for practices using biopsy results when registry data is not available.

METHOD AND MATERIALS

Using consecutive screening mammograms (1/1/2006 to12/31/2013) from a single institution academic breast imaging practice, we calculated CDR_B and CDR_R according to BI-RADS definitions. We compared the outcomes (per year and in aggregate) using McNemar's test. We calculated ascertainment rate (AR)-defined as the fraction of biopsies performed (B_perf) of the number recommended (B_rec)-to reconcile the difference between CDR_B and CDR_R. Finally, we developed an algorithm with 95% confidence intervals to estimate CDR_R (CDR_R-est) using CDR_B.

RESULTS

For 83,895 consecutive screening mammograms, we found the overall CDR_B of 4.79/1000 significantly underestimated the CDR_R of 5.09 ($p < 0.001$), despite a relatively high AR of 89.0%-Table; a pattern of underestimation that was systematically re-demonstrated for each year. We developed a conversion algorithm based on data elements (e.g. positive predictive value of biopsy performed-PPV3) typically available in practices without a registry match: CDR_R-est = CDR_B + (((B_rec-B_perf)*PPV3)/# of screening mammograms), for which the confidence interval contained the observed CDR_R for each year and all years in aggregate.

CONCLUSION

Cancer registry-matching, is onerous, costly, difficult to implement, and therefore not used routinely in practice. The existing guidelines to use CDR_B can significantly underestimate CDR and may lead to erroneous conclusions about performance, thus a conversion algorithm providing an accurate range accounting for practice-level AR, is important to avoid CDR underestimation and promote more accurate comparisons across clinical practices.

CLINICAL RELEVANCE/APPLICATION

Because most practices use biopsy results, not registry-matching as reference standard, systematic underestimation of CDR is likely; a problem addressed by the conversion algorithm that we propose.

SSM01-03 County-level Factors Predicting Low Uptake of Screening Mammography

Wednesday, Nov. 29 3:20PM - 3:30PM Room: E451A

For information about this presentation, contact:

samantha.heller@nyumc.org

PURPOSE

The purpose of this study is to investigate county-level geographic patterns of mammographic screening uptake throughout the United States and to determine the impact of rural vs. urban settings on breast cancer preventive services.

METHOD AND MATERIALS

This descriptive study used a de-identified aggregate dataset, the County Health Rankings (CHR), to identify the percent of Medicare enrollees age 67-69 per US county having at least one mammogram in 2013. This uptake was matched with U.S. Department of Agriculture Rural Atlas (USDARA) data categorizing counties as metropolitan vs. non-metropolitan and along an urban continuum scale (1-9) based on county population size (large defined as population >= 20,000; small <20,000) and metropolitan proximity. Univariable and multivariable analyses were performed using SAS 9.3 software.

RESULTS

2,243,294 Medicare beneficiaries aged 67-69 were eligible for mammograms. Mean mammographic uptake per county was 60% (range 26%-86%). Uptake was significantly higher for metropolitan vs. non-metropolitan counties in 19 states, significantly lower in 4 states, and not significantly different in the remainder. Uptake was significantly higher for large counties in 25 states and

significantly lower in only 1 state. County-level mammographic uptake was positively correlated with the number of Medicare enrollees (r=+0.27, p<0.001), % white residents (r=+0.16, p<0.001), income level (r=+0.34, p<0.001), and % of residents with some college education (r=+0.40, p<0.001), and negatively correlated with ratio of population to primary-care providers (PCP) ratio (r=-0.31, <0.001), age-adjusted mortality (-0.41, p<0.001), and % Hispanic residents (-0.11, p<0.001). Multivariable analysis demonstrated that the % of white and black residents, income level, PCP ratio, mortality rate, and % of non-English proficient residents were significant independent predictors of mammographic screening uptake.

CONCLUSION

Uptake of mammographic screening services varies widely at the county level and is lower in less metropolitan counties and in counties with smaller populations.

CLINICAL RELEVANCE/APPLICATION

In conjunction with predictive factors such as income, race, and primary care access, county-level geographic categorizations may help identify communities needing breast cancer screening education.

SSM01-04 Attitudes Towards Mobile versus Fixed Facility Preferences for Obtaining a Mammogram Among Latinas

PURPOSE

Mobile mammography services have been proposed as a way to increase Latinas' screening mammography rates and reduce their disproportionate late-stage presentation compared to White women. However, our recent study suggested that this service may not significantly increase their screening rates. This study evaluates potential reasons why Latinas may not use mobile mammography services and evaluates changes in their preferences after using these services.

METHOD AND MATERIALS

Using a mixed methods approach, we conducted a secondary analysis of survey data (n=538) from a randomized controlled trial to improve screening mammography rates among Latinas in Washington. Descriptive statistics and bivariate regression were used to characterize mammographic location preferences, and to test for associations with demographic factors such as sociodemographics, healthcare access, and perceived breast cancer risk and beliefs. Based on these findings, a qualitative study (n=18) was used to evaluate changes in perceptions after using mobile mammographic services.

RESULTS

More Latinas preferred obtaining a mammogram at a fixed facility (52.3%, n=276) compared to having no preference (46.3%, n=249) and mobile mammography services (1.7%, n=9). Concern about privacy and comfort (15.6%, n=84), having multiple reasons (13.2%, n=71) and concerns about general quality (10.6%, n=57) were common reasons for preferring a fixed facility. Only a history of a prior mammogram was significantly associated with having no mammogram location preference (P<0.05). In the qualitative study, Latinas expressed similar initial concerns about the quality and privacy and comfort of the mobile mammography service, however, became positive towards the mobile mammography services after having a mammogram.

CONCLUSION

While most Latinas preferred obtaining a mammogram at a fixed facility because of concerns about the quality, safety, and privacy of mobile mammography service, positive experiences changed their attitudes towards these services. These findings highlight the need to include community education when using mobile mammography service to increase screening mammography rates in underserved communities.

CLINICAL RELEVANCE/APPLICATION

Mobile mammography services providing screening mammography to underserved communities should study and address concerns and cultural issues related to delivery of these services as part of their program.

SSM01-05 Self-Compression in Mammography: A Randomized, Non-Inferiority Phase 3 Trial

p.henrot@nancy.unicancer.fr

PURPOSE

To evaluate the non-inferiority of the self-compression mammography technique on the breast thickness compared to standard compression.

METHOD AND MATERIALS

549 women aged from 50 to 75 years old from 6 institutions were randomly assigned in a 1:1 ratio to the self-compression or standard compression group after checking their capability to run self-compression. The primary outcome was the breast thickness. The predefined non-inferiority margin was a difference of 3 mm for each view: right/left Craniocaudal (CC) and right/left mediolateral oblique (MLO). Compression force in Newton and image quality blindly quoted with a 4-points scale were also recorded for each view. Overall pain (10 points visual analogue scale) was recorded after CC and MLO views. Additional views (lateromedial LM, spot views, ...) were performed after pain evaluation and their number was recorded. 548 women were included in the intention-to-treat analyses (275 in the self-compression group and 273 in the standard compression group).

RESULTS

The reproducibility of the breast thickness measures was excellent for the four views with an intra-class correlation coefficient of 0.917 (95%CI, 0.902 to 0.929). The right CC breast thickness was 50.78 +/- 15.3 mm in self compression and 51.54 +/- 13 in the standard procedure (difference -0.76; 97.5%CI -8 to -1.24, p = 0.001). Compression force was higher in the self-compression arm versus standard compression arm for the 4 views. No difference was reported in the quality score in the two groups. Pain evaluation was 2.86 +/- 2.32 in the self-compression arm and 3.40 +/- 2.42 in the standard arm (p= 0.009). A median of 2 extra-views per woman was performed in both group (p=0.638).

CONCLUSION

Self-compression mammography technique is not inferior to standard compression technique to achieve the minimal breast thickness. Overall pain is inferior in the self-compression technique without compromising image quality.

CLINICAL RELEVANCE/APPLICATION

Self-compression could be proposed in the mammography practice and decrease the discomfort sometimes associated with mammography.

SSM01-06 Breast Radiology: Reduced Diagnostic Efficacy in a Developing South-East Asian Country

PURPOSE

Breast cancer is the leading cause of death in women worldwide. Prevalence in South-East (SE) Asia has shown a 30% increase in cases in the last ten years. In one developing SE Asian country up to 80% of cancers are being detected at stage 3 or 4, demonstrating the need for improvements in diagnostic efficacy. This study aims to investigate the ability of radiologists from one developing (n=35) and one developed (n=15) SE Asian country, using Australian radiologists (n=53) as a baseline.

METHOD AND MATERIALS

A data set containing 60 mammographic cases were used; 40 being normal and 20 showing malignancies. These were read by radiologists in their own countries. Demographic data were obtained from each reader. Each radiologist placed location markers on the lesions they identified, and provided confidence ratings between 2 and 5 with a higher value indicating higher confidence that a cancer exists. Data were compared between the three country-based radiologist groupings using the nonparametric two-tailed Kruskall Wallis and Mann Whitney U tests with a statistical significance set at P-value of <0.05.

RESULTS

Significant differences in scores were shown between radiologist groupings, with those from the developing SE Asian country demonstrating lower sensitivity, specificity, location sensitivity, ROC and JAFROC values (P<0.05). Demographic data indicated that radiologists from the developing countries were significantly younger (P<0.0001), read fewer mammographic cases each week (P<0.0001), read for fewer hours (P=0.0004) and had read for fewer number of years than their Australian (P<0.0001) radiologists. Similar differences were also shown between the developing and developed SE Asian Country.

CONCLUSION

Important variations in diagnostic efficacy between countries for breast cancer detection have been shown. Cost-effective and versatile educational solutions must be sought to address causal agents, so that the efficacy of cancer detection is not dependent on where women are located.

CLINICAL RELEVANCE/APPLICATION

The ability to detect cancer should be similar for women wherever they are located. This study examines if this is the case in a developing and developed SE Asian country compared with a developed westernised country.

PURPOSE

Digital breast tomosynthesis (DBT) has been shown to improve the diagnostic accuracy of breast cancer screening and diagnosis, and was approved by the FDA for clinical use in 2011. However, there is limited literature on the current use of DBT in clinical practice. This study seeks to determine the volume of screening and diagnostic DBT in the Medicare population.

METHOD AND MATERIALS

We evaluated the national Medicare Part B Physician/Supplier Procedure Summary Master Files from 2015, the first (and only) year in which procedural billing codes for DBT are available. Screening and diagnostic full-field digital mammography (FFDM) and DBT volume counts were determined by tabulating global and professional component claims. Medicare specialty codes were used to categorize the specialty of the interpreting physicians as radiologists or non-radiologists.

RESULTS

In 2015, a total of 5,730,635 screening FFDM exams were performed, of which 1,084,256 (18.9%) included DBT as an add-on procedure. Diagnostic FFDM exams totaled 1,402,966, with 226,682 (16.2%) including DBT. The vast majority (over 96%) of mammograms were billed by radiologists. Among radiologists, DBT studies were used in conjunction with 19.1% of the digital screening studies and 16.4% of the digital diagnostic studies. For non-radiologist physicians, DBT studies were used with 16.7% of digital screening studies and 8.7% of digital diagnostic studies.

CONCLUSION

The utilization of DBT was rather limited in the first year of its introduction as a billable Medicare procedure, occurring in conjunction with less than 20% of digital mammography exams. Radiologists appear to be earlier adopters of this technology compared with non-radiologists, possibly related to the fact that the latter have far less involvement in the field.

CLINICAL RELEVANCE/APPLICATION

2015 is the first and only year for which DBT volume data are available and it will be important to follow the adoption of the technology in subsequent years.

SSM02-02 Can Tomosynthesis Reduce the Benign Biopsy Rate within the Assessment Setting of Women Recalled From Breast Screening?

Wednesday, Nov. 29 3:10PM - 3:20PM Room: E451B

nisha.sharma2@nhs.net

PURPOSE

Digital Breast Tomosynthesis (DBT) within the UK can be used in women recalled for assessment following an abnormal screening mammogram. It is recognised that DBT as a screening tool has improved the cancer detection rate and reduced the false positive rate of women screened. We wanted to assess the impact DBT would have on our assessment clinics regarding biopsy rates and cancers detected. This was an IRB approved prospective study where all women recalled following abnormal screening mammogram were asked to take part in the study. The tomosynthesis study was read within 6 weeks of the assessment clinic which was performed as standard with the DBT images not avaialble for review so was unable to influence the standard assessment.

METHOD AND MATERIALS

The study ran from 01/11/2015 to 29/07/2016. All women recalled following an abnormal screening mammogram were invited to take part in the study. All women had standard assessment performed. The DBT was double read within 6 weeks of attending the assessment clinic. The number of women who had an intervention, which included FNA and core biopsies, was recorded and the outcome of assessment was also recorded

RESULTS

709 women were recruited to the study. 30 women were excluded as they were clinical recalls. 679 women took part in the study. There were a total of 105 breast cancers in this study (36 non invasive and 79 invasive).475/679 women (70%) had a biopsy as part of the standard assessment and 103 cancers were identified in 102 patients (22% PPV).216/694 women (30%) were discharged following further assessment. If DBT had been used in the assessment setting then 199 biopsies would have been performed based on mammographic findings alone and an additional 44 biopsies due to US findings (36%). 103 cancers were identified (42% PPV), 2 cases of non-invasive were only identified by DBT and 2 cases of malignancy missed by DBT.DBT generated 6 additional biopsies, of which 2 were malignant.

CONCLUSION

DBT in the assessment setting is a cost effective imaging tool as it would have reduced the number of benign interventions and improved the positive predictive value of identifying malignancy. 2 cancers were missed on DBT but these were 2 cases of low volume malignancy that may be considered over diagnosis in this current era.

CLINICAL RELEVANCE/APPLICATION

DBT is a vital addition with regards to triple assessment and minimising benign biopsies within the screening assessment setting

SSM02-03 The Radial Scar Dilemma: Incidence and Surgical Upgrade Rates with Tomosynthesis

PURPOSE

To evaluate the incidence and malignant upgrade rates of surgically excised radial scars before and after the implementation of tomosynthesis.

METHOD AND MATERIALS

Institutional review board approval was obtained for this Health Insurance Portability and Accountability Act-compliant protocol. Medical records of patients diagnosed with radial scar at our institution in the last 8 years were retrospectively reviewed. The incidence of radial scar diagnosed as the primary imaging finding in the 3 years prior to tomosynthesis was compared to that in the 5 years after its implementation. For each lesion, type of mammographic finding; patient age and presentation; lesion size; core needle biopsy imaging guidance, needle gauge, and number of samples; core biopsy histology; and final pathology at surgical excision were reviewed, and upgrade to malignancy at surgical excision was calculated. Statistical significance was evaluated using chi square with Yates' correction.

RESULTS

129 surgically excised radial scars were identified, 27 in the 3 years prior to tomosynthesis and 102 in the 5 years since then. The pre-tomosynthesis incidence of radial scar was 0.5/1000 patients, compared to 1.3/1000 patients after tomosynthesis ($p<0.0001$). Architectural distortion on screening mammography was the most common presentation, representing 58.9% (76/129) of radial scars overall, and 79.4% (81/102) of radial scars after tomosynthesis. 90.7% (117/129) of lesions were evaluated histologically with core needle biopsy prior to surgical excision. Of these, 6.8% (8/117) were upgraded to malignancy on surgical excision. The likelihood of malignant upgrade increased with patient age and lesion size, and decreased with larger volume of tissue sampling. The strongest correlation was seen with presence of atypia on core biopsy pathology. Malignant upgrade for radial scars with atypia was 29.2% (7/24) compared to 1.1% (1/93) for those without atypia on core needle biopsy.

CONCLUSION

The incidence of radial scars has increased significantly since the implementation of tomosynthesis. The low upgrade rate of radial scars without atypia on core needle biopsy suggests that mammographic follow up may be a reasonable alternative to surgical excision for some patients.

CLINICAL RELEVANCE/APPLICATION

with the increased detection of radial scars with tomosynthesis, it may be possible to identify a subset of patients that can be safely followed.

SSM02-04 Architectural Distortion Outcome: Detection only on Tomosynthesis Versus 2D Mammography

PURPOSE

To compare the outcome of architectural distortion (AD) detected only on digital breast tomosynthesis (DBT) with AD seen at 2D mammography

METHOD AND MATERIALS

This retrospective study was IRB approved and HIPAA compliant. All consecutive cases with architectural distortion assigned BI-RADS 4 or 5 categories from 2009 to 2016 were included. Three readers with 1 to 10 years of experience reviewed all cases for visibility of AD (2D visible vs. DBT detected). Consensus was achieved when 2 readers agreed. Each reader also assigned level of suspicion using a Likert scale (1 to 5) based on mammographic images only. CNB and surgical excision results were compared between 2D- and DBT-detected AD. Frequencies were compared by way of the McNemar test and the Pearson's Chi-square exact test.

RESULTS

181 AD lesions were included; 122 (67.4%) were 2D-detected while 59 (32.6%) were DBT-detected. The malignancy rate at CNB was significantly higher for 2D-detected AD (38.5%) compared to AD detected only on DBT (6.8%) ($p < 0.001$). Likewise, the final malignancy rate after excision of high risk and benign discordant lesions was significantly higher for 2D- detected (43.4%) compared to DBT-detected AD (10.2%) ($p< 0.001$). An US correlate was more likely to be present with AD detected by 2D (n= 103/122, 84.4%) than DBT (n= 33/59, 55.9%) ($p < 0.001$). When no US correlate was present among DBT-detected AD, the malignancy rate was low (7.7%) but not significantly different than when an US correlate was present (12.1%)($p = 0.65$). Regarding the level of suspicion of AD, there was substantial inter-reader agreement (κ Coefficient= 0.61-0.77). When NPV is considered as Likert 1-2, NPV is high (93.8, 81.4, 82.9) but not sufficient to consider follow up over biopsy based on radiologist level of suspicion.

CONCLUSION

DBT-detected AD has significantly lower malignancy outcome compared to 2D-detected AD (10.2% vs. 43.4%), however the malignancy rate is still sufficiently high to warrant biopsy

CLINICAL RELEVANCE/APPLICATION

DBT-detected AD has a lower risk of malignant outcome than AD detected at 2D, but still warrants biopsy even when there is not an US correlate.

SSM02-05 Pure Architectural Distortion on Digital Breast Tomosynthesis: Imaging Characteristics and Histopathologic Outcomes

apujara@gmail.com

PURPOSE

To evaluate imaging characteristics of pure architectural distortion on digital breast tomosynthesis (DBT) and assess their association with histopathologic outcomes.

METHOD AND MATERIALS

This retrospective study was approved by the institutional review board and HIPAA-compliant. DBT exams performed between January 2014 and December 2015 were reviewed for architectural distortion without an associated mass. Imaging characteristics evaluated were size, one versus two-view visualization, and conspicuity compared with 2D mammography. Corresponding ultrasound (US) and MRI exams were assessed for correlates to pure architectural distortion on DBT. Biopsy and surgical pathology were reviewed. A two-tailed t test and Fisher's exact tests were performed.

RESULTS

During this two-year period, 101 cases of pure architectural distortion were visualized on DBT in 97 patients (ages 36 - 83 years,

mean 56 years). Core needle biopsy or surgical excision of 95 cases of pure architectural distortion yielded malignant pathology in 43/95 (45%) tissue samples, of which 39/43 (91%) were invasive and 39/43 (91%) were nuclear grades 1 or 2. The most common benign pathologies were radial scar/complex sclerosing lesion and stromal fibrosis, with each present in 19/52 (36%) benign biopsy specimens. Associations between imaging characteristics of pure architectural distortion on DBT and histopathologic outcome were not statistically significant, including size (2.7+1.3 cm malignant vs 2.4+0.9 cm benign; P=0.12), two-view visualization (39/43 malignant vs 44/52 benign; P=0.54), and increased conspicuity on DBT compared with 2D mammography (32/43 malignant vs 36/52 benign; P=0.65). The presence of an US correlate was associated with malignancy (38/43 malignant vs 27/52 benign; P=0.0001). MRI was performed in 31 cases. The presence of an MRI correlate was associated with malignancy (25/25 malignant vs 3/6 benign; P=0.004).

CONCLUSION

Pure architectural distortion on DBT is malignant in nearly half of cases, demonstrating low or intermediate grade invasive cancers in the majority of such cases. The presence of US and MRI correlates is associated with malignancy.

CLINICAL RELEVANCE/APPLICATION

Detection of pure architectural distortion on DBT has a high positive predictive value for malignancy, particularly in the presence of an ultrasound correlate.

SSM02-06 Synthetic 2D Mammography Can Replace Digital Mammography as an Adjunct to Digital Breast Tomosynthesis: Experience with a Wide-angle Tomosynthesis System

clauser.p@hotmail.it

PURPOSE

To evaluate the lesion detection and diagnostic performance of synthetic 2D mammography (SM) with wide-angle digital breast tomosynthesis (WA-DBT) compared to digital mammography (DM) alone and in combination with WA-DBT.

METHOD AND MATERIALS

Included in this retrospective study were patients who underwent bilateral DM and WA-DBT between March 2015 and June 2015. The standard of reference was histology and/or one-year stability at follow-up. Ultimately, 205 women with 179 lesions were included (89 malignant, 90 benign). Four readers, blinded to results, randomly evaluated images from five different protocols: two view 2v-DM alone; 2v-DM with 2v-WA-DBT; 2v-SM with 2v-WA-DBT; one view (medio-lateral oblique) 1v-DM with 1v-WA-DBT; and 1v-SM with 1v-WA-DBT. Images were evaluated according to the BI-RADS lexicon. Lesion detection, sensitivity, specificity, and accuracy were calculated and compared using multivariate analysis (Generalized Estimating Equations).

RESULTS

Average detection rate was 75.4% for 2v-DM, 80.2% for 2v-DM with WA-DBT, 78.5% for 2v-SM with WA-DBT, 77.4% 1v-DM with WA-DBT, and 75.0% 1v-SM with WA-DBT. Differences in lesion detection were found between reading protocols (P=0.001) and readers (P<0.001). Regardless of inter-reader variations, 2v-DM with 2v-DBT achieved a higher detection compared to 2v-DM (P=0.004). No significant differences in detection were found between 2v-DM with WA-DBT and 2v-SM with WA-DBT (P>0.110). Detection was higher when two views were available, for both SM and DM (P<0.034). Average sensitivity, specificity, and accuracy were: 72.5%, 60.2%, 67.5% for 2v-DM; 82.6%, 64.6%, 75.0% for 2v-DM with WA-DBT; 83.1%, 67.7%, 76.8% for 2v-SM with WA-DBT; 81.7%, 64.0%, 74.7% 1v-DM with WA-DBT; 79.8%, 69.9%, 75.8% 1v-SM with WA-DBT. Sensitivity and accuracy were lower with DM alone compared to the other reading protocols (P<0.001). There were no other significant differences in sensitivity, specificity or accuracy.

CONCLUSION

Compared to 2v-DM alone, 2v-WA-DBT with 2v-DM or 2v-SM improves detection, sensitivity, and accuracy with no significant effect on specificity. 2v-SM with 2v-WA-DBT performed as well as 2v-DM with 2v-WA-DBT. Two-view protocols allow for higher lesion detection.

CLINICAL RELEVANCE/APPLICATION

2v-WA-DBT with 2v-DM and 2v-WA-DBT with 2v-SM allow for a higher detection rate and an improved diagnostic performance than 2v-DM. SM can be safely used to replace DM, in combination with 2v-WA-DBT.

PURPOSE

To assess a free-breathing self-navigated three-dimensional (SN3D) radial whole-heart MR angiography (MRA) pulse sequence for the evaluation of coronary artery (CA) anatomy in patients with congenital heart disease (CHD).

METHOD AND MATERIALS

SN3D datasets were previously acquired in 109 patients (20.1±11.8 years) as part of a prospective clinical trial for the assessment of CHD anatomy using a 1.5T scanner. SN3D datasets, retrospectively evaluated by three radiologists, were scored based on the appearance of CA segments and reader confidence in determining CA dominance using a two-point scale. A three-point scale was used to rate overall image quality along with the ability to freeze cardiac and respiratory motion. Vessel sharpness of the internal thoracic artery (ITA, representing respiratory motion), the left anterior descending (LAD) and right CA (RCA, representing a combination of respiratory and cardiac motion) were quantitatively measured using a dedicated prototype application (SoapBubble). Wilcoxon statistics, Pearson correlation, and Intra-Class Correlation (ICC) were used to evaluate the data.

RESULTS

The average duration of the SN3D acquisition was 9.1±2.4 minutes. The mean score for overall image quality was 2.35, with excellent agreement (ICC 0.95). A diagnostic study was obtained in 83.7% of scans with excellent image quality in 51.7% of them. The SN3D technique was able to successfully visualize the individual CAs in the following percentage of cases: left main 92.6% (ICC 0.66), LAD 88.3% (ICC 0.59), RCA 87.8% (ICC 0.55), left circumflex 82.8% (ICC 0.74), posterior descending 50.2% (ICC 0.46), and first diagonal 39.8% (ICC 0.64). Diagnostic confidence for the assessment of CA dominance was scored at 1.56. Image quality was affected more by cardiac motion freezing (mean score, 2.18; Pearson's r=0.73, P<0.029) than respiratory motion freezing (mean score, 2.20; r=0.58, P<0.029). The ITA, RCA, and LAD vessel sharpness scores were 53.1, 52.5, and 48.7%, respectively.

CONCLUSION

In the majority of young CHD patients, SN3D MRA allows for the visualization of the proximal CAs with excellent quality. However,

the quality of cardiac motion freezing still has a strong impact on image quality.

CLINICAL RELEVANCE/APPLICATION

SN3D MRA is a promising technique in CHD patients especially when impaired breath-holding capacity limits the visualization of CA anatomy due to motion artifacts.

SSM03-02 Evaluation of 3D Magnetic Resonance Imaging of Autopsied Human Heart Specimens for Computational Modeling of Congenital Heart Diseases

PURPOSE

Autopsied human heart specimens of congenital heart disease are valuable for medical education and surgical simulation in understanding complex anatomical structure. Because of the decreasing number of autopsies and the deterioration of human heart specimens over time, digitalization, such as computational modeling using 3D image data, is an effective approach to capture these valuable specimens. This study aimed to compare the visibility of formalin-fixed heart among various 3D MRI sequences and to clarify the optimal sequence for the computational modeling of congenital heart disease.

METHOD AND MATERIALS

Five human hearts with various types of congenital heart diseases obtained during autopsy and preserved with formalin fixation underwent ex vivo MRI with a 3T clinical machine. The different types of 3D MRI sequences were performed in the same spatial resolution (1.0*1.0*1.0mm): T2-SPACE (3D with a constant flip angle to acquire bright blood imaging), True-FISP (SSFP imaging), MPRAGE (inversion-recovery-based T1WI), and FLASH (basic GRE sequence). The autopsied heart was scanned in a plastic container filled with normal saline. Among the four 3D sequences, we compared the contrast ratio between the myocardium and the ventricular lumen and between the vascular wall and the lumen. In addition, we visually assessed the cardiovascular structure using MPR and 3D images.

RESULTS

The average contrast ratios between the myocardium and the ventricular lumen in MPRAGE, T2SPACE, FLASH, and True FISP were 0.80, 0.31, 0.26, and 0.28, respectively. The average contrast ratios between the vascular wall and the lumen were 0.78, 0.43, 0.32, and 0.20, respectively. MPRAGE showed the best contrast for the imaging of both the myocardium and the vascular structure. By visual assessment, MPRAGE also provided more detailed information on morphology and cardiovascular continuity.

CONCLUSION

MPRAGE is the optimal sequence for the computational modeling of human autopsied heart specimens fixed by formalin, which replaces water in cardiac tissue, with congenital heart diseases.

CLINICAL RELEVANCE/APPLICATION

MPRAGE showed the best contrast for imaging a formalin-fixed heart. The computational cardiac modeling of autopsied heart using MPRAGE plays a critical role in surgical simulation and education.

PURPOSE

To correlate native T1 mapping (nT1) of the right ventricle (RV) with biventricular functional parameters and pulmonary regurgitation.

METHOD AND MATERIALS

We prospectively evaluated 27 patients (24±10y, mean ± standard deviation) who underwent a cardiac magnetic resonance exam at1.5T. Six patients were treated with percutaneous pulmonary valve. For each patient left (LV) and right ventricle (RV) functional evaluation was performed. Pulmonary flow analysis with phase-contrast sequences was performed and regurgitation fraction (RF) was calculated. A native modified look-locker inversion recovery (MOLLI) prototype sequence was acquired at basal, mid and apical-ventricular level in short-axis view in systole, by starting the data acquisition at the individually adopted trigger time. The MOLLI sequence included motion correction and subsequent automatic generation of T1 maps. Spearman and Mann Whitney U test were used for statistical analysis.

RESULTS

LV functional parameters were: end-diastolic volume (EDVi) 77±20 (mean±standard deviation), LV end-systolic volume (ESVi) 29±16, LV stroke volume (SV) 82±16 and ejection fraction (EF) 63±8. RV functional parameters were: RVEDVi 101±27, RVESVi 47±17, RVSV 96±30 and EF 55±10. Mean RF was 26±18 % and mean nT1 was 1025±38 ms. A negative significant correlation between RVEF and nT1 (r=-333, P=.045) and between RF and nT1 (r=-234, P=.047) was found. nT1 was 1006±95 ms in patients before pulmonary valve treatment and 1087±87 ms in patients after percutaneous implantation (P = .057).

CONCLUSION

Native RV T1 mapping was negatively correlated with PR and RVEF, reflecting an adaptation of RV muscle to the pulmonary conduit dysfunction. A borderline significant increase of nT1 in patients after pulmonary percutaneous treatment was found.

CLINICAL RELEVANCE/APPLICATION

RV T1 value should be used as an early indicator of RV dysfunction in patients with congenital heart diseases.

SSM03-04 Anatomy of Retroesophageal Major Aortopulmonary Collateral Arteries in Pulmonary Atresia with Ventricular Septal Defect: Results from Preoperative CTA

Wednesday, Nov. 29 3:30PM - 3:40PM Room: S502AB

Participants

jiaqianjun@126.com

PURPOSE

There is little information in the literature available on major aortopulmonary collateral arteries (MAPCAs) anatomy, especially about the retroesophageal MAPCAs (REM). This study aimed to assess the anatomy of REM in pulmonary atresia with ventricular septal defect and major aortopulmonary collateral arteries (PA-VSDMAPCAs) patients.

METHOD AND MATERIALS

We retrospectively analysed 130 consecutive PA-VSD-MAPCA patients with preoperative CTA who underwent cardiac surgery. A detailed analysis of the MAPCAs anatomy was made using CT imaging, including the total number, origin and stenosis of MAPCAs, the presence or absence of a retroesophageal course for MAPCAs, relationship between MAPCAs and tracheal at the pulmonary hilum. MAPCAs were divided into two groups on the basis of REM diagnosis by CT: REM group (REM diagnosed by CT, n=94) and Not REM group (no REM diagnosed by CT, n=183).

RESULTS

A REM was identified in 82 of the 130 patients (63%), all of which were located on the side opposite the arch. REM group originate higher level of thoracic vertebrae (level 6), compared with Not REM group (level 5) (P<0.01), and REM group have a higher probability to originate from the lateral side of the aorta median degree of 144, contrast to median degree of 90 for Not REM group (P<0.01). There was a difference in the occurrence of stenosis comparing REM group to Not REM group (89% vs 78%), ($\chi 2$=9.79, P< 0.01). A midsegment stenosis was present more often in REM group compared with Not REM group (31% vs 21%), ($\chi 2$=6.27, P= 0.01). Relative to trachea, there was a difference in the anterior-posterior position comparing REM to Not REM group at the pulmonary hilum (91% MAPCAs posterior to tracheal vs 51% MAPCAs posterior to tracheal), ($\chi 2$=50.81, P<0.01).

CONCLUSION

Sixty-three percent of patients with PA-VSD-MAPCAs have a retroesophageal MAPCA, and a left aortic arch was associated with a higher prevalence of the retroesophageal MAPCAs. Compared with not retroesophageal MAPCAs, the retroesophageal MAPCAs associated with higher level, more lateral origin, more stenosis, particularly a midsegment stenosis, and were prone to course posterior to tracheal at the pulmonary hilum.

CLINICAL RELEVANCE/APPLICATION

The anatomy of retroesophageal MAPCAs is highly relevant and useful for surgeons in identifying the retroesophageal MAPCAs to perform unifocalization procedures for PA-VSD-MAPCAs patients

SSM03-05 Common Atrium and the Associated Malformations: Evaluation by Low-Dose Dual-Source Computed Tomography

Wednesday, Nov. 29 3:40PM - 3:50PM Room: S502AB

PURPOSE

To determine CA characteristics and diagnostic accuracy in assessing associated malformations in these patients with low-dose DSCT.

METHOD AND MATERIALS

This study was approved by the Institutional Review Board, and informed consent was obtained from all patients. Twenty-one pediatric and adolescent CA patients underwent low-dose DSCT. Different ventricular types and associated malformations were assessed. The diagnostic accuracy of DSCT and transthoracic echocardiography (TTE) in evaluating associated malformations were assessed by reference to surgical results. The effective doses of low-dose DSCT were calculated.

RESULTS

Seven CA patients and 14 CA with single ventricle (SV) were finally included. In the CA with SV, three types of SV morphology were distinguished: single left ventricle (n = 4), single right ventricle (n = 5) and undifferentiated ventricle (n = 5). Seventy-eight associated malformations were observed, among which 22 were seen in CA and 56 in CA with SV. DSCT was superior to TTE for detection of intracardiac anomalies (sensitivity: DSCT, 92.31% vs. TTE, 76.92%), anomalies of great vessels (sensitivity: DSCT, 100.00% vs. TTE, 77.50%), and of collateral vessels (sensitivity: DSCT, 100% vs. TTE, 20.00%). The estimated mean effective dose was 0.95 ± 0.44 mSv (<1 mSv).

CONCLUSION

Low-dose DSCT is an excellent alternative for pediatric and adolescent patients with CA, providing morphological details of CA and associated malformations with high accuracy.

CLINICAL RELEVANCE/APPLICATION

Common atrium (CA) is a rare complex congenital heart disease. Those with associated malformations who do not receive surgical treatment usually have a poor prognosis. Low-dose DSCT is an excellent alternative for pediatric and adolescent patients with CA, providing morphological details of CA and associated malformations with the high accuracy needed to conduct treatment effectively.

SSM03-06 Anomalous Right Coronary Artery from the Left (ARCA-L): Dual-Source Computed Tomography Angiography (DSCT) Findings in Southwest China

Wednesday, Nov. 29 3:50PM - 4:00PM Room: S502AB

kaiyuediao@qq.com

PURPOSE

We sought to provide the anatomic particularities of anomalous right coronary artery from the opposite (ARCA-L) in Southwest China on a relatively large scale under the postulation that some anatomy features on DSCT could help predict adverse clinical events.

METHOD AND MATERIALS

Over 18000 patients' coronary computed tomography angiography (CCTA) data was screened from Jan 2012 to Aug 2015. The prevalence of ARCA-L was computed and the subtype was decided by the spatial relationship between the right coronary artery with the pulmonic valve. CCTA was used to evaluated the proximal stenosis, observe the high-risk anatomy features including the take-off angle, proximal length as well as the ostium type and analyze the accompany anomalies. Follow-up was done by telephone and the major adverse clinical event (MACE) was recorded. Wilcox test and Chi-square test were used for testing the difference between groups. Cox hazard analysis was performed to identify prognosis predictive factors. P<0.05 was considered significant and Bonferroni correction of P value was used when necessary.

RESULTS

A prevalence of 0.70% (127/18226) was observed in our population and younger people tend to have higher degree of vessel stenosis (the age among the mild vs the middle vs the severe: 64.7 vs 59.6 vs 56.9, p=0.04). RCA origins from below the pulmonary valve was the most common type in our population. The take-off angle and the proximal stenosis length were found to have significant difference between mild (<30%) and severe stenosis (>=60%) group. An average of 15.3 ± 9.2 months' follow-up was conducted on 65 non-CAD patients. Stenosis severity was the most predictive factor among the anatomy features with a RR of 5.23 (95% CI: 2.34 to 8.47, P<0.001).

CONCLUSION

ARCA-L found on CCTA in the Southwest China has a comparable prevalence with other regions with certain variations in high-risk anatomy features. Stenosis severity was the most reliable prognosis predictive factor for patients with conservative therapy.

CLINICAL RELEVANCE/APPLICATION

Our study proved some potentially malignant anatomic features on CCTA for evaluating patients with ARCA-L. Avoiding overloading exercise might be necessary for such patients.

Harold I. Litt, MD, PhD, Philadelphia, PA (*Presenter*) Research Grant, Siemens AG ; Research Grant, Heartflow, LLC; ;

For information about this presentation, contact:

tanyahang@163.com

PURPOSE

The discordance between stenosis and ischemia may affect triage efficiency in acute chest pain patients after coronary CT, therefore methods to predict ischemia based on CT data are relevant to this population. CT derived FFR (cFFR) calculated on-site can evaluate the hemodynamic significance of a lesion quickly. High-risk plaque features (HRF) are also predictive of events in acute chest pain patients. We evaluated the correlation between HRF and cFFR in patients with suspected acute coronary syndrome (ACS).

METHOD AND MATERIALS

Patients with suspected ACS from the ACRIN PA 4005 and CT-COMPARE trials who had undergone both CT and either stress testing or catheter angiography were included. cFFR was calculated on-site using experimental software (Siemens cFFR). Degree of stenosis and presence of HRF (positive remodeling (PR), low attenuation plaque, spotty calcification) were assessed by two readers. Ischemia was defined as cFFR<=0.80. Logistic regression analysis was used to evaluate whether HRFs were independently associated with ischemia on a per-vessel level.

RESULTS

Degree of stenosis, HRF and cFFR were assessed in 320 vessels in 148 patients. Average total processing time for cFFR was approximately 40 minutes per patient. By cFFR, ischemia was present in 94 vessels (29%). In multivariate analyses, risk of ischemia was observed for PR (OR=2.64; 95%CI: 1.13-6.17; p=0.025), presence of 1 (OR=3.48; 95%CI: 1.50-8.14; p=0.004) and >1 (OR=4.43; 95%CI: 1.29-15.20; p=0.018) HRFs independent of stenosis. In 148 vessels with 30-90% stenosis, ischemia was present in 78 vessels (53%). In multivariate analyses, 70-90% stenosis (OR=20.22; 95%CI: 5.12-79.79; p<0.001), presence of 1 and >1 HRFs (OR=2.39; 95%CI: 1.05-5.45, p=0.038; OR=4.73, 95% CI:1.09-12.77, p=0.036, respectively) remained predictors of ischemia, while 50-70% stenosis and PR did not.

CONCLUSION

In patients presenting acute chest pain, presence of any HRF, stenosis>50% and PR are associated with cFFR<=0.80, while in vessels with 30-90% stenosis, presence of any HRF and 70-90% stenosis remained. Therefore, assessment of HRF may determine the need for further testing in acute chest pain patients.

CLINICAL RELEVANCE/APPLICATION

CT derived FFR calculated on-site allows rapid evaluation of the significance of a stenosis. Assessment of high-risk plaque may determine the need for further testing in acute chest pain patients.

SSM04-02 Coronary CT Angiography-Derived Fractional Flow Reserve Based on Machine Learning for Risk-Stratification of Non-Culprit Lesions in Patients with Acute Coronary Syndrome

PURPOSE

This study sought to investigate the prognostic value of coronary CT angiography (CCTA)-derived fractional flow reserve (CT-FFR) in patients with acute coronary syndrome (ACS) and multivessel disease to gauge significance and guide management of non-culprit lesions.

METHOD AND MATERIALS

We analyzed data of 48 patients (55.8±9.6 years, 60% male) who were admitted for symptoms suggestive of ACS and underwent dual-source CCTA followed by invasive coronary angiography (ICA) with culprit lesion intervention. Culprit lesions were retrospectively identified on CCTA utilizing images obtained during ICA. Non-culprit lesions with >=30% luminal stenosis and deferred intervention were evaluated using a machine learning CT-FFR algorithm (Frontier, Siemens) to determine lesion-specific ischemia, defined as CT-FFR <=0.80. Follow-up was performed to record major adverse cardiac events (MACE).

RESULTS

CT-FFR identified lesion-specific ischemia in 23/81 non-culprit lesions. After a median follow-up of 19.5 months, MACE occurred in 14 patients (29%). Univariate Cox regression analysis revealed that CT-FFR <=0.80 (hazard-ratio (HR) 3.77 [95%CI 1.16-12.29], p=0.027), Framingham risk score (FRS) (HR 2.96 [1.01-7.63], p=0.038), and a CAD-RADS™ classification >=3 (HR 3.12 [1.03-10.17], p=0.051) were predictors of MACE. In a risk-adjusted model controlling for FRS and CAD-RADS™ >=3, CT-FFR <=0.80 remained a predictor of MACE (1.56 [1.01-2.83], p=0.048). Receiver operating characteristics analysis including FRS, CAD-RADS™ classification >=3, and CT-FFR <=0.80 (Area under the curve [AUC] 0.78) showed incremental discriminatory power over FRS alone (AUC 0.66, p=0.032).

CONCLUSION

CT-FFR <=0.80 of non-culprit lesions in patients with ACS and multivessel disease adds prognostic value to identify risk for future MACE.

CLINICAL RELEVANCE/APPLICATION

CT-FFR may have utility to risk-stratify the vulnerability of non-culprit lesions for the prediction of future major adverse cardiac events in patients with acute coronary syndrome (ACS) and multivessel disease.

SSM04-03 Fully Automated Volumetry of Peripheral Lung Vasculature based on Pulmonary CT Angiography for Non-Invasive Diagnosis of Pulmonary Hypertension

PURPOSE

To evaluate fully automated volumetry of peripheral lung vasculature based on pulmonary CT angiography (CTPA) for non-invasive diagnosis of pulmonary hypertension (PH).

METHOD AND MATERIALS

93 consecutive patients who underwent right heart catheterisation (RHC) and CTPA within two weeks for suspected PH at our institution were retrospectively reviewed. 19 patients with chronic thromboembolic PH were secondarily excluded resulting in the final study population of 74 patients (mean age 66.2 years, 50 female). In-house developed software was used for fully automated segmentation of the pulmonary vasculature and peripheral vascular volume within 10 mm, 15 mm and 20 mm from the lung borders was caculated for each patient. Vascular volumes were compared between patients with PH (mean pulmonary arterial pressure (mPAP) >= 25 mm Hg) and patients without PH using Stundent's T-test. ROC analyses were done, AUC-values of the vascular volume within 10 mm, 15 mm and 20 mm of the lung periphery were compared and diagnostic accuracy for the detection of PH assessed.

RESULTS

42 out of 74 patients had PH (mPAP 37±11 mm Hg, 57%), 32 had nomal mPAP-values (17±4 mm Hg). Peripheral vascular volumes were significantly enlarged in patients with PH: 86±29 vs. 66±23 cmCubed within 20 mm, 59±24 vs. 42±19 cmCubed within 15 mm and 31±17 vs. 19±14 cmCubed within 10 mm of the lung periphery (p-values < 0.002). AUC-values for the detection of PH were 0.73 for 20 mm, 0.74 for 15 mm and 0.75 for 10 mm of the peripheral vascular volume. Highest diagnostic accuracy was achieved at a cut-off value of 19.4 cm for the 10 mm peripheral vascular volume which identified RHC-confirmed PH with 74% sensitivity, 72% specificity, 78% positive and 67% negative predictive value.

CONCLUSION

Fully automated volumetry of peripheral lung vasculature based on CTPA revealed significantly enlarged peripheral vascular volumes in patients with RHC-confirmed PH compared with patients without PH. Vascular volume within 10 mm of the lung periphery demonstrated the best diagnostic performance and identified PH with high diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

Fully automated volumetry of peripheral lung vasculature based on CTPA is a promising, non-invasive tool to identify patients who require further workup for suspected PH.

SSM04-04 Quantitative Assessment of Pulmonary Hypertension Severity Using Late Gadolinium Enhancement and T1 Mapping Techniques of 3T Cardiac Magnetic Resonance

Wednesday, Nov. 29 3:30PM - 3:40PM Room: S504AB

Participants
Ming-xi Liu, Beijing, China (*Presenter*) Nothing to Disclose

Xiaojuan Guo, PhD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
Lu Liang, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
Yuan-Hua Yang, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To quantitatively assess the severity of pulmonary hypertension (PH) using late gadolinium enhancement (LGE) and T1 mapping techniques.

METHOD AND MATERIALS

We retrospectively analyzed the data of ten control subjects and 21 patients with clinically diagnosed PH caused by chronic thrombotic PH, Takayasu arteritis, idiopathic PH, atrial septal defect, and Ebstein anomaly. CMR examinations were performed with a 3T scanner including LGE, Cine, and T1 mapping sequences. Based on the New York Heart Association (NYHA) functional class and right heart catheterization, the patients were divided into mild and moderate PH patients and severe cases. Myocardial fibrosis volume (FV), percentage of myocardial fibrosis (pFV), and the parameters reflecting right ventricle function were calculated. Native T1, post-contrast T1, and ECV values in the regions of interest (ROI) at the mid-ventricular short-axis section were measured for the anterior and posterior interventricular insertion points (AIP and PIP), septum (S) (Figure 1), lateral wall and blood pool. Student's t-test, Pearson correlation coefficient and the receiver operating characteristic (ROC) were used for data statistics.

RESULTS

Myocardial fibrosis was present in 19/21 (90.48%) PH patients. FV in PH patients was (5.81 ± 4.76) ml, and the median of pFV was 8.33%. Significant differences between the PH patients and control subjects were present for ECV - AIP ($t = -2.878$, $P = 0.011$), ECV - PIP ($t = -3.816$, $P = 0.002$), and ECV - S ($t = -3.749$, $P = 0.002$). ECV - AIP and ECV - PIP were significantly different from the lateral wall ($t = 2.406$ and 3.970, $P = 0.024$ and 0.001). Table 1 illustrates those correlations between the parameters above and values of right heart catheterization in PH patients. Based on ROC curves (Figure 2), it was observed pFV > 7.25% is capable of identifying severe from mild and moderate PH patients.

CONCLUSION

The pFV and ECV values in the IP and septum could be other markers associated with PH cardiomyopathy. With the increase in PAP and PVR, the areas of myocardial fibrosis were inclined to expand, whereas the extent of myocardial fibrosis did not increase significantly.

CLINICAL RELEVANCE/APPLICATION

CMR quantitative assessment of myocardial fibrosis in the IP and septum may provide more information on the myocardial state, right heart function, treatment and prognosis in PH in the future.

SSM04-05 Incidental Solid Pulmonary Nodules in Emergent Coronary CT Angiography for Suspected Acute Coronary Syndrome: Impact of Revised 2017 Fleischner Society Guidelines

janerikscholtz@gmail.com

PURPOSE

A major criticism of coronary computed tomography angiography (CTA) for suspected acute coronary syndrome (ACS) is that it leads to more downstream testing, mostly follow-up chest CT for lung nodules, than alternative diagnostic tests. In 2017 the Fleischner Society released guidelines with the potential to substantially reduce follow-up testing for incidental lung nodules. Our aim was to evaluate the effect of the revised 2017 Fleischner Society Guidelines on recommendations for follow-up chest CT of incidental lung nodules versus 2005 guidelines in Emergency Department (ED) patients undergoing coronary CTA for ACS assessment.

METHOD AND MATERIALS

Our IRB approved retrospective study included 2,066 ED patients with suspected ACS who underwent coronary CTA between 2012 and 2016. All patients with incidental lung nodules were abstracted from the Radiology Information System (RIS). Recommendations for follow-up chest CT for incidental solid pulmonary nodules according to the 2005 and 2017 Fleischner Guidelines were compared. Patients with a history of smoking were classified as "high risk". Data were analyzed with Student's t test.

RESULTS

413 patients (20%) aged >= 35 years had indeterminate solid pulmonary nodules. 301 patients (73%) were considered low risk and most patients (347/413; 84%) had < 6mm nodules. Per 2017 Fleischner Society Guidelines, follow-up CT of solid lung nodules would only be recommended in 66 (3.2%) of all patients compared to 191 patients (9.2%) based on the 2005 guidelines which resulted in a net reduction of 65% (p<0.001).

CONCLUSION

Application of the 2017 Fleischner Society Guidelines resulted in significantly fewer recommended downstream follow-up CT recommendations for solid nodules compared to 2005 guidelines in patients who underwent emergent coronary CTA for suspected ACS.

CLINICAL RELEVANCE/APPLICATION

Incidental lung nodules are common on coronary CTA; adoption of the 2017 Fleischner Society Guidelines will substantially reduce the number of follow-up chest CT recommendations.

SSM04-06 Lung Cancer Detected on Calcium Scoring CT: Factors Affecting Delayed Diagnosis and Predictors for Survival

Wednesday, Nov. 29 3:50PM - 4:00PM Room: S504AB

rongzusuh@gmail.com

PURPOSE

To investigate the factors affecting delay in diagnosis among patients who had lung cancer which was detected on coronary artery calcium (CAC) scoring CT and to determine prognostic factors which can predict mortality.

METHOD AND MATERIALS

A total of 156 patients (94 men, mean age 68.5±8.95 years) who underwent CAC scoring CT between January 2010 and December 2014 and were subsequently diagnosed as lung cancer, were retrospectively enrolled. Delayed diagnosis was defined as time interval between CAC scoring CT and the diagnosis of lung cancer more than 1 year. For cases with delayed diagnosis, the reason of delay was assessed. Follow-up clinical outcome data regarding clinicopathologic stage of lung cancer at the time of diagnosis and all-cause mortality were obtained. Logistic regression analysis was performed to identify predictors for advanced stage (stage IV), and Cox proportional hazard regression analysis was performed to determine predictors for mortality.

RESULTS

Among 156 lung cancers, 59 lesions (37.8%) had been delayed in diagnosis. The most common reason was missed lesion on CAC scoring CT (49.2%), and the followings were follow-up strategy with imaging than tissue confirmation in subsolid lesion (22.0%), and interpretation error (malignant lesion being considered as inflammatory lesion, 16.9%). In multivariate logistic regression analysis, age (Odds ratio[OR) 1.047, 95% confidence interval[CI] 0.997-1.099) and lesion size (OR 1.023, 95% CI 0.998-1.049) were significant positive predictors for the advanced stage (P<0.2), and subsolid lesion characteristics (OR 0.186, 95% CI 0.0724-0.478) was a negative predictor (P=0.0005). In multivariate Cox proportional hazard regression analysis, age (hazard ratio[HR] 1.062, 95% CI 1.013-1.114) and lesion size (HR 1.023, 95% CI 1.008-1.038) showed increased hazard ratio for mortality (P<0.2), and subsolid lesion characteristics had decreased hazard ratio (HR 0.34, 95% CI 0.15-0.77;P=0.01).

CONCLUSION

On CAC scoring CT, concerns for detection and interpretation errors for lung cancer may prevent delayed diagnosis. Older age and larger lesion size may have poor survival, in contrast, subsolid lesion characteristics may have better survival.

CLINICAL RELEVANCE/APPLICATION

Concerns for detection and interpretation of lung nodule on CAC scoring CT is required to reduce diagnostic delay of lung cancer, especially in patients with older age and larger lesion size.

SSM05-01 Whole-Tumor Histogram Analysis of Apparent Diffusion Coefficient Maps for the Differentiation of Thymic Carcinoma from Lymphoma

Wednesday, Nov. 29 3:00PM - 3:10PM Room: S404AB

Participants
wei zhang, nan jing, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

fskzhangwei@126.com

PURPOSE

To assess the performance of whole-tumor histogram analysis of apparent diffusion coefficient (ADC) maps in differentiating thymic carcinoma from lymphoma, and compare with that of commonly used hot-spot region of interest (ROI) based ADC measurement.

METHOD AND MATERIALS

Diffusion weighed imaging (DWI) data of 15 patients with thymic carcinoma and 13 patients with lymphoma were retrospectively collected and processed with mono-exponential model. The measurement of ADCs were performed by using histogram-based and hot-spot ROI based approach. In histogram-based approach, following parameters were generated, including mean ADC (ADCmean), median ADC (ADCmedian), 10 and 90 percentile of ADC (ADC10 and ADC90), kurtosis and skewness. The difference of ADCs between thymic carcinoma and lymphoma was compared using t test. Receiver operating characteristic analyses were conducted to determine and compare the differentiating performance of ADCs.

RESULTS

Lymphoma demonstrated significantly lower ADCmean, ADCmedian, ADC10, ADC90 and hot-spot ROI based (mean) ADCs than thymic carcinoma (all p values < 0.001), while no differences were found on kurtosis (P=0.412) and skewness (P=0.273). ADC10 demonstrated optimal differentiating performance [cut-off value, 0.403×10-3 mm2/s; area under curve (AUC), 0.977; sensitivity, 92.31%; specificity, 93.33%], followed by ADCmean, ADCmedian, ADC90 and hot-spot ROI based ADC. The AUC of the ROC curve of ADC10 was significantly higher than that of hot-spot ROI based ADC (0.977 vs 0.797, P=0.036).

CONCLUSION

Compared with commonly used hot-spot ROI based ADC measurement, histogram analysis of ADC maps holds the promise in improving the differentiating performance between thymic carcinoma and lymphoma.

CLINICAL RELEVANCE/APPLICATION

our preliminary study results indicated that histogram analysis of ADC maps could be a promising approach to improve the differentiating performance between thymic carcinoma and lymphoma.

SSM05-02 Can CT Textural Analysis Predict the World Health Organization (WHO) Classification of Thymic Epithelial Neoplasms?

Wednesday, Nov. 29 3:10PM - 3:20PM Room: S404AB

Participants

Azadeh Tabari, Boston, MA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate if CT textural analysis (CTTA) can differentiate between low-risk and high-risk thymic epithelial neoplasms (TENs) on routine CT images.

METHOD AND MATERIALS

The preoperative CT scans of 48 patients diagnosed with a TEN over a 10-year period were reviewed with respect to contour, enhancement pattern, degree of enhancement (relative to skeletal muscle), calcification, pleural effusion, pleural seeding, pericardial effusion, and invasion of local structures. CTTA was performed with commercially available software (TexRAD) that applies a filtration-histogram technique for characterizing tumor heterogeneity. TENs were divided into two groups based on the WHO classification (low-risk = types A, AB and B1; high-risk = types B2, B3 and C). Student t-test was used to compare the mean value of each texture parameter between the two groups. Receiver operating characteristics (ROC) analysis was performed and area under the curve (AUC) was calculated for texture parameters that differed significantly. Sensitivity and specificity were calculated using the cut-off value with the highest AUC.

RESULTS

28 low-risk TENs (3 type A, 18 type AB, 7 type B1) and 20 high-risk TENs (11 type B2, 6 type B3, 3 type C) were included. The degree of enhancement differed significantly between the two groups (p=0.021). No significant difference was identified with respect to contour, enhancement pattern, calcification, pleural effusion or seeding, pericardial effusion, or invasion of local structures. Histogram analysis of CT values showed statistically significant differences in average Mean (SSF0, p=0.03) standard deviation (SD)(SSF0,p=0.006), entrophy (SSF0, p=0.04), mean positive pixels (MPP)(SFF6, p=0.008) and kurtosis (SSF3, p=0.02) values between the low-risk group (Mean 67.1 +/- 20.2/SD 21.2 +/- 6.5/entropy 4.3 +/- 0.3/MPP 32.8 +/- 21.1/kurtosis 0.23 + 0.75) and high-risk group (Mean 55.4 +/- 12.6/SD 16.6 +/- 3.6 /entrophy 4.1 +/- 0.2/MPP 21.1 +/- 6.4/kurtosis 1.14 +/- 1.83). Using an MPP threshold of 26.5, the sensitivity and specificity for differentiating low-risk from high-risk lesions was 90% and 54%, respectively (AUC 0.72).

CONCLUSION

CTTA may be able to separate TENs into low- and high-grade WHO histologic subtypes.

CLINICAL RELEVANCE/APPLICATION

The ability to preoperatively predict the WHO subtype of thymic epithelial neoplasms may help determine the need for preoperative adjuvant treatment.

SSM05-03 A Comparison between 3T MR and Endoscopic Ultrasound for Preoperative T Staging of Potentially Resectable Esophageal Cancer with Histopathological Correlation

qjryq@126.com

PURPOSE

To compare the value of 3T magnetic resonance imaging (MRI) and endoscopic ultrasonography (EUS) in the preoperative T staging of potentially resectable esophageal cancer.

METHOD AND MATERIALS

Patients with resectable EC diagnosed by clinical and pathological biopsy were prospectively collected. All patients underwent MRI (including T2-TSE-BLADE, DWI and a radial-VIBE sequence prototype) and EUS within one week before surgery. T staging was assigned on MR and EUS by two independent radiologists and one endoscopist in accordance with the 7th edition of AJCC TNM Classification for EC. Two readers separately determined the EC segment and evaluated the MR image quality using a 5-point score. The consistency of image quality score between two MRI readers and the correlation coefficient between image quality and EC segment were calculated using SPSS 20.0. Considering postoperative pathological T staging results as the gold standard, the performance of MRI (T2-TSE-BLADE + DWI + radial-VIBE) and EUS was evaluated based on the calculation of sensitivity, specificity, positive predictive value and negative predictive value.

RESULTS

A total of 70 patients were enrolled in the study, 16 cases were stage T1, 18 cases were stage T2, 30 cases were stage T3, and 6 cases were stage T4a. The evaluation of the image quality by two readers was almost identical (Kappa=0.825, P <0.001). The correlation coefficients between image quality score and EC segment by two readers were (r = -0.665, P <0.01)and (r = -0.619, P <0.01). The sensitivity values obtained by the two MRI readers for T1-T4a staging were 93.75%, 100%, 90%, 100% and 81.25%, 94.44%, 93.33%, 100%, and the specificity values were 100%, 94.23%, 100%, 98.44% and 100%, 90.38%, 97.50%, 100%; using EUS, the sensitivity and specificity values for T1-T4a staging were 81.25%, 83.33%, 53.33%, 50% and 96.3%, 67.31%, 92.50%, 98.44%.

CONCLUSION

MRI was comparable to EUS in the staging of T1 and T2, and showed advantage over EUS for T3 and T4a staging. MRI can accurately assess the depth of invasion of EC, which can be used as a routine examination for preoperative staging of EC and provide the basis for the formulation of a clinical treatment plan.

CLINICAL RELEVANCE/APPLICATION

(dealing with preoperative T staging of esophageal cancer)"MRI was comparable to EUS in the staging of T1 and T2, and showed

advantage over EUS for T3 and T4a staging."

SSM05-04 Accuracy of a Machine Learning Algorithm for Anterior Mediastinal Mass Diagnosis

nmiskin@partners.org

PURPOSE

The purpose of this study is to evaluate the accuracy of a machine learning algorithm as a diagnostic aid for anterior mediastinal masses (AMM), and to compare the accuracy to expert clinical assessment.

METHOD AND MATERIALS

Cases were identified by searching our medical record for patients with an AMM evaluated with CTs, from 2012-2015. 223 cases were found: 103 thymomas, 40 lymphomas, 12 germ cell tumors, 65 benign lesions (cyst, thymic hyperplasia), and 3 fibrosing mediastinitis. The latter group was excluded as there were too few for reliable diagnosis. We divided the remaining 220 cases into 122 training and 98 test cases. One thoracic radiologist reviewed the training cases for the following: size, attenuation in Hounsfield Units, attenuation homogeneity, shape, midline location, intralesional fat, calcification, vascularity, cystic spaces, preservation of fatty septum, supraclavicular, mediastinal, or internal mammary lymphadenopathy (LAD), chest wall invasion, lung invasion, pulmonary metastases, pleural metastases, and pleural effusion. We evaluated the predictive efficacy of each parameter, as well as age and sex, using the Weka machine learning software. Parameters most predictive of diagnosis were then used to generate a ruleset-based classifier using the JRip algorithm. A thoracic radiologist then blindly reviewed the 98 test cases for the presence of each parameter, to be fed into the classifier, and provided a best-guess diagnosis. A related-samples McNemar test was performed to assess differences in accuracy.

RESULTS

Using the machine learning software, the most predictive parameters for the diagnosis of an AMM were: age, sex, size, attenuation, shape, midline location, internal mammary LAD, mediastinal invasion, and pleural effusion. For the training set, the ruleset classifier correctly diagnosed 103/122 cases (84%). For the test set, the radiologist's best-guess diagnosis achieved an accuracy of 72/98 (74%). The ruleset classifier achieved an accuracy of 79/98 (81%). No significant difference in accuracy was seen (p=0.23). A ruleset-based classifier was constructed from the data.

CONCLUSION

A ruleset-based classifier can achieve accuracy comparable to a thoracic radiologist when evaluating the diagnosis of an anterior mediastinal mass.

CLINICAL RELEVANCE/APPLICATION

This algorithm is a potential semi-automated tool for accurate anterior mediastinal mass diagnosis in resource poor areas.

SSM05-05 Combination of DCE-MRI and DWI in Predicting the Treatment Effect of Concurrent Chemoradiotherapy in Esophageal Carcinoma

Wednesday, Nov. 29 3:40PM - 3:50PM Room: S404AB

PURPOSE

To study the value of dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) combined with diffusion-weighted imaging (DWI) in evaluating the effect of concurrent chemoradiotherapy (CCRT) in patients with esophageal carcinoma.

METHOD AND MATERIALS

A total of 76 patients with newly diagnosed esophageal carcinoma were enrolled in this study. All the participants were examined with DCE-MRI and DWI at baseline (pre-treatment) and during the third week after the start of CCRT (post-treatment). The volume transfer constant (Krans), rate contrast (Kep), the contrast agent percentage in the extracel¬lular fluid space (Ve), and the apparent diffusion coefficient (ADC) were measured by two radiologists with greater than 10 years' individual experience. The changes in lesion volume on CT were measured at the completion of radiotherapy and was used as an endpoint to evaluate the predictive ability of DCE-MRI and DWI. All the quantitative parameters were analyzed with the paired t-test and a p-value of less than 0.05 indicated statistical significance.

RESULTS

A total of 76 and 56 DCE-MRI and DWI scans were available for analysis at baseline and at the third week, respectively. Pre-treatment Krans, pre-treatment Kep, pre-treatment ADC ($P < 0.05$), and post-treatment Krans ($P < 0.05$) and ΔKrans, ΔADC ($P < 0.05$) were significantly different after CCRT. Based on the binary logistic model, the ROC analysis demonstrated that the combined predictors demonstrated a high diagnostic performance with a threshold of 0.211 and an AUC of 0.939. The sensitivity and specificity were 98.6% and 73.8%, respectively.

CONCLUSION

The combination of DCE-MRI and DWI, as a noninvasive method, allows for the visualization of esophageal carcinoma lesions and can be used as an early biomarker in the prediction of the effect of CCRT three weeks after treatment initiation.

CLINICAL RELEVANCE/APPLICATION

DCE-MR can detect the effects of radio- and chemotherapy at early time points and is recommended as part of a MR study prior to esophageal carcinoma.

SSM05-06 CT Features of Thymic Epithelial Tumors: Correlation with the Clinical Stage Classification Using the Recently Proposed TNM Staging System

sumi_akiko@kurume-u.ac.jp

PURPOSE

To evaluate the CT features of thymic epithelial tumors with recently proposed TNM staging system and to determine the CT features helpful in predicting patient outcome.

METHOD AND MATERIALS

This retrospective study included 116 patients with thymic epithelial tumor surgically treated. Two radiologists interpreted independently the 21 categories of CT findings and finally classified each category into two groups. Correlation of these categories with new TNM staging system and with prognosis were assessed.

RESULTS

The patients were 68 women and 48 men (median age, 59 years; range, 27-82 years). WHO histologic classification included Type A in 10, Type AB in 22, Type B1 in 28, Type B2 in 24, Type B3 in 10, and Carcinoma in 22 patients. The clinical stage using by TNM staging system were stage I in 92, stage II in 3, stage IIIa in 10, stage IIIb in 2, stage IVa in 3, and stage IVb in 6 patients. In the present study, stage II and greater (stage II-IV) tumors were considered an invasive tumor. There was statistically significant relationship between WHO histologic classification and tumor invasiveness (Fisher, $P < .001$). In multivariable analysis, there were statistically significant differences in tumor contour, adjacent chest wall change, pericardial thickness, and vascular invasion between stage I and stage II-IV (all, $P < .05$). Multivariate analysis using a stepwise forward Cox proportional hazards regression model showed that tumors with lobulated and irregular contour, lobulated and irregular contour with mediastinal fat, presence of hemorrhage/cyst/necrosis, and presence of band-like opacity in the lung were significantly associated with disease progression (all, $P < .05$). Patients with three or four of these factors had a significantly shorter cause-specific survival than the other patients ($P < .001$).

CONCLUSION

CT characteristics of thymic epithelial tumors may be helpful in the classification of the new TNM staging system and the prediction of the worse prognosis.

CLINICAL RELEVANCE/APPLICATION

CT features suggestive of invasiveness in thymic epithelial tumor were irregular contour, absence of chest wall's fat layer, presence of pericardial thickness or vascular invasion. Patients with these factors had the worse prognosis.

PURPOSE

To establish gender specific cut-off values for cardiac chamber enlargement and left ventricular hypertrophy (LVH) on non-ECG-gated chest CT using cardiac MRI as the reference standard.

METHOD AND MATERIALS

218 patients who had contrast enhanced non-ECG-gated chest CT (64-320 detector) and cardiac MRI (1.5-3T) performed within 7 days were identified retrospectively (53% male, 52.9±15.8 years, mean interval between CT and MRI 3.4±2.2 days). The presence of cardiac chamber enlargement and left ventricular hypertrophy (LVH) was established by cardiac MRI as the reference standard, according to current guidelines. Multiple measurements were obtained on axial CT images to evaluate left atrial (LA), left ventricular (LV), right atrial (RA) and right ventricular (RV) chamber size, and LV wall thickness, blinded to the reference standard. ROC analysis was performed to determine optimal gender-specific CT measurement cut-off values for the diagnosis of chamber enlargement (LAE, LVE, RAE, and RVE, respectively) and LVH, with specificity (Sp) >=90%. Inter-observer agreement was evaluated with intra-class correlation (ICC) in a random subset (n=40).

RESULTS

LAE was present in 69 (34%), LVE in 47 (23%), RAE in 45 (21%), RVE in 32 (15%) and LVH in 38 (19%). The following CT measurements were the best discriminators. For LAE, LA anterior-posterior (AP) diameter >=50 mm for males (sensitivity (Sn)=47%, Sp=92%, AUC=0.795) and >=44 mm for females (Sn=54%, Sp=92%, AUC=0.839). For LVE, LV transverse diameter >=58 mm for males (Sn=55%, Sp=92%, AUC=0.842) and >=53 mm for females (Sn=29%, Sp=93%, AUC=0.771). For RAE, RA transverse diameter >=67 mm for males (Sn=59%, Sp=91%, AUC=0.825) and >=63 mm for females (Sn=75%, Sp=92%, AUC=0.925). For RVE, RV transverse diameter >=58 mm for males (Sn=56%, Sp=90%, AUC=0.805) and >=57 mm for females (Sn=57%, Sp=91%, AUC=0.850). For LVH, LV maximal wall thickness >=17 mm for males (Sn=55%, Sp=91%, AUC=0.881) and >=15 mm for females (Sn=78%, Sp=92%, AUC=0.910). Inter-observer agreement was excellent (ICC range 0.887-0.973).

CONCLUSION

Cardiac chamber enlargement and LVH can be reliably identified on contrast enhanced non-ECG-gated chest CT with moderate sensitivity and high specificity.

CLINICAL RELEVANCE/APPLICATION

This study provides gender-specific cut-off values for measurements that can easily be obtained on axial non-ECG-gated CT images to identify cardiac chamber enlargement and LVH with high specificity.

SSM06-02 Correlating Computed Tomography Test Bolus Imaging Dynamics with Pulmonary Vascular Resistance in Pulmonary Hypertension

Wednesday, Nov. 29 3:10PM - 3:20PM Room: S406B

Participants

Dhiraj Baruah, MD, Milwaukee, WI (*Presenter*) Nothing to Disclose
Kaushik S. Shahir, MD, Tampa, FL (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

dbaruah@mcw.edu

PURPOSE

Pulmonary vascular resistance (PVR) is an important parameter in the management of pulmonary hypertension and serves as a primary endpoint to assess the treatment efficacy in several newer targeted therapies. Currently, invasive cardiac catheterization is the gold standard to accurately assess the severity of pulmonary hypertension by providing hemodynamic measures such as PVR and mean pulmonary artery pressure (mPAP). Currently there are no established CT parameters to correlate with PVR. We propose an innovative method using test bolus imaging parameters performed for routine CTPA to correlate with PVR.

METHOD AND MATERIALS

This is an IRB approved retrospective study performed in two separate institutions. Patients included are with known pulmonary hypertension who had a CTPA study within one month of right heart catheterization. CTPA were performed on a 64 slice multidetector CT. Bolus dynamics with 15 mL of intravenous nonionic contrast (Omnipaque 350) and repeated axial images with breath hold at the level of the main pulmonary artery. Full width at half maximum (FWHM) of the test bolus is the width of the main pulmonary artery enhancement curve at half its maximum density.

RESULTS

Out of 221 patients who had undergone CTPA study between January 2010 to December 2013 for evaluation of pulmonary hypertension, 52 of them also had a right heart catheterization within one month of CTPA. Of these 52 patients, 37 fulfilled the selection criteria. A correlation of established size parameters and also FWHM was obtained with catheter angiographic data. There was a strong correlation between FWHM and mPAP ($r=0.65$, p value<0.00001), PVR ($r=0.8$, p value<0.00001) and PVR ($r=0.75$, p value<0.00001) (Fig. 3a, 3b and 3c). There was a poor correlation between MPA, RPA, LPA, MPA/Aorta ratio, A/B and RV/LV and mPAP, PVR and PVRI.

CONCLUSION

This innovative study shows routine CT test bolus dynamic information (FWHM) from CTPA is a simple, reliable and easily available noninvasive method that has a very strong correlation with mPAP and PVR/PVRI as compared with conventional CTPA parameters.

CLINICAL RELEVANCE/APPLICATION

Being noninvasive, these CTPA test bolus parameters are potentially helpful for follow up of patients with pulmonary hypertension, mainly to assess treatment response and progression. Among all the parameters we evaluated the FWHM of test bolus correlates strongly with catheter angiographic parameters.

SSM06-03 Correlation between the Degree of Systemic Collateral Supply and the Severity of Chronic Thromboembolic Pulmonary Hypertension: A CT Angiography Study Using Intra-Arterial Injection

PURPOSE

It is known that systemic collateral supply develops in chronic thromboembolic hypertension (CTEPH). The aim of this study was to assess whether the degree of shunts from systemic artery to the pulmonary vascular system identified by CT angiography using intra-arterial injection was associated with clinical severity in patients with CTEPH.

METHOD AND MATERIALS

A total of 23 patients with inoperable CTEPH were referred to our cardiology department. During diagnostic right and left heart cardiac catheterization, CT angiography using intra-arterial injection from a catheter in the ascending aorta was performed. One-hundred-and-five ml of 1/3 diluted iodine contrast media (35 ml of 350mgI/ml contrast media and 70 ml of saline) was injected at a speed of 9 ml/sec. CT was imaged at scan delay of 9 sec with a 80-kVp tube voltage setting. Two radiologists evaluated CT images by consensus reading. We measured CT values of the pulmonary trunk (HUpt), sub-segmental pulmonary arteries (HUpa) and segmental pulmonary veins (HUpv).HUdiff was calculated as HUpa (or HUpv) - HUpt. The shunt level was zero of HUdiff < 50. For each additional 50 increase of HUdiff, the shunt level was increased by 1. Two shunt scores in each patient were defined separately as the sum of shunt levels in 42 sub-segmental arteries and 18 segmental veins. Mean pulmonary artery pressure (mPAP) and pulmonary vascular resistance (PVR) were measured by right heart catheterization. Correlations between the shunt scores and hemodynamics were evaluated by Pearson's correlation. A p value < 0.05 was considered to reflect statistical significance.

RESULTS

The mean ± standard deviation of mPAP in the 23 patients was 41.4 ± 8.9 mmHg [range, 25-58]. The mean arterial shunt score was 15.3 ± 16.4 [range, 0-60]; the venous shunt score was 11.7 ± 10.2 [range,1-41]. The shunt score of pulmonary vein was significantly correlated with the mean PAP ($r = 0.56$, $p < 0.01$), whereas the shunt score of pulmonary artery was not ($r = 0.13$, $p = 0.56$)

CONCLUSION

Localization of shunts from systemic artery to pulmonary vessels was possible. The degree systemic collateral supply as indicated by the shunt score may attribute to the clinical severity of inoperable CTEPH.

CLINICAL RELEVANCE/APPLICATION

Systemic collateral supply localized by CT angiography was correlated with the severity of inoperable CTEPH and may give information for stratifying balloon pulmonary angioplasty.

SSM06-04 Treatment Effect of Balloon Pulmonary Angioplasty in CTEPH Quantified by Automatic Comparative Imaging in CTPA

z.zhai@lumc.nl

PURPOSE

Balloon pulmonary angioplasty (BPA) in patients with inoperable chronic thromboembolic pulmonary hypertension (CTEPH) can have variable outcomes. To gain more insight into this variation, we aimed to visualize and quantify changes in lung perfusion using CT pulmonary angiography (CTPA). We validated these measurements of perfusional changes against hemodynamic changes measured during right-heart catheterization.

METHOD AND MATERIALS

We studied 14 consecutive CTEPH patients (12 female; age: 65±17), who underwent CTPA and right-heart catheterization, before and after BPA. Post-treatment images were registered to pre-treatment CT scans (using the Elastix toolbox) to obtain corresponding locations. Pulmonary vascular trees and their centerlines were detected using a graph-cuts method and distance transform. Areas distal from vessels were defined for measuring perfusional changes in the parenchyma. Subsequently, the density changes within the vascular and parenchymal areas were calculated and corrected for inspiration level differences, and displayed in color-coded overlays. For quantification, the median and inter-quartile range (IQR) of the density changes were calculated in the vascular and parenchymal areas (ΔVD and ΔPD, respectively). The recorded changes in hemodynamic parameters included changes in systolic, diastolic and mean pulmonary artery pressure (ΔsPAP, ΔdPAP and ΔmPAP, respectively) and in vascular resistance (ΔPVR). The Spearman's correlation coefficients between perfusional changes and hemodynamic changes were tested.

RESULTS

PAP and PVR were significantly improved after BPA. Comparative imaging maps showed distinct patterns in perfusional changes between patients. Within vessels, the IQR of ΔVD correlated with ΔsPAP (R=-0.58, p=0.03), ΔdPAP (R=-0.71, p=0.005), ΔmPAP (R=-0.71, p=0.005) and ΔPVR (R=-0.77, p=0.001, see Figure). In the parenchyma, the median of ΔPD correlated with ΔdPAP (R=-0.71, p=0.005) and ΔmPAP (R=-0.68, p =0.008).

CONCLUSION

Comparative imaging in CTEPH patients offers insight into differences in BPA treatment effect. Quantification of these perfusional changes provides non-invasive measures that reflect hemodynamic changes.

CLINICAL RELEVANCE/APPLICATION

CTPA studies before and after balloon pulmonary angioplasty in CTEPH can demonstrate density changes in the vascular and parenchymal areas and is recommended to monitor treatment effects.

SSM06-05 Radiologist Performance in the Detection of Pulmonary Embolism: Features That Favor Correct Interpretation and Risk Factors for Errors

Wednesday, Nov. 29 3:40PM - 3:50PM Room: S406B

skligerman@umm.edu

PURPOSE

To assess factors contributing to accurate detection and erroneous interpretation of PE

METHOD AND MATERIALS

Over 13 months, all CTPA studies were retrospectively re-read by a chest radiologist (rad) with 9 yrs experience. Any disagreement

Over 15 months, all CTPA studies were retrospectively re-read by a chest radiologist (rad) with 9 yrs experience. Any disagreement with the initial read was independently assessed by 2 additional chest rads. Studies with uniform disagreement from initial read were labeled false - (FN, miss) or false + (FP overcall). Studies concordant between initial and re-read were true + (TP) or true - (TN). Number (single vs. multiple), most proximal extent (central [C], lobar [L], segmental [S], and subsegmental [SS]), and specific location of PE were recorded. Also assessed were specialty training, experience, time of study, kV used, resident preliminary read, use of iterative recon (IR), signal to noise ratio (SNR), and reports describing study as 'limited'. Parametric and non-parametric statistical testing was performed (significance $p<0.05$)

RESULTS

Of 2555 CTPA cases assessed, there were 230 TP (170 multiple, 60 single PE), 2271 TN, 35 FN (15 multiple and 20 single PE), and 19 FP studies. Overall sensitivity, specificity, PPV, NPV and accuracy of rads was 86.8%, 99.2%, 92.4%, 98.5%, and 97.9%. Sensitivity for detection of multiple PE (92.4%) was significantly higher than single PE (74.1%, $p<0.01$). Sensitivity for C (100%) and L (97.8%) PE was significantly higher than S (85.9%) and SS (74%, $p<0.01$ for both). Sensitivity of thoracic rads (91.7%) was higher than non-thoracic (82.8%) but only reached significance for isolated PE (89.2% vs 61.4%, $P<0.02$). SNR of both TP (13.4) and TN (13.8) studies was significantly higher than FN (11) and FP(11.6). Other factors were not significant. Compared to other S and SS, there were significantly more FNs in the upper lobe posterior and lower lobe lateral S or SS. There were significantly more FP in the inferior lingula. FP studies were more likely to be described as 'limited' in the report.

CONCLUSION

Accuracy for PE detection is high but errors occur, especially in isolated S or SS PE in posterior S or SS of upper and lateral S or SS in lower lobes. Sensitivity was higher in studies with high SNR and if read by thoracic rads

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that although radiologists are accurate in the detection of PE, errors occur most commonly due to location or PE in specific ' blind spots', especially in studies with poor SNR and when interpreted by a non-thoracic radiologist.

SSM06-06 The Power of Axial Scans with 16cm Wide-Detector Scanner: Dose Reduction in Triple-Rule-Out CT Angiography

PURPOSE

To explore the value of using three consecutive axial scans in the triple-rule-out (TRO) examination for chest pain on a 16cm wide-detector CT system.

METHOD AND MATERIALS

Forty patients with acute chest pain underwent TRO scan and were assigned to study group (group A, n=20) and control group (group B, n=20). In both groups, 120kV tube voltage and automatic current modulation to obtain noise index of 21HU and contrast agent iopamidol (370 mg / ml) were used. For Group A, the time-density curves for pulmonary artery and aorta were monitored to calculate the scan delay time. Two-phasic contrast injection was used: 25mgI/kg/s for 12s in 1st phase and at 3.0ml/s injection rate for 20ml in 2nd phase. The pulmonary artery, coronary artery and aorta were scanned in succession in axial mode to cover the thoracic entrance to the top of the diaphragm. For Group B, scan was triggered by the threshold (100HU) for pulmonary artery to include the thoracic portal to the top of the diaphragm; the coronary artery was scanned after 7 seconds delay, followed immediately by scanning aorta in an helical mode. Contrast agent injection protocol: 25mgI/kg/s for 14s. Images were reconstructed with 80%ASIR-V. CT number and standard deviation (SD) of the thoracic aorta, pulmonary artery, coronary artery, fat and erector spinae muscle were measured to calculate SNR and CNR. Image quality was also assessed using a 5-point system (5: best, 1: worst). Measurements were statistically compared.

RESULTS

There was no difference in age, heart rate and body mass index between the two groups ($P> 0.05$); The CT number, SNR, CNR and subjective score of the two groups were statistically the same ($p>0.05$). However, There was a significant difference in total effective radiation dose between group A (3.3±1.2 mSv) and group B (5.56±0.67mSv) ($P<0.05$), resulting in40.3% effective dose reduction using the 3 consecutive axial scan mode.

CONCLUSION

Using 3 consecutive axial scans in in triple-rule-out (TRO) CTA on a 16cm wide-detector CT reduces both radiation dose and exposure times while maintaining image quality compared with the conventional TRO scanning protocol.

CLINICAL RELEVANCE/APPLICATION

Axial scans may be used on a 16cm wide-detector CT in triple-rule-out CTA to reduce radiation dose and maintain image quality.

For information about this presentation, contact:

TWTRINH@BWH.HARVARD.EDU

PURPOSE

To test the hypothesis that Dual Energy CT derived surrogates for bone mineral density can differentiate between elderly patients with a demonstrated fragility fracture and control patients without fractures.

METHOD AND MATERIALS

12,595 consecutive abdominal/pelvic dual energy CT (DECT) scans (Siemens FLASH scanner, Syngo Via software version VB10) from 4/2013 to 6/2016 were retrospectively reviewed. 585 met inclusion criteria for non-contrast scan in a female aged >=65 with exclusion criteria of osseous metastases, spinal hardware, or motion. The cohort included 101 patients with fragility fractures defined as spinal compression, femoral neck, or pelvic insufficiency fractures visible on the study CT scan. The control group included 97 patients without fragility fractures. Recorded metrics included L1 (or the nearest adjacent non-fractured) vertebral body HU values, calcium concentration (converted from iodine to calcium concentration using a scaling factor derived from calcium phantom calibration scans), and calcium HU values (determined from a virtual non-calcium subtraction algorithm).

RESULTS

Mean average vertebral body ROI values for the fracture and control groups, respectively, were: 86 and 132 HU, 60 and 88 mg/ml Ca, and 119 and 162 calcium HU (t-test $p<0.00001$ for all). ROC analysis showed areas under the curve of 0.75, 0.72 and 0.72 for HU values, Ca concentration, and Ca HU values, respectively. Selecting a high sensitivity value of 90% for use as a meaningful screening test yields threshold values of 138 HU, 172 mg/ml Ca, and 94 Ca HU, with resultant specificities of 42%, 36%, and 38% for HU values, Ca concentration, and Ca HU values, respectively.

CONCLUSION

Patients with fragility fractures have significantly decreased vertebral body HU values, as well as DECT derived Ca concentration and Ca HU values. Ability of these measures to predict patients at risk for fragility fractures is comparable at high sensitivity values considered acceptable for screening. Further work is needed to optimize DECT techniques in order to determine optimal cutoff values, and to potentially improve performance compared to traditional HU values.

CLINICAL RELEVANCE/APPLICATION

Dual Energy CT derived surrogates for bone mineral density may allow for opportunistic bone mineral density screening in patients undergoing abdominal and pelvic CT for other reasons.

SSM07-02 A Focused MRI Protocol for Efficient Detection of Pathology Associated with Thoracolumbar Spine Fractures

Wednesday, Nov. 29 3:10PM - 3:20PM Room: S403B

smkarim@post.harvard.edu

METHOD AND MATERIALS

Retrospective study of adult patients from 2 affiliated Level I trauma centers. Eligible patients presented to the emergency department between 2008 & 2015 with >= 1 fracture of the thoracic or lumbar spine on CT and MRI of the entire thoracic & lumbar spine within 10 days of CT. Exclusion criteria: > 4 levels fractured, pathologic fractures, isolated transverse/spinous process fractures, osteoporotic fractures, prior vertebral augmentation, prior TL spine instrumentation. Patients with neurologic deficits were not excluded. MRIs were reviewed independently by an orthopaedic spine surgeon and an emergency radiologist. MRIs were reviewed for posterior ligamentous complex (PLC) integrity, marrow edema, epidural hematoma, and cord contusion. Pathology identified outside of 3 levels above & below the fractured level(s) ('focused zone') were reviewed by the spine surgeon to determine if treatment would be altered.

RESULTS

126 patients with 216 fractures on CT identified. Demographics: 81 males (64%); median age 49; 62 (49%) TL junction injuries; 47 (37%) managed operatively. PLC injury identified by at least one reader in 41 (33%) patients with percent agreement for PLC injury between two readers of 96%; κ =0.91. Both readers independently agreed there was no pathology on the complete MRIs outside the focused zone in 101 (80%) patients. None of the outside pathology altered patient management. Percent agreement for the absence of outside pathology was 87%; κ =0.47.

CONCLUSION

A focused MRI protocol of 3 levels above & below a known thoracolumbar spine fracture(s) may miss radiographic pathology, but this pathology does not alter patient care.

SSM07-03 Radiological Predictors for Medial Collateral Ligament (MCL) Injury of the Elbow in the Emergency Department (ED)

jordan_lebovic@hms.harvard.edu

PURPOSE

The Medial Collateral Ligament (MCL) is a primary stabilizer of the elbow and is well visualized on MRI. Specific radiological findings indicating MCL injury on radiographs and CT are under recognized by radiologists. Unrecognized MCL injury can cause post-operative instability and recurrent dislocations. The purpose of this study is to determine whether radiological findings can predict MCL injury in patients with elbow fracture-dislocations.

METHOD AND MATERIALS

Operative reports of 287 patients with elbow fracture-dislocations were reviewed to identify patients with injured and intact MCL. Radiology reports were also reviewed for MCL injury. Both Xrays and CTs were analyzed specifically for MCL injury by radiologist and elbow surgeon.

RESULTS

Only 4.5% (13/287) of the radiology reports for patients with elbow-fracture dislocations mentioned the status of the MCL attachment sites. 46 MCL injuries were evaluated and 19 were found to have either a fracture of the medial epicondyle or the sublime tubercle (5 sublime tubercle fractures and 14 medial epicondyle fractures). 16 intact MCLs were confirmed by operative visualization. 0 of the 16 intact MCLs had either a medial epicondyle fracture or a sublime tubercle fracture. 43% of patients with known MCL injury were found to have fracture (s) at the MCL attachment sites. Using fractures of either the medial epicondyle or sublime tubercle as predictor of MCL status had a sensitivity of 63% (CI 51%-74%), a specificity of 100% (CI 79%-100%) and a negative predictive value of .37 (CI .27-.50).

CONCLUSION

While MRI remains the optimal modality to assess for MCL injury, it is rarely used in ED for elbow fracture-dislocations. Presence of fractures involving medial epicondyle and sublime tubercle on radiographs and CT are critical and must be reported by radiologists to help guide the management.

CLINICAL RELEVANCE/APPLICATION

Using radioglogical predictors for MCL injury could identify patients requiring MCL repair, and thereby prevent post-operative instability and recurrent dislocations.

SSM07-04 Imaging of Necrotizing Fasciitis of the Upper Extremity: Distinguishing Cellulitis from Necrotizing Fasciitis

Wednesday, Nov. 29 3:30PM - 3:40PM Room: S403B

Participants
Mohammad Mansouri, MD, MPH, Boston, MA (*Presenter*) Nothing to Disclose
Michael H. Lev, MD, Boston, MA (*Abstract Co-Author*) Consultant, General Electric Company; Institutional Research Support, General Electric Company; Stockholder, General Electric Company; Consultant, MedyMatch Technology, Ltd ; Consultant, Takeda Pharmaceutical Company Limited; Consultant, D-Pharm Ltd
Ajay K. Singh, MD, Boston, MA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Cellulitis is a relatively common infection of the skin and subcutaneous tissues which may comprise up to 14% of emergency visits.Necrotizing fasciitis (NF) is a potentially fatal, uncommon infection of the soft tissues which can be difficult to diagnose and distinguish from cellulitis.We aim to analyze and compare imaging findings of cellulitis and NF of upper extremity in our large academic medical center.

METHOD AND MATERIALS

This is a HIPAA compliant, IRB approved, retrospective study of cases imaged between 2003 and 2017. Imaging database of our institution was searched for all cases of upper extremity cellulitis and NF. The reference standard for diagnosis was surgery, and/or clinical follow-up. Medical records were reviewed for patient clinical and imaging variables.

RESULTS

A total of 50 cases were included (mean age:44.5, 25 male 25 female). 15 cases had proven NF by surgery and 35 cases had cellulitis proven surgically and/or clinical follow-up. CT was acquired in 60.0% of NF cases (9/15) and 74.3% of cellulitis cases (26/35). Other imaging modalities used were MRI, plain radiograph, and US. Air was significantly more common present in NF compared with cellulitis (53.3%,8/15 and 20.0%,7/35 respectively) (p=0.04). Other common associated imaging findings with NF were subfascial fluid (n=6) and fascial thickening (n=8). NF was significantly more likely to be fatal compared with cellulitis (20.0%,3/15 and 0%,0/35 respectively) (p=0.02). All cases of cellulitis with soft tissue air, had history of recent incision and drainage, penetrating trauma, IV drug use, injection of steroid or immunization. Skin thickening and superficial subcutaneous tissue involvement was seen in all cases of cellulitis who had CT or MR. Soft tissue abscess was seen more commonly in cellulitis (31.4%,11/35) compared with NF (26.7%,4/15). Cellulitis cases who had soft tissue abscess, had significantly more intramuscular edema (66.7%, 6/9), compared with the cases without abscess (13.6%,3/22)(p=0.007).

CONCLUSION

Soft tissue air, fascial thickening and subfascial fluid collection are significantly more common in the NF than cellulitis.Majority of soft tissue air in cellulitis cases can be explained by history of recent trauma, IV drug use, immunization, incision and drainage, and injection.

CLINICAL RELEVANCE/APPLICATION

Soft tissue air, fascial thickening and subfascial fluid collection are significantly more commonly seen in the NF than cellulitis.

SSM07-05 One-Shot Volume Wrist CT as a Screening Tool: Impact on Detection and Treatment of Fractures

Monique.Brink@radboudumc.nl

PURPOSE

Although conventional radiography (CR) is standard, computed tomography (CT) improves fracture detection in patients with wrist fractures. We implemented a fast set-up volume CT protocol in our clinic. Our objective was to evaluate fracture detection and therapeutic impact of this one-shot volume CT protocol in clinical practice.

METHOD AND MATERIALS

Between June 2013 and April 2014, we performed a prospective study on all adult patients with suspicion of acute fractures of the wrist or carpus. After informed consent, all patients first underwent CR, thereafter volume CT of the wrist, and then one year follow-up. Likelihood of fracture presence on a five-point scale was prospectively collected before and after CT. Three surgeons blinded to actual patient treatment independently proposed a treatment regimen (functional, cast, or operation), both based on anonymous clinical and radiological data, first with knowledge of CR, and thereafter with knowledge of CT. A radiologist and a surgeon served as reference standard for presence of fractures based on all data. Observer variability was evaluated with Fleiss kappa statistics. We performed receiver operating curve analyses for fracture detection and calculated proportion of wrists with treatment changes based on CT as compared to CR.

RESULTS

Ninety-eight patients participated (37 % male, mean age 53, range 18-87 years old), with 100 wrist CTs (mean DLP: 36 mGycm). CT detected true-positive fractures in 61 (41 radial, 14 ulnar, 26 carpal fractures), and CR in 45 patients (39 radial, 13 ulnar, 6 carpal fractures). AUC for fracture detection was 0.85 (95% CI:0.77-0.93) for CR and 0.97 (95% CI: 0.93-1.00) for CT. Agreement

on treatment was moderate after CR (Fleiss kappa 0.61 (95% CI 0.51-0.70)) and good after CT (0.75 (95% 0.66-0.84). Treatment changed in 24 (24%, 95% CI 16-33%) - 31 (31%, 95% CI 23-41%) wrists, mostly including refraining from cast immobilization (14-16 patients).

CONCLUSION

Volume CT increases accuracy of fracture detection, mainly of carpal injuries. This has a significant impact on cast immobilization changes in this patient population.

CLINICAL RELEVANCE/APPLICATION

Implementation of low threshold, fast-set up volume CT in patients with suspicion of wrist fractures improves carpal fracture detection and has a high potential to avoid unnecessary cast treatment.

SSM07-06 Emergency Department Overcrowding Delays Time to Radiography and Adversely Affects Outcomes for Hip Fracture Patients

PURPOSE

The purpose of this study was to identify if ED overcrowding caused a delayed TTR in our institution and if so what effect it has on patient outcome.

METHOD AND MATERIALS

Patients were identified using the hip fracture database at a tertiary referral urban hospital with an annual ED census of over 53,000 patients. 154 consecutive cases were analysed. ED electronic records (Maxims™) and Radiology (PACS) records were then used to assess the Time to Radiography (TTR). Results were analysed using logistic regression in SPSS™.

RESULTS

154 patients were included (115 female). Mean age was 81.04 (SD; range) (10.28; 44-102). Mean TTR was 110 minutes (73.1; 4-431). The mean total number of patients in the ED at presentation was 59.8 (16.67; range 27-99). Using ANOVA increasing numbers of patients was significantly associated with increasing time to radiography ($p=0.003$). Furthermore the TTR was significantly less (61 minutes vs. 113 minutes) when the ED was not above capacity of 33 patients ($p<0.001$). A regression model built to predict radiography in less than 60 minutes showed that only the total number of patients in the ED was independently associated with TTR ($p=0.03$). Analysing the hip fracture database for outcomes, delay to imaging was not associated with a delay in time to surgery ($p=0.174$), but was significantly associated with Time To Ward (TTW) ($p=0.03$) and length of stay ($p=0.024$).

CONCLUSION

TTR and overall outcomes for patients with a hip fracture are negatively impacted by the number of patients in the ED when they arrive.

CLINICAL RELEVANCE/APPLICATION

The authors hope these data will highlight the need for adequate resourcing of the ED and the healthcare system to deal with overcrowding and, in doing so, help avoid poorer outcomes for patients with time-dependent pathology.

Tae-Hyung Kim, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Sanghyup Lee, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate whether CT reconstruction algorithms affect CT texture features of the liver parenchyma.

METHOD AND MATERIALS

This retrospective study included 72 patients (normal liver, n=36; chronic liver disease (CLD), n=36) who underwent 4-phase liver CT scan on a Brilliance iCT scanner (Philips Healthcare). All CT images were reconstructed with filtered back projection (FBP), hybrid iterative reconstruction (iDose4TM), and iterative model-based reconstruction (IMR, L1). On the arterial phase (AP) and portal venous phase (PVP) CT imaging, quantitative texture analysis of the liver parenchyma with single-slice ROI measurement was performed at the level of hepatic hilum using a filtration-histogram statistic-based method (TexRAD) with different filter values (fine, medium, coarse). Texture features including mean attenuation (M), standard deviation (SD), entropy (E), mean of positive pixels (MPP), skewness (S), and kurtosis (K) were compared among three reconstruction methods and between normal liver and CLD.

RESULTS

Iterative reconstruction techniques affected various CT texture features of the liver parenchyma in the same individuals, across the different filters. Among the CT texture features, SD and E were significantly different regardless of filter values, both on the AP and PVP imaging between iDose/IMR vs. FBP, and iDose vs. IMR($P<.05$). When comparing patients with CLD with patients with normal liver, E from the AP images of fine filter was significantly different regardless of reconstruction algorithms($P<.05$).

CONCLUSION

CT texture features of the liver parenchyma on a filtration-histogram method were significantly affected by CT reconstruction algorithms.

CLINICAL RELEVANCE/APPLICATION

Texture analysis using a uniform reconstruction algorithm would be important for a more reliable inter-subject comparison as well as intra-subject longitudinal monitoring.

PURPOSE

To access the performance of virtual hepatic venous pressure gradient (vHVPG) in diagnosing clinically significant portal hypertension (CSPH) and predicting risk of variceal hemorrhage (VH).

METHOD AND MATERIALS

102 patients were prospectively recruited in 3 high-volume liver centers in China between August 2016 and March 2017 [NCT02842697]. All participants were scheduled to undergo clinically-indicated hepatic venous pressure gradient (HVPG) measurement, CT angiography (CTA), and Doppler ultrasound. vHVPG values were calculated from the reconstructed three-dimensional model of hepatic vein-portal vein system and computational fluid dynamics analysis. The performance of vHVPG in diagnosing CSPH (HVPG >= 10 mmHg) and predicting risk of VH (HVPG >= 12 mmHg) were assessed and compared with that of the imaging-based models (HVPGCT score, Portal diameter) and serum-based models (aspartate aminotransferase [AST] to alanine aminotransferase ratio [AAR], AST to platelet count ratio index [APRI], fibrosis index based on 4 factors [FIB-4]).

RESULTS

As expected, vHVPG was successfully interpreted in patients both with and without CSPH [Figure 1A, 1B]. For diagnosing CSPH, area under receiver operating characteristics curve (AUC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of vHVPG were 0.875 (0.796-0.953), 0.759 (0.639-0.928), 0.895 (0.737-0.100), 0.969 (0.925-0.100), and 0.459 (0.365-0.581), respectively. Also, for predicting risk of VH, AUC, sensitivity, specificity, PPV, and NPV were 0.865 (0.777-0.953), 0.822 (0.726-0.904), 0.828 (0.690-0.966), 0.923 (0.861-0.983), and 0.649 (0.538-0.781), respectively. Overall, vHVPG showed a better diagnostic performance than that of imaging-based models (HVPGCT score, Portal diameter) and serum-based models (AAR, APRI, FIB-4) [Figure 1C, 1D].

CONCLUSION

The proposed vHVPG provides a novel approach for predicting degree of portal hypertension noninvasively and might facilitate patient counseling, decision-making regarding individualized diagnosis and monitoring. Moreover, it is promising to serve as a surrogate measurement of HVPG when invasive procedure is not available.

CLINICAL RELEVANCE/APPLICATION

(Dealing with portal hypertension) The vHVPG could be used in non-invasive diagnosis of clinically significant portal hypertension and predicting risk of complications like variceal hemorrhage in patients with portal hypertension.

SSM08-03 Dual-Energy CT in Patients with Small HCC: Utility of Noise Reduced Monoenergetic Images on Detection of Wash Out and Image Quality in Delayed Phase

Wednesday, Nov. 29 3:20PM - 3:30PM Room: E353A

Participants
Megumi Matsuda, MD, Toon, Japan (*Presenter*) Nothing to Disclose
Takaharu Tsuda, MD, PhD, Toon, Japan (*Abstract Co-Author*) Nothing to Disclose
Hiroaki Tanaka, MD, Onsen-Gun, Japan (*Abstract Co-Author*) Nothing to Disclose
Teruhito Mochizuki, MD, Toon, Japan (*Abstract Co-Author*) Nothing to Disclose

METHOD AND MATERIALS

From April 2016 to March 2017, 20 patients with 33 small HCCs who underwent liver dynamic CT using dual-source dual-energy CT were enrolled. Delayed phase images were generated by 120-kVp-equivalent linear-blended and monoenergetic reconstructions at 40, 55 and 70 keV by standard monoenergetic reconstruction algorithm (sMERA: 40, 55, 70) and nMERA: 40+, 55+, 70+. As the objective analysis of image quality, liver-to-lesion contrast (CR), signal-to-noise ratio of the liver parenchyma and tumor (SNR liver, and SNR tumor), and contrast-to-noise ratio of the tumor (CNR) were calculated and compared. We selected 40+, 55+ and M120 images based on the results of earlier objective analysis, and two independent readers scored conspicuity of wash out in small HCC (tumor conspicuity) on 4-point scales and image quality on 5-point scales as the subjective analysis.

RESULTS

There was no significant difference between CR in nMERA and that in sMERA. At 40keV and 55keV, SNR liver, SNR tumor and CNR in the nMERA were significantly higher than those in the sMERA. The CR, SNR liver, SNR tumor, and CNR at 40+ image were significantly higher than those at other images except for 55+ image. There was no significant difference in these evaluation items between at 40+ image and at 55+ image. According to two observers, the scores of tumor conspicuity and image quality were greatest at 55+ image. The agreements of tumor conspicuity and image quality at 40+, 55+, and M120 images were good or

excellent between the two observers.

CONCLUSION

The 40+ and 55+ images can improve image quality and conspicuity of wash out in small HCC in the delayed phase, especially 55+ image may be most appropriate to detect the wash out of small HCC in delayed phase from the results of both objective and subjective analysis.

CLINICAL RELEVANCE/APPLICATION

The virtual monoenergetic images reconstructed with nMERA, especially 55+ image is useful to detect wash out of HCC in delayed phase.

SSM08-04 Assessment of Patient Size Cutoffs for Acceptable 80 kV And Mixed-kV Image Quality at Abdominal Volume-Mode 2-Rotation kV-mA Switching Dual Energy CT

Wednesday, Nov. 29 3:30PM - 3:40PM Room: E353A

PURPOSE

Volume-mode 2-rotation kV-mA Switching (V2S) Dual Energy CT (DECT) is a unique DECT technical solution available in 320-row scanners that utilizes 80 kV data. Our purpose was to determine patient size limits that result in unacceptable 80 kV and mixed-kV image quality with this technology (not yet investigated), so that the benefits of V2S DECT can be appropriately utilized.

METHOD AND MATERIALS

We retrospectively reviewed 4-phase V2S DECT abdominal scans reconstructed with 3mm slice thickness, noting patients' weight, body mass index (BMI), anteroposterior diameter (AP) and lateral width (LW). Three GI radiologists examined images in the middle of the liver, pancreas and kidneys, grading overall image quality (IQ) of 80 kV and mixed-kV datases (1=excellent to 5=severe degradation) and image artifacts/reader confidence (1=no artifacts/high confidence to 5= severe artifacts, nondiagnostic). Quantitative assessment of noise and enhancement-to-noise-ratio (ENR) in each organ and abdominal fat was completed. Patient sizes that resulted in unacceptable IQ rankings (i.e., >=4 by any of the 3 readers) were determined.

RESULTS

Forty patients were included. Mean IQ scores were not significantly different for different organs ($p > 0.054$). Difference of mean weight, LW and AP+LW between patients with acceptable and unacceptable IQ was statistically significant (p values of 0.227, 0.0018 and 0.0008), in contradistinction to the difference between BMIs (p=0.0749). There was no statistically significant difference between noise/ENR levels of patients with acceptable and unacceptable quality. Median patient sizes (weight, BMI, LW and AP+LW) that resulted in unacceptable image quality and artifacts were 86 kg, 28.1 kg/m2, 38.3 cm and 73.3 cm. Weight, LW and AP+LW cutoffs that resulted in unacceptable image quality were 74.9 kg, 35.9 cm and 65.9 cm. IQ of mixed-kV datasets was acceptable in all patients with unacceptable 80 kV IQ. Readers agreement was moderate (k=0.522).

CONCLUSION

In very large patients image noise and artifacts can render low kV images unacceptable. Knowledge of the cutoffs for each technology allows better patient selection for low kV and DECT.

CLINICAL RELEVANCE/APPLICATION

Knowledge of size cutoffs for acceptable IQ at 80 kV with V2S DECT allows for appropriate implementation of the low kV and DECT imaging performed with the tested technique.

SSM08-05 K-Edge Spectral Photon-Counting CT Using Dual Contrast Protocol for Peritoneal Cavity Imaging

PURPOSE

To assess the feasibility of using a prototype spectral photon-counting computed tomography (SPCCT) to explore the peritoneal cavity in rats using simultaneously two contrast agents within blood and peritoneal compartments.

METHOD AND MATERIALS

Approval from the animal ethics committee was obtained. SPCCT with multiple energy bins was performed in two sets of two adult rats using gadolinium intraperitoneal (IP) and iodine intravenous (IV) injections (Protocol A), and conversely (Protocol B). After the 10 minutes needed to perform IP injection, helical scans were performed to explore the abdomen and pelvis without and 30 and 60 seconds after injection. Delayed 3 minutes helical scans were then performed only on organs of interest (OOI), e.g. liver (standard parenchyma enhancement reference), kidney and bladder (contrast agents urinary clearance). Two radiologists performed in consensus a qualitative analysis on conventional CT and K-edge images using a peritoneal opacification index (POI) in 13 regions, as defined in the peritoneal cancer index (score=0 to 3 per region depending on the degree of opacification). Regions of interest were manually drawn on material decomposition iodine and gadolinium K-edge images in OOI for measuring the concentrations of contrast agents.

RESULTS

IP diffusion of both contrast agents was excellent with similar POI on conventional and peritoneal k-edge images of 36/39, 36/39 in protocol A, and 34/39, 37/39 in protocol B. K-edge images showed clear visual separation of the contrast agents with a good IV enhancement (POI of IV agents=0/39 in the 4 rats) and IP opacification. Quantitative analysis in OOI showed IV contrast agent enhancement in the liver (e.g 1.6±0.3mg/mL for iodine, 1.3±0.2 mg/mL for gadolinium at 30 seconds), and excretion in the renal pelvis (e.g 27.8±0.2mg/mL for iodine, 7.8±0.5mg/mL for gadolinium at 60 seconds). Progressive IP excretion of the contrast agents within the bladder was present, consistent with blood diffusion and renal excretion.

CONCLUSION

SPCCT can be used to perform a complete peritoneal dual contrast protocol using K-edge imaging which has potential to evaluate detection and tumoral response of peritoneal metastases.

CLINICAL RELEVANCE/APPLICATION

SPCCT with K-edge imaging is feasible using dual contrast agents within peritoneal and blood compartments allowing a good assessment of the peritoneal cavity in rats.

SSM08-06 Material Density Iodine Images in Dual-Energy CT: Detection and Characterization of Hypervascular Liver Lesions Compared to Magnetic Resonance Imaging

Wednesday, Nov. 29 3:50PM - 4:00PM Room: E353A

PURPOSE

To determine the diagnostic potential of Material Density (MD) iodine images in dual-energy CT (DECT) for the detection and characterization of hypervascular liver lesions, using MRI as reference standard.

METHOD AND MATERIALS

Fifty-two patients with 236 hypervascular liver lesions (benign, n=31; malignant, n=205; mean diameter, 29.4mm) were included. All of them underwent both contrast-enhanced DECT and contrast-enhanced abdominal MRI within three months. Late arterial phase CT imaging was performed with dual energies of 140 and 80 kVp. Protocol A showed monoenergetic 65 keV images, and protocol B presented MD-iodine images. Three radiologists independently evaluated randomized images, and lesion detection, characterization, and reader confidence were recorded. Liver to lesion contrast ratio (LLR) and contrast-to-noise ratio (CNR) were assessed. Paired t tests were used to compare LLR, CNR, and the number of detected lesions.

RESULTS

All three observers correctly identified more liver lesions using protocol B vs protocol A: 83.13% vs 63.64%, 84.57% vs 68.09%, and 79.37% vs 65.52%. There was no significant difference between the three observers in classification of a lesion as benign or malignant. LLR was significantly increased in protocol B (2.8±2.33) compared to protocol A (0.77±0.55) and MRI (0.61±0.66). CNR was significantly higher in protocol B (0.08±0.04) compared to protocol A (0.01±0.01) and MRI (0.01±0.01). However, higher diagnostic confidence was reported more frequently by the experienced radiologist when using protocol B vs protocol A (84.6% vs 75%).

CONCLUSION

MD iodine images obtained from dual-energy CT increase the conspicuity in the detection of hypervascular liver lesions with comparable diagnostic performance to MRI.

CLINICAL RELEVANCE/APPLICATION

MD iodine images in DECT improve detectability of hypervascular benign and malignant liver lesions. Improved diagnostic confidence with dual-energy CT can potentially help to reduce the number of additional diagnostic procedures.

SSM09-01 The Application Value of Spectral CT Low Dose Scanning Protocol Preoperatively Optimized for T Stage on Esophageal Cancer

Wednesday, Nov. 29 3:00PM - 3:10PM Room: E353B

Participants
Yue Zhou, Zhengzhou, China (*Presenter*) Nothing to Disclose
Jianbo Gao, MD, Zhengzhou, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the T stage for esophageal cancer using low dose spectral CT technique, and to discuss the diagnosed accuracy of T stage based on low dose scanning.

METHOD AND MATERIALS

Fifty-two patients with esophageal cancer confirmed by surgery or esophagoscopy randomly divided into two groups were enrolled in our study. Dual-phase chest CT enhancement was performed by using GE HD750 CT. Spectral CT were performed in study group with 350mgI/kg contrast medium injection, while control group underwent conventional 120KVp CT with 450mgI/kg contrast medium injection. Patients were divided into two sub-groups with A/C (FBP reconstruction) and B/D (ASIR). The SNRs, CNRs and subjective image quality score were calculated in four groups. Radiation dose were measured automatically in study group and control group. T stages were evaluated by a radiologist with 10 years experience of CT diagnosis.

RESULTS

The CNR and SNR in four groups showed significant difference ($P<0.05$). The SNR in group B was the highest, followed by group A, group C was the lowest. The overall image quality score and anatomy detailed score among four groups exhibited significant difference ($P<0.05$). Group B was the highest while group C was the lowest. The sensitivity and accuracy in study group (A and B) in terms of T1/2 stage were higher than control group (C and D). With regard to T3, the sensitivity and specificity in study group (A and B) were higher than control group (C and D). The accuracy in diagnosis of T4 between study group and control group were similar.

CONCLUSION

Low dose spectral CT scanning optimized the image quality for chest CT enhancement and reduced the radiation and contrast medium dose. Compared to conventional CT, low dose spectral scanning promoted the differential diagnosis between T1/2 and T3, and improved the sensitivity and specificity in differential diagnosis between T1/2 and T3.

CLINICAL RELEVANCE/APPLICATION

Low dose spectral CT scanning reduced the contrast medium and radiation dose, and improved the sensitivity and specificity in differential diagnosis between T1/2 and T3 for esophageal cancer.

SSM09-03 Fractal Dimension Analysis of Glucose Metabolism in Esophageal Cancer by FDG-PET: Correlation between the Quantitative Evaluation of Tumor Heterogeneity and Malignancy

Wednesday, Nov. 29 3:20PM - 3:30PM Room: E353B

tochigi819@gmail.com

PURPOSE

Intratumoral heterogeneity is a well-recognized characteristics of cancer. The purpose of this study is to assess the heterogeneity

of the intratumoral glucose metabolism using fractal analysis, and evaluate its prognostic value in patients with esophageal squamous cell carcinoma (ESCC).

METHOD AND MATERIALS

18F-fluorodeoxyglucose positron emission tomography (FDG-PET) was performed in 125 consecutive patients with ESCC. FDG-PET images were analyzed using a fractal analysis software, where differential box-counting method was employed to calculate the fractal dimension (FD) of the tumor lesion. Maximum standardized uptake value (SUVmax) and FD were compared with overall survival (OS).

RESULTS

The median FD was 1.97 (range, 1.7941 -2.0359). The survival curve was analyzed using the median FD as the cutoff value. The survival rate in the high-FD group was significantly better than that in the low-FD group as determined by the Kaplan-Meier method (P = 0.0029). In the multivariate survival analysis, the FD was identified as an independent prognostic factor for the overall survival (<0.0001). Furthermore, we analyzed the overall survival rate in the patients who were treated with surgery alone and with neoadjuvant chemotherapy. The Kaplan-Meier analysis of this data also showed that the high-FD group had a significantly better survival than did the low-FD group (P = 0.0011, P = 0.0177)

CONCLUSION

Metabolic heterogeneity measured by fractal analysis can be a novel imaging biomarker for survival in patients with ESCC.

CLINICAL RELEVANCE/APPLICATION

The preoperative tumor metabolic heterogeneity was a useful biomarker for OS of patients with ESCC, and was independent of clinical markers such as TNM-staging.

SSM09-05 MRI of the Gastric Antrum for the Quantification of Gastric Motility: Comparison between Obese and Normal Weight Patients

simona.picchia@gmail.com

PURPOSE

To compare differences in gastric motility between obese and normal weight patients with MRI.

METHOD AND MATERIALS

Motility antral scans were obtained by Magnetic Resonance Imaging (MRI) after a liquid meal: patients drunk 650-ml standardized liquid meal over 10 min (Nutridrink) plus two egg yolks and one albumen and 150 ml of water. This 525-kcal meal was composed of 25% fat, 25% protein, and 50% carbohydrate. Imaging was performed on a 1.5-Tesla system. CineMRI for motility analysis was performed using a coronal and axial 2DtrueFISP. Images have been acquired before (T0), immediately after the end of the meal assumption (T1) and every 20 minutes (T2-T5), for a total exam time of 100 minutes. Each gastric motility scan lasted 60 seconds, with 100 images acquired in free breathing. Images have been evaluated on a dedicated software. Two measurements were evaluated. The distal antral contraction waves (ACWs) and the antral diameter. The ACWs were measured as the distance between the proximal and distal border of a segmental contraction of the distal antrum. The antral diameter was measured at the level of the measured ACWs. The measurement lines have been propagated into the next image of the MRI sequence, and the newly detected distance registered. This process has been repeated for every single image of the cine sequence. The temporal changes of the antrum diameter and ACWs over time have been plotted on a graph thus displaying gastric motility frequencies and magnitude. Results obtained in obese and normal weight patints were compared.

RESULTS

Twenty patients were included in the study (10 obese and 10 normal weight). Motility antral scans in obese antrum showed that, during fasting and in the late-postprandial period of a liquid meal, the length of the antrum was significantly shorter with lower maximal contraction amplitude and frequency.

CONCLUSION

MRI is able to identify differences in antral motility between obese and normal weight patients.

CLINICAL RELEVANCE/APPLICATION

This study confirmed the presence of antral motility disfunction in obese patients. These results can be correlated with the previously published in vitro evidence that in antral smooth muscle of obese patients the alteration in VIP pathway occurs, suggesting that smooth muscle might represent a new therapeutical targets in gastrointestinal motility disorders.

SSM09-06 Imaging Assessment of Lauren Classification for Gastric Cancer Using a Non-Gaussian Fractional Order Calculus Diffusion Model

mkaraman@uic.edu

PURPOSE

To evaluate the performance of a new set of parameters (*D*, *ß*, and *μ*) from a fractional order calculus (FROC) diffusion model for imaging assessment of Lauren classification in gastric cancer.

METHOD AND MATERIALS

With IRB approval, 41 patients (12 females and 29 males) with gastric cancer underwent MRI scans at 1.5T. Surgical specimens were obtained for pathology analysis to determine the cancer type according to Lauren classification, resulting in 10 patients with diffuse type, 23 with intestinal type, and 8 with mix type. For the statistical analysis, the diffuse and mix types were combined as mixed-and-diffuse type (MDT) to be differentiated from the intestinal type (IT). The MRI protocol included T1-weighted (VIBE), T2-weighted (turbo spin echo with respiratory-trigger), and diffusion-weighted imaging with 11 *b*-values (0 to 2000 s/mm2). Three parameters of the FROC model, diffusion coefficient *D*, fractional order parameter *ß* (which correlates with intra-voxel tissue heterogeneity), and a microstructural quantity *μ* were estimated from the diffusion data. The mean values of FROC parameters over the tumor regions of interest were computed. Receiver operating characteristic (ROC) analysis was then performed to assess the performance of FROC model for gastric cancer type differentiation. The combination of FROC parameters (*D*, *ß*, *μ*) were compared to using only *D*, which is equivalent to apparent diffusion coefficient.

RESULTS

A significant difference between MDT and IT were observed in the combination of *D*, *ß*, and *μ* with a p-value < 0.05. The combination of FROC parameters also produced a better accuracy (74.3% vs. 69%), specificity (73.9% vs. 56%), and area under the curve (78.5% vs. 65.2%) than using *D* alone, while providing a comparable sensitivity (75% vs. 78.2%).

CONCLUSION

The combined FROC parameters (*D*, *ß*, *μ*) outperformed *D* in non-invasive imaging assessment of Lauren classification for gastric cancer.

CLINICAL RELEVANCE/APPLICATION

The combined FROC parameters (*D*, *ß*, *μ*) perform better than using diffusion coefficient alone for imaging assessment of Lauren classification in patients with gastric cancer.

darioderosa18@gmail.com

PURPOSE

This study evaluated the role of contrast-enhanced ultrasound CEUS in the secondary prevention of testicular tumours.

METHOD AND MATERIALS

Forty patients (median age 25 years, range 18-36 yrs) with a focal testicular lesion underwent B-mode ultrasound (US), Doppler and CEUS.Then all patients underwent orchiectomy and the histological exam of the mass was performed.Histological features and ultrasound images were recorded and compared for each patient.

RESULTS

The medium diameter of the lesions was 12 mm (range 3- 29 mm). 30 of 50 patients had malignant tumours (75%), 5 had benign tumours (12,5%) and 5 non-neoplastic lesions (12,5%).B-mode US detected neoplastic characteristics only in 9 of the 35 tumoural lesions; with color-Doppler techniques in 10 of 35 tumours was found intralesional hypervascularization (B-mode and color-Doppler US findings suggestive of neoplastic disease were irregular margins and internal hypervascularization).On qualitative CEUS evaluation 34 of the 35 neoplastic lesions showed intense enhancement; on quantitative CEUS all tumours showed different kinetics from the surrounding parenchyma, according to a rapid wash in and wash out for malignant tumours and rapid wash-in but delayed wash-out for benign tumours (CEUS findings suggestive of neoplastic disease were intense enhancement of contrast, rapidity of wash-in and wash-out and peak characteristics).

CONCLUSION

In this study, we confirmed the CEUS high accuracy in the differentiation between malignant and benign small lesions and its utility in the early diagnosis of testicular cancer.Conventional US revealed in all patients the presence of a solid testicular mass and color-Doppler revealed presence of increased blood flow signal, but in small testicular tumours it did not show vascularization and only CEUS was able to do a differential dignosis.Using CEUS, the temporal perfusion dynamics of the contrast enhancement help in the differentiation between malignant and benign tumours; the intensity of contrast enhancement helps in the differentiation between neoplastic and non-neoplastic lesions.Therefore, CEUS is useful in the secondary prevention of small testicular masses with an ambiguous color-Doppler pattern and permits, rapidly and without damage, to predict the lesion nature.

CLINICAL RELEVANCE/APPLICATION

CEUS can add relevant information for surgical decision making in small testicular lesions.

SSM10-02 Utility of Ultrasound Elastography (Acoustic Radiation Force Impulse Imaging) in Differentiating Ovarian Endometriomas from Hemorrhagic Ovarian Cysts; In Correlation with Histopathology

PURPOSE

To study the usefulness of ARFI in the differentiation of ovarian endometriomas and hemorrhagic ovarian cysts.

METHOD AND MATERIALS

It is a prospective observational study conducted in the department of radiodiagnosis of our institution from january to december 2016. The study population consisted of 35 women(n=40, 5 women with bilateral lesions) of reproductive age group (20-45 y) presenting to the department of radiodiagnosis with unilateral or bilateral adnexal cystic lesions with homogenous internal echoes, diagnosed by grey scale ultrasound.Cystic lesions with mural nodules/solid components/ internal vascularity were excluded from the study. Measurements were performed with SIEMENS ACUSON S 2000 ultrasound system enabled with virtual touch quantification software.Grayscale ultrasound with full bladder was performed on all the patients to clearly define the pelvic anatomy and the lesion position. The lesion was identified and a region of interest (1x0.5cm box within the lesion) within the lesion was selected. The stiffness was measured well within the capsule of the lesion. Five succesful measurements were taken for ARFI shear wave velocity, measured in meters per second and the median value was calculated.Histopathology results, post surgery were obtained for all the 40 lesions and correlated with the SWV values.

RESULTS

Ultrasound elastography (ARFI)was performed on all the 40 lesions and the median shear wave velocities(SWV) were calculated.The definitive diagnosis was made by post operative histopathological examination results and the SWV values were correlated. Out of the 40 cystic lesions, 23 lesions were endometriomas and 17 lesions were hemorrhagic cysts. All the lesions histopathologically proven as endometriomas had higher SWV values compared to those proven as hemorrhagic ovarian cysts.A cut-off value of 2.85m/s was established, concluding the lesions with SWV values above 2.85m/s were more likely to be endometriomas and those below 2.85m/s were more likely to be hemorrhagic cysts with a sensitivity and specificity of 94% and 100% respectively.

CONCLUSION

ARFI imaging is a feasible technique for pre-operative discrimination of ovarian endometriomas and hemorrhagic ovarian cysts.

CLINICAL RELEVANCE/APPLICATION

With the use of this modality clear preoperative diagnosis of the two lesions can be established and the existing diagnostic dilemma leading to unnecessary surgeries can be avoided.

SSM10-03 Quantitative Shear-Wave Elastography of the Testicle: Normal Values and Assessment of the Common Pathological Conditions on a Large Cohort

Wednesday, Nov. 29 3:20PM - 3:30PM Room: E351

Participants

catherine.roy@chru-strasbourg.fr

PURPOSE

Shear wave elastography (SWE) is the last development in ultrasonic assessment of the tissue elasticity. Our aim was to evaluate the values of the stiffness in normal parenchyma and in common pathologies in order to determine a threshold value for diagnosis.

METHOD AND MATERIALS

This prospective study recorded 235 patients (mean age 43.2±17.2 years, range 17-90) using a Toshiba AplioTM 500 (Toshiba Medical Systems, Japan).Young modulus(YM) values were recorded by mean of a circular ROI over the color map. The cohort was divided into two groups according the grey scale aspect : a normal group of 110 patients with 902 values (67 bilateral, 43 unilateral+125controlateral -3 localizations (superior, mid , inferior) - including microlithiasis and hydrocele) and a pathological group of 125 patients with 375 values (87 lesions up to 5mm, 38 diffuse abnormalities). Final diagnosis was done by clinical findings, follow up or histological analysis. For statistical analysis a Mann-Whitney test was used and the optimal cut off value was calculated from the ROC curves analysis. A P value below 0.05 was considered as significant.

RESULTS

The YM values of free lesion testicle was 4.56±1.53kPa, median = 3.85kPa.There was no significant difference concerning the side, the localization, the presence of hydrocele or stage I or II microlithiasis. There was a significant higher mean value stiffness with age (>60 years: 4.97kPa; p<0.001), stage III microlithiasis (6.27kPa; p<0.001) and in case of contralateral tumor (5.60kPa; p<0.001). The stiffness values and cut off thresholds were for tumors (n= 48, mean = 21.31±7.01kPa, median =19.60kPa , p<0.001) and 16.1kPa(Se= 0.82 - CI95[0.48-0.98], Sp= 0.81 kPaCI95[0.74-0.86], AUC= 0.881), orchitis (n=43, mean = 9.48±3.91kPa, median =6.65kPa, p<0.001) and 5.7kPa (Se= 0.63 - CI95[0.49-0.76], Sp= 0.77 - CI95[0.70-0.83], AUC=0.764) and fibrosis (n=34, mean = 31.55±9.08kPa, median =25.20kPa, p<0.001) and 26.3kPa (Se= 0.82 - CI95[0.63-0.94], Sp= 0.85 -

CI95[0.79-0.90], AUC= 0.872), respectively. By analyzing the distributions between the different pathologies, the difference was statistically significant between orchitis and fibrosis (p= 0.002) and tumors and fibrosis (p<0.001).

CONCLUSION

SWE is a complementary tool to differentiate fibrosis from a tumoral process.

CLINICAL RELEVANCE/APPLICATION

Quantitative SWE is an efficient mean to differentiate a fibrous tissue from a tumoral process on a localized gray scale lesion.

SSM10-04 Clinical Significance of the Slope of the Increasing Pressure Curve When Injecting Ultrasound Contrast Agent during the Evaluation of the Fallopian Tubal Patency

Wednesday, Nov. 29 3:30PM - 3:40PM Room: E351

Participants
Ye Qiang, Nanjing, China (*Presenter*) Nothing to Disclose
Yiyun Wu, Nanjing, China (*Abstract Co-Author*) Nothing to Disclose
Meimei Zhang, Nanjing, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

13913306601@139.com

PURPOSE

To explore the association between Fallopian tubal patency and the slope of the increasing pressure curve for ultrasound contrast agent.

METHOD AND MATERIALS

A total of 145 patients underwent hysterosalpingo contrast sonography (HyCoSy) between August 2015 and January 2016. HyCoSy was performed with the Voluson E8 ultrasound system (GE Healthcare, Zipf, Austria) equipped with an RIC5-9-D probe. The ultrasound contrast agent was injected and the pressure curve was recorded with a liquid-injecting machine (YLD YZ-800, Yi Lida Corp., Zhu Hai, China) that records the injection pressure in real time and automatically traces it as a pressure curve. We used SonoVue (Bracco International BV, Amsterdam, The Netherlands) as the ultrasound contrast medium. The statistical analysis was performed with SPSS Statistics, version 19 (IBM, Chicago, USA), and $P < 0.05$ was deemed statistically significant.

RESULTS

We divided the patients into three groups according to their different Fallopian tubal patency status: 71 patients (48.97%) in bilateral tubal patency group, 45 (31.03%) in unilateral tubal patency group (one side patent, and the other either passable or occluded), and 20 in bilateral tubal lesion group (both sides passable or occluded). The slopes of the increasing pressure curves for the three groups were 1.242 ± 0.572, 1.472 ± 0.638 and 2.068 ± 1.236 kpa/s, respectively. There was some correlation between the slope of the increasing pressure curve and tubal patency ($R = 0.287$, $P < 0.05$). The slopes differed significantly between the bilateral tubal patency group and the bilateral tubal lesion group ($P < 0.05$) and between the unilateral tubal patency group and the bilateral tubal lesion group ($P < 0.05$). However, the difference between the bilateral tubal patency group and the unilateral tubal patency group was not significant ($P > 0.05$).

CONCLUSION

The slope of the curve tracing the increase in the pressure of the injected contrast agent during HyCoSy is associated with the tubal patency.

CLINICAL RELEVANCE/APPLICATION

Therefore, it can be used as an objective index of tubal patency, and should have utility in both diagnosis and treatment.

SSM10-05 Vasectomy Related Changes in the Scrotum on Ultrasound

Wednesday, Nov. 29 3:40PM - 3:50PM Room: E351

Participants
Pramod K. Gupta, MD, Plano, TX (*Presenter*) Nothing to Disclose
Ann M. Mottershaw, MD, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose
Vidisha V. Ghole, MD, Irving, TX (*Abstract Co-Author*) Nothing to Disclose

pramod.gupta@va.gov

PURPOSE

-Vasectomy is a popular method of male contraception, so that a signification proportion of men referred for scrotal sonography will have had a vasectomy. -The purpose of our study is to evaluate the sonographic changes in the scrotum after vasectomy and compare them with the sonographic appearance of non vasectomy patients.

METHOD AND MATERIALS

We performed a comparative study of 75 patients with a history of vasectomy and 75 patients without this history who were referred for scrotal sonography for various indications. Ultrasound findings in these two groups were tabulated and compared.

RESULTS

Certain ultrasonographic findings were more commonly observed in the patients with vasectomy than in non-vasectomy patients. These findings were:Thickened epididymides (41% versus 2%), Tubular ectasia of epididymis(57% versus 4%), both thickened epididymides and epididymal tubular ectasia together (36% versus 2%), sperm granulomas (21% versus 2%), tubular ectasia of rete

testis (29% versus 7%), mediastinal cysts (15% versus 4%), medial rotation of the testis in the scrotal sac which is determined by location of testis-epididymis complex (33% versus 3%). No significant difference was found in the incidence of epididymal cysts, varicoceles and hydroceles in the vasectomy and non vasectomy groups.

CONCLUSION

There was significantly higher incidence of thickened epididymides, epididymal tubular ectasia, sperm granulomas, tubular ectasia of rete testis and mediastinal cysts in the post vasectomy patients as compared to non vasectomy patients. These changes most likely occur due to postvasectomy obstruction, sperm statis and increased intraluminal pressure in the efferent ducts, epididymis and vas deferens. Medial rotation of the testis in the scrotal sac was also more common in the vasectomy group, which is likely due to iatrogenic changes in the structural support mechanism of the testis with resultant increased mobility of the testis within the scrotum.

CLINICAL RELEVANCE/APPLICATION

Familiarity with common ultrasound findings in vasectomy patients may help suggest post vasectomy status when history is not provided and in some cases may help avoid unnecessary intervention.

SSM10-06 Transvaginal Ultrasound (TVUS) Shear Wave Elastography (SWE) for the Evaluation of Benign Uterine Pathologies

PURPOSE

To evaluate myometrial stiffness using TVUS SWE in women with benign myometrial pathologies including adenomyosis and leiomyoma vs. normal myometrium, using pelvic MR as the reference standard.

METHOD AND MATERIALS

Between January 2015 to June 2016, premenopausal women without a history of gynecologic malignancy presenting with pelvic pain and/or bleeding were enrolled in this IRB-approved prospective study. TVUS was performed in SWE mode with multiple regions of interest (ROIs) (>=1 cm2) in the uterus. Multiple shear wave velocities (SWVs) were recorded in each location and averaged. Reference pelvic MR exams were performed with multiplanar T2WI, and T1WI pre and post IV gadolinium administration . MR exams were reviewed in consensus by two radiologists blinded to the US findings, and the presence or absence of adenomyosis and/or leiomyomata was assessed using published criteria. US images were reviewed in consensus by two different radiologists and SWV for each ROI tabulated by anatomic area. Continuous variables were analyzed using means, t-tests and ANOVA, assuming $p < 0.05$ for statistical significance.

RESULTS

34 premenopausal women (mean age 36.8 years, range 22-52) were enrolled with mean time between US and MR 11 days (±27, range 0-118). MR diagnosed adenomyosis in 6 women involving 12 uterine locations, and leiomyomata in 12 women involving 28 uterine locations. Mean SWV in 16 women with normal myometrium was 4.3 m/s (±1.7, range 1.8-9.4), compared with 5.7 m/s (±2.3, range 1.7-9.9) in 18 women with adenomyosis or leiomyomata ($p < 0.0002$, 95% CI of difference -2.2, -0.6).

CONCLUSION

Our pilot study demonstrated that myometrial SWVs were higher in women with adenomyosis or leiomyomata than in women with normal myometrium ($p < 0.0002$), indicating increased tissue stiffness associated with common benign myometrial diseases.

CLINICAL RELEVANCE/APPLICATION

Because women with benign myometrial conditions have increased myometrial stiffness, quantitative ultrasound SWE may be helpful in diagnosis and treatment response assessment for these disorders.

PURPOSE

The purpose of this study was to assess the diagnostic yield of abdomen magnetic resonance imaging (MRI) in the inpatient setting following computed tomography (CT).

METHOD AND MATERIALS

All inpatient abdominopelvic MRIs performed on patients from October 1, 2014 to September 30, 2015 were identified and medical records were retrospectively reviewed for the following information: clinical impact of MRI on patient care and length of stay (LOS). Only MRIs with a preceding CT were included in the study.

RESULTS

A total of 221 MRIs were included. Forty exams were deemed technically inadequate due to motion while 9 more patients did not tolerate a full examination. The most common indications were focal liver lesion (n=101), pancreaticobiliary ductal dilatation (n=39), abnormal liver function tests (n=26), acute pancreatitis (n=14), abdominal pain (n=10) and fever/sepsis (n=9). Eighty-three (38%) MRI exams were recommended on CT and 138 (62%) were requests from the care team. In 63 (29%) cases, MRI offered new information over CT. Thirty-two MRIs recommended by radiologists affected patient management whereas only 31 MRIs (23%; p = .010) recommended by the care team affected management. Twenty-nine of these cases changed immediate inpatient management, requiring further intervention (IR drainage, ERCP or surgery) or changing medical therapy. MRI identified abscesses (n=17), choledocholithiasis (n=8) or confirmed cholecystitis (n=2), which were not confidently diagnosed on CT. Patient LOS increased in 24 patients in order to receive an MRI. The average scan time for inpatient MRI was 57 minutes compared to 35 minutes for an outpatient MRI.

CONCLUSION

Inpatient abdomen MRIs have limited impact on patient care following a CECT while they entail higher scan time, utilize more resources and increase patient LOS. Therefore, it is prudent to reserve MRI exams for select clinical indications in consultation with a subspecialty radiologist, allowing other exams to be performed on an outpatient basis, to maximize its value.

CLINICAL RELEVANCE/APPLICATION

In a climate of rising healthcare costs, we must be mindful when utilizing scarce resources, particularly abdominopelvic MRI, which may only be necessary in select indications.

SSM11-02 Diagnostic Performance of MRI for Differentiation of Papillary Renal Cell Carcinoma versus Non-Papillary Renal Tumors: A Systematic Review and Meta-analysis

Wednesday, Nov. 29 3:10PM - 3:20PM Room: S104B

Awards
Student Travel Stipend Award

Participants
Matthew Chiarello, MD, New York, NY (*Presenter*) Nothing to Disclose
Stella Kang, MD,MSc, New York, NY (*Abstract Co-Author*) Author, Wolters Kluwer nv

For information about this presentation, contact:

stella.kang@nyumc.org

PURPOSE

To perform a systematic review and meta-analysis of the performance of MRI in differentiation of papillary-type renal cell carcinoma (RCC) from non-papillary renal tumors.

METHOD AND MATERIALS

We performed searches of three electronic databases from January 2000 through March 2017 for studies that utilized MRI techniques to differentiate papillary RCC from other renal lesions. Methodologic quality was assessed to identify potential sources of bias using QUADAS-2. Diagnostic performance was summarized quantitatively using bivariate random-effects modeling.

RESULTS

12 studies involving 1,382 patients and 343 papillary RCC lesions met inclusion criteria. The overall quality of studies was moderate. Six studies using relative tumor enhancement for papillary RCC prediction were pooled quantitatively, with overall sensitivity of 79.3% (95% CI, 62-90%) and specificity of 91.3% (95% CI,76.4-97.1%). All six studies used comparator groups of clear cell RCC and oncocytic tumors. These studies' performance characteristics demonstrated a threshold effect (rho = -0.5), supporting a tradeoff in sensitivity for specificity among the chosen quantitative enhancement thresholds, and therefore representation along a summary receiver operator characteristic (ROC) curve. The area under the summary ROC curve was 0.85. Inclusion of tumor T2 characteristics increased specificity from 84% to 95.6%. Three studies used signal loss on in-phase imaging to predict papillary RCC but marked statistical heterogeneity precluded pooling. There were less than 3 studies focused solely on use of tumor T2 signal characteristics compared with renal cortex or diffusion weighted imaging for papillary RCC prediction.

CONCLUSION

Meta-analysis supports moderate sensitivity and excellent specificity of tumor enhancement for differentiation of papillary RCC versus non-papillary renal tumors and further, prospective study of test accuracy may be warranted. The apparent heterogeneity in test performance among studies is accounted for in part by a tradeoff in sensitivity for specificity among the different enhancement thresholds selected for test positivity. Though requiring further study, inclusion of T2 signal characteristics of the renal tumor may further improve specificity.

CLINICAL RELEVANCE/APPLICATION

The high specificity of contrast-enhanced MRI for detection of papillary RCC among renal tumors may be useful in candidate selection for watchful waiting, given the general indolence of this tumor subtype.

SSM11-03 Piradsv2: Correlation with Clinical Risk Scores and Implications for Risk Stratification

PURPOSE

The aim of this study was to assess the relationship between PIRADSv2 scores and clinical risk scores in patients with prostate cancer and thus evaluate the potential role of the PIRADS score in risk stratification.

METHOD AND MATERIALS

Two hundred patients with suspected prostate cancer were included in this retrospective study. Patient age varied between 41 and 82y (66y on average). The mean prostate-specific antigen level (± SD) at the time of the biopsy was 10.52 ± 9.0 ng/ml. All patients underwent multiparametric prostate MRI (mpMRI) at 3T. The PIRADSv2 scoring system was used for MRI lesion classification. All patients underwent MRI/ultrasound fusion-guided biopsy. Based on the biopsy results and additional parameters (PSA value, clinical stage, count of positive biopsy punches etc.) the following clinical risk scores were calculated for each patient: D'Amico score, UCSF-CAPRA score and Epstein Criteria. The relationship between the maximum PIRADS score and the clinical risk scores was analyzed using a logistic regression model and Tukey's range test as a post-hoc test.

RESULTS

The highest PIRADS score was 5 in 35/200 patients, 4 in 62/200 patients, 3 in 66/200 patients and 2 in 27/200 cases. In 10/200 patients no lesions could be identified based on MRI. PIRADS scores of 5 ($p < 0.001$) and 4 ($p < 0.01$) were shown to be significant predictors for all three clinical risk scores, while maximum PIRADS scores of 1, 2 or 3 were not significant predictors. Patients with a PIRADS score of 5 had significantly higher clinical risk scores than patients with a maximum PIRADS of 1, 2 or 3 (D`Amico: $p < 0.001$; UCSF-CAPRA: $p < 0.001$; Epstein: $p < 0.001$), while there was no significant difference between PIRADS 4 and lower maximum PIRADS scores. Among patients with PIRADS 5, the percentage of high-risk cases was 86.3% according to the D'Amico score, 90.2% according to UCSF-CAPRA and 94.1% according to the Epstein Criteria.

CONCLUSION

A PIRADS score of 5 is a significant predictor for the three evaluated clinical risk scores. A PIRADS score of 5 is associated with significantly higher clinical risk scores than maximum PIRADS 1, 2 or 3. Patients with a PIRADS score of 5 include a large precentage of high-risk prostate cancer cases.

CLINICAL RELEVANCE/APPLICATION

The results imply that a PIRADS score of 5 can help identify high-risk prostate cancer cases even before the tumor is confirmed by biopsy.

SSM11-04 MRI Orders Prioritization and Associated Effects on Appropriate Utilization of MRI at a Large Public Hospital

atrofim@emory.edu

PURPOSE

To determine changes in MRI order prioritization and downstream effects on appropriate utilization of MRI at a large public hospital from 2012 to 2015.

METHOD AND MATERIALS

Retrospective IRB approved study of MRI exams (MRIs) performed at a large public hospital from 2012 to 2015. The following parameters were analyzed: total number of MRIs; number of STAT and routine MRIs; type of MRI exams; ordering hospital services; mean total turnaround time (MTAT) for different MRIs per month; for MRIs performed in 2015 - per the day of the week and time of the day when the order was placed. The analyzed data were used to develop an on-line survey distributed to ordering providers to assess their knowledge of the order priority policy and evaluate factors which contribute to decision making in prioritization of MRI orders.

RESULTS

From 2012 to 2015 the total number of MRIs have increased by 35% reaching 10921 in 2015. STAT MRIs increased by 76%, routine MRIs increased by 12%. STAT MRIs increased by 72% for outpatients, 132% for inpatients and decreased by 35% for ER patients. MRI of the brain, lumbar spine and head/neck MRA represented 58% of all MRIs scans. The total number of brain MRIs increased by 38%, STAT brain MRIs increased by 82%, routine brain MRIs increased by 2%. 5 out of 89 hospital services ordered 70% of brain MRIs and 70% of those were ordered STAT. In 2015 MTAT for STAT brain MRI was 52% higher than for routine orders. MTAT is significantly affected by month of the year for STAT brain MRI, for routine brain MRIs MTAT is significantly higher for orders placed on Sunday and from 7 pm till 8 am. 97 providers (36% faculty; 64% trainees) completed the survey. Only 4% of responders were familiar with the timing of the STAT MRI order per hospital policy with significant difference as a function of specialty and level of training. Prevalent expectations for time to complete STAT MRI was "same day" for ER and inpatient and "2-3 days" for outpatient MRI orders.

CONCLUSION

Misuse of order priority system leads to disproportionate increase in STAT MRI orders with STAT brain MRI total turnaround time being 52% higher than routine brain MRI.

CLINICAL RELEVANCE/APPLICATION

Inappropriate MRI order prioritization significantly affects diagnostic imaging resources utilization and decreases quality of patient care by increasing turnaround time when STAT MRI is indicated.

SSM11-05 Improvement of Provider and Patient Satisfaction in a Large Outpatient Imaging Practice Following Practice-Wide Implementation of a Structured Service-Excellence Training Program

Wednesday, Nov. 29 3:40PM - 3:50PM Room: S104B

Participants
Monica Salama, Houston, TX (*Abstract Co-Author*) Nothing to Disclose
Joseph R. Steele Jr, MD, Houston, TX (*Abstract Co-Author*) Consultant, Adient Medical Inc; Stockholder, Adient Medical Inc;
Habib Tannir, MS, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

Low patient satisfaction scores and the need to improve upon referrals prompted us to address the experience we were providing. The implementation of our Service Excellence Academy (SEA) has already led to measurable improvement in our scores, increased

collaboration and positively charged our work environment.

METHOD AND MATERIALS

Informal interviews with providers showed they believed they were providing excellent service, but Press-Ganey scores showed patients did not always perceive the service as excellent. To improve providers' understanding of what patients and family members consider excellent service and thereby improve patient satisfaction, we created the SEA by evaluating best practices of service leaders across industries, and applying the strategies to our culture and healthcare setting. This ten-hour, three-module program was designed as an interactive discussion, leveraging clinical examples and role-playing. Sessions were led by one content expert and a member of leadership. The involvement of the leadership connected real examples and demonstrated their commitment to the culture shift.

RESULTS

Since launching the SEA in 2015, we have seen our outpatient survey scores stabilize, rise and recover from outside influences. All metrics show percentile improvement ranging from 9% to 34%. We are also using our employee survey as a benchmark to establish if we have affected the environment we create for ourselves. Finally, we collected feedback before, during and after the sessions to validate the engagement and buy-in of the participants. Participants felt a greater connection with the institutional culture, were more comfortable making decisions, felt more empowered and had developed greater empathy and skills to meet the needs of others.

CONCLUSION

Large scale training of providers and staff is possible and effective. Implementation of the SEA demonstrated both objective and subjective improvement of the patient and employee satisfaction. We have implemented strategies to build upon relationships and empowered our team members to make this a living part of our culture that continues to adapt, grow and improve our outcomes. This program is now being adapted for institutional implementation.

CLINICAL RELEVANCE/APPLICATION

Open lines of communication create an environment where colleagues are more inclined to consult on challenging cases, or proactively discuss options before ordering, resulting in better outcomes.

PURPOSE

The Medicare Access and CHIP Reauthorization Act (MACRA) of 2015 revised the system used by the Centers for Medicare and Medicaid Services (CMS) to pay physicians for care provided to Medicare patients [1]. The Quality Payment Program (QPP), created by MACRA, is intended to incentivize providers to deliver care that increases value and improves quality and/or lowers cost [2]. The QPP specifies four performance categories, each containing various numbers of required measures. Performance above a threshold will result in a bonus payment. Poor performance, or non-participation, will result in payment deductions, with these payment changes beginning in 2019. The program is intended to be budget neutral, meaning that the penalties fund the bonuses. Our radiology group, consisting of locally-led practices with over 350 radiologists serving more than 260 sites in nine states, developed a comprehensive, robust, and adaptable program to manage performance on these measures. The size of our practice provided both challenges and opportunities. The practice has the scale to invest in resources to optimize our performance, but simultaneously the large and multi-centric nature of our practice makes coordination more challenging. The primary goal of our program is to support our broader practice mission of enhancing value for healthcare systems and improving patient care. This is done alongside the financial incentives created by MACRA and the QPP. This presentation describes our approach and the development of our MACRA program.

RESULTS

For each practice, the above questions were answered and a spreadsheet was created (Figure). The figure lists several of our sites, as well as the pace they are reporting at, their patient-facing status, and which measures in the four performance categories they are reporting. Note that we are only reporting on Quality and Improvement Activity measures. Since no practice (radiology or otherwise) has to manually report Cost data, no requirements for this performance category were included. Additionally, since all of our practices are considered non-patient-facing, which has a reduced reporting burden including exclusion from the fourth performance category, Advancing Care Information, no measures here are reported.

CONCLUSION

We have described a comprehensive program for management of the Quality Payment Program created by MACRA, and the various measures required of physicians who provide services to Medicare patients. As the financial implications of the QPP are substantial, starting with a +/- swing of four percent in 2019 and quickly escalating, medical practices serving Medicare patients must have a robust program to manage the complex system with its numerous and still evolving variables. In addition, the intuition behind MACRA, that is payment for better and more value-based care, supports our broader practice goals of enhancing value and improving patient care.

METHODS

Our process has three main components. First, we created a diversified team to develop and manage our MACRA program. Second, we reviewed the necessary decisions and then determined how to best match the reporting requirements with the goals of our

program and our practice strengths. Finally, we established an education program along with performance tracking to ensure optimal and consistent achievement of the desired measures. We initially created a multi-disciplinary team to develop and manage our MACRA program. The team is led by the chief revenue officer, someone with extensive experience in healthcare revenue cycle management. The other members of the team include physicians, support analysts, billing and coding specialists, and information technology (IT) personnel. Another skillset, which was provided by the physician liaisons, was societal and policy affairs expertise. This was felt to be crucial as our practice recognizes the importance of working in conjunction with the American College of Radiology. The team then set about determining the key questions and answering them. This includes: 1) Will each practice report as patient-facing or non-patient-facing? 2) Should the local sites report as a group or as individuals? 3) Which measures should each site report on? 4) How will the measures be reported (claims or registry)? 5) What pace should each local practice choose to report at? Each of these five questions had to be answered for every local practice. We then developed an educational program for our radiologists. This was composed of three live web-based seminars, group emails, and posts on our internal practice website. Radiologists were given opportunities to ask questions, raise concerns, and make suggestions. After education, we began tracking performance through use of analysts and IT solutions. We provide monthly feedback to the practices on their performance in the form of a scorecard.

PURPOSE

Manual contouring remains the most laborious task in radiation therapy planning and is a major barrier in implementing routine Magnetic Resonance Imaging (MRI) guided-guided Adaptive Radiation Therapy (MR-ART). To address this, we propose a new artificial intelligence-based auto-contouring method for abdominal MR-ART modeled after human brain cognition for manual contouring.

METHOD AND MATERIALS

Our algorithm is based on two types of information flow: top-down and bottom-up. Top-down information is derived from simulation MR images. It grossly delineates the object based on its high-level information class by transferring the initial planning contours onto daily images. Bottom-up information is derived from pixel data by a supervised, self-adaptive, active learning based support vector machine. It uses low and middle level pixel features such as intensity and location to distinguish each target boundary from the background. The final result is obtained by fusing top-down and bottom-up outputs in a unified framework through fuzzy logic. For evaluation, we used a dataset of four patients with locally-advanced pancreatic cancer treated with MR-ART using a clinical system (MRIdian, Viewray, Oakwood Village, OH). Each set included the simulation MRI and on-board T1 MRI corresponding to a randomly selected treatment session. Each MRI had 144 axial slices of 266×266 pixels. Using Dice Similarity Index (DSI) and Hausdorff Distance Index (HDI), we compared manual and automated contours for liver, left and right kidney and spinal cord.

RESULTS

Average auto-segmentation time was 2 minutes per set. Visually, the automatic and manual contours were similar. Fused results achieved better accuracy than either the bottom up or top down method alone. DSI values were above 0.82±0.03, except for the spinal canal. The spinal canal contours yielded a low HDI value at the expense of a relatively low DSI value.

CONCLUSION

With a DSI significantly higher than the usually reported 0.7, our novel algorithm yields a high segmentation accuracy. To our knowledge, this is the first fully automated contouring approach using T1 MRI images for adaptive radiotherapy.

CLINICAL RELEVANCE/APPLICATION

Minimal computational time coupled with high accuracy make our algorithm ideal for the MR-ART implementation thus minimizing the time gap between image acquisition and radiation delivery.

SSM12-02 Personalized Survival Prediction Using Random Forest Survival Model on MR Radiomic Features in

Gliomas

PURPOSE

To determine the feasibility of personalized survival prediction using MR radiomic features for patients with glioma.

METHOD AND MATERIALS

The MRI and survival data of 178 subjects with primary glioma were obtained from the Cancer Imaging Archive, including 100 glioblastoma data from the TCGA-GBM collection and 78 lower-grade glioma (grade II or III) data from the TCGA-LGG collection. This dataset was randomly partitioned into two subsets, 80% for model training (142 subjects) and 20% for validation (36 subjects). MRI, pathology, and DNA data (IDH and 1p/19q status) of 8 patients with primary glioma were recruited from local hospitals to further test the constructed prediction model. MR radiomic features were calculated from the postcontrast T1 weighted images and apparent diffusion coefficients based on the previously proposed approach. A Random Forest Survival model was constructed using the MR radiomics as predictors. The most informative predictors (260 of 868 features) was selected based on their hierarchy in the decision trees, i.e. the importance scores among all the predictors.

RESULTS

The receiver operating characteristic curves on the validation data (36 subjects) showed a promising prediction performance of the proposed survival model with the area under the curve between 0.826 and 0.971 at different time points after diagnosis. The personalized survival prediction on the 8 testing patients also provided plausible predictions in concordance with the current understanding of the prognosis in different grading, IDH, and 1p/19q status. The only exception is a grade III glioma (subject #2) who had a poorer survival prediction than glioblastoma. The real survival of recruited patients will be recorded by continuous monitoring to verify the proposed model.

CONCLUSION

The established survival prediction model based on MR radiomics is feasible and can be used to promote the personalized medicine of prognosis and treatment strategy in glioma.

CLINICAL RELEVANCE/APPLICATION

Predicting individual survival by efficient MR radiomics and machine learning can benefit the healthcare in patients with glioma from providing a reliable prognosis without high-cost gene assays.

SSM12-03 Automatic Cancer Staging from PET/CT Reports for Large Cohort Studies Using Natural Language Processing and Machine Learning

PURPOSE

To evaluate supervised machine learning (ML) algorithms for automatic cancer stage classification of >12'000 patients based on the radiology report.

METHOD AND MATERIALS

The radiology reports of >12'000 FDG-PET/CT exams between 2007 and 2014 were extracted from the hospital database. A randomly selected set (n = 1254) was manually read and split into subsets for training (80%) and testing (20%). Each report was assigned to one of five distinct cancer stages: 0 = No cancer, 1 = minimal/inactive residual, 2 = single tumor, 3 = locally advanced

disease, 4 = distant metastasis. The reports were preprocessed using basic natural language processing (NLP) techniques. Five common ML classifiers were evaluated: Naive Bayes Classifier (NBC), Support Vector Machines (SVM), Decision Trees (DTC), Random Forest (RFC), and K-nearest neighbors (KNN). Performance was expressed as area under the receiver operating curve (Az) obtained by stratified 10-fold cross-validation of the training set as well as the classification accuracy of the test set.

RESULTS

The number of reports assigned to each stage showed the following distribution: n0=324, n1=336, n2=161, n3 = 142, n4=291. SVM exhibited the best performance in the training set (Az = 0.90 / 0.87 / 0.81 / 0.87 / 0.91 for class 0/1/2/3/4, respectively), followed by NBC (0.88 / 0.86 / 0.79 / 0.85 / 0.90), RFC (0.85 / 0.73 / 0.75 / 0.81 / 0.88), KNN (0.85 / 0.79 / 0.74 / 0.80 / 0.82) and DTC (0.70 / 0.59 / 0.55 / 0.64 / 0.70). Mean classification accuracy of the test set was highest for NBC (0.57), followed by SVC (0.55), RFC (0.5), KNN (0.48) and DTC (0.45). Classification for the whole cohort was feasible with all classifiers.

CONCLUSION

Automatic detection of cancer stages was feasible with all tested ML methods. SVM and NBC performed best among the tested classifiers.

CLINICAL RELEVANCE/APPLICATION

Automatic cancer staging from radiology reports using natural language processing and supervised machine learning is a useful tool for the creation of large cohort studies.

SSM12-04 Semantic Image Segmentation in Breast MR Image with Deep Convolutional Neural Network

PURPOSE

To propose and validate the semantic segmentaion method with deep-learning in breast MR images to differentiation of various kinds of tissues for deformation modeling of breast parenchyma with tumor and 3D printing.

METHOD AND MATERIALS

This research is an advanced task for 3D printing and prediction of deformation model of breast parenchyma with tumor between prone and supine position. At first, it is necessary to segment the image on the regions of interest accurately. For the segmentation model of CNN, 10 volumetric breast MR images with prone and supine position of a patient were collected and drawn with five areas (background, lung_heart, muscle_bone, parenchyma_cancer, fat_skin) manually by an expert. The data were split into 8 subjects for training and 2 subjects for validation. Because of no significant change in the axial direction, each subject was considered as 2D images with axial direction so that it was trained with 1732 images and validated with 410 images. And we constructed segmentation model based on U-net. However, U-net showed low performance in this task so that the structures were overall modified and the batch normalization was added. Because it is somewhat similar between prone and supine position images, we compared network trained each position image with sum of them. To calculate accuracy and loss, we used the dice coefficient. Although it trained with axial 2D images, we evaluated the performance with 3D volume results to measure accurately. In addition, the accuracies were measured on each class, because each class has different quantity in the 3D volume.

RESULTS

Building the ground truth took 4-5 hours per subject, while it took about 20 seconds per subject with NVIDIA TITAN X. The result which is predicted with network trained each position image was higher than sum of them. The total accuracy is about 98% on whole cases. In addition, it shows the lowest accuracy on the parenchyma_cancer class as supine-86 % and prone-90 % on average) because it has large variation.

CONCLUSION

We applied semantic segmentation method for breast MR image, and it showed high performances to segment on our regions of interest and greatly reduced time as compared with manual process.

CLINICAL RELEVANCE/APPLICATION

This segmentation method can be used to differentiation of various kinds of tissues for deformation modeling of breast parenchyma with tumor in breast MR images between prone and supine position.

SSM12-05 A Clinically-Actionable Fully Convolutional Network for Brain Tumor Segmentation

rsub@stanford.edu

PURPOSE

We propose a fully convolutional network (FCN) for glioblastoma (GBM) segmentation using MRI data that has very few tunable parameters, making easy to drop in to clinical applications.

METHOD AND MATERIALS

We tackle the task of using an algorithm to automatically segment three-dimensional MRI images of GBM patients' brains-classifying each voxel of the image as cancerous--regions of edema, necrosis, and active tumor-or not. Our network uses six convolutional layers with true three-dimensional filters, followed by a voxel-wise softmax classifier. Our pre-processing pipeline is parameter-free and only depends on the voxel values of the input MRI image. We forgo post-processing and use the raw outputs of the network as our output segmentations. We trained and validated our network using MRI and ground-truth expert segmentation data from the BRATS 2015 dataset. This dataset contains 220 examples, and we used 75% of these for training and the remaining 25% for validation.

RESULTS

For the cancerous vs. non-cancerous task, with a 75%/25% training/validation split and no post-processing, we achieve the following validation results. We achieve an average Dice score of 0.865, an average Jaccard score of 0.771, and an average overlap score of 0.927. In the attached figure, we provide a histogram of validation Dice scores for the cancerous vs. non-cancerous task with four-fold cross-validation. For comparison, the average pairwise Dice score between the eleven experts who put together the ground truth data is 88%.

CONCLUSION

The proposed FCN algorithm performs almost as well as human experts and represents a segmentation solution that is clinically actionable. It can be used seamlessly in a clinical diagnostic environment with very little manual tuning.

CLINICAL RELEVANCE/APPLICATION

Accurate, automatic medical image algorithms like the proposed segmentation technique can assist radiologists in their interpretation of medical images.

SSM12-06 Automatic Classification of Acute Ischemic Stroke Patient within 4.5 Hours Symptom Onset: Comparison between Deep and Shallow Learning Approaches

younggon2.kim@gmail.com

PURPOSE

Determination of symptom onset time for acute ischemic stroke is crucial because the treatment options highly depend on time window. Here, we propose automatic methods based on deep learning (DL) which is the state of art of machine learning and support vector machine (SVM) to classify acute ischemic stroke patients within 4.5 hours symptom onset and compare their performances.

METHOD AND MATERIALS

We retrospectively evaluated 214 patients within 24 hours of symptom detection and underwent 1.5T magnetic resonance imaging (MRI). Some patients were excluded due to missing MRI sequences (22), low image quality (3), false infarct segmentation (7), or small infarct size (33 and 42 for SVM and DL). Finally, 140 and 149 patients were analyzed for the DL and SVM, respectively. Infarct legions were automatically segmented on apparent diffusion coefficient (ADC) maps by applying adaptive thresholding based on histogram normalization. Fluid attenuated inversion recovery (FLAIR) images were registered into the corresponding ADC map. For DL, only axial slices containing infarct regions were used as inputs of Inception V3 network. For SVM, image features including intensity, gradient, and texture information were extracted from infarct regions. The classifier parameters were tuned based on F0.5 and class weights to obtain good specificity.

RESULTS

A 5-fold cross-validation was conducted for training and testing of DL and SVM. For using single modality, accuracy and sensitivity of DLs are significantly higher than those of SVMs ($p<0.05$, t-test), with a similar level of specificity. The DL using all of three modalities tended to show significantly better performance in terms of accuracy (0.88 ± 0.02), sensitivity (0.95 ± 0.04), and specificity (0.78 ± 0.04), except sensitivity of ADC (0.96 ± 0.05).

CONCLUSION

We proposed the automatic classification systems for acute ischemic stroke patients within 4.5 hours of symptom onset using deep and shallow learning methods. In results, the DL showed good identification of acute ischemic stroke patients within 4.5 hours of symptom onset.

CLINICAL RELEVANCE/APPLICATION

The proposed classification systems might be useful for identifying unknown-onset stroke patients who could be candidates for

reperfusion therapy.

lindayuan1991@126.com

PURPOSE

The purpose of this study is to utilize whole-body Dixon fat-water separation technique to quantify adipose tissue (AT) distribution and fat content of different organs, to investigate characteristics of fat distribution, and to determine whether these quantitative parameters are risk factors of metabolic syndrome (MS).

METHOD AND MATERIALS

We recruited 39 male volunteers and 71 female volunteers, with an average age of 58.7±9.1 years and an average BMI of 26.1kg/m2, among which 19 female and 11 male volunteers were diagnosed with metabolic syndrome. Whole-body fat and water images were acquired using a Dixon-VIBE sequence on MAGNETOM Skyra 3T MR scanner. Scan parameters were as follows: TR 5.26ms, TE 1.24ms, Flip angle 9°, FOV 500mm x 500mm, 44-60 slices,slice thickness 5.0mm, total acquisition time 60s. ImageJ software was applied to measure the volume of intra-thoracic AT (ITAT), intra-abdominal AT (IAAT), truncal subcutaneous AT (TSAT), and lower limb AT (LLAT). Osirix software was utilized to measure fat fraction(FF) of liver, pancreas, L2-L4 vertebral bodies, and skeletal muscle of lower limbs.

RESULTS

Compared with female group, male volunteers possessed more ITAT and IAAT, less TSAT, LLAT and total adipose tissue (TAT), and a higher ratio of IAAT (IAAT%). The senior group (>=60 years old) contained more ITAT, IAAT, and IAAT% than the junior group (<60 years old). Compared with premenopausal females, post-menopausal females had less TAT, more ITAT, and higher IAAT%. FF of skeletal muscle in lower limbs was higher in senior, female, and postmenopausal groups. FF of the vertebral body was higher in post-menopausal groups. Multiple binary logistic regression analysis demonstrated that volume of IAAT was a risk factor for MS.

CONCLUSION

The Dixon fat-water separation technique can be used to quantify whole-body adipose tissue and fat fraction of different organs. Distribution of adipose tissue and organ fat fraction varied in different sex and age groups. Accumulation of intra-abdominal adipose tissue may increase the risk of developing metabolic syndrome.

CLINICAL RELEVANCE/APPLICATION

This technique allows precise quantification of whole-body fat, which may enable the individualized diagnosis and evaluation of diseases with mal-distribution of adipose tissue or fat content.

SSM13-03 CEST MRI of Surgically-Removed Prostate Correlates with Histological Stratification

PURPOSE

While muiltiparametric MRI combining T2-weighted (T2-w) imaging with functional imaging techniques can provide moderate sensitivity and specificity for diagnosis of prostate tumor, there is still a great need in developing novel MRI methods for reliable risk stratification of prostate lesions. Chemical exchange saturation transfer (CEST) MRI as an emerging metabolic and molecular MRI method based on endogenous tissue contrasts has been demonstrated to assess aggressiveness of brain tumor. The aim of this study was to investigate the value of CEST MRI in the risk stratification of prostate pathologies. To pave the path for in vivo clinical studies, this study was initiated by scanning whole surgically-removed prostates with high resolution and correlating with the corresponding pathological images.

METHOD AND MATERIALS

Under an approved IRB protocol, whole prostate specimens from patients (n=5, 62±3 yrs) were studied immediately after surgery. MRI was performed on a horizontal 9.4-T animal MRI scanner with a commercial volume coil (72 mm in diameter). T2-w fast spin echo and diffusion-weighted images (DWI) were acquired. In addition, ADC was constructed from DWI images. CEST Z-spectra were then collected using a customized sequence with a frequency-selective saturation pulse (B1 = 100 Hz, 2 s). CEST data was corrected for static field B0 inhomogeneity. CEST asymmetry contrast was computed and normalized by signal at +100 ppm. Immediately after MRI, the specimens were processed for histopathological studies. Prostate lesions and Gleason patterns were prescribed by a clinical pathologist on histological images (H&E stained) from the slices close to the MR imaging planes.

RESULTS

By comparing the CEST contrast maps with the corresponding histological images, we found CEST contrast in tumor was significantly lower than that of normal tissue (4.8±0.1 vs. 6.5±0.3 %, $p<0.05$). On the other hand, CEST contrast in benign prostatic hyperplasia (BPH) (12.7%) was much higher than that of both normal tissue and tumor. In general, CEST contrast maps demonstrated a close correlation with regional Gleason patterns in histological images.

CONCLUSION

CEST MRI contrast, once further confirmed with a large sample size and in vivo clinical studies, may have great potential for risk stratification of prostate pathologies.

CLINICAL RELEVANCE/APPLICATION

CEST MRI has the clinical potential for characterization of prostate diseases.

SSM13-04 Utilizing Radiomics to Differentiate Hot and Cold Tumor Immune-Microenvironment in Biopsy-Proven Malignant Melanoma: A Pilot Study

PURPOSE

An immunogenic tumor microenvironment (hot) is a strong and independent predictor of improved patient outcome. Additionally, new immune checkpoint inhibitor therapies can activate anti-tumor immune response and trigger an immune-infiltration which is responsible for the pseudoprogression phenomenon. Pseudo-progression masks effective therapy efficacy since a transitory increase in tumor volume is observed. We aimed to explore if radiomics can predict the immune-infiltration profile in malignant metastatic melanoma patients treated with immune checkpoint blockade by anti-PD-1.

METHOD AND MATERIALS

We retrospectively recruited metastatic melanoma patients treated with anti-PD1. All patients had a contrast-enhanced CT-scan as well as a tumor biopsy with a 360 gene panel RNA-expression profile. We divided patients in two categories: hot and cold tumor immune microenvironment. "Hot" was defined by a quantitative expression of RNA above the median in at least two out of four key immune pathways: cytotoxic lymphocytes (CD8A and CD8B), human inducible T-cell co-stimulator (ICOS); and interleukin 2 (IL2). We contoured the tumor lesions in 3D and extracted 89 radiomic imaging features. Area under the curve (AUC) calculated the accuracy of imaging features for the detection of hot immune infiltration.

RESULTS

61 lesions in total were contoured: 33 hot and 28 cold. The two best imaging features for the detection of a hot immune infiltration were Entropy of Grey Level Concurrence Matrix and Skewness. Their respective AUCs (95CI; p-value) were: 0.75 (0.62-0.88; P=0.001) and 0.74 (0.60-0.88; P=0.001). Combining these two features, a correct classification of hot vs. cold (95CI) was achieved in 77% (65-87%) of lesions.

CONCLUSION

This pilot study provides proof of concept regarding an association between tumor imaging phenotype assessed by radiomics on CT-scan and the presence of a hot tumor immune infiltration according to biopsy RNA-sequencing. Prospective validation in larger cohorts is warranted.

CLINICAL RELEVANCE/APPLICATION

The classification of tumor immune microenvironment by imaging biomarkers could provide prognostic information and improve response assessment accuracy, especially in immuno-oncology.

SSM13-05 Using the Least Solid State Detectors to Achieve the Most: Pushing the Envelope of Digital Photon Counting TOF PET by Simulating Sparse-Ring Configuration

Wednesday, Nov. 29 3:40PM - 3:50PM Room: S504CD

zhang.538@osu.edu

PURPOSE

To leverage and go beyond accepted conventions in PET detector designs by investigating the new generation solid state digital photon counting (DPC) PET detectors in simulated sparse-ring PET configuration for oncologic FDG PET/CT

METHOD AND MATERIALS

A solid state DPC PET/CT system (Vereos) with 23,040 individual crystal-to-SiPM detector couplings (18 fiat modules, 4 tangential by 5 axial array tiles on each, 8x8 matrix pixels on each tile) was used. Investigational wholebody FDG PET/CT of 10 oncology patients were performed (13.1±0.4mCi FDG; 75±5min p.i). PET was reconstructed using 3D TOF OSEM in 4x4x4mm3 using A) full ring data, and sparse-ring PET simulation by disabling B) 1 pixel of every 2 pixels in tangential (50% crystal-detector reduction), C) 1 of every 3 pixels in tangential (33% reduction), D) 1 of every 4 pixels in tangential (25% reduction) and E) the 2nd and 4th entire rings in axial (40% reduction). NEMA phantom with hot spheres was performed using the same approaches. All results were compared and analyzed to assess image quality (IQ) and PET quantification

RESULTS

All lesions on the full-ring PET were visible on sparse-ring PET simulation (C)-(E). though most lesions were identifiable on sparse-ring PET in (B), artifacts appeared. Reducing the number of crystal-detector couplings to 25% (D) maintained PET IQ without giving significant SUV variances compared to full-ring PET ($p<0.01$). Keeping detector rings intact in tangential with 40% detector reduction in axial using (E) surprisingly demonstrated good results without compromising much of IQ. Applying counts-adaptive reconstructions by optimizing recon parameters further improved PET IQ. Radically either up to 40% cost can be saved or up to 40% axial FOV can be extended without adding new detectors. Comprehensive data assessment will be presented

CONCLUSION

1:1 coupling of crystal:detector DPC PET is a technology leap however with trade-off of high cost limited axial FOV. The study challenged its current designs and pushed the envelope to go beyond its boundaries in improving axial FOV and system sensitivity without adding additional cost by sparse-ring PET simulation.

CLINICAL RELEVANCE/APPLICATION

Solid state digital PET is a technology leap with great potentails of using least solid state detectors to achive the most without adding cost while retaining reliable image quality for oncology PET and the study investigated this using sparse-ring PET simulation.

SSM13-06 Texture Analysis of 68Ga-DOTATATE Positron Emission Tomography and Computed Tomography Images as a Prognostic Biomarker in Adults with Neuro-Endocrine Cancers Treated with 177Lu-DOTATATE

PURPOSE

Neuroendocrine tumors (NETs) are a rare, heterogeneous group of cancers whose behavior can be hard to predict. A better understanding of prognosis would aid individualized management decisions. We aim to demonstrate the prognostic potential of tumor heterogeneity and avidity in NETs using PET and CT textural analysis (PTA & CTTA) and standardized uptake values (SUV).

METHOD AND MATERIALS

The baseline 68Gallium-DOTATATE PET/CT scans of 49 prospectively recruited patients with NETs (carcinoid, pancreatic, thyroid, head and neck, catecholamine-secreting and unknown primary tumors) treated with 177Lutetium-DOTATATE at a tertiary center were retrospectively analyzed. Non-contrast CT and PET heterogeneity was assessed using a commercially available TexRAD texture analysis software (TexRAD Ltd www.texrad.com, part of Feedback Plc, Cambridge, UK) which employed a filtration-histogram technique. Regions of interest encircled the most prominent metastases of each patient (up to 5 tumour foci) as seen on the 68Ga-DOTATATE PET scan. Gallium uptake on PET was quantified as SUVmax and SUVmean. Association between imaging and clinical markers with progression-free (PFS) and overall survival (OS) were assessed using univariate Kaplan-Meier and multivariate Cox regression analysis.

RESULTS

Clinical factors did not generally predict survival. Measures of texture heterogeneity (quantified as skewness and kurtosis) on unfiltered and filtered (fine-medium texture scale) CT and unfiltered PET images predicted PFS (CT: p=0.0126, PET: p=0.0047) and OS (CT: p=0.0061, PET: p=0.0028). Furthermore patients with SUVmax >8.73 and SUVmean >5.19 showed significantly superior PFS (p=0.0164) and OS (p=0.0061). Multivariate analysis identified that CTTA (fine texture scale - skewness: HR=6.98, 95%CI=2.281-21.372, p=0.001) and SUVmax (HR=4.439, 95% CI=1.679-11.739, p=0.003) were independent predictors of PFS. PTA (without filtration skewness : HR=20.68, 95%CI=3.24-131.99, p=0.001) was an independent predictor of OS.

CONCLUSION

68Ga-DOTATATE PET/CT texture heterogeneity and SUV measurements could act as prognostic biomarkers in NETs and potentially play a key role in risk stratifying these patients.

CLINICAL RELEVANCE/APPLICATION

68Ga-DOTATATE PET/CT texture heterogeneity analysis and SUV measurements independently predict survival in NETs. Their role as prognostic biomarkers could significantly improve stratification of NET patients.

PURPOSE

To determine the efficacy of percutaneous US-guided needle lavage of symptomatic rotator cuff calcifications using a sodium hexametaphosphate (SHMP) solution (0.5%), in comparison with the same technique using simple saline

METHOD AND MATERIALS

We evaluated 24 calcifications (4 type A, 11 type B, 9 type C according to Gartner classification, mean size 24.7mm, range 9-31mm) in 24 patients (13 males, 11 females, mean age 34.8 years). Patients were divided into 2 groups and treated by percutaneous fragmentation and lavage using SHMP (Group 1, 12 patients) or simple saline (Group 2, 12 patients). Pre- and post-procedure (at 2 and 4 weeks follow-up) imaging evaluation was performed in all patients, including conventional radiography (RX) and ultrasound (US) examination to assess location, size and type of calcifications. Imaging findings after treatment were evaluated by two independent raters and defined as "partial" or "subtotal" dissolution. Pre- and post-procedure clinical evaluation (at 2 and 4 weeks follow-up) was assessed using the Constant Shoulder Score for functionality and the VAS Score for pain

RESULTS

The two study groups were homogeneous in terms of patient demographics, size and type of calcifications. 2 weeks after treatment in Group 1 we found subtotal dissolution of calcifications in 8 patients (66.7%) and partial dissolution in 4 (33.3%); of these, 2 (50%) showed subtotal dissolution at the 4 weeks follow-up. In Group 2 we found subtotal dissolution in 58.3% and partial in 41.7% ($p<=0.05$). 1 patient (20%) showed subtotal dissolution at the 4 weeks follow-up. Clinical evaluation showed significant improvement in VAS and Constant scores in 91.7% of patients of Group 1 and in 83.3% of Group 2 ($p<=0.05$). No major complications were reported in both groups.

CONCLUSION

The use of SHMP showed superior results in terms of imagingfindings and clinical improvement compared to the treatment with simple saline

CLINICAL RELEVANCE/APPLICATION

With its chemical action of calcium chelation and dissolution, besides the mechanical action, percutaneous lavage with SHMP is an effective procedure, suitable for different types of calcifications, providing a safe, valid and cost-effective alternative treatment management for calcific tendinitis

SSM14-02 Effect of Compression Stockings on the Development of Delayed-Onset Muscle Soreness: A Quantitative Assessment with 3T MRI, Contrast-Enhanced Ultrasound (CEUS) and Acoustic Radiation Force Impulse (ARFI) Elastography

Wednesday, Nov. 29 3:10PM - 3:20PM Room: E353C

PURPOSE

To investigate the influence of commercially available sport compression garments on changes in muscle perfusion, muscle stiffness and the development of exercise induced intramuscular edema in the context of DOMS.

METHOD AND MATERIALS

DOMS was induced in fifteen healthy participants. They had to perform a standardized eccentric exercise of the calf muscles. After exercise a conventional sports compression sock (class I, 18-21 mmHg) was placed accordingly manufacturer's instructions at one randomized calf for 60h. MRI (normalized T2 signal intensity and T2-time), CEUS (Peak enhancement (PE) and Wash-in Area Under Curve (WIAUC)) and ARFI (shear wave velocities (SWV)) of the gastrocnemius muscle (GM), as well as creatine kinase activity, extension range of the ankle joint, calf circumference and muscle soreness were assessed at baseline and 60 h after exercise at both calves.

RESULTS

After exercise the normalized T2 signal intensity (1.0±0.30 vs. 1.94±1.05, p=0.008), the T2-time (37.52±9.67 vs. 55.64±12.72 ms, p=0.015) was significantly higher in the GM in the compressed calf; but no change for WIAUC (4322±521 vs. 11730±3536, p=0.88), PE (474±54 vs. 1185±345, p=0.51) and ARFI SWV (2.16±0.31 vs. 2.13±0.32, p=0.60) were observed. In the non-compressed calf all assessed parameters changed significantly: T2: 1.0±0.16 vs. 2.20±1.16, p=0.001; T2-time: 37.75±9.28 vs. 55.67±14.78 ms, p=0.005, WIAUC: 2461±660 vs. 5297±743, p=0.01, PE: 328±45 vs. 753±31, p=0.005, ARFI SWV: 2.2±0.26 vs. 1.78±0.24m/s, p=0.008. No significant difference was observed in normalized T2 signal intensity (p=0.397), T2-time value (p=0.953), WIAUC (p=0.93) and PE (p=0.730) in the GM comparing the compressed and non-compressed lower leg after exercise. Only ARFI SWV values in the same comparison revealed a statistically significant difference (p=0.001).

CONCLUSION

Our results indicate that wearing conventional sports compression socks after inducing DOMS may shorten the normalization of muscle stiffness, but have no significant effect on the degree of intramuscular edema or perfusion of the MGM. Furthermore, no effects on occurring muscle soreness or reduced range of motion were noticed.

CLINICAL RELEVANCE/APPLICATION

Muscle injuries are common sports injuries. Delayed onset muscle soreness (DOMS), an entity of ultrastructural muscle injury is one of the most common reasons for impaired muscle performance in professional and recreational athletes.

SSM14-03 Repeated Ultrasound-Guided Core Needle Biopsy of Musculoskeletal Lesions: Clinical Utility According to the Types of the Lesions

Wednesday, Nov. 29 3:20PM - 3:30PM Room: E353C

Participants
Kyungjun Min, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

Min Hee Lee, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Myung Jin Shin, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the clinical utility of repeated ultrasound-guided core needle biopsy(US-CNB) of musculoskeletal lesions according to the types of the lesions.

METHOD AND MATERIALS

We retrospectively reviewed 1996 consecutive US-CNBs performed for bone or soft-tissue lesions in 1914 patients during 10 years at a single institution. Repeated biopsy cases for the same lesion were enrolled in this study. The reasons for repeat biopsies were nondiagnostic results, different from clinical expectations, or negative culture results. The reference standard was culture result for infection and pathological diagnosis at excisional biopsy for others. Concordance rate of initial and repeat biopsies were compared according to the types of the lesions by tumors, infection, or others. McNemar's test were used for their statistical significance ($p < .05$).

RESULTS

Of the 30 cases of repeat biopsy, final pathologies were bone and soft tissue tumor, 18(60%); infection, 8(27%); and others, 4(13%). Among the 18 tumors, 16(89%) cases were soft tissue tumors and 14(78%) were malignancy. The overall concordance rate of initial biopsy was 23%(7/30) and that for repeat biopsy was 60%(18/30), which revealed significantly higher concordance for repeated biopsy (p=0.001). The initial and repeated concordance rates of bone and soft tissue tumor were 22%(4/18) and 72%(13/18), respectively. Repeated US-CNB for bone and soft tissue tumor increased diagnostic rate significantly compared to the initial biopsy (p=0.008). The pathogen concordance rates between the initial and repeated US-CNB for infectious cases were 0%(0/8) and 13%(1/8), which showed no significant difference (p=1.000).

CONCLUSION

Repeated US-CNB of musculoskeletal bone and soft tissue tumors can be useful for accurate diagnoses. However, in cases of

Repeated US-CNB of musculoskeletal bone and soft tissue tumors can be useful for accurate diagnoses. However, in cases of infection, repeated US-CNB may have limited clinical utility for pathogen determination.

CLINICAL RELEVANCE/APPLICATION

Repeated US-CNB can be useful for accurate diagnoses of musculoskeletal bone and soft tissue lesions. However, we should consider the types of the lesions. Although repeated CNB increased diagnostic rate for bone and soft tissue tumors, but did not increase the pathogen determination for infection.

SSM14-04 Adhesive Capsulitis of the Shoulder: Evaluation with US-Arthrography Using a Sonographic Contrast Agent

Wednesday, Nov. 29 3:30PM - 3:40PM Room: E353C

Participants
Man Lu, PhD, Chengdu, China (*Presenter*) Nothing to Disclose
Xueqing Chen, Chengdu, China (*Abstract Co-Author*) Nothing to Disclose

graceof@163.com

CONCLUSION

Consequently, US-arthrography was more effective method than US for assessment of AC. Filling defects of joint cavity and synovitis-like abnormality in the joint are characteristic US-arthrography findings for diagnosing AC.

Background

Adhesive capsulitis (AC) is a painful and disabling disorder, which caused restricted motion and chronic pain of shoulder. Intracavitary contrast-enhanced ultrasound has recently applied to assess obstructive bile duct diseases, tubal patency, vesicoureteric reflux and so on.

Evaluation

The aim of this study was to detect the value of US-arthrography by injecting the contrast agent SonoVue into glenohumeral joint compared with US in diagnosing AC.

Discussion

US and US-arthrography images of 45 patients with AC were compared with that of 45 control subjects without AC with MRI as a gold standard.Patients with AC had a significantly thickened CHL (3.1 mm) and inferior capsule (3.5 mm) on US, and a decreased volume of axillary recess (1.14 ml) on US-arthrography compared with the control subjects. Filling defect (91.1%) and synovitis-like abnormality (75.6%) in the joint on US-arthrography were more sensitive than that of rotator interval abnormality (71.1%), thickened CHL more than 3 mm (64.4%), thickened inferior capsule more than 3.5 mm (66.7%) on US respectively for diagnosis of AC.

SSM14-05 Contrast-Enhanced Ultrasound (CEUS) as a New Method in Diagnostic Imaging of Muscle Injuries: Systematic Comparison of Conventional Ultrasound, CEUS and Findings in MRI

Thilo Hotfiel, Erlangen, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To emphasize the diagnostic value of contrast-enhanced ultrasound (CEUS) in imaging of muscle injuries with different degrees of severity by comparing findings to the established imaging modalities as conventional ultrasound and magnet resonance imaging (MRI).

METHOD AND MATERIALS

A total of 15 patients were examined after indirect muscular injuries on the lower extremity. Within 24 - 48 hours after injury, a conventional sonography and a CEUS were performed. Direct after the sonography, an MRI was performed as a 'gold standard' in order to graduate the lesion and to determine the spatial extent of the lesion as a reference variable. The classification was carried out according to the modified, four-stage Peetron classification described by Ekstrand et al..

RESULTS

All 15 injuries were identified on MRI and CEUS, whereas 10 injuries showed abnormalities in conventional ultrasound. The determination and measurement revealed significant differences between conventional ultrasound and CEUS depending on the injuries' severity. CEUS revealed an impairment of microcirculation in grade I lesions (corresponding to intramuscular edema observed in MRI), which were not detectable in conventional ultrasound.

CONCLUSION

Our results indicate that performing CEUS seems to be a sensitive additional diagnostic modality in the assessment of muscle injuries in the acute phase after injury. Our results provide advantages of CEUS in imaging of low grade lesions compared to

conventional ultrasound, as they show its superiority in the identifiability of intramuscular edema.

CLINICAL RELEVANCE/APPLICATION

Muscle injuries are frequently observed during recreational and professional sports and have been reported as one of the most common sports injuries. Diagnostic imaging is essential to provide a correct assessment of the injury's severity. So far MRI has shown its superiority over ultrasound examination and has been reported as the preferred modality providing detailed image analysis and characterization of an intramuscular lesion. In clinical practice, however, MRI is often reserved for high-level athletes or serious injuries in which a pronounced structural damage is expected. In conventional ultrasound diagnostic of low grade lesions (ultrastructural lesions and muscle strains), the concerned muscle tissue often appears normal. In this context CEUS may be a new investigative tool in the diagnostic imaging of low grade muscle lesions.

SSM14-06 Quantitative Assessment of Skin Stiffness in Localized Scleroderma Using Ultrasound Shear-Wave Elastography

liyunwang1992@qq.com

PURPOSE

The purpose of this study was to evaluate the usefulness of ultrasound shear-wave elastography (US-SWE) in characterization of localized scleroderma (LS), as well as in the disease staging.

METHOD AND MATERIALS

21 patients with 37 LS lesions were enrolled in this study. The pathological stage (edema, sclerosis or atrophy) of the lesions was characterized by pathological examination. The skin elastic modulus (E-values, including Emean, Emin, Emax and Esd) and thickness (h) was evaluated both in LS lesions and site-matched unaffected skins (normal controls) using US-SWE. The relative difference (ERD) of E-values was calculated between each pair of lesion and its normal control for comparison among different pathological stages.

RESULTS

Of the 37 LS lesions, 2 were in edema, 22 in sclerosis and 13 in atrophy. US-SWE results showed a significant increase of skin elastic modulus and thickness in all lesions ($p<0.001$ in sclerosis and $p< 0.05$ in atrophy) compared to the normal controls. The measured skin elastic modulus and thickness were greater in sclerosis than in atrophy. However, once normalized by skin thickness, the atrophic lesions, which were on average thinner, appeared significantly stiffer than those of the sclerosis (normalized ERD: an increase of 316.3% in atrophy vs. 50.6% in sclerosis compared to the controls, $p = 0.007$).

CONCLUSION

These findings suggest that US-SWE allows to quantitatively evaluate the skin stiffness of LS lesions in different stages; however, the E-values directly provided by US-SWE system alone do not distinguish between the stages, and the normalization by skin thickness is necessary. This non- invasive, real-time imaging technique is an ideal tool for assessing and monitoring LS disease severity and progression.

CLINICAL RELEVANCE/APPLICATION

Ultrasound shear-wave elastography can measure skin stiffness in LS patients which can be used to assesse and monitor LS disease severity and progression.

PURPOSE

The objective of this study was to evaluate hybrid 11C-MET PET/MRI for detection of recurrent glioma.

METHOD AND MATERIALS

Fifty consecutive patients with histopathological proven glioma (9 Low Grade Glioma (LGG), 33 High Grade Glioma (HGG), 8 Oligodendroglioma (OGG)) were prospectively enrolled for a hybrid 11C-MET PET/MRI to differentiate recurrent glioma from treatment induced changes. Sole MRI data were analyzed based on RANO. Sole PET data and in a second session hybrid 11C-PET/MRI data were assessed for metabolic respectively metabolic and morphologic glioma recurrence. Reference standard was either histopathological report (n = 22) or follow-up imaging (n=28), whereas only patients of at least 6 months with follow up imaging were included. Based on the reference standard 35 patients were classified with recurrent glioma, whereas 15 patients with treatment induced changes.

RESULTS

Hybrid 11C-MET PET/MRI was performed in 50 patients for differentiation between recurrent glioma and treatment induced changes.Sensitivity, specificity, positive predictive value and negative predictive was calculated 86,11%, 71,43%, 88,57%, 66,67 for 11C-MET PET alone; 96,77%, 73,68%, 85,71%, 93,33% for MRI alone and 97,14%, 93,33%, 97,14%, 93,33% for hybrid 11C-PET/MRI, respectively. In all 50 patients diagnoses based on the reference standard were correct in 82% for 11C-MET PET, 88% for MRI alone and 96% for hybrid 11C-PET/MRI. A significant difference was found among hybrid 11C-MET PET/MRI and 11C-MET PET (p=0,016), whereas no significant difference was found among hybrid 11C-PET/MRI and MRI alone or MRI alone and 11C-MET PET alone. Furthermore, significant ($P < 0.05$) higher scores were found for diagnostic confidence when comparing 11C-MET PET/MRI (4,26 ± 0,777) to 11C-MET PET alone (3,44 ± 0.705) or to MRI alone (3,56 ± 0.733).

CONCLUSION

Hybrid 11C-MET PET/MRI offers metabolic and morphological information for the assessment of glioma recurrence. The hybrid imaging concept increases accuracy and showed significant higher scores for diagnostic confidence when compared to MRI or PET.

CLINICAL RELEVANCE/APPLICATION

Hybrid 11C-MET PET/MRI might have the potential to strengthen RANO classification by adding the metabolic information. This should be evaluated in larger study cohorts.

SSM15-02 Does 18F-FDG PET/MR Increase the Diagnostic Performance for Recurrence Diagnostics in Comparison to MRI in Patients Suffering From Adenoid Cystic Carcinoma of the Head and Neck?

PURPOSE

To compare the diagnostic performance between 18F-fluorodeoxyglucose positron emission tomography / magnetic resonance (18F-FDG PET/MR) and MR imaging for the detection of recurrent adenoid cystic carcinoma (ACC) of the head and neck and locoregional metastases.

METHOD AND MATERIALS

In this retrospective analysis, a total of 31 dedicated 18F-FDG PET/MR examinations of the head and neck performed for recurrence diagnostics and locoregional metastases detection in patients after primary therapy of ACC were included (12 patients, mean age 59 years). In separate sessions, MRI and 18F-FDG PET/MR images were analyzed by two individual readers. Tumor recurrence or metastatic disease was confirmed by clinical and radiological follow-up examinations. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated on a per lesion basis and diagnostic accuracy between both modalities was compared using McNemar's test. $p<0.05$ was considered as statistically significant.

RESULTS

Tumor recurrence and / or locoregional metastases were detected in 20 examinations. 18F-FDG PET/MR correctly identified all 20 suspicious examinations, while MRI detected 19 of 20 examinations. On a per lesion basis, sensitivity, specificity, PPV and NPV were 77%, 94%, 95% and 73% for MRI and 96%, 84%, 90% and 93% for 18F-FDG PET/MR, respectively. On a per lesion basis, the diagnostic accuracy of 18F-FDG PET/MR (91%) was significantly higher in comparison to MRI (84%, $p<0.05$).

CONCLUSION

In patients suffering from ACC of the head and neck, 18F-FDG PET/MR is superior to MRI in detection tumor recurrence and locoregional metastases. Especially the superior NPV of 18F-FDG PET/MR is advantageous in regular follow-up examinations after primary tumor treatment in patients suffering from ACC.

CLINICAL RELEVANCE/APPLICATION

In comparison to MRI, 18F-FDG PET/MR provides a superior diagnostic performance in follow-up examinations after primary treatment of adenoid cystic carcinoma of the head and neck.

SSM15-03 4'-[Methyl-11C]-Thiothymidine PET/CT for Early Assessment of Disease Control Of Chemoradiotherapy for Head and Neck Squamous Cell Carcinoma: Comparison with FDG PET/CT

Wednesday, Nov. 29 3:20PM - 3:30PM Room: S505AB

Participants
Katsuya Mitamura, Kita-gun, Japan (*Presenter*) Nothing to Disclose
Yuka Yamamoto, MD, PhD, Kagawa, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

A new radiopharmaceutical, 4'-[methyl-11C]-thiothymidine (4DST), has been developed as an in vivo cell proliferation marker based on the DNA incorporation method. The purpose of this study was to evaluate the usefulness of 4DST PET/CT for early assessment of disease control of chemoradiotherapy for head and neck squamous cell carcinoma (HNSCC), in comparison with 2-deoxy-2-18F-fluoro-D-glucose (FDG) PET/CT.

METHOD AND MATERIALS

A total of 28 patients with HNSCC underwent 4DST and FDG PET/CT studies before, during, and after therapy. Uptake of 4DST and FDG was examined visually and semiquantitatively using standardized uptake value (SUV) for before, during and after therapy (SUVbefore, SUVduring and SUVafter, respectively). Percent change (during) was calculated from SUVbefore and SUVduring and percent change (after) was calculated from SUVbefore and SUVafter. Based on histopathological verification or radiologic follow-up, patients were divided into relapse-free and relapse groups. Relapse-free group was defined as those having no local recurrence or distant metastasis.

RESULTS

In all 28 patients, focally increased 4DST and FDG uptake in primary lesion was visible. On both 4DST PET/CT scans during and after therapy, 23 patients showed no increased uptake in primary lesion. On FDG PET/CT scans during and after therapy, 16 and 18 patients showed no increased uptake in primary lesion, respectively. Twenty-two patients were found to be relapse-free group and 6 to be relapse group. SUVduring and SUVafter values from 4DST PET/CT in relapse-free group were significantly lower than those in relapse group ($p<0.001$, respectively). The percent change (during) and percent change (after) values from 4DST PET/CT in relapse-free group were significantly higher than those in relapse group ($p<0.001$, respectively). Using FDG PET/CT, SUVduring, SUVafter, percent change (during) and percent change (after) were not significant differences between relapse-free and relapse groups.

CONCLUSION

The results of this preliminary study suggest that, compared with FDG PET/CT, 4DST PET/CT may be useful for early assessment of disease control of chemoradiotherapy in patients with HNSCC.

CLINICAL RELEVANCE/APPLICATION

4DST PET/CT may be useful for early assessment of disease control of chemoradiotherapy in patients with HNSCC.

SSM15-04 The Value 18F-FDG PET/CT in Early Stage Squamous Cell Carcinoma of the Oral Cavity

PURPOSE

The purpose of this study is to evaluate the value of 18-F fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) for staging of early stage squamous cell carcinoma (SCC) of the oral cavity. Nodal staging on 18F-FDG PET/CT was compared with magnetic resonance imaging (MRI) of the neck and correlated with pathological staging on neck dissections.

METHOD AND MATERIALS

A retrospective review of all patients with clinically T1 and T2, biopsy-proven, squamous cell carcinoma of the oral cavity, and a clinically node-negative neck, between 2012 and 2017 was carried out. All patients that underwent both 18F-FDG PET/CT and MRI neck prior to surgical resection were included. The N and M stages on PET/CT were recorded, according to the AJCC/UICC TNM staging system, along with any incidental findings requiring further investigation. N stage on MRI was also recorded. Pathology reports were reviewed for pathological staging of the primary tumour and nodal status.

RESULTS

Sixty-four patients have been reviewed to date. Fifty-seven (89%) patients proceeded to neck dissection. Of these patients, 47 (82.5%) were histologically-proven node negative and 10 (17.5%) had histologically-proven nodal metastases. Of those patients with nodal metastases, 4 patients were staged N1 on PET/CT and 6 were staged N0. There were 2 patients with nodal metastases staged N1 on PET/CT but N0 on MRI. Of the node negative patients, 44 were staged N0 on PET/CT and 3 were staged N1. This yields a sensitivity of 40%, specificity of 93.6%, positive predictive value of 57.1% and negative predictive value of 88%. All patients were staged as M0 on PET/CT. Incidental findings requiring further clinical and radiological investigation were detected on PET/CT in 23 (35.9%).

CONCLUSION

Occult cervical nodal metastases are relatively infrequent in early stage SCC of the oral cavity with a clinically node negative neck. The relatively high specificity and negative predictive value of PET/CT in this study is due to the low prevalence of nodal metastases in this patient cohort. This study demonstrates that PET/CT is of limited value in conjunction with MRI for the detection of nodal metastases in these patients.

CLINICAL RELEVANCE/APPLICATION

The clinically node negative neck in early stage SCC of the oral cavity poses a potential treatment dilemma. PET/CT is of limited value in the detection of nodal metastases in these patients.

SSM15-05 Clinical Value of Three-Dimensional SPECT/CT Imaging For Assessment of Jaw Bone Invasion in Oral Cancers

PURPOSE

Imaging diagnosis of jaw bone invasion in oral cancers is still challenging due to dental artifacts as well as difficulty in detecting morphological change of early invasion. We have recently developed three-dimensional (3D) single-photon emission computed

tomography-computed tomography (SPECT/CT) imaging. We aimed to investigate the diagnostic performance of 3D SPECT/CT imaging for jaw bone invasion in comparison with other imaging modalities.

METHOD AND MATERIALS

Preoperative 3D SPECT/CT, contrast-enhanced CT (ceCT), and MRI images in 14 oral cancer patients were retrospectively evaluated by an oral surgeon. Each of the 3 image sets was independently reviewed with the knowledge of the tumor locations as to the likelihood of jaw bone invasion. When reviewing 3D SPECT/CT images, 3D volume-rendered SPECT/CT images with and without clip-plane editing were generated in order to grasp 2D and 3D bone anatomy and metabolism. The likelihood was classified using a 5-point diagnostic confidence scale. A jaw bone without cancer invasion that was scored as 1, 2 or 3 was considered true negative. A jaw bone with cancer invasion that was scored as 4 or 5 was considered true positive. Imaging results were compared with postsurgical results.

RESULTS

Seven of the 14 patients had jaw bone invasion of cancer cells and the other 7 did not. The sensitivity, specificity, positive and negative predictive values in the diagnosis of jaw bone invasion were 100% (7/7), 71% (5/7), 78% (7/9) and 100% (5/5) in 3D SPECT/CT, 43% (3/7), 86% (6/7), 75% (3/4), 60% (6/10) in ceCT, and 57% (4/7), 86% (6/7), 80% (4/5) and 67% (6/9) in MRI, respectively. Receiver operating characteristic analysis showed that 3D SPECT, ceCT and MRI had an area under the curve of 0.837, 0.786 and 0.704, respectively (not statistically different). Two cases with false-positive findings in 3D SPECT/CT had destruction of both periosteal and alveolar bones with severe inflammatory cell infiltration around the tumor sites.

CONCLUSION

3D SPECT/CT may be more sensitive than ceCT or MRI in the detection of jaw bone invasion.

CLINICAL RELEVANCE/APPLICATION

3D SPECT/CT appears more sensitive than ceCT or MRI in detecting jaw bone invasion in oral cancers and may be useful when jaw bone invasion is unclear with ceCT or MRI.

SSM15-06 The Usefulness of Initial Treatment Effects Based On PERSIST Criteria in Predicting the Three Years Disease Free Survival of Head and Neck Cancer

Wednesday, Nov. 29 3:50PM - 4:00PM Room: S505AB

Participants

Toshinori Hirai, MD, PhD, Miyazaki, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The study was done to evaluate the usefulness of the initial treatment effects based on PERSIST criteria in predicting the disease free survival (DFS) 3 years after the initial therapy of head and neck cancer (HNC).

METHOD AND MATERIALS

We analyzed retrospectively fifty-one cases of HNC, 35 male and 16 female, 18 hypo-pharynx cancer, 9 gingival cancer, 9 tongue cancer, 7 laryngeal cancer, 4 maximal cancer and 4 oropharynx cancer. All cases were performed FDG-PET/CT on both before and after the initial therapy. Chemo-radiotherapies were done in 35 patients and radiotherapies were done in 16 patients. We divided all patients into 2 groups, the responders (CMR+PMR) and the non-responders (SMD+PMD), based on the result of RECIST criteria. Then we compared the diagnostic ability of predicting DFS 3 years after the initial therapy among the result of initial therapeutic effect by PERCIST criteria and three kinds of FDG uptake parameters. The FDG uptake parameters were SUL max (< 16.0) ,SUL peak (< 12.0) and TLG(< 180g) obtained before the initial therapy respectively.

RESULTS

Among 36 responders, 25 cases (69.0%) reached 3 years DFS. In contrast, only 5 of 15 cases non-responders (33.0%) could reach 3 years DFS. The diagnostic accuracy of initial treatment effects based on PERSIST criteria for predicting 3 years DFS was 68.6%. Regarding FDG uptake indices before the initial therapy, TLG (<180g) was the most powerful predictor among three kinds of indexes (TLG 68.6%, SUL max 51.0%, SUL peak 52.9 %, in accuracy).

CONCLUSION

We could predict 3 years DFS with high probability based on the result of PERCIST criteria after the initial therapy in patients of HNC. Similarly, TLG (<180g) before the initial therapy was also good predictor of 3 years DFS.

CLINICAL RELEVANCE/APPLICATION

The result of the initial therapy based on PERCIST is useful not only for diagnosing therapeutic effect but also for predicting DFS 3 years after the initial therapy in HNC patients.

PURPOSE

The neurotoxic potential of intracranial gadolinium (Gd) deposition following intravenous administration of gadolinium based contrast agents (GBCAs) is undefined. In the current study, we used the world's largest prospective population-based cohort on aging to study the effects of Gd exposure on neurologic and neurocognitive function.

METHOD AND MATERIALS

The Mayo Clinic Study of Aging (MCSA) cohort was enumerated from the Rochester Epidemiology Project in 2004 to study the incidence and natural history of cognitive impairment and dementia. All participants underwent extensive longitudinal clinical (neurologic evaluation, neuropsychological testing) assessment at baseline and 15-month follow-up intervals. Neurologic and neurocognitive scores were compared using standard multivariate methods between MCSA patients with no history of prior Gd exposure and those who underwent prior Gd-enhanced MRI. Progression from normal cognitive status to mild-cognitive impairment and dementia was assessed using multistate Markov model analysis.

RESULTS

Among 4261 cognitively normal study participants aged 50-90 (mean age (SD): 71.9 yrs (10.7), mean study participation (SD): 3.7 yrs (3.0)), 1092 (25.6%) received one or more GBCA doses (median: 2 doses, range: 1-28 doses) unrelated to their participation in the MCSA. Median time since first Gd exposure was 5.6 years (IQR=2.2-9.3 years). After adjusting for age, sex, education level, baseline neurocognitive performance, Charlson comorbidity index, and ApoE4 status, GBCA exposure was not a significant predictor of cognitive decline (changes in clinical dementia rating (p=.48), Blessed dementia scale (p=.68), or mental status exam score (p=.55)), diminished neuropsychological performance (p=.13), or diminished motor performance (Unified Parkinson's Disease Rating Scale (p=.43)). No dose-related effects were observed among these metrics (p=.89-.20). Finally, Gd exposure was not an independent risk factor in the rate of cognitive decline from normal cognitive status to dementia in this cohort (p=.91).

CONCLUSION

GBCA administration was not associated with worse overall neurologic or neurocognitive performance nor does it significantly affect the natural progression of cognitive decline in a large population-based cohort.

CLINICAL RELEVANCE/APPLICATION

Despite evidence of Gd accumulation following intravenous GBCA administration, Gd exposure is not associated with adverse neurologic outcomes.

SSM16-02 Differences in Gadolinium Retention after Repeated Injections of Macrocyclic MR Contrast Agents to

Rats

PURPOSE

To investigate whether significant differences exist among macrocyclic MR contrast agents with respect to their retention in cerebellum, brain, kidneys and other organs.

METHOD AND MATERIALS

Gadobutrol (Gadovist®; Bayer), gadoterate meglumine (Gd-DOTA, Dotarem®; Guerbet), gadoteridol (ProHance®; Bracco) or Saline solution (0.9% w/v NaCl) were administered at 0.6 mmol/kg (1.2 mL/kg for saline) four times a week for five weeks to healthy male Wistar Han rats, randomly assigned to each of the four groups (n=15/group). After the end of the treatment, a recovery period of 4 weeks (28 d) was allowed before sacrifice. Organs (blood, cerebrum, cerebellum, liver, femur, kidneys and skin) were then collected for ICP-MS determination of gadolinium. Based on available amounts of samples, the LOQ (Limit of Quantitation) for Gd was 0.1 nmol/mL for blood, 0.1 nmol/g for cerebrum/cerebellum, 0.5 nmol/g for femur, 1 nmol/g for liver and skin. 1.7 nmol/g for kidneys. Statistical analysis was carried out by an independent expert.

RESULTS

Both in cerebellum and in cerebrum ProHance resulted in significantly ($p < 0.001$) lower levels of gadolinium compared both to Dotarem and to Gadovist. Also in the kidneys ProHance showed a residue that was significantly lower than both Dotarem (6 times higher; $p < 0.01$) and Gadovist (8 times higher; $p < 0.001$). In the femur, the differences were less pronounced, with only gadoterate meglumine showing a lower accumulation than gadobutrol ($p < 0.001$) and gadoteridol ($p < 0.05$). Gd concentration in blood, liver and skin samples was < LOQ.

CONCLUSION

After repeated injections of the 3 macrocyclic GBCAs and a 4-week off-dose period, ProHance resulted in significantly lower gadolinium concentrations than either Dotarem or Gadovist in cerebellum, cerebrum and kidneys. The observed differences, in the absence of dechelation, point to differences in wash-out rates, with gadoteridol being the GBCA that is most efficiently removed from both CNS and renal tissues.

CLINICAL RELEVANCE/APPLICATION

This non-clinical study shows that also macrocyclic MR contrast agents differ in the extent of retention in CNS and renal tissues, with ProHance giving less retention than Gadovist or Dotarem.

SSM16-03 Absence of Toxicity in Extended Duration Study of Gadolinium in Rodent Brains after Repeat Dosing of Gadodiamide: Investigation of Concentration, Location and Cell Ultrastructure

paul.m.evans@ge.com

PURPOSE

Recent studies report low levels of gadolinium based contrast agents in the brain following repeat exposure. The purpose of this study was to evaluate the levels of Omniscan in the rat brain up to one year post-dosing, to evaluate the location of retained gadolinium, and to determine if there were any neurohistopathological sequelae.

METHOD AND MATERIALS

This study reports on a 50-week experimental endpoint from a previously published study (Smith et al. Radiology, 282:3, March 2017) together with additional analyses at the 1, 20 and 50 week timepoints. Gadolinium concentrations were quantified in blood and brains of rats 50 weeks after the cessation of dosing (cumulative dose 12 mmol/kg over 5 weeks) using inductively coupled plasma mass spectrometry (ICP-MS). Brain sections at standard toxicological levels were evaluated by standard toxicological

assessment. A portion of the Deep Cerebellar Nucleus (DCN) was reserved and processed for transmission electron microscopic (TEM) cell ultrastructure analysis and TEM with electron dispersive spectroscopy (TEM-EDS).

RESULTS

Gadolinium levels at 50 weeks were comparable to those observed at 20 weeks. Toxicologic histopathology analysis revealed no findings, and cell ultrastructural TEM analysis similarly revealed no findings, indicating that this extended period of gadolinium exposure for up to 1 year did not result in any tissue injury. A TEM-EDS analysis of gadolinium localization in the DCN showed approximately 100 nanometer foci located in the basal lamina, abluminal to the endothelium.

CONCLUSION

We conclude that whilst a small portion of gadolinium in the brain after repeat doses of GBCA is subject to long term retention (approximately 1/1,000,000 of the injected dose), this does not result in any observable tissue injury. We further propose that this gadolinium is in perivascular foci, and we have not found foci in the brain parenchyma.

CLINICAL RELEVANCE/APPLICATION

These observations are consistent with clinical observations of brain Gd in the human brain but without histopathological changes or a corresponding clinical syndrome.

SSM16-04 Long Term Deposition with Slow Clearance of Gadolinium in Cerebellum After Repeated Injections of Gadodiamide as compared to Gadoterate Meglumine in Rats

PURPOSE

The objective of this study is to compare the long-term kinetics of Gd deposition in the cerebellum for gadodiamide (Omniscan®, linear contrast agent) and gadoterate meglumine (Dotarem®, macrocyclic contrast agent).

METHOD AND MATERIALS

Injection protocol: N=120 healthy rats received 5 intravenous injections of 2.4 mmol/kg of gadodiamide or gadoterate meglumine (N=60/agent) over a period of 5 weeks (1 injection per week) according to a published protocol (Robert 2016). Rats were divided in 6 groups with 0, 1, 2, 3, 4 and 5 months of washout period (N=10/agent, groups M0, M1, M2, M3, M4 and M5 respectively). Gd dosing: At each delay, animals were sacrificed. Blood and cerebellum were sampled and total Gd concentrations were dosed by the ICP-MS technic. Pharmaco-kinetics analysis: tissue Gd elimination kinetics in the cerebellum were fitted to estimate the tissue elimination half-lives in days along the 5 months of washout.

RESULTS

At all time-points, a significantly higher concentration of total Gd was found in cerebellum for gadodiamide groups as compared to gadoterate groups. Five months after the last injection, 30-fold more Gd was measured in the cerebellum in the gadodiamide group (2.29±0.30nmol/g) versus gadoterate (0.075±0.037nmol/g, $p<0.0001$). At this time-point, no remaining Gd was detected in the blood for both products. For gadodiamide, mean half-life of elimination (T1/2) of Gd accumulated in the cerebellum was 410 days. For comparison, more than 87% of Gd was cleared from the cerebellum with a T1/2 of 15 days for gadoterate meglumine.

CONCLUSION

A 30-fold higher total Gd concentration in the cerebellum was found 5 months after gadodiamide treatment as compared to gadoterate. Elimination of Gd from the cerebellum was 28-fold slower after injection of gadodiamide as compared to gadoterate meglumine. Recent studies have shown that a large amount of Gd is present under dechelated form one month after repeated injections of linear Gd contrast agents (Frenzel 2017) in contrary to macrocyclic Gd contrast agents which are excreted in chelated form. Such speciation analysis are ongoing on these long term data.

CLINICAL RELEVANCE/APPLICATION

After injection of linear Gd-based contrast agent gadodiamide, long term total Gd concentration in the cerebellum is 30-fold higher and elimination rate is 28-fold slower as compared to the macrocyclic gadoterate meglumine.

SSM16-05 Penetration and Distribution of Gadolinium-Based Contrast Agents into Cerebrospinal Fluid in Humans

Florian.Berger@irm.uzh.ch

PURPOSE

Signal hyperintensity on unenhanced T1-weighted magnetic resonance (MR) images correlating with gadolinium deposition has been reported after multiple administrations of gadolinium-based contrast agents (GBCAs). This increase seems to be primarily associated with the repeated use of linear GBCAs. Recent studies on healthy rats have furthermore demonstrated that the blood-cerebrospinal fluid (CSF) barrier is permeable to not only linear but also macrocylcic GBCAs. The aim of our clinical study was to evaluate whether gadolinium (Gd) can be detected in CSF, to the best of our knowledge, for the first time in humans.

METHOD AND MATERIALS

This study was approved by the local Ethics committee with patient's consent authorizing use of tissue samples in research studies. For inclusion, all patients with a lumbar puncture between January and August 2016 were screened for at least one previous MR examination with GBCA administration (gadoterate meglumine at a dose of 0.1 mmol/kg bodyweight) within a time frame of 60 days prior to CSF extraction. A total of 39 consecutive samples fullfilling these criteria were identified. These patients were enrolled and their CSF was analyzed for the presence of Gd. The control group consisted of 10 patients without any prior intravenous GBCA administration according to medical files. Gd measurements in the CSF were performed using inductively coupled plasma mass spectrometry by monitoring the response of the 158Gd isotope.

RESULTS

In all cases with prior GBCA administration, Gd could be detected in the CSF. Gd concentration in the CSF showed a steady increase over 6 hours following the intravenous injection of the contrast agent. A significant decrease of Gd concentration compared to the peak values could be detected 24 hours after injection. Less amounts but still measurable concentrations of Gd could be detected several days/weeks after contrast enhanced MR examination. Control groups were all negative for Gd presence as expected.

CONCLUSION

Gadoterate meglumine, a macrocyclic GBCA, crosses the blood-brain barrier in humans and penetrates the CSF, in accordance with previous preclinical studies on healthy rats. Traces of GBCA can be detected in the CSF days/weeks after iv administration.

CLINICAL RELEVANCE/APPLICATION

It seems that the glio-vascular pathway via the CSF is a potential entrance way for GBCA into the brain.

SSM16-06 Cerebrospinal Fluid (CSF) Gadolinium Accumulation after Intravenous Gadobutrol-Enhanced MRI

Wednesday, Nov. 29 3:50PM - 4:00PM Room: N226

PURPOSE

Recent studies in the setting of an intact blood brain barrier (BBB) have demonstrated intracranial gadolinium deposition following MRI with gadolinium-based contrast agents (GBCAs). While the mechanism of gadolinium distribution from bloodstream to neuronal tissue remains unclear, a proposed mechanism is through the blood-cerebrospinal fluid (CSF) barrier. This study evaluates gadolinium accumulation in the CSF after intravenous Gadobutrol administration.

METHOD AND MATERIALS

Patients who underwent a Gadobutrol-enhanced MRI and subsequent lumbar puncture (LP) within a period of 30 days (Gadobutrol group) were included versus a control group who had an LP without prior history of receiving gadolinium-enhanced MRI. Serum samples were also obtained following MRI exam. Gadolinium in CSF and serum samples was quantified using inductively coupled plasma mass spectrometry. Intact BBB was defined as total CSF protein less than or equal to 35 mg/dL. The relationship between gadolinium clearance and patient characteristics (ie. age, gender, CSF protein), and between serum and CSF gadolinium concentration were examined using regression models.

RESULTS

Eighty two (n=82) pediatric and adult patients (68 Gadobutrol, 14 control) were included. Time between Gadobutrol exposure and CSF collection ranged from 1.1 and 594 hours. Gadolinium was detected in the CSF of all Gadobutrol group patients (range 0.2 to 1494 ng/mL); alternatively the median gadolinium concentration in the control group patients was 0 ng/mL (IQR 0 - 0 ng/mL). Pediatric patients (<18 years) and those with an intact BBB had significantly faster clearance of gadolinium compared to adult patients and those with compromised BBB (CSF protein >35 mg/dL) (p=0.046 and <0.001, respectively). Furthermore there was significant correlation between gadolinium concentrations in the serum (range 2.2 - 277.8 ng/mL) and CSF samples (p<.0001).

CONCLUSION

Intravenous administration of Gadobutrol results in gadolinium accumulation within the CSF, even in the setting of normal renal function and no BBB dysfunction. Further research is required to determine the mechanism and clinical significance of gadolinium accumulation in CSF.

CLINICAL RELEVANCE/APPLICATION

Gadolinium accumulates in the CSF following intravenous administration of Gadobutrol in the absence of neurologic pathology and normal renal function, suggesting a route for intracranial deposition.

PURPOSE

Cerebral arterial vasospasm and clinical delayed cerebral ischemia (DCI) following aneurysmal subarachnoid hemorrhage (aSAH) accounts for up to 30% of the morbidity and mortality in these patients. Neurologic examinations, daily transcranial Doppler ultrasound (TCD), and screening CT/CT Angiography/CT Perfusion studies have limited sensitivity and specificity in identifying DCI. Intravoxel incoherent motion (IVIM) MRI extracts microvascular perfusion information from a multi-b value diffusion-weighted sequence. We determined whether decreased IVIM perfusion on brain MRI may identify patients with DCI and cerebral vasospasm.

METHOD AND MATERIALS

We performed a retrospective cohort study of patients with aneurysmal SAH rupture at our neurovascular center. Consecutive patients who underwent a brain MRI after ruptured aneurysm treatment with neurologic deterioration and possible DCI were included. Intravoxel incoherent motion was included in all MRI examinations during the study period. Patient demographic, DCI development, aneurysm and vasospasm treatment, and outcome data were determined by electronic medical record review. Statistical analysis was performed using Excel and SPSS.

RESULTS

16 patients (11 female; 5 male; p=0.9) were included. 10 patients (63%) developed DCI and vasospasm requiring endovascular treatment (DCI+ group) and 6 (37%) did not (DCI- group). DCI+ patients were younger (mean 59 years versus 70 years in the DCI- group; p=0.03); there were no differences in medical co-morbidities between these groups. Presentation Glasgow Coma Scale, Hunt and Hess Scale, and Fisher Grade were also similar between these groups. 20 MRI studies (14 in DCI+ and 6 in DCI-) were performed. All MRIs were performed prior to endovascular vasospasm treatment in DCI+ patients. Whole brain microvascular blood volume on IVIM was significantly reduced in DCI+ patients (mean±sd 0.13±0.02 mm2/s) compared to DCI- patients (0.9±0.03 mm2/s; p=0.03). There was no significant difference in arterial spin labeling or perfusion weighted imaging measures of cerebral perfusion between DCI+ and DCI- patients.

CONCLUSION

Decreased microvascular blood volume on IVIM correlates with DCI development following cerebral aneurysm rupture.

CLINICAL RELEVANCE/APPLICATION

IVIM perfusion may be a useful biomarker for DCI and a triage tool for endovascular vasospasm treatment. Prospective studies should validate this hypothesis.

SSM17-02 Assessment of Steal Phenomenon in MMD Patients with Combination of T-ASL and MRA

Wednesday, Nov. 29 3:10PM - 3:20PM Room: N227B

Participants
XINYI GAO, MSc, Shanghai, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

10301010213@fudan.edu.cn

1030101213@fudan.edu.cn

PURPOSE

Steal phenomenon is an independent risk factor for future stroke. We aimed to generalize the steal phenomenon conducted by the first and the second collaterals separately using t-ASL combining with MRA in MMD patients, and to explore the relationship between pre-operation hemorrhage and the steal phenomenon.

METHOD AND MATERIALS

Forty-three patients with bilateral moyamoya disease underwent t-ASL, MRA and DSA. Clinical factors including sex, age, hypertension, diabetes metabolic, hyperlipidemia, current smoking, history of taking Aspirin were gathered. Correlation analysis was used to compare the relationship between the amount of steal phenomenon and Suzuki staging. Univariate logistic regression analyses were performed to examine the relationship between pre-operation hemorrhage and each of the factors separately. Forward stepwise multivariate logistic regression analyses were performed to determine the crucial risk factor.

RESULTS

In every MMD patient steal phenomenon was positive (total amount 136). SP could be divided into five types on t-ASL images (ICA-contralateral ACA, ICA-contralateral MCA, anterior circulation-ipsilateral posterior circulation, posterior circulation-ipsilateral anterior circulation, external carotid circulation) and three groups according to MRA and t-ASL. The amount of SP was not associated with SUZUKI stage (P=0.122, 0.689). Out of all the clinical and imaging factors, high SUZUKI stage (P=0.038) and the existence of the steal phenomenon completely conducted by the second collateral (P=0.002) showed great power for predicting pre-operation hemorrhage. Forward stepwise multivariate logistic regression analyses revealed steal phenomenon completely conducted by the second collateral (OR: 29.499, 95% CI: 3.629-239.780; P =0.002) was more powerful than high SUZUKI stage (OR: 0.265, 95% CI: 0.098-0.718; P =0.009).

CONCLUSION

Steal phenomenon in MMD can be divided into five types by t-ASL and three groups according to MRA and t-ASL. Comparing with high SUZUKI stage, the existence of the steal phenomenon completely conducted by the second collateral is a stronger risk factor for pre-operation hemorrhage in MMD patients.

CLINICAL RELEVANCE/APPLICATION

Comparing with high SUZUKI stage, the existence of the steal phenomenon completely conducted by the second collateral is a stronger risk factor for pre-operation hemorrhage in MMD patients.

SSM17-03 High Resolution Time-of-Flight Magnetic Resonance Angiography with Volume Rendering Algorithm for Detection of Cerebral Aneurysms: Correlation with Standard Digital Subtraction Angiography (DSA)

aleerad@schmc.ac.kr

PURPOSE

We investigated the diagnostic performance and increased discriminative value of the biomarkers of high-resolution MRA(HR-MRA) with volume rendering(VR) post-processing techniques for the detection of cerebral aneurysms compared with conventional MRA(C-MRA), using digital subtraction angiography(DSA) as the gold standard.

METHOD AND MATERIALS

HR-MRA was performed for 38 patients with 51 possible aneurysms on C-MRA. For each possible aneurysm, two readers recorded their level of confidence on a 5-point scale. All patients were performed DSA, which was used as the standard of reference. ROC analysis was conducted to determine the effectiveness of C-MRA and HR-MRA in detecting aneurysm with and without VR. The sensitivity, specificity, PPV, and NPV for each category was calculated. AUC and the 95% CI of the area were computed to evaluate the detective ability. The increased discriminative value of the biomarkers was examined by calculation of NRI and IDI indices.

RESULTS

DSA revealed 37 aneurysms in 26 patients. Both in aneurysm-based and patient-based analyses, HR-MRA showed higher diagnostic accuracy than C-MRA, and when a VR algorithm was added, increased diagnostic accuracy was revealed(C-MRA vs. HR-MRA $p<0.01$; in addition of VR, $p<0.01$, respectively). Although the addition of VR to the HR-MRA did not improve the AUC(0.8031 vs. 0.8658, $p=0.16$), the IDI(19.38%, $Z=3.18$, $p<0.01$) and NRI(46.3%, $Z=6.32$, $p<0.01$) were statistically significant. When using the 5-point scale of MRA finding, C-MRA showed better performance than that of categorized MRA finding, without statistically significant difference of AUC ($p=0.27$). And the addition of VR to the HR-MRA did not improve the AUC(0.9228 vs. 0.9188, $p=0.14$), but the IDI(29.5%, $Z=4.3$, $p<0.01$) and NRI(73%, $Z=15.39$, $p<0.01$) were statistically significant. For aneurysms less than 3 mm, when HR-MRA with VR was applied, the detection rate was further increased than that of aneurysms greater than or equal to 3 mm.

CONCLUSION

The application of HR-MRA with a VR algorithm improved diagnostic performance for the detection of intracranial aneurysms, especially when the aneurysm was less than 3 mm.

CLINICAL RELEVANCE/APPLICATION

The application of HR-MRA with a VR algorithm has high accuracy, sensitivity and specificity for the detection of intracranial aneurysms, which is recommended to improve diagnostic performance for the detection of intracranial aneurysms.

SSM17-04 Comparative Study of 4D CTA and DSA for Vascular Assessment in Moyamoya Disease

Wednesday, Nov. 29 3:30PM - 3:40PM Room: N227B

Participants
Bing Tian, MD, Shanghai, China (*Presenter*) Nothing to Disclose
Bing Xu, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose
Qi Liu, MD, PhD, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose
Jianping Lu, MD, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

We use 4D CTA to evaluate the vascular changes in moyamoya disease, including the vascular stenosis (modified Suzuki score, Houkin score) and collateral circulation (basicranial moyamoya vessels, posterior circulation collaterals and ECA collaterals). DSA was used as the gold standard to determine the value of noninvasive angiography in moyamoya disease.

METHOD AND MATERIALS

101 patients with confirmed moyamoya disease were underwent 4D CTA and DSA with an interval of <1 week. Two neuroradiologists evaluated the 4D CTA (VR and MIP) and DSA images independently or jointly in the case of disagreement. The performance of 4D CTA relative to DSA was determined using consistency checks (kappa values, 95% CI) and correlation analysis.

RESULTS

We obtained the following kappa values for consistency between 4D CTA and DSA: modified Suzuki score, 0.714 (0.649-0.778); Houkin score, 0.846 (0.780-0.911); the basicranial moyamoya vessels, 0.594 (0.525-0.663); posterior circulation collaterals, 0.435 (0.325-0.544); and ECA collaterals, 0.591 (0.483-0.699). The corresponding correlation coefficients (P values) were 0.843 (<0.001), 0.872 (<0.001), 0.792 (<0.001), 0.635 (<0.001) and 0.797 (<0.001).

CONCLUSION

In the evaluation of the vascular changes of moyamoya disease, 4D CTA (VR and MIP) showed strong consistency and correlation with DSA in terms of the vascular stenosis score, but was insufficient in collateral circulation evaluation.

CLINICAL RELEVANCE/APPLICATION

We adopted the modified Suzuki score and Houkin score to evaluate intracranial vascular stenosis in MMD, and also evaluated collateral circulation (the basicranial moyamoya vessels, and collaterals from the posterior circulation and ECA). Here, we discuss the value of 4D CTA for vascular assessments in adult MMD patients as compared with the gold standard, DSA. Upon analyzing the 4D CTA and DSA images of 101 adult patients with confirmed MMD, we concluded the following: (1) 4D CTA has high consistency and correlation with DSA in terms of the Suzuki and Houkin scores; and (2) 4D CTA has fair correlation and moderate consistency with DSA for the assessment of collateral circulation, specifically, the basicranial moyamoya vessels, and collaterals from the posterior circulation and ECA.

SSM17-05 4D Flow MRI Analysis of Cerebral Blood Flow Before and After High-Flow EC-IC Bypass Surgery

PURPOSE

One of the treatment options for complex ICA aneurysm is the ligation of the ICA with the high-flow extracranial-intracranial (EC-IC) bypass surgery. Though the cerebral hemodynamics is thought to be changed drastically after the surgery, there has been no published papers performing quantitative evaluation. The purpose of this study was to clarify the change of the hemodynamics after the high-flow EC-IC bypass surgery by using time-resolved 3D-phase contrast (4D Flow) MRI.

METHOD AND MATERIALS

We enrolled 11 patients (2 men; mean age 62.8) who underwent ICA ligation and high-flow EC-IC bypass surgery with radial artery graft for treatment of a complex ICA aneurysm. They underwent 4D Flow MRI preoperatively and 3 weeks after the bypass surgery. The imaging parameters; 3.0-T MRI (Aheiva, Philips), TR/TE=8.4/5.4, VENC=100cm/sec, voxel size=0.82X0.82X1.4mm, heart phase= 15, scan time= approx. 6 min. We measured blood flow volume (BFV) of bilateral ICAs, BA, and bypass artery by using GT Flow (Gyro Tools). The BFV of each vessel and total brain BFV (t-BFV = bilateral ICAs + BA + bypass) were compared between before

and after surgery by using paired t-test. We evaluated post-operative hyperperfusion based on CT perfusion and clinical symptoms within 3 weeks after the surgery.

RESULTS

In all patients, the patency of the bypass artery was confirmed by 4D Flow MRI. The BFV of contralateral ICA and BA were statistically increased after the surgery (ICA: 5.89±2.08 vs. 7.22±1.88 ml/sec (p=.0018), BA: 3.06±0.17 vs. 4.12±0.14 ml/sec (p<.001)). T-BFV was statistically increased after surgery (12.99±8.65 vs. 15.18±3.14 ml/sec (p=.0067)). While, there was no evidence of hyperperfusion in any cases based on CT perfusion or clinical symtoms.

CONCLUSION

In the current study, we could prove that the drop of BFV from sacrificed ICA is compensated by both native arteries (contralateral ICA and BA) and the bypass. Though the CT perfusion and clinical symtoms confirmed there is no hyperperfusion, the t-BFV increased 16.8%. It may indicate 4D Flow MRI could reveal the subtle hyperperfusion. In conclusion, 4D Flow MRI could quantify the change of hemodynamics after the high-flow bypass surgery. It provides insight to the autoregulation system in the cerebral blood flow.

CLINICAL RELEVANCE/APPLICATION

4D Flow MRI is one of the optimized imaging modalities for the quantitative assessment of the cerebral hemodynamic change after high-flow EC-IC bypass surgery.

SSM17-06 Angiogram-negative Non-perimesencephalic Subarachnoid Hemorrhage: A Meta-Analysis of Follow up Strategies

Wednesday, Nov. 29 3:50PM - 4:00PM Room: N227B

Participants
Long Tu, MD, New Haven, CT (*Presenter*) Nothing to Disclose
Yiyuan Fang, New Haven, CT (*Abstract Co-Author*) Nothing to Disclose
Xiao Wu, New Haven, CT (*Abstract Co-Author*) Nothing to Disclose
Ajay Malhotra, MD, Stamford, CT (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The purpose of this study is to synthesize the current literature into recommendations regarding the follow up of non-perimesencephalic subarachnoid hemorrhage. Specifically, we will investigate the utility of various imaging modalities (CTA, DSA, MRA) of repeat imaging after an initially negative angiographic study (usually CTA or DSA).

METHOD AND MATERIALS

PUBMED, EMBASE, SCOPUS and research meeting abstracts were searched up to March 2017 for studies of patients with spontaneous subarachnoid hemorrhage (SAH) and an initially negative angiographic study (DSA, CTA, or MRA). Title/abstract and then full text screening was performed by two independent reviewers. Study quality was assessed via the Cochrane Risk of Bias Tool (CRBT). Where appropriate, meta-analysis was conducted using random effects models.

RESULTS

A total of 1917 studies were identified, of which 178 underwent full text review; 95 studies were included. Diagnostic methods for initial angiographic as well as follow up studies were variable. Preliminary assessment of study quality by CRBT also showed variability; however, most studies had a low risk of bias. Preliminary data suggest superiority of DSA and CTA to MRA for follow up of angiogram-negative NPSAH.

CONCLUSION

Spontaneous SAH may be categorized as perimesencephalic, diffuse aneurysmal , peripheral (convexity, sulcal), or CT-negative (detected only on lumbar puncture) based on the distribution of acute hemorrhage. Follow up imaging for patients with perimesencephalic patterns of hemorrhage has been shown to be unlikely to find an underlying structural lesion or to change outcome for this relatively benign entity. The optimal management strategies for non-perimesencephalic SAH however are not clear. Preliminary data from our meta-analysis suggest superiority of DSA (including rotational 3D angiogram) and CTA over MRA for NPSAH with an initially negative angiographic study.

CLINICAL RELEVANCE/APPLICATION

Our study will make recommendations on the optimal management of the more concerning (non-perimesencephalic) subtypes of spontaneous SAH based on existing literature.

Weili286@163.com

PURPOSE

To investigate the feasibility and advantages of ' one-stop' axial scanning of coronary and spiral scanning of head-neck CTA.

METHOD AND MATERIALS

78 patients were randomly divided into three groups: Group A (n=26) performed helical scanning of head and neck CTA and axial scanning of CCTA altogether with one-time injection of contrast medium. The switching delay between the two scanning modes was as short as 1.1 s. Group B (n=26) performed conventional head-neck CTA exams with a scanning range from aortic arch to calvarium. Group C (n=26) performed conventional CCTA scanning. The effective radiation dose (ED) and usage of contrast medium volume were recorded for each patient. Double-blinded evaluation of the image quality of the three groups were completed by two physicians.

RESULTS

The image quality of coronary and head and neck in Group A was not different from that in Group B and Group C (4.63±0.42,4.34±0.73,p>0.05). The volume of contrast medium used in Group A was significantly less that the total volume in Group B and C (53.1±3.9ml:115.2±10.6ml, t=15.9 p<0.001). The ED in Group A was not different from the combined ED in Group B and C (2.1±0.4mSv vs. 1.9±0.5mSv).

CONCLUSION

The "one-stop" scanning protocol enabled CTA of coronary and head-neck with one-time injection of contrast medium, resulting a reduction of 50% contrast medium dose, while the image quality and radiation dose were comparable with separate scanning protocols.

CLINICAL RELEVANCE/APPLICATION

The combination of axial and spiral CT angiography is the first choice for evaluation of cardiovascular and cerebrovascular diseases.

SSM18-02 Achieving Good Images in Head CT with Optimized Iterative Reconstruction Algorithm (ASIR-V) in Combination with EC2 to Further Reduce Radiation Dose

zhuyanan1977@163.com

PURPOSE

To evaluate the head CT image quality and radiation dose reduction potential with optimized third generation adaptive statistical iterative reconstruction (ASIR-V).

METHOD AND MATERIALS

Prospectively enrolled 80 adults for non-enhanced head CT on a 16cm wide-detector 256-row Revolution CT scanner. Participants were randomly divided into two groups: Group 1 (n=40) with the standard low dose scan and reconstruction protocol of 120kVp / 200mAs and 60%ASIR-V algorithm; Group 2 with the reduced radiation dose of 120kVp / 120mAs scan protocol. Images in Group 2 were reconstructed using ASIR-V at 0%-100% to select the optimal strength for getting the highest subjective image quality. The subjective image quality was evaluated by 2 board-certificated radiologists using a 5-point scoring system with 3 and above being acceptable for diagnosis. Enhanced Contrast Level 2(EC2) reconstruction was done at the optimal ASIR-V (in Group 2). The CT numbers and their standard deviation (SD) of cerebellum and centrum ovale were measured to calculate signal to noise ratio (SNR) and contrast to noise ratio (CNR) for cerebellum. Radiation dose was recorded. Measurements from the two groups were compared between the optimal ASIR-V (in Group 2) in combination with EC2 and the conventional Group (Group 1).

RESULTS

With the increase of ASIR-V strength from 0% to 100%, noise decreased while CNR and SNR increased monotonically. The highest subjective image quality was achieved at 70% ASIR-V. There was no statistical difference in the noise in centrum ovale and the overall subjective image quality scores between Group 1 and the group of 70% ASIR-V in combination with EC2. However, compared with the conventional group (Group 1), the group of 70% ASIR-V in combination with EC2 significantly raised the CNR of the cerebellum by 21.4% (3.74±0.84 vs. 4.59±0.73) ($P<0.05$). On the other hand, compared with the standard low dose group, the reduced dose group with 70% ASIR-V significantly reduced effective radiation dose by 56% (0.44 vs. 1.01 mSv) ($P<0.05$).

CONCLUSION

The CT image quality of the head was acceptable on a 256-row, 16cm wide-detector CT with 70% ASIR-V algorithm in combination with EC2 at 44% dose, compared with standard low dose head CT scan and reconstruction protocol.

CLINICAL RELEVANCE/APPLICATION

Good images of the 120mAs head can be achieved on a wide-detector CT with 70% Asir-V in combination with EC2 reconstruction to reduce the radiation dose.

PURPOSE

In the rapidly evolving field of acute stroke diagnosis and management, multiphase CTA (mCTA) has been recently developed, allowing better evaluation of collateral filling with temporal resolution and permitting a semi-quantitative collaterals score. To assess radiation dose and patterns of use of mCTA in a stroke referral center, we reviewed all patients who underwent mCTA. We also illustrate how the imaging protocol was modified to reduce the effective dose.

METHOD AND MATERIALS

All patients presenting with acute stroke symptoms who underwent our stroke imaging protocol were retrospectively evaluated. The protocol consists of non-contrast CT (NCCT) and mCTA. After intracranial hemorrhage was excluded on NCCT, mCTA was performed. Most patients were imaged on a Siemens Somatom Definition scanner. In case the former was unavailable a Philips Brilliance 16 was used. Scan parameters are shown in Tables 1 and 2. Iodine-based contrast medium (60mL,370mg/mL) was injected at 5mL/s followed by 40mL of saline solution at 5mL/s. From April 2017 the 3 mCTA phases on Definition were lowered from 120kVp to 100kVp, keeping the other parameters constant. The assessment of organ doses (brain and lens) was performed on stylized human phantoms implemented in CT-Expo v2.3 software.

RESULTS

From 1st June 2015 to April 10th 2017 we analyzed 274 consecutive patients who underwent NCCT and mCTA (median age 68, range 14-92, males percentage 56%). Radiation doses are reported in Tables 1 and 2. Effective dose (according to ICRP 103) ranges from 9.4 to 10.4mSv for the old protocols, aligned with previous reports for mCTA, and lower than the protocols including CT perfusion, in particular for eye lens. The new 100kVp protocol allows a reduction of the effective dose of 30%, from 10.4 to 7.3 mSv.

CONCLUSION

The NCCT+mCTA protocol was designed to be fast to perform and interpret, in order to provide critical information on brain parenchyma and vasculature while minimizing door-to-groin time in patients who are candidates for mechanical thrombectomy. By

lowering voltage of mCTA to 100kVp the effective dose reduction was substantial, without perceived loss of diagnostic accuracy from multiple viewers and even enhancing arterial contrast.

CLINICAL RELEVANCE/APPLICATION

Multiphase CT angiography as part of an acute stroke imaging protocol is associated with low radiation dose and provides critical information on brain parenchyma and vasculature.

SSM18-04 Carotid-CTA at 70 Kilovolt (kV) in Comparison to Automated Tube Voltage Adaption in Respect to Radiation Exposure and Image Quality

Wednesday, Nov. 29 3:30PM - 3:40PM Room: N229

matthias.may@uk-erlangen.de

PURPOSE

To evaluate a 70 kV protocol in computed tomography angiography (CTA) of the carotid arteries in respect to image quality and radiation exposure compared to automated tube voltage adaption.

METHOD AND MATERIALS

Ninety consecutive patients were included in this prospective study. Fourty-five (64, 35 - 84 years) were randomized to the study group (70 kV, 167 ref.mAs) and 45 (65, 24 - 87 years) were randomized to the control group (automated kV adaption, 70 - 150 kV). CT dose index (CTDIvol) and dose length product (DLP) were recorded from the examination protocol. Image quality was assessed by region of interest (ROI) measurements and calculations of signal to noise (SNR) and contrast to noise ratio (CNR). Subjective image quality and image artifacts were evaluated by two observers with a 4-point scale (3-excellent; 0-not diagnostic).

RESULTS

Radiation exposure was significantly lower in the study group (CTDIvol reduction of 22%, DLP reduction 20%; each $p<0.001$). Contrast ($p=0.15$), SNR ($p=0.4$), and CNR ($p=0.5$) did not show significant differences between the groups. Subjective image quality was without significant differences between the two groups ($p=0.56$). Also artifacts due to contrast medium influx were without significant difference ($p=0.17$). Artifacts due to beam hardening in the height of the shoulder girdle were significantly more affecting in the scans from the study group ($p=0.04$) while there was also no significant difference on the height of the skull base ($p=0.65$).

CONCLUSION

Carotid-CTA using fixed 70 kV is feasible at very low radiation dose levels while overall image quality is constant to protocols using automated tube voltage selection.

CLINICAL RELEVANCE/APPLICATION

Lowest available tube voltages (70 kV) can increase the radiation dose efficiency in CT angiographies of the carotids compared to individual tube voltage adaptation.

SSM18-05 Dual Energy CT Angiography of the Carotid Arteries: Quality, Bone Subtraction and Radiation Dosage Using Second- and Third-Generation Dual-Source CT

Wednesday, Nov. 29 3:40PM - 3:50PM Room: N229

Participants
Yu Chen, MD, Beijing, China (*Presenter*) Nothing to Disclose
Yuanli Zhu, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
Huadan Xue, MD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
Zhengyu Jin, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To study the differences in vascular image quality, bone substraction, and dose of radiation of dual energy CT angiography (CTA) of the supraaotic trunks using second- and third-generation dual-source CT (DSCT). Comparing the diagnostic performance of arterial stenosis between the third-generation dual-source CT and digital subtracted angiography (DSA).

METHOD AND MATERIALS

CTA of the supraaortic trunks in 40 patients were retrospectively reviewed. 20 patients used second-generation dual-energy CT (DECT) system (100/Sn140 kp tube voltage) and 40-mL contrast material. Another 20 patients used third-generationDECT system (90/Sn150 kV tube voltage) and 30-mL contrast material. The attenuation was measured in common carotid artery (CCA), C7 segment of internal carotid arteries, and cervical muscle (CM). The noise of CCA and CM was recorded. The signal-to-noise ratio (SNR) of CCA and contrast-to-noise ratio (CNR) were calculated. 5-scoring system was used for bone removal of C1-C7 segments of internal carotid arteries (1=poor, 5=excellent). DSA was performed if necessary. Accuracy, sensibility, specificity were calcuated.

RESULTS

The attenuation of third-generation group was significant higher on C7 (P=0.001), and not different on CCA (all P = 0.317) compared with that of second-generation group.Both SNR and CNR of CCA were significantly higher in second-generation group than third-generation group (both p < 0.05). The dose-length product in second-generation group was lower than that of third-generation group (299.7 ± 16.7 vs. 218.3 ± 27.8 mGy×cm, P<0.001).Scores of the bone removal of C2, C3, C4 and C7 were were evaluated as 5 score in the third-generation group, which were higher than that of second-generation group were lower (all P < 0.05). 6 patients in the third-generation group received DSA examination, the accuracy, sensibility, specificity for detecting >50% arterial stenosis were 98.8%, 100% and 98.8%.

CONCLUSION

Third-generation dual-energy scan mode is is able to decrease the volume of contrast material, reduce the radiation dose and improve the image quality of bone removal compared with second-generation grouu. the accuracy, sensibility, specificity are high compared with DSA.

CLINICAL RELEVANCE/APPLICATION

Dual-energy scan mode of third-generation CT provides better bone-subtraction quality of carotid arteries and is equal to DSA in detecting arterial stenosis.

SSM18-06 Using a Low Tube Voltage Protocol with Adaptive Statistical Iterative Reconstruction in Craniocervical Computed Tomographic Angiography Provides Better Image Quality with a Reduced Radiation Dose

Wednesday, Nov. 29 3:50PM - 4:00PM Room: N229

Participants
Chih-Wei Chen, MD, Kaohsiung City, Taiwan (*Presenter*) Nothing to Disclose
Po-An Chen, MD, Kaohsiung, Taiwan (*Abstract Co-Author*) Nothing to Disclose
Yun-Pei Lin, Kaohsiung City, Taiwan (*Abstract Co-Author*) Nothing to Disclose

Rita S. Wu, Kaohsiung City, Taiwan (*Abstract Co-Author*) Nothing to Disclose
Ping-Hong Lai, Kaohsiung, Taiwan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate image quality and radiation dose by using a lower kVp protocol (100 kVp) and 50% ASiR-V for Craniocervical Computed Tomographic Angiography (CCCTA) in comparison with the conventional protocol (120 kVp).

METHOD AND MATERIALS

A total of 121 volunteers (47 men, 74 women; age range, 15-78 years) were enrolled and randomly divided into 3 groups: group A (conventional protocol): 120 kVp and filtered back-projection reconstruction; group B: 120 kVp and 50% ASiR-V; group C: 100 kVp and 50% ASiR-V. All patients were scanned by a 256-slice CT machine with the slice thickness of 0.625 mm. Objective values(arterial attenuation value, signal-to-noise ratio [SNR], contrast-to-noise ratio [CNR]) of arteries was obtained at head, neck and shoulder levels and compared among three groups. Subjective image quality and radiation dose (volume CT dose index [CTDIvol], dose-length product [DLP]) were also compared. The quantitative parameters and radiation dose were analysis by ANOVA. Subjective image quality was evaluated by two experienced radiologists independently and inter-rater reliability was calculated using kappa (k) analysis.

RESULTS

For the radiation dose, the CTDIvol and DLP of group C were the lowest among three groups. For the objective values, the arterial attenuation in head, neck and shoulder were significant higher in group C than those in group A and B (each P <0.05). The SNR and CNR of group B and C were significant higher than the conventional group A (each P <0.05), and there were no significant difference for the SNR and CNR between group B and C. In subjective image quality analysis, group C revealed significant better image quality than group A and B (P <0.05). The inter-rater reliability was good (k=0.73).

CONCLUSION

In CCCTA, using 100 kVp and 50% ASiR-V protocol showed better arterial attenuation, SNR, CNR and subjective imaging quality with a reduced radiation dose compared to the conventional protocol.

CLINICAL RELEVANCE/APPLICATION

Using ASiR-V with a lower kVp protocol in CCCTA, better objective and subjective imaging quality can be obtained with a reduced radiation dose compared to the conventional protocol.

sehayatg@texaschildrens.org

PURPOSE

To compare the complications from percutaneous renal biopsies performed using real time ultrasound-guidance versus pre-procedure ultrasound-aided skin marking in children.

METHOD AND MATERIALS

An a priori analysis yielded a sample size of 850 procedures required to detect a difference in complications between the two groups (power: 0.8). Consecutive patients who underwent a percutaneous renal biopsy at our tertiary care academic medical center were retrospectively identified. Demographic information, biopsy technique, and post-biopsy complications were recorded. Complications were categorized according to Society of Interventional Radiology (SIR) criteria. Complication rates were compared using Fisher's exact test.

RESULTS

The study population consisted of 850 renal biopsy procedures in 626 patients. Real-time ultrasound guidance was performed in 375 biopsies (age range: 0-29, mean: 12.1 yrs); 475 biopsies used pre-procedure ultrasound-aided skin marking (age range: 2-27, mean: 13.6 yrs). Diagnostic yield was obtained in all biopsies with real-time ultrasound (mean cores: 2.63+/-1.52) and in 471/475 (99.2%) of those using pre-procedure skin marking (mean cores: 2.64+/- 0.72; p=0.91). Overall, 283 (33.3% of biopsies) complications were detected in the study cohort; 60 (16% of biopsies) in the real-time ultrasound guidance group and 223 (47% of biopies) in the conventional skin marking group (p<0.001). In the real-time ultrasound group, 43 complications (11.5% of biopsies) were SIR A and 8 (2.1% of biopsies) SIR B. In the skin marking group, 156 (32.8%) biopsies resulted in SIR A complications and 54 (11.4%) SIR B. The groups were statistically different for both SIR A (p<0.001) and SIR B (p<0.001) complications. There was no detectable difference in major complications between the groups [p=0.83; real-time ultrasound guided: 6 (1.6%) SIR C and 3 (0.8%) SIR D; skin marking: 12 (2.5%) SIR C and 1 (0.2%) SIR D].

CONCLUSION

Patients who underwent real-time ultrasound-guided renal biopsies had significantly fewer minor complications, including those that required follow-up medical care (SIR B), compared to those who underwent pre-procedure ultrasound-aided skin marking.

CLINICAL RELEVANCE/APPLICATION

Patients with an ultrasound-guided renal biopsy required less additional medical care for complications. This is important in value based healthcare that pursues quality outcomes at controlled costs.

SSM19-02 Onyx Embolization in Pediatric Neuro-interventional Procedures

tahaamin.shokuhfar@northwestern.edu

PURPOSE

Although AVMs are rare among pediatric population, nearly half of spontaneous intracranial hemorrhages in children are due to these malformations. Onyx, as an FDA approved embolizant for adults, has limited studies regarding its safety and efficacy among children. Here, we evaluate the safety and efficacy of Onyx embolization in pediatric neurointerventional procedures.

METHOD AND MATERIALS

In this study, all pediatric Onyx embolization of intracranial AVM cases are evaluated over a period of 10 years. Medical record and radiology imaging were reviewed for each patient regarding demographic data, clinical presentations, embolization procedure and related complications.

RESULTS

Seventy-two patients (female = 26 (36%)) with intracranial AVMs underwent total of 122 embolization procedures. Age of patients ranged between 1 month to 17 years with the mean of 10.2 years. Forty-four patients underwent a single embolization procedure and staged embolization was required for the remaining 28 patients prior to definitive treatment. Onyx embolization resulted in complete occlusion of the AVM in 10 patients (14%). A total of 66 patients underwent subsequent surgical treatment. Overall 13 complications occurred in total of 122 Onyx embolizations (10.6%) which resulted in 7 transient neurological deficits and 6 clinically silent complications (Table 1). None of the complications resulted in mortality or permanent morbidity. No significant demographic characteristic differences observed in patients with or without complications.

CONCLUSION

In this study we propose the safe and effective utilization of Onyx for embolization of pediatric cerebral AVMs. The relative low rate of complications (10.6%) along with no mortality or permanent morbidity, suggests the safe utilization of Onyx as a preoperative or primary embolization treatment of pediatric intracranial AVMs. However, specific attention should be considered for its indications and technical limitations according to the broad spectrum of complications.

CLINICAL RELEVANCE/APPLICATION

Onyx utilization can be feasible for preoperative or primary embolization in the treatment of pediatric AVMs. We report here the largest series of Onyx embolizations of brain AVMs in the pediatric population. The results, in terms of clinical and angiographic improvement, with a low rate of transient morbidity and no permanent morbidity or mortality, are encouraging.

SSM19-03 Magnetic Resonance-Guided Focused Ultrasound Surgery for Treatment of Osteoid Osteoma in Pediatric Patients Only: A Multicenter Experience

PURPOSE

To retrospectively evaluate the effectiveness and safety of MRgFUS of Osteoid Osteoma in paediatric patients (age <18 years) based on the experience of three university hospitals. Since OOs mostly affect patients in paediatric age, it is of paramount importance that the employed techniques be as minimally invasive as possible. MRgFUS aims to become the standard care, producing no skin lesion or damage to the soft tissues.

METHOD AND MATERIALS

Over a period of 4 years, we used MRgFUS on 33 patients (age <18 years, mean 13.8) affected by symptomatic non-spinal Osteoid Osteoma. Inclusion criteria were: (i) clinical diagnosis of osteoid osteoma (pain, more typically nocturnal, relieved by NSAIDs: mean pre-treatment VAS value: 7.5 (CI: 4-10)); (ii) positive imaging for OO with typical features; (iii) subperiosteal or cortical lesions only: a periosteal reaction or a cortical thickening (more than 6 mm) surrounding the lesion was considered as a technical contraindication for MRgFUS treatment. The outcomes were evaluated with clinical and imaging follow-up studies up to 5 and 3 years, respectively.

RESULTS

After treatment, absence of pain was observed in 31 patients (94% of complete success; VAS: 0), confirming the effectiveness of the procedure. One patient reported VAS: 1 during follow-up, but because the condition was considered satisfactory by the patient, an additional treatment was not deemed necessary. Only one patient was treated twice to obtain complete pain relief. Nor relapse or complications were observed. The long term imaging control showed a progressive restoration to the original condition of the bone segments without signs of treatment or residual inflammatory findings.

CONCLUSION

MRgFUS is safe and effective for treatment of selected localizations of osteoid osteoma; for superficial lesions it could be

MRgFUS is safe and effective for treatment of selected localizations of osteoid osteoma. For superficial lesions it could be considered the first and definitive choice for patients in paediatric age. The possibility of treating only subperiosteal or cortical lesions is a limit but non too notable, because the greater part of the osteoid osteomas belong to these two categories. This touch-less approach does not leave any sign of the procedure nor interference with the normal growth of the bone.

CLINICAL RELEVANCE/APPLICATION

This treatment could represent the less invasive step for the treatment of Osteoid Osteoma.

SSM19-04 Mynxgrip Vascular Closure Device Use in Pediatric Neurointerventional Procedures

Wednesday, Nov. 29 3:30PM - 3:40PM Room: S102CD

Participants
Tahaamin Shokuhfar, MD, Chicago, IL (*Presenter*) Nothing to Disclose
Anas Al-Smadi, MD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
Sameer A. Ansari, MD,PhD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
Michael C. Hurley, MBBCh, Dublin, Ireland (*Abstract Co-Author*) Nothing to Disclose
Ali Shaibani, MD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The application of arterial closure devices has been broadly investigated and previously approved in adults but their feasibility and safety have not been approved in pediatric patients and any application of such devices in children is considered off-label. The decision to use the Mynxgrip in our practice has been made based on the low reported rate of complications in adults and the fact of no intra-luminal component regarding the usage of Mynxgrip.

METHOD AND MATERIALS

A Retrospective review of all pediatric patients undergoing diagnostic or interventional neurovascular procedures was conducted. Mynxgrip was applied to any pediatric patient with adequate depth of subcutaneous tissue and common femoral artery (CFA) diameter. Patients' demographic and procedural data was recorded. Hemostasis status and complication reassessment for outpatients and pre-operational inpatients were documented.

RESULTS

During the period of 36 months, a total of 83 Mynxgrip was deployed on 53 children (23 male and 30 female, mean age = 14.5 years) undergoing diagnostic/interventional neuro-endovascular procedures through common femoral artery access site. About 46% procedures were diagnostic angiography and the remaining were angiography with embolization. CFAs' diameter were ranged between 4mm to 8.5mm with the average diameter of 6.24 (SD± 1.16). Deployment of Mynxgrip was successful in 82 procedures (98.8%). There was a single (1.2%) device failure and no other immediate or delayed major complications were recorded.

CONCLUSION

Comparing with the manual compression as the current standard of care, the application of Mynxgrip in our practice brought immediate hemostasis at common femoral artery access site, along with earlier ambulation and shorter duration of hospitalization.

CLINICAL RELEVANCE/APPLICATION

To the best of our knowledge, current study is the first report of the application of Mynxgrip arterial closure device among pediatric population. We reported the feasibility of Mynxgrip as a safe and efficient way of hemostasis achievement at CFA arteriotomy site in children undergoing diagnostic or neuro-interventional procedures.

SSM19-05 Percutaneous Ablation of Malignant and Locally Aggressive Solid Tumor in Pediatric Patients

gonzala2@mskcc.org

PURPOSE

Present the oncologic outcomes of our series of pediatric patients treated with ablation for primary and metastatic cancers.

METHOD AND MATERIALS

Retrospective review of a HIPAA compliant prospectively maintained percutaneous ablation database. All ablations performed in patients younger than 18 years since 2002 were reviewed. RFA was performed using the the Cool-tip system (Covidien, Boulder, CO). Cryoablation was performed using the Endocare system (HealthTronics, Inc. Austin TX).Patients were watched for 4 hours after ablation and discharged home in the absence of complications. Patients were admitted for pain or other complications. CT and/or PET/CT scan was obtained 1 month after ablation. Subsequent imaging studies were obtained as indicated by the pediatric oncologist to assess for findings of local tumor progression (LTP). Patient and tumor characteristics were described and summarized. Survival end points of interest include overall survival (OS) and local tumor progression free survival (LTPFS) . Survival end points were analyzed using Kaplan-Meier method.

RESULTS

8 pediatric patients were identified in our database that includes 1471 patients treated with ablation since 2002. There were 4 males and 4 females. Mean age was 12.8 years (range 3 - 17). Mean weight was 49.5 kilos (15 - 60 kilos). These 8 patients underwent 12 ablations to treat 9 lesions. Mean lesion size was 3.4 cm (Range 0.8 -7.8 cm). Mean hospital stay was 2.1 days (median 2.3 days, range 0-4). There was one major complication (SIR classification D) in a patient with lung metastases from chondrosarcoma. He developed parenchymal bleeding that required intubation for less than 24 hrs. Mean follow up was 79 months. OS at 5 years was 75%. Median LTPFS was not reached. At the end of follow up 2 lesions developed LTP. LTPFS rates were 88% at 1 year and 77% at five years .

CONCLUSION

Ablation can be performed safely and effectively in a carefully selected group of pediatric patients with cancer. We consider that the use of these technologies should be used more often and in conjunction with other cancer treatments, always in the setting of multidisciplinary consensus.

CLINICAL RELEVANCE/APPLICATION

Ablation can be performed safely and with good results in pediatric patients.

SSM19-06 Transjugular Intrahepatic Portosystemic Shunts (TIPS): Safety and Efficacy in the Pediatric Population

jeng@bcm.edu

PURPOSE

To report the experience of a tertiary pediatric referral center with creation and revision of transjugular intrahepatic portosystemic shunts (TIPS) in children and adolescents.

METHOD AND MATERIALS

10 consecutive patients over a 10 year period with 9 undergoing TIPS creation and 1 undergoing TIPS revision (initially placed at an outside institution). 8 patients were under the age of 18: 2 infants (ages 9 and 10 mos), 5 children (ages ranging from 5 y, 11 mo to 12 y, 1 mo), and 1 adolescent (age 16 y, 6 mo). All had gastroesophageal variceal bleeding as the reason for TIPS creation/revision. Causes of liver dysfunction were biliary atresia in 5 patients, cystic fibrosis in 1, veno-occlusive disease secondary to chemotherapy in 1, and Ellis-van Creveld Syndrome in 1.

RESULTS

The technical success rate was 100%. 6 patients received Viatorr endografts while 1 patient received a Luminex endograft and a Wallstent. 4 TIPS were created using a 10 mm endograft, 2 using an 8 mm endograft, and 1 using a 2 cm endograft. The mean portosystemic pressure gradient was reduced from 19 mmHg to 8 mmHg. Flow was successfully restored in the patient undergoing TIPS revision. Primary patency during initial ultrasound follow-up performed 1 to 2 days post procedure was 100%. Follow-up imaging performed up to 23 months post procedure demonstrated 100% stent patency. There were no major complications or mortalities associated with TIPS creation. One patient continued to experience intermittent hemoptysis, though likely related to underlying cystic fibrosis, while one developed a single episode of transient hyperammonemia. One patient underwent balloon angioplasty 3 days post TIPS creation for decreased hemoglobin and concern for GI bleeding with no stenosis or thrombosis discovered on portal venogram. There were no other repeat interventions, shunt dysfunctions, or recurrent episodes of GI bleeding. 6 children have since received hepatic transplants with 3 children receiving transplants 23, 20, and 8 days post TIPS creation.

CONCLUSION

TIPS placement can be successfully performed in young pediatric patients with low complications rates and excellent initial and intermediate patency.

CLINICAL RELEVANCE/APPLICATION

TIPS is a well-documented method for treating portal HTN and its sequela in adults. With increasing use in the pediatric population, we wanted to determine its effectiveness and safety in children.

sebastian.fischer@kgu.de

CONCLUSION

Hyperpolarized water might be a promising future alternative to Gadolinium based contrast agents in MR angiography or even further diagnostics without risking the potential adverse effects or intracorporal remnants of Gadolinium based contrast agents.

Background

The administration of Gadolinium based contrast agents is associated with the risk of allergic reactions and the development of a systemic nephrogenic fibrosis (NSF). Current research showed remnants of some types of Gadolinium based MR contrast agents in the brain - with unknown long-term effects. Purpose of our work is the development of an alternative method to create MRI contrast by using dynamic nuclear polarization (DNP). The tested liquid-state Overhauser DNP is a technique to achieve hyperpolarization by microwave irradiation of electron spins in TEMPOL radicals, which are coupled with the nuclear spins of water molecules.

Evaluation

Our setup comprises a 42 GHz microwave source and an in-bore DNP polarizer, equipped with a multimode resonator inside a standard clinical 1.5 T scanner, which allows a continuous hyperpolarization of water molecules with a flow rate about 1.2 ml/min. In this work we characterized the performance of the DNP setup for MR imaging in various vascular models by comparing it to standard Gadolinium-based contrast media. We used 2D and 3D scan protocols with GRE- and VIBE-sequences for measurements, which feature up to a 30-fold signal enhancement of the hyperpolarized aqueous solution. A comparison to Gadolinium enhanced signals of physiologic intravascular conditions shows 12-fold enhancement rates and an increased absolute sensitivity.

Discussion

The used liquid state in-bore DNP setup creates hyperpolarized water, which features high T1 MR signal enhancements and a short relaxation time. SNR and CNR values were substantially improved by DNP and capillary diameters down to 75µm could be visualized. In our comparing experiments the hyperpolarized water showed an enhancement higher than gadolinium, which allows imaging down to small vascular structures in a standard clinical 1.5 T scanner.

SSM20-02 Intravoxel Incoherent Motion Diffusion-weighted Imaging of Bone Marrow Microstructure in Patients with Acute Leukemia

Wednesday, Nov. 29 3:10PM - 3:20PM Room: S403A

Participants

PURPOSE

Intravoxel Incoherent Motion Diffusion-weighted Imaging of Bone Marrow Microstructure in Patients with Acute Leukemia

METHOD AND MATERIALS

28 patients with AL underwent MRI scans at 1.5T using conventional diffusion weighted imaging (DWI) and IVIM (b= 0, 10, 25, 50, 100, 200, 400, 600, 800, 1000, 1200s/mm2) in the sagittal plane covering the lumbar bone marrow before standard chemotherapy. The IVIM parameters (perfusion fraction [f], molecular diffusion coefficient [D], and perfusion-related D [D*] and apparent diffusion coefficient (ADC) were extracted from the bone marrow images. The microvessel density (MVD) and vascular endothelial growth factor(VEGF) was confirmed by bone marrow biopsy of the iliac crests, whichwere used to evaluate bone marrow microstructure. All patients were divided into complete remission (CR) and non-remission (NR) group according to the treatment response.

RESULTS

All patients underwent the first remission induction chemotherapy, with 19 patients achieved CR and 9 patients achieved NR.The ADC and D* values were not significant different between the two groups. However, D value of CR group was significantly higher (p=0.003), and f value of CR group was significantly lower (p=0.039) than those of NR group. Using receiver operator characteristic (ROC) analysis, the area under the curve (AUC) of D and f were 0.848 and 0.746 respectively in evaluating prognosis of AL before treatment. The fshowed significantly statistical correlations with MVD (r= 0.384) and VEGF (r= 0.439).

CONCLUSION

The D , f value ofbone marrow could play a potential role in prognosticating patients with AL. The f value could be used as noninvasive biomarkers to evaluate the microstructure bone marrow.

CLINICAL RELEVANCE/APPLICATION

Evaluation of bone marrow microstructure and prognosis of leukemia patients

SSM20-03 Auto-Calibrated Correlation Time Diffusion Brain qMRI and the Principle of Diffusional Homeostasis

Wednesday, Nov. 29 3:20PM - 3:30PM Room: S403A

CONCLUSION

A fully automated and auto-calibrating DCT mapping algorithm has been developed and could be useful for aiding in the diagnosis of pathologic entities that disrupt diffusional homeostasis such as acute ischemic stroke.

Background

Standard diffusion MRI is based on the pulsed field gradient (PFG) experiment and probes molecular water motions at the 10-100millisecond time scale depending on experimental conditions. Despite the very different water micro-environment in gray matter (GM) and white matter (WM), one of the most remarkable findings of DPFG MRI is the near equality of the mean diffusivities of water in both tissues at diffusion times reported in the literature. Correlation time diffusion (DCT) MRI is based on T1 relaxometry and therefore probes water diffusion at the very short time scale of the correlation time: approximately 20ps for brain tissue. We hypothesize that the herein termed "*principle of diffusional homeostasis*" is valid at such short time scales and apply it to develop a self-calibrating DCT mapping algorithm whereby the one external model parameter -specifically, the magnetization transfer coupling constant (kappa in Fig. 1)-- is auto-determined by minimizing the WM-to-GM diffusional differences to within one half the standard deviation.

Evaluation

This is a HIPAA compliant prospective study approved by the local IRB that included ten patients without major abnormalities ranging in age from 2 to 87years. MR images acquired with the mixed turbo spin echo pulse (mixed-TSE) sequence were qMRI processed generating maps of T1, T2, and PD. These maps were used to generate DCT maps using an algorithm which calculates the pure correlation time without magnetization transfer effects. In all ten cases, the DCT maps were in quantitative agreement (<5%) with the DPFG maps for GM, WM, and cerebrospinal fluid.

Discussion

The developed fully auto-calibrating DCT mapping algorithm is based on the assumption of diffusional homeostasis, which is supported by a wealth of DPFG evidence in the healthy brain. Differences between DCT and DPFG may arise in pathologic conditions whereby the long time scale diffusion tissue properties may be abnormal via restricted diffusion.

SSM20-04 Metal Artifact Reduction for Myocardial Scar Assessment in Patients with Cardiac Implanted Electronic Devices Using Cardiac Magnetic Resonance

CONCLUSION

The developed wideband IR technique minimizes the CIED-generated hyperintensity artifacts without increasing scan time, and allows for accurate identification of arrhythmogenic substrate in VT patients.

Background

An important application of late gadolinium enhancement (LGE) cardiac magnetic resoncance (CMR) is assessment of myocardial scar in patients with ventricular tachycardia (VT) before ablation. LGE imaging in patients with cardiac implanted electronic devices (CIEDs) is challenging because of device-generated metal artifacts that compromise the effect of the inversion recovery (IR) pulse and obscure the region of interest. In 2016 we have performed 180 CMRs in patients with CIED at our institution. In this abstract we will discuss the use of modified IR technique to alleviate metal artifacts and improve diagnostic image quality.

Evaluation

The modified sequence includes a wideband IR pulse with adjustable frequency offset and bandwidth, which allows for optimal myocardial signal nulling in the presence of off-resonance effects. A phantom experiment was conducted on a 1.5T scanner using conventional and wideband IR sequences with different frequency offset and bandwidth (BW) values. Then, 20 patients (18 males, age=62±17) with CIEDs (8 Boston Scientific, 10 Medtronic, and 2 St Jude) were imaged on the same scanner using the conventional and optimized wideband LGE techniques prior to ablation. The imaging parameters were optimized for each patient. Conventional IR sequence resulted in severe artifacts that obscured ventricular segments in 15 out of 20 patients. The wideband IR sequence significantly minimized the artifacts. Optimal BW was in the range of 2000-3000Hz with optimal frequency shift up to 1000Hz.

Discussion

Increasing the IR frequency BW results in better artifact reduction, although this comes at the cost of incomplete myocardial nulling. So, BW should be set to the minimum value that eliminates the artifact, which is affected by the device type and location. Similarly, the frequency offset of the IR pulse affects the artifact appearance, so proper setting of the frequency offset could allow for removing the artifact without the need to increase the frequency BW.

SSM20-05 TSE-Based DWI of the Prostate as an Alternative to SS-SE-EPI DWI

Wednesday, Nov. 29 3:40PM - 3:50PM Room: S403A

Participants
Antonio Luna, MD, Jaen, Spain (*Presenter*) Consultant, Bracco Group; Speaker, General Electric Company; Speaker, Toshiba Medical Systems Corporation

Javier Sanchez, MD, PhD, Madrid, Spain (*Abstract Co-Author*) Nothing to Disclose

CONCLUSION

DWI TSE has a potential role as an alternative to SS-SE-EPI DWI in MR protocols for prostate cancer detection.

Background

DWI is a key MR imaging contrast for prostate cancer detection. In clinical practice, a SS-SE-EPI sequence is used. EPI readout is prone to geometrical distortion and susceptibility artifact due to the presence of air content within the rectum or metallic implants. These limitations make more difficult the proper spatial localization of the lesions. Also, the use of DWI to localize suspicious areas in targeted MR/ultrasound fusion guided biopsy is limited. Turbo Spin Echo-based DWI is proposed as a potential alternative to eliminate geometric distortion and local susceptibility artefacts. In this presentation, its geometric validation is performed to demonstrate spatial accuracy of DWI-TSE images compared with conventional DWI-SE-EPI sequence.

Evaluation

All images were acquired in a 3.0 T Achieva scanner (Philips Healthcare, The Netherlands) with a 16ch body coil on 15 patients with prostate cancer in targeted MR/ultrasound guided biopsy. On these patient, two DWI sequence were performed with equal b values (0, 1000 and 1500 s/mm2) wit DWI-SE-EPI (TR/TE=4500/90ms) and DWI-TSE (TR/TE=11173/131ms) sequences. DWI images were acquired in the same orientation of conventional TSE T2-weighted sequence. Both acquisitions shared equivalent spatial resolution (2.6x2.8x4.5 mm3) with no gap between slices. Total scan time was 118s and 290s for SS-SE-EPI and TSE respectively. ADC maps were calculated using b0 and b 1000 s/mm2 for both sequences. SNR and CNR were compared for all b values and ADC maps. Also, the presence of geometric distortion and susceptibility artifacts was recorded. Both sequences were also compared to target prostate biopsy using an specific MR/ultrasound fusion device.

Discussion

TSE-based DWI presented free geometric distorted images in all cases with similar CNR, although with a moderate increase in acquisition time. Also, this approach permits to delineate lesions for targeted biopsy with advantage over SS-SE-EPI DW-sequence due to good geometrical performance.

SSM20-06 Measuring Frequency Drift in MR Spectroscopy on a 3 T MRI

CONCLUSION

Change in gradient temperature from heavy usage negatively impacts scanning quality for MRS sequences. Methods exist to compensate for frequency drift, but significant drift can still negatively impact quantification of the metabolite concentrations due to the poor water suppression. Quantifying the time required for gradients to stabilize after intense use, in this example of a Siemens Skyra 3 T, can inform scheduling of MRS studies to maximize their stability, and reduce the need for drift correction tools.

Background

MR spectroscopy (MRS) is susceptible to frequency drift caused by gradient warming, more so than other MR imaging modalities. Frequent switching of gradients in fMRI and DTI causes heating and the frequency of the magnet to change in an unpredictable way. Frequency drift in functional brain imaging can cause spatial drift over time, especially in the z direction, but is easily corrected by realignment. Frequency drift in MRS degrades the water suppression and quality of the spectrum through increased linewidth. We examine the effects of gradient heating on frequency drift and map the time required for gradients to stabilize on a specific magnet.

Evaluation

Drift was tested on a Siemens 3 T Skyra MRI, with a 32-channel receive-only head-coil, standard gradients, and an MRS phantom. Using a PRESS sequence, transmitter voltage and water suppression flip angle were adjusted to produce optimal water suppression. At 10 minute intervals over a period of 3 hours, magnet frequency was adjusted to convergence and the new frequency recorded. Two 9 min fMRI sequences (TR = 700ms) were run starting 20 minutes after initial frequency measurement.

Discussion

Frequency drift was negligible prior to perturbation of gradients from fMRI, but increased 5.6Hz/min to a peak of 70 Hz above baseline after the second fMRI sequence. Frequency returned to baseline 120 minutes after completion fMRI at a rate of 0.83 Hz/min for the first 60 minutes. Spectra collected using LASER sequence after perturbation showed significant drift, and spectra collected before perturbation showed no drift.

SSM21-01 Outcomes of Early Stage Breast Cancer with Nodal Micrometastases

Wednesday, Nov. 29 3:00PM - 3:10PM Room: S105AB

Participants
Yazan A. Abuodeh, MBBS, Tampa, FL (*Presenter*) Nothing to Disclose

ABSTRACT

Purpose/Objective(s): Nodal micrometastases (N1mi) in breast cancer patients carry a slightly worse prognosis compared to node negative disease. This study aims to assess factors predictive of N1mi outcome and the effect of treatment modality for this cohort.Materials/Methods: Retrospective analysis of T0-T2 N1mi breast cancer patients were obtained by chart review and the Total Cancer Care Database from 2000-2014. Patient, tumor, and treatment characteristics were analyzed in regards to outcome, which include: locoregional failure (LRF), distant metastasis (DM), disease free survival (DFS), and overall survival (OS). Cox-regression univariate (UVA) and multivariate (MVA) analyses were used to determine association between variables and outcome. Variables predictive of outcome on UVA (pResults: We identified 129 female breast cancer patients with stage IB/IIB, with a median age of 58 (30-58) years. Patients were most commonly Caucasian (85%) with left breast involvement (54%). Patients were either treated with breast conserving therapy (BCT) (n=48,37%), mastectomy only (n=52, 40%), or mastectomy with postmastectomy radiation (PMRT) (n=29, 23%).” Axillary evaluation was either by sentinel biopsy alone (n=85, 66%) or by axillary dissection (n=44, 34%). Invasive ductal carcinoma was found in 106 (82%) patients. Tumor stage was primarily T1 (46.5%) and T2 (51.9%), with 2 (1.6%) T0. Median tumor size was 2(0-5) cm. Grades were 1,2,3, and unknown in 24(18.6%),66 (51.2%),38(29.5%) and 1(0.8%), respectively. Multifocal disease (MF) and lymphovascular space invasion (LVSI) were present in 29(22.5%) and 32(24.8%) patients, respectively. Number of involved lymph nodes were 1, 2, 3 in 115(89%), 11(9%), and 3(2%) patients, with extracapsular extension present in 6(5%) cases. Estrogen receptor, and HER2neu were positive in 116(90%) and 13(10%) patients, respectively. Oncotype Dx scores were low, intermediate, high or was not done in 34(26%), 21(16%), 6(5%), and 68(53%), respectively. Systemic treatment was delivered as chemotherapy, hormonal, and targeted therapy in 71(55%), 111(86%), and 9(7%), respectively.With a median follow up of 39 months, there were 2 (2%) LRF, 5 (4%) DM, and 4 (3%) deaths. On univariate analysis, no factors predicted for LRF, but MF and size predicted for DM and DFS (pConclusion: Locoregional control of N1mi disease was not affected by treatment modality. Larger tumors or MF have worse DM and DFS, and may benefit from systemic treatment intensification.

SSM21-02 Her-2 Positive is Associated with Increased Risk of Locoregional Recurrence of Breast Cancer Patients Treated with Neoadjuvant Chemotherapy and Breast Conserving Surgery

Wednesday, Nov. 29 3:10PM - 3:20PM Room: S105AB

Participants
Qing-Lin Rong, Oak Brook, IL (*Presenter*) Nothing to Disclose

ABSTRACT

Purpose/Objective(s): Neoadjuvant chemotherapy (NAC) decreases tumor size and increase the chance of breast conserving surgery (BSC) for patients with large primary tumors. This study is to evaluate the outcomes of this group of patients and identify risk factors of locoregional recurrence (LRR) for further individualized treatment.Materials/Methods: A total of 108 breast cancer patients treated with NAC and BSC between 1999 and 2013 were retrospectively reviewed. There were 4 clinical stage I, 66 stage II and 38 stage III patients. After surgery, 103 (95.4%) had negative margins. 99 (91.7%) patients received adjuvant radiotherapy (RT) to the whole breast, with 41 patients received supraclavicular nodal RT simultaneously. Of patients with positive hormone receptor disease, 76 (88.4%) received endocrine therapy. Of patients with positive Her-2 disease, 16 (61.5%) received targeted therapy with trasuzumab. The rates of locoregional recurrence (LRR), distant metastasis (DM), disease-free survival (DFS) and overall survival (OS) were calculated using the Kaplan-Meier method, and differences were compared using the log-rank test.Results: The overall clinical response to NAC was achieved in 92 (85.2%) patients, with a complete response rate of 6.5% and a partial response rate of 78.7%. 32 (100%) patients with cT3-4 disease and 56 (84.8%) with cT2 achieved T-stage degradation. For 38 patients with clinical stage III, 30 (78.9%) was downstaged, and 8 (21.1%) achieved pathologic complete response (pCR). For 66 patients with clinical stage II, 30 (45.5%) was downstaged, and 8 (12.1%) achieved pCR. With a median follow-up time of 64 months, 12 patients had LRR, including 6 breast recurrence and 6 regional recurrences. Eighteen patients had DM. The 5-year rates of LRR, DM, DFS and OS for all patients were 11.0%, 15.1%, 77.9% and 97.0%, respectively. In univariate analysis, patients with Her-2 positive disease had higher LRR rate as compared with Her-2 negative (27.0% vs. 6.3%, P = 0.020), whereas there were no significant differences in LRR between clinical III and stage I-II (15.4% vs. 10.0%, P = 0.448) or between pathologic stage III and stage 0-II (10.8% vs. 11.1%, P = 0.518).Conclusion: BCS performed selectively after NAC for breast cancer patients is safe, and the LRR is acceptably low. Her-2 positive is associated with increased risk of LRR, although 61% Her-2 positive patients

received anti HER-2 targeted therapy. Further study is warranted to verify this finding.

SSM21-03 Interplay between AlignRT Tracking Accuracy and Breast Surface Topography

PURPOSE

AlignRT is a commercial 3D-optical surface imaging system specifically designed for radiation oncology applications. It is often used for chest surface motion tracking for the breast cancer patients treated with deep-inspiration breath-hold (DIBH) protocol. Since AlignRT tracking accuracy and reliability are highly ROI-dependant, a variation in breast topography could result in incorrect patient shifts. So far, no study has examined how AlignRT tracking accuracy is affected by changes in breast surface topography. The goal was to understand hidden interconnections and establish corresponding clinical guidelines.

METHOD AND MATERIALS

An anthropomorphic phantom and 8 breast phantoms of different shapes were used in this study.The diameters of the breast phantoms were 12.9, 15.0, 15.8, 16.0, 17.7, 21.5, and 28.0 cm with central elevations of 1.7, 5.4, 3.0, 3.8, 1.4, 0.9, and 1.5 cm. For each set of measurements, a breast phantom was attached to the anthropomorphic phantom. A reference surface image was acquired. To eliminate ROI-dependency effect, an identical ROI was used throughout the study. The couch was then manually shifted by -1.0, -2.0, 1.0, and 2.0 cm in VRT, LAT, and LNG directions sequentially. The AlignRT-measured shifts were obtained by acquiring a static treatment surface image and registering with the reference surface image.

RESULTS

We found that AlignRT tracking accuracy was not significantly affected by variations in breast topography as long as an ROI much larger than the breast was used. Breast tissue with higher elevations tended to yield better tracking results. A couch shift further away from isocenter tended to produce less accurate tracking results. The tracking uncertainties were found to be ~1.0 mm in translations and ~1.0° in rotations. These often occurred in LAT shift and yaw rotation.

CONCLUSION

For breast and chest wall applications, AlignRT tracking accuracy is independent of breast surface topography as long as a large ROI (covering the entire breast, SCV, axilla, sternum, and some lateral aspects of the chest) is used.

CLINICAL RELEVANCE/APPLICATION

AlignRT uses structured light to measure 3D surface of a cancer patient for pre-treatment setup and intra-fractional motion tracking.

SSM21-04 Analysis of Treatment Effectiveness and Complications Associated with Accelerated Partial Breast Brachytherapy in Patients Treated at a Single Institution

ABSTRACT

Purpose/Objective(s): MammoSite™ is a form of Accelerated Partial Breast Irradiation (APBI) designed to deliver targeted doses of radiation from within breast tumors. This method of radiation delivery allows higher doses of radiation, reduces treatment fractions, and aims to reduce toxicities from external beam radiation therapy. While the use of MammoSite™ has been well studied, the results from the only randomized control trial, RTOG 0413/NSABP B-39, are pending. We aim to present efficacy and toxicity data for follow-up of over five-years for patients receiving MammoSite™ at our institution. Materials/Methods: We performed a retrospective analysis of patients at a single institution who presented with early stage breast cancer and received breast conserving surgery. These patients elected to receive accelerated partial breast irradiation (APBI) using the MammoSite™ catheter device. Patients were treated with 30.6 - 34.0 Gy in 3.4 Gy fractions given twice daily with fractions at least six hours apart utilizing either a spherical or ellipsoidal catheter device. Patient data was collected regarding the specific treatment and planning

volumes, complications and toxicities occurring during and after treatment, and the overall outcome of each patient relating to tumor-free survival.Results: From October 2005 through November 2010, 78 patients with 79 lesions were treated with APBI using the MammoSite™ catheter device and were eligible for our retrospective analysis. Patients with less than 24 months follow up were excluded from the study. 79.5% of patients were ER positive, 55% were PR positive, and 17.9% were HER2/neu positive. Seven patients (9.0%) had N1 disease. The median follow-up time was 80 months. Of the patients in our study, there were a total of 10 recurrences (12.8%), with 5 local recurrences (6.4%), 2 local recurrences that developed into distant metastases (2.6%), and 3 distant metastases (3.8%). Two recurrences were considered new primary lesions due to receptor status change in the new tumor. Specific toxicities include 12 patients with skin erythema (15.4%), 7 patients with seroma (9%), 8 patients with localized edema (10.3%), and 6 patients with infection (7.7%).Conclusion: This case series of 78 patients with a median follow-up of 80 months, from a single institution, provides important data regarding failure analysis with MammoSite™ accelerated partial breast irradiation. Our results show a higher rate of metastatic recurrence in the group of patients with positive nodal disease as expected. Further prospective analysis, such as the B-39 trial, is required to fully assess the efficacy and safety of MammoSite™ in the treatment of cancer with APBI.

SSM21-05 Prospective Study of Accelerated Partial Breast Irradiation Using Three Dimensional-Conformal Radiotherapy for Early Stage Breast Cancer

Wednesday, Nov. 29 3:40PM - 3:50PM Room: S105AB

ABSTRACT

Purpose/Objective(s): In Japan, only a few trials of accelerated partial breast irradiation (APBI) using three dimensional-conformal radiotherapy (3D-CRT) have been reported so far. The aim of this study is to evaluate the efficacy and safety of APBI using 3D-CRT for Japanese women.Materials/Methods: Eligibility criteria for this protocol included age=40 years old, no preoperative systemic treatment, stage Tis-2N0-1M0, negative surgical margins (>5 mm) following breast conserving surgery, and surgical clips intraoperatively placed at the cranial, caudal, medial, and lateral edge of the seroma cavity. For image-registration, the positions of the clips in daily kV x-ray images were matched to those in the planning digitally reconstructed radiographs. We adopted beam arrangements of four- or five- 6 MV X-ray noncoplanar fields with 5-mm multi-leaf collimator. The prescribed dose was 38.5 Gy in 10 fractions over 2 weeks. The toxicity grading was based on Common Toxicity Criteria for Adverse Events (CTCAE) v4.0.Results: Between January 2012 and June 2016, 50 patients with early stage breast cancer were enrolled for the trial of APBI using 3D-CRT following breast conserving surgery at Kyoto University Hospital. Since two of them were excluded because of the dose constraint of contralateral breast, we analyzed 48 patients who underwent APBI. All patients completed the radiation treatment. The median age was 57.5 years old (range, 42–81 years old). The disease was Stage 0 in 6 (13%), Stage IA in 34 (70%), Stage IIA in 8 (17%) patients. Seven patients received adjuvant chemotherapy, followed by APBI within 6 weeks after the end of chemotherapy. At the median follow-up of 31 months (range, 5.4–55 months), no locoregional recurrence or distant metastases of breast cancer were observed. Two-year overall survival was 100 %. Grade 2 adverse events were breast atrophy (4%), breast pain (2%), fibrosis (2%), dermatitis (2%), fever (2%), and pigmentation (2%). Grade 3 soft tissue cellulitis of the breast was observed in one patient. There was no grade 4-5 toxicity. Cosmesis outcomes by four point scale were excellent/good for 77% of patients at pretreatment state and for 63% at 1 year after APBI. The cosmesis scales were improved in 3 patients (6%), worsened in 7 patients (15%), and unchanged in the rest of the patients (79%) at 1 year after APBI.Conclusion: Two-year disease control treated with this APBI protocol using 3D-CRT for Japanese early-stage breast cancer patients was good, and the adverse events and cosmesis outcomes were feasible and satisfactory.

SSM21-06 Risk of Early Onset Breast Cancer among Women Exposed to Thoracic CT in Pregnancy or Early Postpartum

Wednesday, Nov. 29 3:50PM - 4:00PM Room: S105AB

kirsteen.burton@utoronto.ca

PURPOSE

The risk of breast cancer may be higher with direct exposure to ionizing radiation from thoracic computed tomography (CT) during pregnancy or postpartum, when breast tissue undergoes proliferation and differentiation.

METHOD AND MATERIALS

We completed a retrospective population-based cohort study. Universal health care databases in Ontario, Canada were used to identify deliveries between 1995-2014. The main exposure was thoracic CT in pregnancy or <= 42 days postpartum. Exposure to VQ scan was used as an active comparator, as there is no direct-beam radiation to the breast. Each was compared to pregnancies unexposed to thoracic CT or VQ scan. The primary study outcome was newly diagnosed breast cancer starting 366 days after the index delivery date.

RESULTS

5,859 pregnancies were exposed to thoracic CT, 97% of which had intravenous contrast; 4075 to VQ scan; and 1,292,059 to neither. After a mean (SD) duration of follow-up of 11.1 (5.7) years, a total of 10,129 women were diagnosed with breast cancer, of which 9,039 (89.2%) were aged <= 50 years. There were 27 new cases of breast cancer (7.1 per 10,000 person-years) following

thoracic CT vs. 10,080 (7.0 per 10,000 person-years) among the unexposed - an adjusted HR of 1.17 (95% CI 0.80-1.70). Following VQ scan exposure, the incidence rate of breast cancer was also 7.0 per 10,000 person-years - an adjusted HR of 1.23 (95% CI 0.81-1.87) compared to the unexposed cohort.

CONCLUSION

Exposure to thoracic CT during pregnancy or postpartum was not associated with an increased short-term risk of maternal breast cancer.

CLINICAL RELEVANCE/APPLICATION

Published recommendations about the safety of ionizing radiation in pregnancy and postpartum have typically focused on the potential teratogenic effects to the fetus, while mentioning the possibility of a higher risk of breast cancer. Although an increased risk of breast cancer following radiological ionizing radiation exposure during pregnancy or lactation has been postulated, this has never been quantified. The current findings help inform those guidelines.

PURPOSE

To report rate of major bleeding complications after percutaneous image-guided core biopsy and to determine risk related to aspirin use and length of aspirin discontinuation prior to biopsy.

METHOD AND MATERIALS

Following IRB approval, we retrospectively reviewed a prospectively-maintained database for all percutaneous image-guided core biopsies performed at our institution between 9/1/2005 and 9/1/2016 (n=30,966). Patients were excluded if aspirin usage data was missing (n=633). Bleeding complications were defined using the Common Terminology Criteria for Adverse Events (CTCEA, version 3) established by the National Cancer Institute and were considered significant if grade 3 or higher. Multivariate models were adjusted for age, gender, platelet count, international normalized ratio (INR), and biopsy target. Three categorizations of aspirin use were examined: any use within 10 days prior, length of discontinuation (>10 days/no aspirin, 8-10, 4-7, and 0-3 days prior), and use on day of biopsy. Associations with bleeding complications were modeled using generalized estimating equations logistic regression models. P-values <=.05 were considered significant.

RESULTS

30,333 biopsies in 21,938 unique subjects were included (mean (SD) age 58 years (16), 57% male). 7,921 (26.1%) biopsies were performed in patients who received aspirin within 10 days of biopsy, 47.5% of which (3,761) took it within 3 days prior to biopsy. 98 significant bleeding complications (grade 3 or higher) occurred across all included cases (0.32%), 34 in those with aspirin use during the prior 10 days (0.43%), 22 within 0-3 days (0.58%), and 17 with aspirin use on same day as biopsy (1.9%). Aspirin use within 10 days of biopsy increased the bleeding risk, but not significantly (OR 1.5 [.96-2.3], p=.08). Days since discontinuation showed significant increase in bleeding only between 0-3 days versus >10 days/no aspirin groups (OR 2.1 [1.3-3.6], p=.004). Aspirin use on day of biopsy showed the greatest increase in risk (OR 6.6 [3.8-11.5], p<.001).

CONCLUSION

Major bleeding complications after percutaneous core biopsy are rare. Aspirin use within 3 days of biopsy is associated with increased risk of bleeding.

CLINICAL RELEVANCE/APPLICATION

A short period of aspirin cessation prior to biopsy may be sufficient to decrease risk of bleeding although risk remains low even in those with recent aspirin use.

SSM22-02 A Team-Science Approach to Support Personalized Cancer Care: Role and Value of Interventional Radiology in Clinical Trials

PURPOSE

Biopsy yield is critical for determining a patient's trial eligibility and treatment. We report our experience with supporting the BATTLE and BATTLE-2 lung cancer trials, focusing on the role of interventional radiologists (IRs).

METHOD AND MATERIALS

The medical records of patients who underwent percutaneous image-guided biopsy for the BATTLE and BATTLE-2 trials were reviewed. A radiology-based, 3-point, lesion scoring system was developed. Lesions were scored a 3 (most likely to yield sufficient material for biomarker analysis) if they met the following criteria: size $\geq$2 cm, solid mass, demonstrate imaging evidence of viability, and technically easy to sample. Lesions that did not meet all four criteria, were scored a 2 with the missing criteria noted as negative factors. The lesions biopsied were retrospectively scored by two IRs and univariate and multivariate analyses were performed to evaluate the score's ability to predict successful yield for biomarker adequacy.

RESULTS

A total of 555 biopsies were performed for BATTLE and BATTLE-2. Overall yield for analysis of the required biomarkers was 86.1% (478/555) and 84% (268/319) and 88.9% (210/236) for BATTLE and BATTLE-2, respectively (p=0.09). Lesions receiving a score of 3 were adequate for biomarker analysis in 89% of cases. Lesions receiving a score of 2 with more than one negative factor were adequate for biomarker analysis in 69.2% (p=0.03) and 74% (p=0.04) of cases when scored by IR1 and IR2, respectively. The kappa statistic between the two IRs scoring was 0.55 [95% CI: (0.48, 0.61)] indicating moderate agreement as lesions were scored the same by both IRs in 78.4% of cases.

CONCLUSION

A team-science approach can facilitate consistent yields for biomarker analysis in clinical trials. IRs play a critical role for lesion selection.

CLINICAL RELEVANCE/APPLICATION

By leveraging the expertise of the individual specialties (medical oncology, pathology, IR), achieving consistently high adequacy rates from image-guided biopsies for biomarker analysis is feasible.

SSM22-03 Causes of Inadequate Sampling in IR Biopsies: Review of 3256 Biopsies

PURPOSE

The role of the interventional radiologist in the Precision Medicine Initiative has become increasingly important in providing the necessary tissue for genetic analysis. However, inadequate sampling rate for DNA testing exceed 20% resulting in repeat biopsies and delays in treatment. The aim of this study was to evaluate variables that associate with inadequate biopsy sampling in a large tertiary medical center.

METHOD AND MATERIALS

This IRB approved, HIPAA compliant study involved a search of our radiology department database for biopsies performed from January 2015 to December 2015. 3256 biopsies were included in the study in which 104 biopsies were ordered for genetic testing. Electronic medical records including radiology and pathology reports were reviewed for lesion size, tissue type, biopsy equipment, aggregate core length, number of samples obtained and the operator experience. Statistical analysis was performed using univariate analysis and logistic regression.

RESULTS

Inadequate tissue sampling rate was 20.1% (21/104). Univariate analysis showed an association between inadequate samples and smaller needle gauge (p=0.02) and smaller core length (p=0.01). There was no association with lesion size (p=0.39) and operator

experience (p=0.8). In logistic regression, the inadequate sampling rate was not different when obtaining 2 or more samples or an aggregate core length of 1-2 cm (P=0.95 and p=0.73). Temno (BD) devices resulted in 31% inadequate sampling rate, Bard (CR Bard) in 8% and BioPince (Argon Medical) in 8%. Genetic testing led to appropriate selection of therapy in 80% of the patients with adequate sampling.

CONCLUSION

Smaller needle gauge and smaller core lengths were associated with higher inadequate sampling rates. There was no added benefit to obtaining more than 2 to 3 biopsy samples or more than 1 to 2 centimeters of aggregate core tissue length. Adequate tissue for DNA testing is critical; results show that they can guide selection of therapy.

CLINICAL RELEVANCE/APPLICATION

Adequate tissue for DNA testing is critical; it can guide selection of therapy.

SSM22-04 Freehand Ultrasound-Guided Targeted Transperineal Prostatic Biopsy Technique (FUGTTPB) for Suspicious Lesions Identified By Magnetic Resonance Imaging (MRI)

PURPOSE

FUGTTPB has many advantages over the traditional transrectal ultrasound-guided technique including lower infection rates. This study aims to investigate the cancer detection rates of this novel technique by comparing Prostate Imaging Reporting and Data System Version 2 (PI-RADS) and Gleason scores.

METHOD AND MATERIALS

A retrospective cohort study was conducted of all men who underwent an MRI Prostate between January 2015 and December 2016 with a lesion graded as PI-RADS 3 or greater followed by FUGTTBP in our institution. These were performed in the outpatient setting with the index lesion targeted free hand without the use of a grid or image fusion, guided by transrectal ultrasound.

RESULTS

99 men (mean age 65 years) referred by 20 Urologists underwent MRI at 6 centres with 129 lesions identified. 75% were imaged based on clinical suspicion whilst 25% were followed for a previous prostatic malignancy. Cancer detection rates for PI-RADS 3, 4 and 5 lesions were 42% (95% CI 27.9 - 57.3), 63% (95% CI 46.9 - 75.9) and 97% (95% CI 77.5 - 99.6) respectively. The PI-RADS 3 and 5 rates are comparable to the only published study comparing PI-RADS Version 2 and Gleason scores. The PI-RADS 4 rate was slightly lower but this may be attributed to the varying experience of the 13 MRI reporters and 4 patients having PI-RADS 4 lesions which were non-index lesions as they also had PI-RADS 5 lesions. 3 patients had positive cores beyond the target area but these were not identified as suspicious on MRI. Only 1 core from each patient was positive and all were graded as Gleason 6 with tumour lengths of 1 mm or less.

CONCLUSION

This pilot study demonstrates promising cancer detection rates of the FUGTTPB technique especially for higher grade PI-RADS lesions. However, it is limited by MRI sensitivity as 3 patients had tiny positive cores outside of the target area. Given the numerous benefits, further evaluation of this technique may result in evolution of prostatic biopsy techniques.

CLINICAL RELEVANCE/APPLICATION

MRI has shown promise in identifying clinically significant prostatic tumours. Targeting these via the FUGTTPB technique has numerous benefits.

SSM22-05 Preliminary Study to Compare the Effectiveness of Four Hemostatic Methods: Locally Injected FFP, Systemic FFP, Local Gelfoam Insertion, or Local Coil Insertion for Preventing Bleeding Complications

John.Haaga@uhhospitals.org

PURPOSE

To assess the efficacy of local hemostatic techniques in coagulopathic patients with abnormal INR. These techniques included: 1) local injection of fresh frozen plasma 2)systemic administration of fresh frozen plasma 3)local insertion of gelfom 4)local insertion of

angiographic coils into intervention site.

METHOD AND MATERIALS

Data was collected from 4 IRB approved studies totaling 182 patients. Procedures and biopsies included 80 liver biopsies, 35 abscess drainages, 21 soft tissue masses, 18 kidney biopsies, 7 cholecystostomies, and 13 chest tubes. Causes of the coagulopathy included anticoagulation treatment, liver failure, hematologic malignancy, chemotherapy, and idiopathic.The most common causes were coumadin and liver failure in 118 patients. INR ranges for each group were: 91 patients treated with local injection of FFP (INR1.4-3.0, avg 2.1), 40 patients treated with gelfoam (INR 2.1-2.9, avg 2.32) , 35 patients with systemic FFP (INR 1.4-3.4, avg 2.1) , and 16 patients treated with angiographic coils (INR avg1.3).. Average amount of FFP used was 20 cc injected locally and 5.2 units intravenously. Average of 2 coils were used per patient. .

RESULTS

Bleeding complications were: drop in hemoglobin, visible hematoma, required transfusion, or intervention.Total//significant bleeding complications were 0//0% for locally injection of FFP, 17.1//2.8% for systemic FFP, 12.5//0% for gelfoam, and 37//12.5% for coils. 6 nonbleeding complications occurred in systemic FFP group and included shortness of breath, shortness of breath requring intubation (systemic group), 1 infection and death in 3 (2 volume overload, 1 idiosyncratic).

CONCLUSION

Of these methods used for hemostasis, local injection of FFP was the most effective, followed by gelfoam, systemic FFP, and local coils.These data provide a basis for organizing a larger prospective, randomized multiinstitutional study to confirm these findings and to study the cost benefit of the FFP groups.

CLINICAL RELEVANCE/APPLICATION

Percutaneous techniques play a major role for diagnoses and treatments. While normal patients have a low complication risk, coagulopathic patients are at greater risk of bleeding. Our comparison of different hemostatic methods provides preliminary data that the new 'local injection of blood products' technique is superior to other methods studied. Before this new method can be used widely, more data needs to be collected from large randomized, prospective studies.

SSM22-06 Percutaneous Hepatic Fiducial Gold Marker Implantation for Real-time Tumor-tracking Radiotherapy

ryo561201@me.com

PURPOSE

The purpose of this study was to evaluate the safety and complications associated with percutaneous fiducial global gold marker implantation into the liver parenchyma for real-time tumor-tracking radiotherapy (RTRT).

METHOD AND MATERIALS

This retrospective study was approved by our institutional review board. Using a medical record and database review, we evaluated data from 100 patients with hepatobiliary malignancies who underwent 116 percutaneous fiducial gold marker implantations in the liver as preparation for RTRT from 1999 to 2016. We used global markers that were 2 mm in diameter. All marker implantations were performed using Seldinger's method. Technical success was defined as completion of gold marker placement at the intended liver parenchyma. Clinical success was defined as successful tracking of the gold marker and completion of planned RTRT. In addition, we assessed complications related to the marker placement.

RESULTS

The technical success rate for fiducial gold marker implantation was 90% (104/116). Twelve of 116 markers could not be used for RTRT because of marker migration after implantation (n=9) or inappropriate location of the implanted marker (n=3). In 9 patients, markers migrated out of the liver; however, no complications occurred from not retrieving them. The clinical success rate was 99% (114/115), and we used another marker and completed RTRT for 1 tumor. Pain occurred in 16 patients, fever in 7, hemorrhage in 7, pneumothorax in 1, and nausea in 1. No major complications occurred.

CONCLUSION

Percutaneous fiducial gold marker implantation into the liver for RTRT is a safe and feasible procedure.

CLINICAL RELEVANCE/APPLICATION

Percutaneous fiducial global gold marker implantation into the liver for image-guided radiotherapy is safe and feasible. Physicians should monitor patients for migration of the implanted marker.

For information about this presentation, contact:

paulyi88@gmail.com

PURPOSE

Although prior studies have shown a significant increase in women in most medical specialties over the past several decades, Interventional Radiology (IR) has traditionally been a male-predominate field and it remains unknown if gender diversity in IR has improved over time. The purpose of this study was to analyze trends in gender diversity in IR in comparison with other related fields over the past 25 years.

METHOD AND MATERIALS

We reviewed data from the American Association of Medical Colleges reported in annual issues on medical education in the Journal of the American Medical Association for the years 1991-2015. We assessed the percentages of women resident and/or fellows in IR fellowships and other related training programs, including Diagnostic Radiology residency, Endovascular Neuroradiology fellowship, Radiation Oncology residency, as well of Medical Students and Residents from all specialties. Changes in the percentages of females from 1991 to 2015 were calculated for each group using Chi-Square tests and Pearson's Correlation Coefficient, as appropriate; statistical significance was set at $p<0.05$.

RESULTS

From 1991 to 2015, the percentage of females in IR fellowship increased from 0% to 23% ($r=0.72$; $p<0.0001$). Similarly, from 1991 and 2015, the percentage of females in medical school and in residency (all specialties) improved from 38% to 47% ($p<0.001$) and 30% to 46% ($p<0.001$), respectively. In 2015, IR had the lowest percentage of females at 9.3% compared to 47% of medical students, 46% of all residents, 29% of radiation oncology, and 27% of diagnostic radiology ($p<0.001$ for all).

CONCLUSION

Although the percentage of women trainees in IR fellowship has significantly increased over the past 25 years, IR is lagging behind other related fields and the general medical student and trainee population in terms of gender diversity. We recommend increased recruitment efforts towards women at different levels of training both during and after medical school to recruit more women into the field of IR.

CLINICAL RELEVANCE/APPLICATION

IR has the lowest representation of women among related specialties. We recommend increased recruitment efforts towards women at different levels of training to help improve gender diversity in IR.

SSM23-02 Percutaneous Vertebroplasty in Aged Patients with Osteoporotic Vertebral Compression Fractures: A Bicentric Retrospective Cohort Study

Wednesday, Nov. 29 3:10PM - 3:20PM Room: E450B

Awards
Trainee Research Prize - Medical Student

Participants
Binyan Zhong, MD, PhD, Nanjing, China (*Presenter*) Nothing to Disclose
Gao-Jun Teng, MD, Nanjing, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

byzhongir@sina.com

PURPOSE

We aim to evaluate the effectiveness and safety of Percutaneous Vertebroplasty (PVP) in patients aged 80 and over with osteoporotic vertebral compression fractures (OVCFs) in two hospitals.

METHOD AND MATERIALS

Patients underwent their first PVP due to OVCFs between January 2006 and December 2014 in two large academic centers were selected to this bicentric retrospective cohort study. Patients were divided into two groups by age (aged 80 or older and no older than 80). The primary outcome of this study was pain relief at 1month and 1 year measured by visual analogue scale (VAS) score. Complications, including new vertebral compression fractures (VCFs) were recorded during the follow-up.

RESULTS

A total of 699 patients (382 in Hospital A and 317 in Hospital B) were included in this study and 139 (19.9%) of them were aged 80 or older. Chi-square test or one-way ANOVA showed that there was no statistical difference of the parameters about the patients between the two hospitals. For the aged patients, mean VAS score decreased from 6.9(95% CI 6.8-7.1) at baseline to 2.3(2.2-2.5) at 1 month ($P<0.0001$) and 1.8(1.7-1.9) at 1 year ($P<0.0001$). Compared to the patients no older than 80, there was no statistical difference of the VAS score. During the median follow-up of 1136 (range 5-2924) days, 40 (28.8%) patients had new VCFs with a median time of 80 (range 5-1022) days. No major complication occurred.

CONCLUSION

PVP is an effective and safe approach for the patients aged 80 or older with OVCFs.

CLINICAL RELEVANCE/APPLICATION

PVP should be regarded as a safe and effective treatment approach for patients aged 80 or older with OVCFs.

SSM23-03 Human Observer Detection Performance of Moving Objects in Fluoroscopic Image Series

Wednesday, Nov. 29 3:20PM - 3:30PM Room: E450B

Participants
Taylor Richards, Durham, NC (*Presenter*) Nothing to Disclose
Steve D. Mann, PhD, Durham, NC (*Abstract Co-Author*) Nothing to Disclose
Ehsan Samei, PhD, Durham, NC (*Abstract Co-Author*) Research Grant, General Electric Company; ; Research Grant, Siemens AG; ; Advisory Board, medInt Holdings, LLC

For information about this presentation, contact:

taylor.richards@duke.edu

PURPOSE

Evaluate human observer detection performance of moving objects in fluoroscopic image series as a function of object velocity and x-ray pulse-width.

METHOD AND MATERIALS

Simulated fluoroscopic image series of a translating wire (1 mm diameter, 30 mm length) in white Gaussian noise were presented to seven trained readers using a 4-alternative forced choice study paradigm. Image series were simulated at eight frames-per-second (8 fps), two wire velocities (10 mm/s, 25 mm/s) and two x-ray pulse-widths (4 ms, 120 ms). Object contrast and image spatiotemporal noise power were held constant for all image series.Each reader was trained to maintain a constant viewing position (50 cm) and to utilize a template image sequence to inform eye-tracking. A total of 200 image series, 50 series for each pulse-width velocity combination, were reviewed by every reader. Their task was to select the image sequence which contained the translating wire.Binary response data from all readers was analyzed using a generalized linear mixed effects model with a probit link function. The model included pulse-width and velocity as fixed effects, and an intercept reader random effect.

RESULTS

Average observer detection performance ranged from 48% correct at the longest pulse-width and fastest velocity (120 ms, 25 mm/s) to 89% at the shortest pulse-width and slowest velocity (4 ms, 10 mm/s). X-ray pulse-width and object velocity were significant predictors of human detection performance (p-value << 0.0001) with an estimated effect size of -0.96 (95% CI: -1.12, -0.79) and -0.90 (95% CI: -1.17, -0.65) respectively. The standard deviation of the reader random effect was estimated at 0.57. The reader random effect can be largely attributed to the fact that one reader group observed each case for double the amount of time (17.7 seconds) as the other reader group (8.7 seconds) and thereby increased average detection performance by 28% correct.

CONCLUSION

Human detection performance of moving objects in fluoroscopic image series decreased significantly and independently with increased velocity and increased pulse-width. Average observation time also effected detection performance.

CLINICAL RELEVANCE/APPLICATION

The use of fluoroscopic imaging for diagnostic and interventional tasks involving substantial anatomic motion may be optimized for detection performance by appropriate x-ray pulse-width selection.

SSM23-04 Academic Interventional Radiology Section Chiefs and the Physician Open Payments Program: Do

General Payments Correlate with Academic Productivity?

Wednesday, Nov. 29 3:30PM - 3:40PM Room: E450B

Awards
Student Travel Stipend Award

jhoffmann@winthrop.org

PURPOSE

While the intent of the Physician Open Payments Program (OPP) reportedly is to increase transparency, the public receives minimal information about what these payments may entail, and patients may assume these are inappropriate or signify bias. To our knowledge, no analysis of payments in relation to academic productivity exists in the literature. Therefore, our goal was to study this relationship among interventional radiology (IR) chiefs at U.S. academic institutions.

METHOD AND MATERIALS

Per institution guidelines, IRB approval was not needed as the project used only publicly available information. A list of IR section chiefs at academic institutions with IR fellowships was created. All non-royalty general payments (NRGP) made to IRs in 2015 was downloaded from the OPP website. Pubmed search was used to correlate this with the academic productivity of each IR chief. Spearman correlation was used to measure the association between productivity and payment. Fisher's Z transformation was used to compute the 95% confidence interval for the correlation as a measurement of the strength of the association. In addition, 2015 payments to IR division chiefs were compared to 2015 payments to IR non-chiefs.

RESULTS

Out of 95 U.S. hospitals with an IR fellowship, 89 chiefs were identified. In 2015, 77 IR chiefs received at least one NRGP, averaging $9,911.88±23,183.91 (median $1628.97). In 2015, 1723 non-chief IRs received at least one NRGP, averaging $3,112.10±16,244.24 (median $243.79). A test of normality of the IR chiefs' NRGP and Pubmed publications revealed that both variables significantly deviate from normal distribution. Thus, the Spearman correlation coefficient is the appropriate measure of their association. Correlation between IR chiefs' productivity and payment is 0.44 with a 95% confidence interval of 0.24-0.59, representing a weak to moderate positive association.

CONCLUSION

A positive association exists between payment amount reported in the OPP system and academic productivity amongst IR section chiefs at academic U.S. institutions in 2015. The median IR chief 2015 NRGP was 668% higher than for non-chief IRs.

CLINICAL RELEVANCE/APPLICATION

The general public should be informed that IR chief payments and relationships with industry may have a link to academic productivity. The greater NRGP for academic IR chiefs may reflect a greater responsibility to interact with industry.

SSM23-05 How Comprehensive are Interventional Radiology Residency Websites?

Wednesday, Nov. 29 3:40PM - 3:50PM Room: E450B

Awards
Student Travel Stipend Award

PURPOSE

Interventional Radiology (IR) residency began its first application cycle this past year. As the majority of residency applicants turn to the Internet to evaluate potential residency programs, maintaining a comprehensive website is crucial for attracting the best and brightest medical students. The purpose of this study was to evaluate the comprehensiveness of IR residency websites during the first application cycle.

METHOD AND MATERIALS

We searched all integrated IR residency programs listed on the Society for Interventional Radiology website for the presence of a dedicated residency website. For programs with a dedicated website, we searched for the presence of 38 criteria previously identified as important considerations for medical students applying to Radiology residency (Image 1). We compared prevalence of these criteria between different regions of the country and size of residency program using T-tests and ANOVA.

RESULTS

Of 61 IR residency programs identified, 44 (72%) had dedicated websites. Of these 44, only 1 program had at least 2/3 of criteria assessed and only 10 programs (23%) had half or more. On average, the websites reported 37% of items evaluated. The most frequently included information was contact e-mail (93%), mailing address (89%), resident social life (64%) and the area surrounding each residency (61%). The least commonly included information was about procedure simulation experience (5%) and description of teaching didactics (5%). There was no significant difference in website comprehensiveness between regions (p = 0.49), or between "large" programs (3+ residents/year) and "small" programs (>3 residents/year) [P = 0.36].

CONCLUSION

Nearly one-third of integrated IR residency programs do not have a dedicated website, and those that do exist are inadequately comprehensive, with less than 40% of assessed criteria present. Contact information and information about life outside of work were the most commonly included information with comparatively less frequent description of the clinical training opportunities. Addressing these gaps in website content will help IR residencies better inform prospective applicants and, in turn, help recruit the best and brightest into the field.

CLINICAL RELEVANCE/APPLICATION

Ensuring comprehensive interventional radiology residency program websites will help recruit the best and brightest medical students into the field.

SSM23-06 Comparative Utilization of Carotid Stenting and Carotid Endarterectomy in the Medicare Population in Recent Years

Wednesday, Nov. 29 3:50PM - 4:00PM Room: E450B

sarah.kamel@jefferson.edu

PURPOSE

In the late 1990s, multiple controlled trials demonstrated that carotid endarterectomy (CEA) is superior to optimal medical therapy for stroke prevention, particularly in patients with high grade symptomatic stenosis. CEA is preferred to carotid artery stenting (CAS) given that the perioperative risk of stroke or death can be up to two fold higher with CAS. Our purpose was to study the recent trends of CEA and CAS in the Medicare population in response to the literature.

METHOD AND MATERIALS

The nationwide Medicare Part B fee-for-service databases for 2003-2015 were used. We selected CPT codes 35301 (thromboendarterectomy, carotid) and 37215 (intravascular stent placement, cervical carotid). The databases indicate procedure volume for each code, which were used to calculate utilization rates per 100,000 Medicare beneficiaries. Medicare specialty codes indicated the specialty of the performing physician.

RESULTS

Utilization rate of carotid endarterectomy was at its highest in 2003 at 355 per 100,000 and has declined steadily to 156 in 2015 (-56%). A CPT code for CAS first became available in 2005. CAS utilization peaked in 2006 at 28, ranged between 25-26 studies from 2007 to 2011 and then declined to 16 by 2015 (-43% compared with peak) In 2015, the percent share of carotid stenting by specialty was: cardiology 45%, vascular surgery 20%, radiology 14%, neurosurgery 8%, neurology 6%, other 6%.

CONCLUSION

Since CEA has been demonstrated to have lower perioperative mortality compared to CAS, it is not surprising that CEA was performed nearly ten times as often in 2015. Considering the proven efficacy of CEA, it is surprising that its utilization rate has dropped 56% since 2003 and that in recent years, CAS use has also declined. Perhaps this decrease in intervention is due to improved efficacy of medical management of atherosclerosis in addition to stricter guidelines defining patients who would most benefit from carotid intervention.

CLINICAL RELEVANCE/APPLICATION

The utilization of both CEA and CAS is declining.

clauser.p@hotmail.it

PURPOSE

To compare a standard dose of Gadoterate Meglumine (Gd-DOTA 0.15 mmol/kg) to a half dose of a high relaxivity contrast agent (Gabobenate Dimeglumine, Gd-BOPTA 0.075 mmol/kg) for breast lesion detection and characterization at 3 Tesla.

METHOD AND MATERIALS

Eligible for this IRB-approved prospective, randomized, intra-individual comparison study were patients with suspicious findings (BI-RADS 4 or 5) on conventional breast imaging (i.e. mammography, tomosynthesis or ultrasound) undergoing additional 3T MR imaging of the breast including high spatiotemporal resolution DCE (TWIST), T2w-TSE and DWI according to international recommendations. Two repeated, identical examinations at least 24h apart from each other were performed with both contrast agents being administered in a randomized order. Histology was defined as standard of reference. Three blinded breast radiologists, not affiliated with the site of enrollment, evaluated the examinations off-site. Lesion detection rate, sensitivity, specificity and accuracy were calculated per-lesion and per-region, and compared using the McNemar test. Multivariate analysis was used to control for inter-reader performance.

RESULTS

109 patients were prospectively recruited. Excluded were 5 patients due to technical problems or lack of reference standard. Finally, 104 women with 142 histologically verified breast lesions (109 malignant and 33 benign) were enrolled. Detection rate with Gd-BOPTA (84.5-88.7%) was not inferior to Gd-DOTA (84.5%-90.8%), P>0.165. In the per-region analysis, Gd-BOPTA had a significantly higher specificity (96.4%-98.7% vs 92.6-97.3%) and accuracy (96.3-97.8% vs 93.6-96.1%) as compared to Gd-DOTA for all three readers. Multivariate analysis demonstrated a reader-independent superior accuracy with Gd-BOPTA.

CONCLUSION

A reduced dose of Gd-BOPTA 0.075 mmol/kg is not inferior to a standard dose of Gd-DOTA 0.15 mmol/kg in breast lesion detection, and superior in lesion characterization at 3T breast MRI.

CLINICAL RELEVANCE/APPLICATION

A reduced dose of Gd-BOPTA (0.075 mmol/kg) achieves breast MRI lesion detection comparable to a standard dose of Gd-DOTA, with a superior diagnostic performance. A reduced dose of Gd-BOPTA can be safely used in clinical practice at 3T breast MRI.

SSQ01-02 American College of Radiology Imaging Network (ACRIN) 6702 Diffusion-Weighted Breast MRI Trial: Image Quality and Factors Associated with Lesion Evaluability

PURPOSE

Diffusion-weighted imaging (DWI) has potential to improve conventional breast MRI specificity. Most DWI sequences use a single-shot echo planar imaging-based readout, which is prone to artifacts that may limit breast DWI reliability. The ACRIN 6702 multisite trial investigated DWI performance for diagnosing breast lesions. Here we describe DWI quality and factors affecting evaluability of apparent diffusion coefficient (ADC) values in breast lesions in the trial.

METHOD AND MATERIALS

The IRB-approved trial was performed at ten institutions on multiple 1.5T and 3T MRI platforms (Philips, GE, and Siemens). Women with MRI-detected BI-RADS 3, 4, or 5 lesions were enrolled in the study (from 3/2014 to 4/2015). Multi b-value (0, 100, 600, 800 s/mm2) DWI was performed in clinical breast MR exams. Each DWI scan was reviewed for image quality factors: fat suppression, signal-to-noise ratio (SNR), artifacts (magnetic susceptibility distortion, aliasing, chemical shift), and misregistration (from eddy-current-induced distortion). Lesions were considered not evaluable if significant image quality factors and/or lack of lesion visibility (due to partial volume averaging) prevented ADC measurement. Associations between image quality factors, field strength, lesion type (mass vs. non-mass), size, and evaluability were explored by Fisher's exact test.

RESULTS

ACRIN 6702 included 103 women with 142 lesions, of which 42 (41%) exams were performed at 1.5T and 61 (59%) at 3T. Poor or incomplete fat suppression affected 21% (22/103) of DWI scans, poor SNR 20% (21/103), artifacts 31% (32/103), and misregistration 20% (21/103). Exams at 1.5T were more prone to misregistration ($p=0.002$), while 3T exams exhibited more aliasing artifacts ($p=0.003$). ADC was evaluable for 100/142 (70%) lesions; factors associated with non-evaluability ($p<0.05$) included poor SNR, misregistration, and small lesion size <10mm (most common factor), but not lesion type or magnetic field strength.

CONCLUSION

This multisite breast DWI trial shows image quality remains a challenge, precluding measurement of 30% of lesions. Protocol optimization and technical advancements are needed to improve reliability and potential for widespread clinical implementation.

CLINICAL RELEVANCE/APPLICATION

Given strong data from this ACRIN 6702 trial that DWI can reduce false-positive breast MRIs, further research investment to improve image quality is warranted to facilitate clinical translation.

SSQ01-03 Contralateral Parenchymal Enhancement on Dynamic Contrast-Enhanced MRI is Complemented by Genomic ER-Pathway Data in Stratifying Outcome of ER+HER2 - Breast Cancer Patients

Thursday, Nov. 30 10:50AM - 11:00AM Room: E450A

bvelden2@umcutrecht.nl

PURPOSE

High contralateral parenchymal enhancement (CPE) on dynamic contrast-enhanced MRI in the healthy breast of patients with ER+HER2- breast cancer receiving hormonal therapy has been associated with superior overall survival (OS). For patients with intermediate CPE, results have been inconclusive. The purpose of this retrospective study was to explore whether estrogen receptor (ER)-pathway activity derived from genomic data of the primary tumor is able to complement CPE in patient risk stratification.

METHOD AND MATERIALS

Between 2000 and 2008, 415 patients with ER+HER2- breast cancer eligible for breast-conserving therapy based on conventional imaging and physical examination received a preoperative MRI in study context. 181 Patients received hormonal therapy. Fresh-frozen tumor tissue of 104 patients was available for RNA sequencing. CPE was calculated using previously reported method. In short, parenchyma was automatically segmented, after which CPE was calculated as the mean of the top-10% relative signal increase. The ER-pathway activity of the tumor was assessed using unsupervised clustering of RNA, protein, and DNA copy number data from the TCGA database [Bismeijer et al.], and re-applied on the current dataset. The assay is strongly associated with activation of ESR1 targets. CPE and ER-pathway were each split in three groups (high, intermediate, low). OS was analyzed using Cox's models between CPE groups, ER-pathway groups, and combinations thereof.

RESULTS

The average patient age was 57 years (range: 32-84). The median follow-up was 87 months (range: 34-146). An event occurred in

11/104 (11%) patients. Patients with high CPE (n=38, 1 event) showed superior OS compared to those with low CPE (n=31, 7 event, P=.043), while for intermediate CPE (n=35, 33%) the test was inconclusive (P=.13). Differences in OS were observed between high and low ER-pathway, although not significant (P=0.12). When combined, patients with low CPE and low ER-pathway activity (n=52, 10 events) showed significantly worse survival than other patients (n=52, 1 event, P=.027).

CONCLUSION

CPE appears to be complemented by genomic-derived ER-pathway activity in stratifying patient survival.

CLINICAL RELEVANCE/APPLICATION

Combination of preoperative parenchymal enhancement on MRI of the healthy breast and ER-pathway axtivity in the primary tumor may predict therapy outcome more efficiently than either one alone.

SSQ01-04 Quantitative Measurement of Background Parenchymal Enhancement in Postmenopausal Women

Thursday, Nov. 30 11:00AM - 11:10AM Room: E450A

Awards
Student Travel Stipend Award

Participants

Alana A. Lewin, MD, New York, NY (*Abstract Co-Author*) Nothing to Disclose
Sungheon G. Kim, PhD, New York, NY (*Abstract Co-Author*) Nothing to Disclose
Linda Moy, MD, New York, NY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To investigate MRI contrast material-enhancement kinetics of breast background parenchyma (BPE) in postmenopausal women with benign and malignant lesions using a semiautomatic method of segmenting fibroglandular tissue for quantitative measurement.

METHOD AND MATERIALS

The institutional review board approved this retrospective HIPAA-compliant study, and informed consent was waived. From January 1, 2013 to December 31, 2013, 83 postmenopausal women who had undergone contrast-enhanced MRI at 3T (90 s/frame) were identified. BPE in 53 malignant cases (age 61.57±8.39; range 50-83) and 30 benign cases (age 60.43±7.60; range 50-76) were analyzed. A method based on principal component analysis (PCA) was used to semi-automatically segment the fibroglandular tissues. The primary eigen component was used for quantitative analysis of signal enhancement in the breast parenchyma in terms of the percentage of enhancement (PE) for the initial (90 s) and delayed (360 s) post-contrast time points. Lesion-PE was measured using manually drawn regions of interest. Statistical analyses were performed using the Mann-Whitney U test.

RESULTS

53 malignant cases, of which 37 were invasive ductal carcinoma (IDC), 11 invasive lobular carcinoma (ILC), and 5 other invasive malignancies, were identified. 30 benign cases of which 11 were fibrocystic changes, 11 stable findings on imaging, and 8 others, were identified. There was no statistical difference in age and lesion size among these 3 groups. No statistical difference existed between initial and delayed BPE-PE in malignant cases compared to benign cases (p=0.051; p=0.09). In women with ILC, the initial and delayed BPE-PE values were significantly higher than in women with IDC (p=0.022 and p=0.02, respectively) and in women with benign lesions (p=0.006 and p=0.01, respectively). Lesion-PEs were not significantly different between IDC and ILC cases.

CONCLUSION

Higher BPE-PEs were seen in cases with malignant lesions compared to those with benign lesions. The sub-group analysis showed that cases with ILC have higher BPE-PE than those with IDC and with benign lesions.

CLINICAL RELEVANCE/APPLICATION

Significantly increased BPE in postmenopausal ILC cases, compared to IDC and benign cases, may be associated with ILC development in the absence of progesterone after menopause.

SSQ01-05 Impact of a Novel Abbreviated Breast MRI Protocol on Kinetic Analysis of Benign and Malignant Lesions

Thursday, Nov. 30 11:10AM - 11:20AM Room: E450A

Participants

Shinnhuey S. Chou, MD, Boston, MA (*Abstract Co-Author*) Nothing to Disclose
Ken Chang, Boston, MA (*Abstract Co-Author*) Nothing to Disclose
Jayashree Kalpathy-Cramer, MS, PhD, Charlestown, MA (*Abstract Co-Author*) Consultant, Infotech Software Solution
Constance D. Lehman, MD, PhD, Boston, MA (*Abstract Co-Author*) Research Grant, General Electric Company; Medical Advisory Board, General Electric Company

For information about this presentation, contact:

SSCHOU@PARTNERS.ORG

PURPOSE

To compare kinetic analyses and discrimination of benign and malignant lesions based on a novel abbreviated breast MRI (AB-MRI) versus a traditional extended dynamic contrast-enhanced MRI (DCE-MRI) protocol.

METHOD AND MATERIALS

This IRB-approved retrospective study included 162 patients with 177 lesions (84 imaged with AB-MRI and 93 imaged with DCE-MRI) assessed as BI-RADS category 4, 5, and 6 between 10/1/2015-8/31/2016. Traditional DCE-MRI included one pre and three post-

contrast phases: initial phase at 60-75 seconds and the third phase at 420-450 seconds post contrast (45 minutes total scan time). AB-MRI included one pre and two post-contrast phases: initial phase at 60-75 seconds and the second phase at 180-205 seconds post contrast (<10 minutes total scan time). Computer-aided kinetic analyses of lesions included delayed-phase volume percentages of washout, predominant curve type, and worst curve type, which were compared using Wilcoxon rank-sum test and Chi-Square test. Receiver operating curve (ROC) analyses for discrimination of benign and malignant lesions were performed.

RESULTS

The AB-MRI group consisted of 21 benign, 2 high risk, and 61 malignant lesions; the traditional DCE-MRI group consisted of 19 benign, 8 high risk, and 66 malignant lesions. Mean delayed-phase percentages of washout were 8% [range 0-45%] versus 9% [range 0-62%] (p=0.36) for benign lesions and 19% [range 0-92%] versus 17% [range 0-71%] (p=0.66) for malignancies in the AB-MRI and DCE-MRI groups respectively. No significant differences were found in the predominant and worst curve types for malignant and benign lesions between protocols (p>0.05). There were no significant differences between the AB-MRI and DCE-MRI in areas under the ROC curves (AUC) for delayed-phase percent washout (AUC 0.67 vs. 0.69, p=0.81), predominant curve type (AUC 0.62 vs. 0.55, p=0.45), or worst curve type (AUC 0.50 vs. 0.56, p=0.53).

CONCLUSION

Our study suggests that our novel AB-MRI protocol does not negatively impact the kinetic analyses and discrimination of benign and malignant lesions compared to traditional DCE-MRI, with malignant lesions demonstrating higher percentages of washout than benign lesions with both protocols.

CLINICAL RELEVANCE/APPLICATION

Abbreviated breast MRI protocol can improve patient comfort and workflow without the loss of diagnostic kinetic information.

SSQ01-06 Diagnostic Value of Electronic Property Tomography (EPT) For Differentiating Benign from Malignant Lesions: Comparison with Standard Dynamic Contrast-Enhanced MRI

PURPOSE

To compare diagnostic utility of EPT to standard DCE-MRI for differentiating benign from malignant lesions.

METHOD AND MATERIALS

Between January 2014 and December 2015, consecutive 67 patients with 83 breast lesions (33 benign and 50 malignant) underwent an IRB-approved 3T-MRI, including 3D turbo spin echo (TSE) sequence and standard dynamic contrast-enhanced (DCE)-MRI scans. Given the transceive phase Φ of a TSE image, EPT estimates tissue conductivity via $\sigma=(\Delta\Phi)/(2\mu o\omega)$ with Δ the Laplace operator, μo the magnetic permeability (assumed to be constant), and ω the Larmor frequency. The lesions were segmented semi-automatically using subtraction DCE-MR images (post-pre-contrast), and the segmented volume of the lesions was registered to the phase images. Conductivity reconstruction was performed only inside lesion volumes, and the mean conductivity of the lesion was obtained. From the standard DCE-MRI, a single voxel whithin each lesion that had the highest signal intensity on the early image was selected, and the initial enhancement rate and the signal enhancement ratio (SER) were caluculated as follows: the initial uptake = (SIearly-SIpre)/SIpre, SER = (SIearly-SIpre)/(SIdelayed-SIpre). The parameters from EPT and standard DCE-MRI were conpared between benign and malignant lesions. P<0.05 was considered significant. After Bonferroni correction of 4 multiple comparisons, the critical value became <0.0125(0.05/4).

RESULTS

The mean conductivity of malignant lesions (1.32±1.21S/m) was significantly higher than benign lesions (-0.09±1.77S/m) (p<0.0001). The SER of malignant lesions (1.19±0.27) was significantly higher than benign lesions (0.89±0.32S/m)(p<0.0001), whereas the initial uptake did not show significant difference between benign and malignant lesions (p=0.027). Receiver operating curve (ROC) analysis revealed that the are under the curve (AUC) of the mean conductivity and SER was 0.76 and 0.82, respectively. There was no significant difference in AUC between the mean conductivity and SER (p=0.41).

CONCLUSION

The mean conductivity might be comparable to standard DCE-MRI for differentiatiation between benign and malignant lesions.

CLINICAL RELEVANCE/APPLICATION

The mean conductivity measured by EPT might be comparable to standard DCE-MRI for differentiation between benign and malignant lesions.

SSQ01-07 Prediction of Low-Risk Ductal Carcinoma in Situ using Whole-Lesion Histogram Analysis of the Apparent Diffusion Coefficient

Thursday, Nov. 30 11:30AM - 11:40AM Room: E450A

youdosa@naver.com

PURPOSE

To investigate the value of histogram-derived apparent diffusion coefficient (ADC) metrics obtained from whole-lesion assessment of diffusion-weighted imaging (DWI) for predicting a low-risk ductal carcinoma in situ (DCIS).

METHOD AND MATERIALS

The institutional review board approved this retrospective study, and waived informed consent. The authors identified 93 women (mean age, 51.9 years; range, 32-76 years) with pure DCIS, who had undergone preoperative MR imaging and DWI from 2013 to 2016. Histogram analysis of pixel-based ADC data of the whole tumor volume and conventional measurement of the mean ADC by placing regions of interest were performed by two radiologists. The mean, median, and 5th and 95th percentile ADCs obtained from whole-lesion histogram and the ROI-based mean ADC were compared between low-grade and non-low-grade DCIS. Associations of whole-lesion histogram ADC metrics with low-grade DCIS were evaluated by receiver operating characteristics (ROC) curve and logistic regression analyses.

RESULTS

In whole-lesion histogram analysis, the mean, median, and 5th and 95th percentile ADCs were significantly different between low-grade and non-low-grade DCIS (1.522, 1.536, 1.207, and 1.854 × 10-3mm2/s versus 1.270, 1.261, 0.917, and 1.657 × 10-3mm2/s, respectively; P=0.004, P=0.004, P=0.003, and P=0.024, respectively). However, ROI-based mean ADC was not significantly different (P=0.278). ROC curve analysis for the differentiation between low-grade and non-low-grade DCIS groups revealed that the most effective threshold for the 5th percentile ADC was > 1.078 × 10-3mm2/s (sensitivity 80%, specificity 75.9%, area under the curve [AUC] 0.786, P=0.001). No differences in the AUC were found among the ADC metrics of whole-lesion histogram. Multivariate regression analysis revealed that a higher 5th percentile ADC (> 1.078× 10-3 mm2/s; odds ratio [OR]=10.494, P=0.016), smaller tumor size (<= 2cm; OR=12.692, P=0.008), and low Ki-67 status (< 14%; OR=10.879, P=0.046) were significantly associated with low-grade DCIS.

CONCLUSION

Assessment with whole-lesion histogram analysis of the ADC could be helpful for identifying patients with low-risk DCIS.

CLINICAL RELEVANCE/APPLICATION

Whole-lesion histogram ADC metrics may serve as DWI biomarkers of DCIS biology, which could help to reduce overtreatment in patients with low-risk DCIS.

SSQ01-08 Unenhanced Breast MRI during Pregnancy Using Diffusion Tensor Imaging (DTI) Parametric Maps: A Feasibility Study

PURPOSE

To investigate the feasibility and clinical utility of DTI parametric maps in the diagnostic workup of pregnancy-associated breast cancer

METHOD AND MATERIALS

This prospective study was approved by our institutional IRB, and a signed informed consent was obtained from all participants. Since November 2016, thirteen pregnant patients (median gestational age: 17 weeks, range:8-30w) were examined by unenhanced breast MRI protocol. Indications included: newly diagnosed pregnancy-associated breast cancer (PABC) (n=5), follow-up on high-risk patients (n=7) and on neoadjuvant-chemotherapy (NAC) treated patient (n=1). MRI protocol included T2-weighted and DTI sequences, recorded at 1.5T (GE) using a breast coil, with total scan duration of ~12min. DTI was acquired using 32 directional diffusion gradients and 0, 700 s/mm2 b-values. DTI parametric maps of the principal diffusion coefficients (λ1,λ2,λ3), mean diffusivity (MD), fractional anisotropy (FA) and maximal anisotropy index (λ1-λ3) were generated and analyzed at pixel resolution using a proprietary software. Regions of interest (ROIs) of lesions and the normal fibroglandular tissue were delineated on λ1 maps and were statistically compared using Student's t-tests.

RESULTS

All scans were completed. One patient complained on positional discomfort during the scan which was endured with extra supports but still ended up with significant artifacts. All other scans were in diagnostic quality and artifact-free. All five known tumors were detected by DTI maps of λ1, λ2, λ3, MD and λ1-λ3 in agreement with their localization based on clinical/mammographic/sonographic findings, exhibiting substantial contrast compared with the ROIs of the apparently-normal surrounding tissue (p<0.001, for all). Representative images of 36 y patient diagnosed with IDC at the 17th week of pregnancy are presented in Fig1. FA ROIs did not help in differentiating malignant and normal tissues (p=0.48). Scans of high risk patients did not

reveal any new suspicious finding, in agreement with US exam. Residual tumor was not identified in the scan of the patient receiving NAC, in agreement with DCE MRI, performed several weeks later after delivery.

CONCLUSION

DTI examination is safe, non-invasive, fast and well-tolerated by pregnant patients and DTI parametric maps helped in characterizing PABC.

CLINICAL RELEVANCE/APPLICATION

DTI appears to have a promising diagnostic value in breast imaging during pregnancy

SSQ01-09 Texture Analysis for Non-Mass Enhancement on Breast MRI: A Preliminary Experience

Thursday, Nov. 30 11:50AM - 12:00PM Room: E450A

For information about this presentation, contact:

gomari@koto.kpu-m.ac.jp

PURPOSE

To evaluate the usefulness of texture analysis for diagnosis of non-mass enhancement (NME) on breast dynamic contrast enhanced (DCE) magnetic resonance imaging (MRI).

METHOD AND MATERIALS

84 patients with 86 NME lesions on breast MRI (from March 2010 to March 2013) were enrolled in this retrospective study (35 benign and 51 malignant with 33 invasive breast cancers (IBC) and 18 ductal carcinomas in situ (DCIS)). Three-dimensional histogram analysis and gray-level co-occurrence matrix (GLCM) based textural features were extracted from lesions' volume of interest (VOI) depicted on both early and delayed phases of DCE-MRI acquired by a 1.5T MRI scanner. In each NME, two different VOIs were placed; VOI-1 was carefully set to include only the enhancing areas, and VOI-2 was placed to cover the whole enhancing region including intervenient non-enhancing areas. Mann-Whitney U-test with false discovery rate control was applied for two groups to compare the extracted textural features in VOI-1; 1) benign and malignant lesions, 2) IBC and DCIS. Several diagnostic models were constructed with elastic net using VOI-1 and -2 data. Receiver operating characteristic (ROC) analysis was performed to evaluate these models. Then the models from 1.5T MRI were validated by comparing it with 3T DCE-MRI data sets (10 benign and 20 malignant with 10 IBC and 10 DCIS).

RESULTS

Total of 138 textural features were derived from VOI-1, and some of them showed statistical significant difference in benign vs malignant and in IBC vs DCIS. By the ROC analysis of benign vs malignant NME, area under curves (AUC) with best performance were 0.854 and 0.849, respectively for VOI-1 and -2. Analysis of IBC vs DCIS were 0.936 and 0.933, respectively for VOI-1 and -2. Diagnostic performance between different VOI settings did not show statistically significant differences neither in benign vs malignant ($p = 0.891$), nor in IBC vs DCIS ($p = 0.933$). The AUCs of 1.5T were comparable to the results of 3T DCE-MRI.

CONCLUSION

Texture analysis using breast DCE-MRI for NME showed good diagnostic performance for the differentiation of malignant vs benign lesions, and of DCIS vs IBC, regardless of the VOI settings.

CLINICAL RELEVANCE/APPLICATION

Texture analysis of breast MRI may be one of the promising tools to improve the diagnostic performance and may provide us with quantitative measures of internal structure for non-mass enhancement.

PURPOSE

To evaluate characteristics of coronary computed tomography angiography (CCTA) findings of neointimal hyperplasia in patients diagnosed coronary stent failure and compare the quantitative measurements of CCTA with optical coherence tomography (OCT) defined in-stent neoatherosclerosis in section-to-section-level.

METHOD AND MATERIALS

Total number of 370 CCTA and OCT cross-sections (18 coronary stent lesions in 18 consecutive patients who diagnosed stent failure from Aug 2008 to Dec 2013 and underwent both pre-procedural OCT and CCTA) were included. Stent area, lumen area, in-stent intimal hyperplasia (IH) area, IH% (IH area/lumen areax100), lipid quadrant, and presence of thin-cap fibroatheroma (TCFA), rupture and thrombus were evaluated using OCT. CT measurements (stent area, lumen area, IH area and IH%) were compared with OCT-derived parameters. Lumen and IH attenuation were measured on CT. CT parameters were analyzed according to lipid quadrant (sections with <= 2 lipid quadrants (n=146) vs. 3 or 4 quadrants (n=117)) or presence of TCFA (n=39).

RESULTS

Stent area (r=0.66, p<0.001) and lumen area (r=0.43, p<0.001) showed moderate correlation, however, IH area (r=0.34, p<0.001) and IH% (r=0.19, p<0.001) showed mild or weak correlation between CT and OCT. Sections with high lipid quadrant (3 or 4) showed low IH attenuation (395 Hounsfield unit [HU]) on CT compared to those with <= 2 lipid quadrant (p<0.001). Neointimal rupture (n=15) or thrombi (n=17) were noted only in sections with high lipid quadrant (each, p<0.001). In multivariate logistic analysis, high lipid quadrant was significantly associated with lumen attenuation (OR,0.994; 95%CI 0.989 - 1.00; p=0.04), IH% (OR, 1.046; 95%CI 1.004 - 1.090; p = 0.03) and IH attenuation (OR, 0.996; 95%CI 0.992 - 0.999; p = 0.01) measured on CT. Sections with TCFA presented larger IH area (3.7mm2) and smaller lumen area (1.8 mm2) than those without TCFA (3.2 mm2 and 2.1 mm2). Presence of TCFA was associated with IH% (OR, 1.057; 95%CI 1.006 - 1.111;p=0.03) on CT.

CONCLUSION

Stent area and lumen area were moderately correlated between CT and OCT. High lipid quadrant in OCT is associated with lumen attenuation, IH attenuation and IH% on CT. TFCA is associated with IH% measured on CT.

CLINICAL RELEVANCE/APPLICATION

Quantitative parameters for in-stent restenosis measured on CCTA may be helpful to assess the presence of high lipid quadrant or

Quantitative parameters for in-stent restenosis measured on CCTA may be helpful to assess the presence of high lipid quadrant of TCFA.

SSQ02-04 Non-invasive Evaluation of Soft-Plaque-Restenosis in Coronary Artery Stents: Initial In-vitro Comparison of a Spectral Photon Counting CT and a Spectral Dual-Layer CT System

Thursday, Nov. 30 11:00AM - 11:10AM Room: S502AB

Monica Sigovan, PhD, Lyon, France (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Even when compared to the latest spectral dual layer CT systems (SDLCT) future spectral photon counting detector CT systems (SPCCT) promise an improved spatial resolution as well as decreased stent related blooming artifacts, two likely beneficial characteristics for the challenging task of evaluating in-stent restenosis. Therefore, we investigated the influence of different conventional (Conv) and monoenergetic (MonoE) reconstructions from a SDLCT and a SPCCT on the delineation of soft-plaque-restenosis in coronary stents.

METHOD AND MATERIALS

Artificial stenosis (~30HU) were implanted into 10 different coronary stents (diameter 3mm) embedded in plastic tubes filled with Iohexol-based contrast agent (~400HU). CT data was acquired with a 128-slice SDLCT (IQon, Philips, 120kV, 100mAs, 0.2x0.2x0.67mm3 voxel size (VS)) and a 9-slice SPCCT (Prototype, Philips, 120kV, 100mAs, 0.2x0.2x0.25mm3 VS). Sharp FBP kernels were used for reconstructions with Conv and MonoE at 50, 70, 100 and 140keV. Visibility of the stenosis and the remaining lumen was evaluated by 2 readers for each stent and reconstruction using a 5-point Likert scale: 1=image quality impedes lumen assessment; 2=lumen appears stenosed, extent unclear; 3=stenosis and extent clear, remaining lumen undistinguishable; 4=stenosis clear and remaining lumen slightly distinguishable; 5= stenosis and remaining lumen clear.

RESULTS

Interrater agreement was very good (weighted kappa=0.9). Stenosis delineation was best in Conv, 50 and 70keV MonoE SPCCT images (median score 5). Differentiation was significantly more difficult in the corresponding SDLCT images (median score 3; $p<0.01$). Despite visibly lower stent blooming artifacts, 100 and 140keV MonoE images showed significantly poorer results compared to the corresponding 50keV MonoE images due to reduced contrast enhancement resulting in impaired visualization of the unaltered stent lumen (median score of 2 for 100keV and 1 for 140keV on both scanners; $p<0.01$).

CONCLUSION

Evaluation of soft-plaque-restenosis can be significantly improved by using conventional and low keV MonoE reconstructions of future SPCCT. High keV MonoE reconstructions are not recommended for coronary stent assessment with SPCCT or SDLCT due to impeded stenosis delineation.

CLINICAL RELEVANCE/APPLICATION

SPCCT will have the potential to significantly improve the important but still challenging non-invasive evaluation of coronary stents and possible restenosis.

SSQ02-05 Low-Dose Coronary CT Angiography with 30 Ml Contrast Medium And Monochromatic Imaging Using Dual-Layer Spectral Detector CT

Thursday, Nov. 30 11:10AM - 11:20AM Room: S502AB

Participants
Man Wang, Beijing, China (*Presenter*) Nothing to Disclose
Yining Wang, MD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
Yun Wang, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
Zheng Yu Jin, MD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To investigate the feasibility of monochromatic imaging for coronary CT angiography (CCTA) with 30 ml contrast medium and low radiation dose.

METHOD AND MATERIALS

Thirty patients with suspected ischemic heart disease underwent CCTA on a dual-layer spectral detector CT. All imageswereacquired with step-and-shoot mode using 120 kVp, 104.4 ± 27.6 mAs with automatic current modulation. Due to the nature of dual-layer detector, the conventional and spectral image data were acquired within the same scan. The conventional and monochromatic 50 keV images were reconstructed. The objective image quality (IQ) was evaluated by placing region-of-interest (ROI) on aorta root (AO), left main artery (LM), distant segment of left anterior descending (LAD), left circumflex (LCX) and right coronary artery (RCA). The attenuation, noise and signal-to-noise ratio (SNR) were measured on conventional and monochromatic images. The subjective IQ was assessed by 2 raters independently using a 4-point scale (1 - excellent, 4 - undiagnostic).

RESULTS

The attenuation of AO, LM, LAD, LCX and RCAwas 311.9 ± 73.9, 297.4 ± 77.3, 210.6 ± 45.3, 214.8 ± 61.1 and 233.1 ± 82.1 HU on conventional images, 634.5 ± 173.2, 569.9 ± 175.7, 353.5 ± 80.9, 372.9 ± 105.4 and 410.5 ± 153.7 HU on monochromatic images. The noise and SNR of AO was 24.8 ± 3.7 and 12.9 ± 4.3 on conventional images, 20.9 ± 2.4 and 30.8 ± 9.6 on monochromatic

images. The attenuation, noise and SNR were significantly better on monochromatic images than those on conventional images (all $p < 0.01$). The subjective IQ score was 2.1 ± 0.5 and 1.2 ±0.4 in two groups.The volume CT dose index, dose length product and effective dose was 12.3 ± 3.3 mGy, 142.9 ± 44.7 mGy×cm, and 2.0 ± 0.6 mSv.

CONCLUSION

The monochromatic 50 keV images provide superior image quality with 30 ml contrast medium and 2 mSv radiation dose in CCTA study compared with conventional 120 kVp images.

CLINICAL RELEVANCE/APPLICATION

It is feasible to apply spectral imaging in CCTA study with low dose of contrast medium and radiation.

SSQ02-06 Accuracy of Virtual Non-Contrast Image of Coronary CT Angiography with Fast Kilo Voltage Switching Dual-Energy CT (DECT): Compared With Non-Contrast Image of Single-Energy CT (SECT)

Thursday, Nov. 30 11:20AM - 11:30AM Room: S502AB

Participants
Satoshi Inada, Hiroshima, Japan (*Presenter*) Nothing to Disclose
Masashi Takahashi, RT, Hiroshima, Japan (*Abstract Co-Author*) Nothing to Disclose
Tsuyoshi Kagimoto, Hiroshima, Japan (*Abstract Co-Author*) Nothing to Disclose
Tomohiro Murakami, Hiroshima, Japan (*Abstract Co-Author*) Nothing to Disclose
Yoji Urabe, Hiroshima, Japan (*Abstract Co-Author*) Nothing to Disclose
Hironori Ueda, Hiroshima, Japan (*Abstract Co-Author*) Nothing to Disclose
Fang Wang, Yinchuan, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The virtual non-contrast (VNC) images technique in fast kilo voltage switching single-source dual-energy CT (ssDECT) is useful to reduce scan dose. The purpose of this study was to evaluate the accuracy of CT-values in VNC images reconstructed from dual-energy coronary CT angiography using the fast kilo voltage switching technique performed on a ssDECT scanner, compared with non-contrasted single-energy CT (SECT) images for true non-contrast images (TNC).

METHOD AND MATERIALS

Twenty patients with coronary artery disease (between February 22nd, 2016 and April 4th, 2016) had non-contrasted SECT (120 kilovoltage) for calcium score and ssDECT for coronary angiography using fast kilovoltage switching dual-energy CT technique (Revolution GSI, GE Healthcare).TNC images were reconstructed from non-contrasted SECT for calcium score, and VNC images were reconstructed from ssDECT for coronary angiography. We measured CT-values of, right atrium (RA), right ventricle (RV), pulmonary artery (PA), left atrium (LA), left ventricle (LV), and ascending aorta (A-Ao) in TNC images and VNC images on an Advantage Workstation ver.4.7 (GE Healthcare). CT-values were compared between TNC images and VNC images.

RESULTS

In TNC images, mean CT-values for RA, RV, PA, LA, LV, and A-Ao were 42 ± 6 Hounsfield Unit (HU), 44 ± 4 HU,40 ± 4 HU, 40 ± 3 HU,42 ± 6 HU,and 41 ± 4, respectively. In VNC images, mean CT-values for RA, RV, PA, LA, LV, and A-Ao were 40 ± 6, 43 ± 6, 46 ± 9, 47 ± 10, 53 ± 11, and 47 ± 10, respectively. There was a no significant difference between CT-values of RA in TNC images and RA in VNC images ($P=0.333$), and between RV in TNC images and RV in VNC images ($P=0.923$). In VNC images, mean CT-values for PA, LA, LV, and A-Ao were about 6 to 11 HU higher than that in TNC ($P<0.05$).

CONCLUSION

CT-values in VNC reconstructed from fast kilo voltage switching ssDECT for coronary angiography were close to that in non-contrasted SECT images.

CLINICAL RELEVANCE/APPLICATION

The virtual non-contrast images (VNC) technique of ssDECT is useful for low DOSE clinical application.

SSQ02-07 Feasibility of Combining Coronary with Carotid and Cerebrovascular CT Angiography using CT with High Temporal Resolution and Wide Detector Coverage

Thursday, Nov. 30 11:30AM - 11:40AM Room: S502AB

Participants
Wanjiang Li, ChengDu, China (*Presenter*) Nothing to Disclose
Liqing Peng, Chengdu, China (*Abstract Co-Author*) Nothing to Disclose
Tao Shuai, Chengdu, China (*Abstract Co-Author*) Nothing to Disclose
Zhenlin Li, MD, Chengdu, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

452766554@QQ.com

PURPOSE

To explore the feasibility of combining coronary with carotid and cerebrovascular CT angiography (CCCTA) using CT system with high temporal resolution and wide detector coverage.

METHOD AND MATERIALS

60 patients with suspected cardiovascular and cerebrovascular disease were randomly divided into groups A and B. Group A (n=30) with integrated CT workflow: CCTA immediately followed by CCCTA after 1.1s delay with one injection of contrast agent. Group B used the traditional CT workflow: CCTA after contrast injection; patient rested for 30min, and contrast re-injection for CCCTA. The amount of the contrast in each injection was weight-dependent at 0.8ml/kg (370mgI/ml) and the flow rate was 5ml/s. The subjective image quality of CTA was assessed by two senior radiologists using a 4-point system for blind assessment (4=best). The

CT values and SD values of the aortic root, right coronary artery opening, left anterior descending branch opening, left rotation opening and fat in the anterior chest wall; and of the aortic arch, carotid cartilage median layer, internal carotid artery M1 segment and muscle at the same level were used to evaluate the objective image quality of CCTA and CCCTA, respectively. SNR and CNR for vessels were calculated. The effective dose was calculated. The corresponding image quality and radiation dose between groups A and B were compared.

RESULTS

The average contrast amount in group A was 51ml, significantly smaller than the 105ml in group B. The examination time was reduced from 40min in group B to 5min in group A. Group B had slightly better SNR and CNR values than group A in CCTA. However, There was no difference in the subjective score between the two groups (3.40±0.67 vs. 3.50±0.63) (P=0.56) and all CCTA images were diagnostic. There was no difference in both objective and subjective image quality of CCCTA between the two groups (P>0.05). There was no difference in total radiation dose between group A (2.42±1.10mSv) and group B (2.94±1.25mSv) (P>0.05).

CONCLUSION

It is feasible to combine CCTA with CCCTA using a 256-row, 16cm wide-detector CT system to simplify workflow, reduce contrast dose and maintain diagnostic images of the heart and head.

CLINICAL RELEVANCE/APPLICATION

Atherosclerotic plaques usually occur in coronary artery,carotid and cerebrovascular arteries simultaneously. Combining CCTA with CCCTA may show all the lesions with one scan.

SSQ02-08 Radiologists Now Predominate in Use of Coronary CT Angiography

Thursday, Nov. 30 11:40AM - 11:50AM Room: S502AB

david.levin@jefferson.edu

PURPOSE

Controversy has long existed between radiologists and cardiologists over who should perform cardiac imaging, and this has extended to the recently-developed technique of coronary CT angiography (CCTA). Our purpose was to compare recent trends in use of CCTA between the 2 specialties.

METHOD AND MATERIALS

HCPCS codes for CCTA have existed since 2006. We reviewed the Medicare Physician/Supplier Procedure Summary (PSPS) Master Files for 2006-2015 and selected the codes for CCTA. Medicare's physician specialty codes identified the specialty of the provider. The PSPS files provide procedure volume for each code each year and we then calculated utilization rates per 100,000 Medicare fee-for-service beneficiaries (37.5 million in 2015) in all places-of-service. We studied the long term utilization trends for CCTA and also for 2 competing modalities, stress echo and myocardial perfusion imaging (MPI).

RESULTS

The total Medicare utilization rate per 100,000 of CCTA was 99 in 2006, rising to 210 in 2007. However, the rate dropped sharply in subsequent years and reached a nadir of 107 in 2012 and 2013. It then increased the next 2 years to 117 in 2015 (+9.3% compared with nadir). Among cardiologists, the rate went from 59 in 2006 to 126 in 2007. It then dropped continuously, reaching a nadir of 47 in both 2014 and 2015. Among radiologists, the rate increased from 31 in 2006 to 67 in 2007, but then declined to a nadir of 44 in 2010. However, since then, radiologists' rate has increased steadily to 65 in 2015. In that final year, radiologists' utilization rate was 38% higher than that of cardiologists. Total utilization rate trends for stress echo and MPI were down in recent years but the levels remained far higher than that for CCTA.

CONCLUSION

In 2007 (the second year in which codes were available for CCTA), cardiologists did almost twice as many CCTAs as radiologists. However, by 2015, radiologists did substantially more than cardiologists. Nevertheless, utilization of both MPI and stress echo is far higher than that for CCTA. Low reimbursement rates and frequent denials by payers may have contributed to the abrupt CCTA declines in the early years.

CLINICAL RELEVANCE/APPLICATION

The utilization rate of CCTA has seen a small increase in the most recent years for which data are available.

SSQ02-09 Improving Specificity of Coronary CT Angiography for the Detection of Functionally Significant Coronary Artery Disease: A Deep Learning Approach

R.W.vanHamersvelt-3@umcutrecht.nl

PURPOSE

Coronary computed tomography angiography (CCTA) is an increasingly important diagnostic tool for the detection of coronary artery disease (CAD). However, due to calcium blooming and beam hardening, specificity for diagnosing functionally significant CAD is limited. The purpose of this study was to evaluate to what extent the specificity of CCTA for detection of functionally significant CAD could be improved by combining simple stenosis grading with deep-learning based analysis of left ventricular myocardium (LVM).

METHOD AND MATERIALS

We retrospectively included 126 patients (77% male, 58.7±9.5 years) who underwent CCTA prior to invasive fractional flow reserve (FFR). Functionally significant CAD was defined as an invasively measured FFR value below 0.78. First, the presence and degree of coronary artery stenosis was analyzed using the CAD-RADS system. Patients without a significant stenosis reported on CCTA scans were scored as functionally non-significant. For the remaining patients, fully automatic deep learning analysis of the LVM was used to identify presence of functionally significant CAD. LVM was first segmented using a convolutional neural network and then characterized by a convolutional auto-encoder (CAE). Based on the encodings generated by the CAE a support vector machine classifier identified patients with functionally significant stenosis. Diagnostic performance of this combined analysis was evaluated and compared with patient identification based only on >=50% stenosis degree as measured in CCTA.

RESULTS

FFR was significant in 64 (51%) of the patients. Sensitivity and specificity of stenosis degree reported on CCTA alone were 91% and 18%, respectively. Adding deep-learning based analysis of LVM to stenosis detection resulted in improved specificity with a slight decline in sensitivity. The combined evaluation resulted in a sensitivity of 83% and a specificity of 73%.

CONCLUSION

Our results show that, at the expense of only a mild sensitivity decrease, a combination of clinical stenosis evaluation and automatic LVM analysis in CCTA led to substantial increase of the specificity.

CLINICAL RELEVANCE/APPLICATION

Adding deep learning analysis of LVM to stenosis assessment holds the potential to substantially increase specificity of CCTA and to decrease number of patients unnecessarily referred to invasive FFR.

PURPOSE

The Phase-Sensitive Inversion Recovery with Motion Correction (PSIRMoCo) is an improved single-shot rapid LGE sequence, which has higher spatial resolution compared to the traditional TrueFISP sequence and shorten acquisition time compared to the TurboFLASH sequence. This study aims to investigate a PSIRMoCo prototype against TurboFLASH and TrueFISP in terms of acquisition time and image quality.

METHOD AND MATERIALS

Inclusion criteria was patients/volunteers undergoing LGE CMR. Exclusion criteria was patients who did not have late gadolinium enhancement images. A total of 70 subjects (70% male, 17% had arrhythmia, 2% were poor breath-holders) were recruited in two hospitals. Patients were recruited consecutively for a 6-month period. Data was all acquired on 1.5T MAGNETOM Avanto scanner (Siemens Healthcare, Erlangen, Germany). MRI TurboFLASH images were acquired first at 8 minutes post contrast injection followed by the PSIRMoCo sequence and the TrueFISP PSIR sequence. Images with poor contrast differentiation between the myocardium and blood pool were excluded from the analysis. Acquisition time was measured based on the timings from the MRI times stated on the images. Image quality was assessed by 2 doctors separately without access to the image information, using a 4-point Likert scale (4 for the best, 1 for the worst). A P-value<0.05 was regarded as statistically significant. ANOVA, Kruskal-Wallis H test and Mann-Whitney U test were used for comparing the three groups.

RESULTS

The total scan times for PSIRMoCo, TurboFLASH and TrueFISP were 187±43 sec, 636±144 sec, and 164±37sec, respectively (p<0.001). There was no statistically significant difference in scan time between PSIR MoCo and TrueFISP. Image quality scores of the three groups were 3.8±0.26, 3.3±0.47, and 3.5±0.31, respectively (p=0.0001). Separately, PSIRMoCo showed a statistically higher image quality score compared to TurboFLASH (p<0.0001) and TrueFISP (p=0.008).

CONCLUSION

PSIR MoCo shows statistically significant time saving compared to TurboFLASH and better image quality compared to TurboFLASH and TrueFISP.

CLINICAL RELEVANCE/APPLICATION

PSIR MoCo should be considered for routine use instead of TurboFLASH as it saves approximately just under 8 minutes in scan time with improved image quality.

SSQ03-02 Detection of Patients with High-Risk Coronary Artery Disease Using Coronary Flow Velocity Reserve:

3T-MRI Fast Velocity-Encoded Cine Study

Thursday, Nov. 30 10:40AM - 10:50AM Room: S504AB

Participants
Yasuka Kikuchi, MD, Sapporo, Japan (*Presenter*) Nothing to Disclose
Masanao Naya, Sapporo, Japan (*Abstract Co-Author*) Nothing to Disclose
Noriko Oyama-Manabe, MD, PhD, Sapporo, Japan (*Abstract Co-Author*) Nothing to Disclose

Fumi Kato, Sapporo, Japan (*Abstract Co-Author*) Nothing to Disclose
Hiroki Shirato, MD, PhD, Sapporo, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

We previously developed a method to measure coronary flow velocity reserve (CFVR) in the left main trunk (LM) during stress (ATP (0.16mg/kg/min)) and at rest non-invasively mainly using healthy volunteers. The purpose of this current study is to evaluate the method's diagnostic value in detecting patients with high-risk coronary artery disease (CAD).

METHOD AND MATERIALS

Fifty-nine patients with suspected CAD (age; 67 ± 11 yr, male; n = 36) who underwent 3.0-tesla (T) magnetic resonance imaging (MRI) and angiography were studied. Coronary flow velocity in LM was measured with breath-hold velocity-encoded cine using 3.0-T MRI during ATP stress and at rest. CFVR was calculated by dividing peak-velocity during stress by that at rest. The extent and severity of angiographic disease of LM, left anterior descending artery (LAD), and left circumflex artery (LCx) were estimated with the use of the Leaman score (LS) which is able to stratify the risk of coronary artery using angiography.

RESULTS

Among the patients evaluated, 24 had 1-vessel disease (LAD (n = 17), LCx (n = 7)) and 18 patients had 2-vessel disease. Four patients had => 50% stenosis in LM. Fifty-one out of 59 patients showed low LS (0-10) and 8 had high LS (=>10.5 (equivalent to proximal LAD = 90-99%)). CFVR of CAD patients with high LS which means high-risk CAD was significantly lower than that of patients with low LS (1.57 ± 0.31 vs. 2.18 ± 0.73, $p < 0.05$) (Figure). In receiver operating characteristic (ROC) analysis of CFVR for detection of high-risk CAD patients, the area under the ROC curve was 0.79 ($p = 0.0296$). Sensitivity was 100% and specificity was 62.8% using a cutoff of 1.98 for detection of high-risk CAD patients.

CONCLUSION

Low CFVR in LM derived by velocity-encoded cine using 3.0-T MRI can predict downstream coronary atherosclerotic burden. This method is a simple and reliable index to detect patients with high-risk CAD without radiation exposure.

CLINICAL RELEVANCE/APPLICATION

Coronary flow velocity reserve measured using 3.0-T MRI is able to evaluate severity of coronary artery disease with high sensitivity.

SSQ03-03 Gadolinium-enhanced Cardiac MR Exams of Human Subjects are Associated with Significant Increases in the DNA Repair Marker 53BP1 but Not the Damage Marker γH2AX

Thursday, Nov. 30 10:50AM - 11:00AM Room: S504AB

PURPOSE

To examine whether MR exams cause double-strand (ds) DNA damage by analyzing changes in the DNA damage and repair markers γH2AX and 53BP1 in patients who underwent a cardiac magnetic resonance (MR) exam.

METHOD AND MATERIALS

Our prospective study of outpatients scheduled for a 1.5 T gadolinium-enhanced cardiac MR exam was subject to Institutional Review Board approval. Patients with history of malignancy or who were receiving chemotherapy, radiation therapy, or steroids were excluded. MR sequence data were recorded for each patient. Blood samples were obtained from immediately before and after MR exposure. An automated immunofluorescence assay quantified γH2AX or 53BP1 foci number in isolated peripheral blood mononuclear cells. Changes in foci number were analyzed within patients using the Wilcoxon signed-rank test. Clinical and MR procedural characteristics were compared between patients who had a >10% increase in γH2AX or 53BP1 foci numbers and patients who did not.

RESULTS

Sixty patients (median age: 55 years, 39 males) were enrolled in our study. The number of γH2AX foci did not significantly change following cardiac MR (median foci per cell pre-MR=0.11, post-MR=0.11, p=.90), but the number of 53BP1 foci significantly increased following MR (median foci per cell pre-MR=0.46, post-MR=0.54, p=0.0140). Clinical and MR characteristics did not differ significantly between patients who had at least a 10% increase in foci per cell and those who did not.

CONCLUSION

MR exposure leads to a small (median 17%) increase in 53BP1 foci, suggesting increased DNA repair. Accordingly, a lack of increase in number of foci of the ds DNA damage marker γH2AX does not necessarily indicate an absence of DNA damage.

CLINICAL RELEVANCE/APPLICATION

1. Elevated DS DNA repair marker levels suggest that cardiac MR may cause DS DNA damage, and further study using both γH2AX and 53BP1 is necessary.

SSQ03-04 Detection of Myocardial Scar by Late Gadolinium Enhancement Cardiac MR using Gadoterate Meglumine

PURPOSE

To compare the efficacy of late gadolinium enhancement cardiac MR (LGE-CMR) for myocardial scar detection between 2 macrocyclic GBCAs (gadoterate meglumine vs. gadobutrol).

METHOD AND MATERIALS

40 subjects (61±11 years, 67.5% men) who were referred for evaluation of cardiomyopathy with LGE-CMR performed using standard of care 0.2mmol/kg gadobutrol were recruited prospectively within an 8-week period for a research CMR scan using 0.2mmol/kg gadoterate meglumine. Both clinical and research CMR scans were performed at 1.5T. All subjects underwent a standard CMR protocol consisting of multiplanar cine steady state free precession (SSFP) and post contrast delayed enhanced PSIR SSFP and PSIR TurboFlash sequences. Myocardial scar quantification was performed on short-axis PSIR-TurboFlash images using commercially available software (Circle 5.3, Calgary, Canada) and myocardial scar percentage mass was calculated. Qualitative scar analysis was performed by 2 observers using the 16-segment AHA model and the area of scar per segment (0=none, 1=1-25%, 2=26-50%, 3=51-75%, 4=76-100% of the segment area) was scored. Segmental ratings were summed across all 16 segments to derive a global scar score for each scan. Reader confidence in visualizing the scar tissue for each agent was recorded on a 5-point scale (1=poor, 2=fair, 3=good, 4=very good, 5=excellent).

RESULTS

With PSIR SSFP technique, percentage myocardial scar mass averaged 5.9±9.8% and 5.2±7.2% for gadobutrol and gadoterate meglumine, respectively (p>0.05, ICC=0.89, 95% CI:0.78-0.94). With PSIR TurboFlash technique, percentage myocardial scar mass was 7.19±11 and 6.03±8.51 for gadobutrol and gadoterate meglumine, respectively (p>0.05, ICC=0.96, 95% CI:0.93-0.98). Global qualitative segmental LGE scores showed comparable scar detection using gadobutrol vs. gadoterate meglumine (5.3±7.5 vs. 5.4±7.2, p>0.05). Reader confidence for scar visualization was similar between gadobutrol and gadoterate meglumine (4.35±0.7 vs. 4.22±0.6, p>0.05).

CONCLUSION

Gadoterate meglumine is comparable to gadobutrol for identifying myocardial scar on LGE-CMR both qualitatively and quantitatively and can detect scar with a similar degree of diagnostic confidence as Gadobutrol.

CLINICAL RELEVANCE/APPLICATION

Gadoterate Meglumine, an alternative macrocyclic GBCA to the more routinely used Gadobutrol, has recently become available in the U.S. and may have comparable efficacy for detecting myocardial scar on routine LGE-CMR

SSQ03-05 Diffuse Myocardial Fibrosis in Diabetes Mellitus: Findings From t1 Mapping Imaging and Cardiac MRI Strain

Thursday, Nov. 30 11:10AM - 11:20AM Room: S504AB

PURPOSE

To investigate diffuse myocardial fibrosis and the relationship between cardiac MRI strain in diabetes mellitus (DM) using T1 mapping and cardiac tissue tracking.

METHOD AND MATERIALS

Thirty-one patients with DM without impairment of renal function (Group1), 21 cases of DM with impairment of renal function (Group2) and 23 normal control individuals were enrolled. All patients underwent cardiovascular magnetic resonance (CMR), including cardiac cine sequence and T1 mapping MOLLI sequence. Cardiac function indexes, tissue tracking and T1 mapping were all measured by cvi42 and compared statistical. Pearson's correlation between the T1 mapping parameters and the left cardiac strain parameters were also investigated.

RESULTS

All the patients recruited finished CMR and the baseline characteristics were recorded. Group2 presented with higher pre-contrast T1 value than Group1 and control group (Group2: 1314.80±43.72ms; Group1: 1259.12±42.48ms; control group: 1264.25±47.45ms, both $P<0.05$). Regarding the post-contrast T1 value, lower post-contrast T1 value were observed in Group2 but the differences were not statistically significant (Group2: 490.25±58.59ms; Group1: 521.61±70.50ms; control group: 508.20±35.82ms, both $P>0.05$). Compared with control group, Group1 and Group2 had significantly higher ECV (Group1: 31.02±2.97ms; Group2: 34.09±4.23; control group: 27.39±2.40ms, both $P<0.05$). Negative correlation was showed between the circumferential peak diastolic strain rate and ECV in Group1 and Group2 ($r=-0.459$, $r=-0.459$, $P<0.05$).

CONCLUSION

T1 mapping is an alternative sequence for the evaluation of diffuse myocardial fibrosis in DM patients. Myocardial fibrosis is correlated with circumferential peak diastolic strain rate in DM patients.

CLINICAL RELEVANCE/APPLICATION

(dealing with T1 mapping imaging and cardiac MRI strain) ' T1 mapping is an alternative sequence for the evaluation of diffuse myocardial fibrosis in DM patients.'

SSQ03-06 Subclinical Left Ventricle Dysfunction in Diabetes Mellitus Patient: Assessed by Cardiac MRI Strain Analysis

Thursday, Nov. 30 11:20AM - 11:30AM Room: S504AB

Participants
Li Jiang, Chengdu, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

jianglifs@163.com

PURPOSE

Cardiovascular disease is the key cause of mortality of diabetes mellitus (DM), for which in-time detection of dysfunction and early intervention can significantly improve the prognosis. The aim of this study is to evaluate the subclinical left ventricle (LV) dysfunction in DM patient and whether the patient with good glycemic control have decreased cardiac function with time using cardiac magnetic resonance (CMR) strain analysis.

METHOD AND MATERIALS

In total, 23 DM patients with normal LVEF, including 13 patients diagnosed not more than 10 years and 10 patients diagnosed more than 10 years, and 25 healthy subjects, underwent CMR examination. LV global myocardial strain parameters including peak strain, peak systolic strain rate and peak diastolic strain rate, as well as global radial, circumferential and longitudinal analysis were calculated and compared among the three patient groups.

RESULTS

DM group had a significantly lower longitudinal peak strain (-15.32 ± 5.18 vs. -19.53 ± 2.76, $p=0.007$) and peak diastolic strain rate (1.22 ± 0.29 vs.1.50± 0.28, $p=0.000$), circumferential peak diastolic strain rate (1.20 ± 0.39 vs. 1.50 ± 0.26, $p=0.000$), and higher radial peak systolic strain (2.59 ± 0.81 vs. 2.0 ± 0.61, $p=0.033$) compared with the normal subjects. The DM patient diagnosed more than 10 years have lower peak systolic strain rate [radial (2.03 ± 0.52 vs. 2.61 ± 0.77, $p < 0.000$), circumferential (-0.89 ± 0.19 vs. -1.02 ± 0.20, $p < 0.000$) and longitudinal (-0.79 ± 0.11 vs. -0.97 ± 0.13, $p < 0.000$), respectively], lower radial peak strain (38.18 ± 9.89 vs. 43.47 ± 10.88, $p < 0.000$) and lower circumferential peak diastolic strain rate(1.01 ± 0.26 vs. 1.24 ± 0.21, $p = 0.004$) compared with diagnosed not more than 10 years.

CONCLUSION

Cardiac MRI strain is sensitive to early dysfunctional of heart, which might help with better management for the DM patients with

normal LVEF. Moreover, the cardiac function is gradually reduced with time, even though the blood glucose controlled well, especially the systolic function.

CLINICAL RELEVANCE/APPLICATION

Cardiac MRI strain is sensitive to early dysfunctional change of DM patients than traditional heart function evaluation parameters, which might help with better management for the DM patients with normal LVEF

SSQ03-07 Aortic Stiffness, Myocardial Fibrosis, Left Ventricular Strain and Epicardial Fat in Hypertension and Diabetes Mellitus

PURPOSE

A combined assessment of aortic stiffness, left ventricular (LV) fibrosis, LV strain and epicardial fat volume (EFV) may decrease risk in patients with cardiovascular risk factors such as hypertension (HTN) or diabetes mellitus (DM). Using a MRI approach these parameters were assessed in 63 patients and related to the presence of HTN and DM.

METHOD AND MATERIALS

20 healthy controls (57.2±8.2years[y]; 26.2±3.9kg/m²), 31 hypertensive patients without DM (HTN-Pts; 59.6±6.7y; 28.4±4.7kg/m²) and 12 with DM (DM-Pts; 58.8±9.9y; 30.7±6.3kg/m²) were examined at 1.5Tesla. No patients had coronary artery disease; all patients had a normal LV ejection fraction. Aortic stiffness was evaluated by velocity encoded MRI to determine pulse wave velocity (PWV) of the aortic arch (Fig. A), EFV by a 3D-Dixon sequence with acquisition of fat-only images and fat-fraction maps (Fig. B&C), LV T1 relaxation times (T1) to detect fibrosis using a MOLLI scheme, and, longitudinal & circumferential systolic strain (LS; CS) by feature tracking software.

RESULTS

Age and gender did not differ significantly; BMI was higher in DM-PTs compared to controls. Results were adjusted for BMI. EFV was highest in DM-PTs followed by HTN-PTs and controls (EFV = 78.4±28.0 vs. 64.2±27.3 vs. 50.3±22.7ml/m²; $P<0.05$). T1 was higher in DM-PTs and HTN-PTs than in controls (T1 = 994.0±43.2 resp. 991.6±35.5 vs. 964.6±40.3ms; $P<0.05$). PWV was significantly higher in DM-PTs and LV strain lower compared to HTN-PTs and controls (PWV = 9.8±3.3 vs. 8.6±1.7 resp. 8.1±1.9m/s; LS = -20.9±5.1 vs. -24.7±4.6 resp. -25.5±3.8%; CS = -24.4±5.7 vs. -27.1±5.0 resp. -28.3±4.1%). Fig. D illustrates a healthy male with a lower T1 compared to a HTN-Pt (Fig. E) and Fig. F with a higher LS compared to a DM-PT.

CONCLUSION

Hypertension and diabetes mellitus are associated with LV fibrosis; cardiac remodeling as well as metabolic and inflammatory mechanisms of an increased EFV may play a role. EFV and aortic stiffness are further increased and LV strain reduced in DM-PTs possibly due to an increased metabolic and inflammatory burden associated with DM. A multi-parameteric assessment of these parameters can easily be integrated into a routine MRI exam and may be supportive for a more accurate cardiovascular risk evaluation.

CLINICAL RELEVANCE/APPLICATION

MRI is an accurate tool for evaluation of cardiovascular risk and prognostic parameters in patients with risk factors, such as hypertension or diabetes mellitus.

SSQ03-08 Strain of Ascending Aorta on Cardiac Magnetic Resonance in 1,027 Patients: Relation with Age, Gender, and Cardiovascular Disease

PURPOSE

To evaluate aortic strain (AS) with cardiac magnetic resonance (CMR) in a large series of consecutive patients with different cardiovascular diseases (CVDs).

METHOD AND MATERIALS

Two-dimensional phase-contrast gradient-echo sequences of the ascending aorta were retrospectively selected in 1,027 patients (726 males, 301 females). In all images, aortic lumen area was segmented using a semi-automatic approach to calculate AS values. Subgroup analysis was performed for patient with normal CMR, Tetralogy of Fallot (ToF), and ischemic heart disease (IHD). Multivariate and post-hoc analyses were performed to evaluate the effect of age, gender and CVDs on AS values. In order to consider also the age factor, the subjects were grouped into 7 age bins of 10 years (0-9, 10-19, 20-29, 30-39, 40-49, 50-59 and >= 60 years).

RESULTS

Taking into account the whole sample, the AS resulted inversely correlated with age ($\rho = -0.51$, $P<.001$). Multivariate analysis showed significant differences in AS among decades of age ($P<.001$), genders ($P=.007$) and CVD subgroups ($P<.001$) without interaction among these factors. Post-hoc analysis showed significantly lower AS in ToF and IHD patients compared to subjects with normal CMR (P<.001). Gender-related differences were significant in ToF subjects ($P=.008$), in particular men with ToF showed a lower AS when compared with men with normal CMR ($P=.005$). In IHD patient, AS was lower compared to normal CMR subjects (men: $P<.001$, women: $P=.016$), without significant difference between genders ($P=.732$). Aortic strain reduction during aging was observed in all CVD groups.

CONCLUSION

Differences in age, gender, and CVD independently affect AS. The lower AS observed in ToF fosters its assessment during follow-up in adulthood. The gender-related difference gives the basis for future studies focused on its possible causes and clinical implications. Nevertheless, further investigations on elderly patients and, in particular, in adults with congenital heart disease are advised.

CLINICAL RELEVANCE/APPLICATION

Our results showed that age, gender, and CVDs independently affect the ascending AS, highlighting the importance of its follow-up assessment, especially in patients with congenital cardiac diseases.

SSQ03-09 Effectiveness of Multiparametric Structure-Function Cardiac MRI in Detection of Acute Cardiac Allograft Rejection

PURPOSE

Acute cardiac allograft rejection (ACAR) is a leading cause of morbidity and mortality in heart transplant (Tx) recipients. Non-invasive screening with cardiac magnetic resonance imaging (CMR) is promising given its ability for comprehensive characterization of acute myocardial injury and subtle left ventricular (LV) structural and functional changes. We hypothesized that CMR-derived T2, T1, extracellular volume fraction (ECV), and LV velocities will differ between 1) healthy controls and Tx recipients without history of ACAR and 2) Tx recipients with and without current evidence of ACAR.

METHOD AND MATERIALS

CMR at 1.5T (Magnetom Aera/Avanto, Siemens, Erlangen, Germany) was performed prospectively on 76 Tx recipients (49.9±15.9 yrs, 45% female) and 14 controls (47.7±16.7 yrs, 36% female) for 131 total studies. Analyses were stratified based on myocardial biopsy grade: Controls (N=14), No ACAR (no history of ACAR, N=68), Past ACAR (history of ACAR, N=34), ACAR+ (active grade>=1R ACAR, N=15). CMR included T2-mapping, pre- and post- contrast T1-mapping (to calculate ECV), and tissue phase mapping (TPM; to generate myocardial velocities).

RESULTS

T2 was significantly higher in No ACAR patients compared to controls (49.4±3.4 ms vs. 45.2±2.3 ms, P<0.01). Compared to No ACAR patients, patients with Past ACAR (51.7±4.1 ms vs. 49.4±3.4 ms, P<0.01) or current ACAR+ (53.8±4.9 ms vs. 49.4±3.4 ms,

P<0.01) had greater T2 values. ECV was significantly elevated in ACAR+ patients compared to recipients without ACAR (31.6±3.6% vs. 26.7±3.2%, P<0.01) regardless of history of ACAR (No ACAR and Past ACAR). ROC analysis for the detection of ACAR+ revealed AUC of 0.80 and 0.85 for T2 and ECV respectively. TPM identified lower peak systolic longitudinal velocities and higher peak diastolic radial velocities in No ACAR patients compared to controls (2.8±1.0 cm/s vs. 4.9±1.1 cm/s, P<0.01; -3.7±0.8 cm/s vs. -2.9±0.7 cm/s, P<0.01).

CONCLUSION

CMR parameters are sensitive to structural and functional change in Tx recipients. T2 and ECV are effective at detecting ACAR, supporting further development of CMR for ongoing surveillance post Tx.

CLINICAL RELEVANCE/APPLICATION

CMR-derived T2 and ECV are effective in detecting acute cardiac allograft rejection (ACAR) following heart transplant, promoting use of multiparametric CMR as an alternative ACAR screening tool.

PURPOSE

To evaluate risk factors for hemoptysis after cone-beam computed tomography (CBCT)-guided percutaneous transthoracic needle biopsy (PTNB) and, in particular, to determine whether the enlargement of main pulmonary artery diameter (mPAD) is a risk factor for PTNB-related hemoptysis.

METHOD AND MATERIALS

After approval from the Institutional Review Board, 4,172 cases of CBCT-guided PTNBs in 3,840 patients (2299 men and 1541 women; mean age, 63.64 years, ranging from 7-to-94 years) were retrospectively included in this study. Various clinical, radiological, and biopsy-related data including mPAD were evaluated using univariate and multivariate logistic regression analyses to figure out significant risk factors for both hemoptysis and severe hemoptysis. Severe hemoptysis was designated when blood transfusion, vascular embolization, or cardiopulmonary resuscitation were required to manage patients with the diagnosis.

RESULTS

Hemoptysis occurred in 5.78% (n=241) of all PTNB procedures, while severe hemoptysis occurred in 0.18% (n=7). Female sex (Odds ratio [OR]=2.703, P<0.001), history of anti-platelet or anti-coagulative drugs (OR=2.362, P=0.002), prolonged activated partial thromboplastin time (OR=1.951, P=0.042), subsolid nodules (OR=3.529, P<0.001), cavitary nodules (OR=3.205, P=0.038), and long pleura-to-target distance (P<0.001) were independent risk factors for hemoptysis, while mPAD enlargement was not a significant risk factor. Regarding severe hemoptysis, however, mPAD enlargement (OR=5.004, P=0.037) was a significant independent risk factor in combination with subsolid (OR=6.648, P=0.046) and cavitary target nodules (OR=20.284, P=0.008).

CONCLUSION

mPAD enlargement was not a significant risk factor for PTNB-related hemoptysis. However, it was a significant risk factor for severe PTNB-related hemoptysis.

CLINICAL RELEVANCE/APPLICATION

mPAD enlargement was a significant risk factor for severe PTNB-related hemoptysis, along with subsolid and cavitary nodule features.

SSQ04-02 Active Targeting Theranostic Iron Oxide Nanoparticles for MRI and Magnetic Resonance-Guided Focused Ultrasound Ablation of Lung Cancer

Thursday, Nov. 30 10:40AM - 10:50AM Room: E351

Participants
Na Tang, Shanghai, China (*Presenter*) Nothing to Disclose

tnwaipodaren@126.com

PURPOSE

To evaluate an active targeting and nano-sized SPIO platform for the enhancement of imaging sensitivity and tumor-ablative efficacy in MRgFUS, and applications of a series of MRI approaches for non-invasive monitoring treatment response were demonstrated using nude rat lung tumor models.

METHOD AND MATERIALS

PEGylated SPIO nanoparticles was further decorated with high affinity anti-EGFR monoclonal antibody to form a nanocomposite (anti-EGFR-PEG-SPIO) , and in vitro and vivo MRI was preformed. 24 rats were then randomly divided into positive control group (n=6), negative control group (n=6), PEGylated SPIO group (n=6), and anti-EPS group (n=6). The nude rats tumors were sonicated after injection of the PEGylated SPIO and anti-EPS solution (1ml) via tail vein at 4.0 h. Prior to sonication, T2W SE were acquired. For each nude rat, two to five sonications were planned. The treated areas were about 0.5 cm2 according to the pretreatment plan. Each dynamic temperature was monitored by real-time MRI temperature mapping of the treated area.

RESULTS

The T2 values for the anti-EGFR-PEG-SPIO and PEGylated SPIO contrast agents at 3.0 T MRI were 10.3ms and 11.2ms, respectively. T2 relativity values were 97.1 s-1mM-1 and 89.3 s-1mM-1, respectively.The T2 SI in targeting group decreased significantly compared with non-targeting group. The rate of SI change was -58.2%, -82.7%, -94.4%, and 98.3% respectively, at the iron concentrations. Thirty minutes after the injection of anti-EPS, the T2 SNR in the lung tumor started to decrease. The T2 SNR at the tumor region decreased more significantly at 4 hours post-injection of anti-EPS compared with the nontargeting group ($p<0.01$). The energy of the targeting group was even lower than that of the control (low enegy) group (32W vs 54 W, $P<0.01$) ,Peak temperature significantly higher than control group. T2W SI and ADC significantly after ablation higher than before ablation in targeting, and nontargeting, control group

CONCLUSION

We have successfully developed anti-EGFR modified PEGyloated SPIO nanoparticles as targeted MR imaging contrast agents and the synergistic agents for MRgFUS lung carcinoma thermotherapy. After tumor ablation, tumor therapeutic efficiency monitored by the clinical MRI equipment can be applied as an attractive potential noninvasive strategy.

CLINICAL RELEVANCE/APPLICATION

Applications of a series of MRI approaches can be applied as an attractive potential noninvasive strategy.

SSQ04-03 Non-Diagnostic CT-Guided Percutaneous Needle Biopsy (PTNB): Predictive Factors and Final Diagnoses

Thursday, Nov. 30 10:50AM - 11:00AM Room: E351

Participants
Thanisa Tongbai, MD, Bangkok, Thailand (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the final diagnosis of pulmonary lesions with an initial non-diagnostic result on CT-guided percutaneous transthoracic needle biopsy (PTNB) and the predictive factors for a non-diagnostic result.

METHOD AND MATERIALS

All PTNB performed over a 4-year period were retrospectively reviewed. The initial pathological results were classified into 3 categories as malignant or suspicious for malignant, benign specific, and non-diagnostic. The demographic data of patients, lesion characteristics, technique, complications, initial pathological results and final diagnosis were reviewed. Statistical analysis was performed using Pearson's X2 test or Fisher's exact test.

RESULTS

Out of a total of 894 consecutive biopsies, 690 (77.2%) were positive or suspicious for malignancy, 55 (6.2%) were specific benign, and 149 (16.7%) were non-diagnostic. Significantly higher non-diagnostic rates were found in cases where the lesion was less than 15mm, the needle tract traversed emphysema, the introducer needle was outside the lesion, total time was greater than 60 minutes and when alveolar hemorrhage was present during the procedure. 122 of 149 non-diagnostic cases had a subsequent diagnosis made by repeat biopsy, surgery or follow-up; and malignancy was confirmed in 44 cases (44/122, 36%). There were statistically significant differences in non-diagnostic biopsy rates for patients with malignant lesions (44/734, 6%) and benign lesions (78/133, 59%) ($p=0.001$). In the non-diagnostic group, patients with history of prior malignancy and patients with atypical cells present in the initial pathological report were more likely to have a final diagnosis of malignancy ($p=0.043$ and $p=0.001$, respectively)..

CONCLUSION

The predictive factors for non-diagnostic results were lesion size less than 15mm, needle tract traversing emphysema, introducer needle outside the lesion, procedure time greater than 60 minutes, presence of alveolar hemorrhage, and a final benign diagnosis. Although the majority of the non-diagnostic cases yielded a benign diagnosis, 36% were malignant. In cases with a history of malignancy or the presence of atypical cells in the biopsy sample repeat biopsy or surgical resection should be considered.

CLINICAL RELEVANCE/APPLICATION

The management of a non-diagnostic PTNB result is difficult, however, the 36% rate of malignancy in this group underscores the need for further diagnostic evaluation in these patients.

SSQ04-04 Evaluation of Rabbit Lung VX2 Tumor after Radiofrequency Ablation by Multi-B Value Based MR Diffusion Weighted Imaging

Thursday, Nov. 30 11:00AM - 11:10AM Room: E351

Participants
Fei Shan, Shanghai, China (*Presenter*) Nothing to Disclose
Zenghui Cheng, MD, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose

Yuxin Shi, PhD, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

shanfeiqz@aliyun.com

PURPOSE

To explore the multi-b value based diffusion weighted imaging (DWI) on evaluation of lung VX2 tumor after radiofrequency ablation (RFA).

METHOD AND MATERIALS

Fifty-three lung VX2 tumor models were examined by multi-b value DWI (b=0,10,20,50,100,150,200,500,800, 1000,2000 s/mm2) at 1 day before RFA, and 1, 3, 7, 14 days after RFA. Both mono-exponential and bi-exponential model (including intravoxel incoherent motion imaging, diffusion kurtosis imaging (DKI) and stretched exponential model (SEM)) were used to calculate corresponding parameters (ADC, D, D*, f, Dk, K, DDC and A) based on ROIs of the maximal cross-sectional tumor before and after RFA by two thoracic radiologists, blindly. The parameters were compared between pre-RFA and post-RFA groups; the complete and incomplete RFA groups based on H&E and TUNEL staining, and correlated with MVD. The t test, Wilcoxon test, or Mann-Whitney U test was used in two-group comparisons. The area under curve (AUC) was used to assess the diagnostic performance. The Spearman correlation was used to analyze the correlation. Bland-Altman method was used to assess the intraobserver repeatability, and the coefficient of variation (CV) <5% was in good repeatability.

RESULTS

ADC, D, Dk, DDC and a values increased after RFA (all p<0.02), while K values decreased at day 3 and day 7, postoperatively (p=0.03; 0.01). ΔADC, ΔD, ΔDk, ΔDDC, Δa and ΔK of the complete RFA group was higher than that of the incomplete RFA group (all p<0.03) at day3; day7; day1-14; day7; day7 and day3, postoperatively, respectively, and the AUC of ΔADC>=0.44×10-3mm2/s; ΔD>=0.18×10-3mm2/s; ΔDk>=0.50, 0.37, 0.19 and 0.19×10-3mm2/s; ΔDDC>=0.16 × 10-3mm2/s; Δa>=0.05; ΔK>=0.23 in determination of tumor with complete ablation, was 0.93; 1.00; 1.00, 0.98, 1.00 and 0.96; 0.88; 0.88; 0.95, respectively. No difference of D*and f value changes was noticed, postoperatively (all P value>0.09). No difference of AUC and no correlation of parameters with MVD (all P values > 0.05). The CV of ADC, DDC, a, Dk, K and D at baseline was 2.18%, 3.33%, 3.45%, 7.18%, 8.65% and 18.62 %, respectively.

CONCLUSION

DKI could be used to evaluate the efficacy of RFA at day 1, postoperatively; ADC (b = 0, 500s/mm2) and DKI could be utilized to evaluate it at day 3, postoperatively; both the DKI and SEM-DWI could evaluate it at day 7 and day 14, postoperatively.

CLINICAL RELEVANCE/APPLICATION

DKI and ADC could be used to early assess the lung tumor after RFA.

SSQ04-05 Risk of Pleural Recurrence after Percutaneous Transthoracic Needle Biopsy in Stage I Non-Small Cell Lung Cancer: A Large Center Experience

PURPOSE

To determine whether percutaneous transthoracic needle biopsy (PTNB) increase the risk of (a) isolated pleural recurrence and (b) concomitant pleural seeding and metastasis in stage I non-small cell lung cancer (NSCLC).

METHOD AND MATERIALS

In this institutional review board-approved retrospective study, medical records of total of 830 consecutive patients with stage I NSCLC who underwent curative resection between 2004 and 2010 were reviewed. Median duration of follow-up was 1843 days (interquartile range, 1006-2734). Multiple logistic regression analyses were performed to identify risk factors of pleural recurrence.

RESULTS

Of 830 patients, 540 patients (65.1%) underwent PTNB before surgery, while 290 patients (34.9%) underwent non-PTNB procedures including bronchoscopic biopsy or exploratory thoracotomy. An isolated pleural recurrence was found in 26 patients (3.1%, [95%CI, 2.1-4.6%]) (20 in PTNB group, 6 in non-PTNB group). There was no significant association between PTNB and isolated pleural recurrence (P=0.197). Concomitant pleural recurrence occurred in 42 patients (5.1%, [95%CI, 3.8-6.8%]) (34 in PTNB group, and 8 in non-PTNB group). Subpleural location (p=0.007), tumor consistency (solid, part-solid, nonsolid) (p=0.046), PTNB (p=0.027), pathologic T stage (p<0.001), microscopic pleural invasion (p<0.001) and microscopic lymphatic invasion

(p=0.019) were associated with concomitant pleural recurrence. The most significant factor of pleural recurrence was only microscopic pleural invasion (Odds Ratio, 4.28; 95% CI, 2.20 to 8.29) (P<0.001) on multiple logistic analysis. Among 540 patients undergoing PTNB, transfissural approach did not have significant association with pleural recurrence (P=0.220), while the most sole significant factor was microscopic pleural invasion (Odds Ratio, 3.40; 95% CI, 1.54 to 7.51) (P=0.002).

CONCLUSION

PTNB did not increase the risk of isolated or concomitant pleural recurrence in early stage NSCLC. Higher incidence of concomitant pleural seeding in PTNB group was presumably attributed to peripheral lung cancer, potentially accompanying microscopic pleural invasion.

CLINICAL RELEVANCE/APPLICATION

PTNB can be performed for confirmatory diagnosis of early stage lung cancer without raising the risk of isolated or concomitant pleural recurrence.

SSQ04-06 Genomic Profiling of Non-Small Cell Lung Cancer (NSCLC) for Personalized Therapy

Thursday, Nov. 30 11:20AM - 11:30AM Room: E351

murphy.84@gmail.com

PURPOSE

Genomic profiling for personalized targeted therapy is emerging for NSCLC. Systematic testing for mutations in BRAF, ERBB2, PIK3CA and ALK translocations, in addition to EGFR and KRAS was introduced in our institution in July 2009. We report the utility, efficacy and safety of CT guided trans-thoracic needle biopsy (TTNB) in this cohort.

METHOD AND MATERIALS

Patients with stage IV/relapsed NSCLC who underwent CT guided TTNB to identify driver mutations prior to therapy were reviewed. Pathology specimens were evaluated for tumor adequacy, then manually dissected and analyzed by a variety of methods, including next generation sequencing for mutations in selected exons of EGFR, KRAS, BRAF, PIK3CA and ERBB2. ALK rearrangements were detected with fluorescence in-situ hybridization (FISH) and/or immunohistochemistry. Complications (pneumothorax, hemorrhage and admission) were recorded.

RESULTS

Between 6/12/2009 and 12/30/2016, 764 patients with NSCLC underwent TTNB. The median age was 67 years. 454(59%) were female, 426(56%) were former/current smokers and 580(75%) had stage IIIB/IV disease. 492(64%) of all TTNB performed were profiled for genomic analysis, of which 426(87%) had sufficient tissue on core biopsies for genomic profiling; 75(10%) of the 492 patients failed analysis for ALK rearrangements due to less than 50 tumor cells on the hybridized slide. The number of samples obtained ranged from 1-10 (2 cm 18-20G). Lesions biopsied ranged in size from 0.6-9.9 cm. PET guidance was used in 323(42%) patients. Targetable alterations were identified in 172/426(40%) patients (EGFR:139(18%); KRAS:101(13%);ALK:10(1%);BRAF:9(1%)). 216(28%) had pneumothoraces:137(<10% in size), 42 (10-30%) and 37(>30%). 79(10%) were admitted post procedure. 85(11%) had pulmonary hemorrhage. There was no statistically significant difference in pneumothorax rate by needle size (p=0.8). Pneumothorax rate significantly correlated with distance from the pleura and emphysema. Treatment strategy was changed in 183(24%) patients based on the biopsy result.

CONCLUSION

CT guided TTNB is a feasible, safe and efficacious technique for genomic profiling for targeted therapy, enabling the acquisition of sufficient tissue for gene mutation analyses.

CLINICAL RELEVANCE/APPLICATION

Personalized medicine has increased the need for rebiopsy in NSCLC; the ability to acquire sufficient tissue with minimal morbidity will help design clinical trials and inform management decisions.

SSQ04-07 Repeat Biopsy for the Patients with Acquired Resistance to EGFR TKIs: Implication of Biopsy-related Factors on Detection of T790M Mutation

khj.snuh@gmail.com

PURPOSE

Identification of T790M resistance mutation through repeat biopsy is essential to determine eligibility of the potential candidate patients for the third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs). We aimed to investigate predictors for the successful repeat biopsy specimen acquisition for mutational analysis and T790M mutation detection.

METHOD AND MATERIALS

We retrospectively reviewed 90 advanced non-small cell lung cancer patients harboring EGFR mutation who underwent repeat cone-beam CT-guided transthoracic needle biopsy. Clinical characteristics as well as repeat biopsy-related factors were compared between the patients with and without adequate biopsy specimen acquisition and between the patients with and without T790M mutation. After univariate analysis, multivariate logistic regression analysis was performed to reveal independent predictors.

RESULTS

Appropriate biopsy specimen was obtained in 90% (81/90) and T790M mutation was found in 61.7% (50/81) of the study population. None of the analyzed variables was significantly associated with successful biopsy specimen acquisition. For the T790M mutation detection, duration of EGFR TKI treatment (P=0.066), duration of total chemotherapy treatment (P=0.026), tumor size (P=0.066), and metastatic lesion as a biopsy target (P=0.029) showed P values less than 0.10. Multivariate analysis revealed that smaller target tumor size (odds ratio, 0.765; 95% confidence interval: 0.600, 0.975; P=0.031) and metastatic lesion as a biopsy target (odds ratio, 4.194; 95% confidence interval: 0.997, 17.637; P=0.050) were significant independent predictors of T790M mutation detection.

CONCLUSION

Detection of T790M mutation at repeat biopsy was associated with smaller target tumor size and selection of metastatic lesion as a biopsy target.

CLINICAL RELEVANCE/APPLICATION

Selection of biopsy target can affect detection of T790M mutation in in patients undergoing repeat biopsy (PTNB) as candidates of third-generation EGFR TKIs.

SSQ04-08 Single Institution Experience in Pre-Operative Pulmonary Lesion Marking Using Fiducial Markers and Micro-Coils in Preparation for Fluoroscopic Wedge Resection: Rates of Success, Complications, and Comparison of Two Labeling Devices

wsmall@emory.edu

PURPOSE

Evaluate the use of either Fiducial Marker (FM) or Microcoils (MC) to aid image-assisted wedge surgical resection of small pulmonary nodules and explore associations between patient/nodule characteristics and development of complications.

METHOD AND MATERIALS

IRB approved , HIPAA compliant database search identified patients who had CT-guided FM or MC implantation for wedge resection of pulmonary nodules from 01/01/95 - 01/22/2016. EMR was searched to extract patient's demographics including age, gender and body mass index. CT images prior to FM/MC insertion were reviewed by a single radiologist for nodule characteristics including size, location and depth. Post procedure CT images were read to measure distance of FM/MC to the nodule and to assess for complications including hemorrhage, pneumothorax and marker migration. Chi squared analysis at <0.05 was used to explore asssociations between patient/nodule characteristics and the development of complications.

RESULTS

We identified 136 nodules in 127 patients (67M:60F). Preoperatively, 130 FMs and 33 MCs were inserted to aid wedge resection in 112 and 15 patients respectively. 97% [124/127] of patients had successful same day resection as planned, two were delayed due to complications and a single patient needed a lobectomy due to lesion location. 68% of patiebnts [88/127] had complications following FM/MC insertion including hemorrhage [32%], pneumothorax [24%], a combination of hemmorhage and pneumothorax [9%] and marker moigration/emolization [3%]. Depth of lesion from skin was significantly associated with developing a complication. No other patient of nodular characteristic was associated with developing a complication. We observed a smaller percentage of patient complications in MC as compared to FM placement and these were of less severity, although statistical significance was not reached (p=0.06)

CONCLUSION

CT-guided pulmonary marking of pulmonary lesions is effective at aiding wedge resection. Complications are relatively common but mild with no significant effect on patient clinical management. Use of MC rather than FM may improve the saftey profile of lesion marking.

CLINICAL RELEVANCE/APPLICATION

Mild complications are relatively frequent but shoiuld not deter FM or MC placement for wedge resection of pulmonary nodules. Our

data suggests MC may have a better safety profile as compared to FM.

SSQ04-09 Rebiopsy of Non-Small Cell Lung Cancer with Acquired Resistance to EGFR Tyrosine Kinase Inhibitor: Clinical and CT Characteristics of Patients with T790M Mutation

mimowdr@gmail.com

PURPOSE

Re-biopsy for T790M mutation analysis of non-small cell lung cancer (NSCLC) after EGFR-tyrosine kinase inhibitor (TKI) treatment failure is important to determine further chemotherapy regimen. However, little is known regarding the clinical and radiologic differences among patients with or without T790 mutation.

METHOD AND MATERIALS

Between Jan 2011 and Jan 2017, 370 lung cancer patients underwent re-biopsy after TKI failure, and among them, 362 were assessed with adequate specimen. Clinical course, serial CT scans and pathologic reports were retrospectively reviewed. Re-biopsy methods are varied: CT or fluoroscopy-guided lung biopsy (n=130), EBUS or BFS-guided (n=71) biopsies, US-guided lymph node (n=40) or liver (n=20) biopsy, pleura biopsy (n=9), other sites (n=48) biopsies including surgical lung resection and pleural fluid analysis (n=44). CT scans obtained at the time of initial diagnosis and re-biopsy were compared between patients with and without T790M mutation.

RESULTS

Among 362 patients, 150 (41.4%) presented T790M mutation on re-biopsy. Two patients who were negative T790M mutation on pleural fluid analysis finally diagnosed as positive T790M mutation by following CT-guided biopsy or surgical lung resection. Mean interval between initial TKI failure and rebiopsy was longer in T790M positive group than negative group (p=0.01). On initial CT, the presence of pleural metastasis was significantly higher in T790M positive group (p=0.006). On CT obtained at the time of rebiopsy, pleural retraction adjacent to primary lung cancer and pleural metastasis were significantly noted, and number of metastatic sites is also higher in patients with positive T790M mutation ($p < 0.01$).

CONCLUSION

T790M mutation may be related to the interval between initial TKI failure and rebiopsy. Pleural retraction adjacent to primary lung cancer and pleural metastasis on CT at the time of rebiopsy were significantly associated factors to positive T790M mutation in NSCLC patients with TKI failure.

CLINICAL RELEVANCE/APPLICATION

On CT at the time of rebiopsy, pleural retraction and pleural metastasis were significantly noted in patients with positive T790M mutation after TKI failure. Negative T790M on pleural fluid analysis could not give a guarantee for true negative, and further core biopsy might be recommended.

PURPOSE

The conventional chest radiograph (CXR) is one of the most widely available modality, but detecting small nodules on CXR remains a demanding task for radiologists. The purpose of this study was to evaluate diagnostic performance of deep convolutional neural network model (Deep learning model, DLM) for detecting a T1 lung cancer.

METHOD AND MATERIALS

For the training set, we collected CXRs from 19,927 individuals at our hospital (M:F = 11,082:8,845; mean age, 55 yrs) including 14,579 normal subjects and 5,348 patients with CT proven lung nodules. We adopted an augmented training method to create a training set of 280,000 images, then developed and trained DLM using a 50-layer deep residual network. For the test set, we collected 2,509 consecutive patients with a surgically-proven T1 lung cancer (M:F = 1,167:1,347; mean age, 60 yrs) between years 2010 and 2015. Inadequate cases (e.g., missing presurgical CXR, long interval between CT and CXR, nodules < 10 mm) were excluded. Two expert radiologists, who reached decisions by consensus, marked and scored nodule visibility on CXR on four levels: 1 (invisible) ~ 4 (obvious). The final test set included 1,483 patients with a lung nodule >= 10 mm. For human observer study, we selected 200 patients from the test set (100 with a nodule of subtlety 3 and 100 with subtlety 4) and 300 matching normal images. Six radiologists (experience of CXR reading ranging from 4 to 21 years) participated as observers. The radiologists marked lesion candidates and scored the confidence of nodule presence from 1 to 10. The detection performance of DLM and observers were evaluated using FROC analysis.

RESULTS

DLM showed sensitivities of 75% for all T1 lung cancers and 88% for subtlety levels 3 and 4, respectively at FPPI 0.3. When compared with human observers, DLM showed sensitivity 82.5% at FPPI 0.1 and 88% at FPPI 0.3. Observers showed mean sensitivity 78% (68 ~ 83%) at FPPI 0.1 and 85% (80 ~ 89%) at FPPI 0.3. Observers showed mean AUC 0.819 (0.754 ~ 0.862) in the FPPI range from 0.03 to 0.44, while DLM showed AUC of 0.858 in the same FPPI range.

CONCLUSION

A DLM developed for the detection of lung nodules on CXR yields high diagnostic performance in detecting T1 lung cancers.

CLINICAL RELEVANCE/APPLICATION

A diagnostic system based on a deep learning model shows promise for the future development of a CR-based, mass screening device for lung cancer identification.

SSQ05-02 Extrapulmonary Malignancy as a Cause of Death in the CT Arm of the National Lung Screening Trial: A Retrospective Analysis of CT Evidence of Disease

Thursday, Nov. 30 10:40AM - 10:50AM Room: S402AB

Participants

Myrna C. Godoy, MD, PhD, Houston, TX (*Abstract Co-Author*) Research Grant, Siemens AG
Caroline Chiles, MD, Winston-Salem, NC (*Abstract Co-Author*) Advisory Board, ImBio, LLC
Charles S. White, MD, Baltimore, MD (*Presenter*) Consultant, Koninklijke Philips NV

For information about this presentation, contact:

mgodoy@mdanderson.org

PURPOSE

To explore CT findings associated with "other neoplasms", which were the cause of death (COD) in 22% of deaths in the National Lung Screening Trial (NLST).

METHOD AND MATERIALS

Three board-certified cardiopulmonary radiologists retrospectively reviewed low-dose screening CTs of the 263 NLST participants whose CODs were one of the 10 most common extrapulmonary malignancies (EPM), either on the death certificate or in the endpoint verification process, and in whom CT images were available. Two readers each reviewed ½ the cases, and a 3rd reader reviewed all 263 cases. The readers were aware of COD in each case. The scans were classified as negative, indeterminate or positive for findings that could be correlated with the EPM listed as the COD. For discrepant reads, the case was reviewed by all three readers to develop a consensus opinion.

RESULTS

The most common EPMs to cause death in the CT arm of the NLST population were pancreas (N = 76), esophagus (N = 35), colorectal (N = 34), brain (N = 21), leukemia (N = 21), bladder (N=19), liver (N = 18), breast (N=14), multiple myeloma (N=13) and lymphoma (N = 12). Of these, the CT scans were positive for EPMs with visualization of the primary tumor or metastatic disease in 15.6% (41/263) of cases. The EPMs that were most likely to be detected on the CT were esophageal (37.1%, 13/35), breast (35.7%, 5/14) and pancreatic (13.1%, 10/76) cancers. In all three tumors, the primary tumor was visible as a solid mass. In colorectal cancer, however, the disease was detected as metastatic to the liver in 11.8% (4/34) cases. The CT scans were classified as indeterminate for detection of the primary malignancy or metastasis in an additional 9.9% (26/263) of cases, but the findings could potentially have prompted additional work-up ultimately leading to the detection of the EPM.

CONCLUSION

Extrapulmonary malignancy is the third most common cause of death in the lung cancer screening population. Findings related to the primary tumor or metastatic disease are present in 15.6% of the most common tumors. The primary tumor was most likely to be seen in esophageal, breast and pancreatic cancers, and appeared as a solid mass.

CLINICAL RELEVANCE/APPLICATION

Detection of an EPM on lung cancer screening CT may help reduce mortality in this high risk population. Esophageal, breast and pancreatic cancers may be visible as solid masses.

SSQ05-03 Outcome of Lung-RADS Category 3 and 4 on Initial Lung Cancer Screening Exams

Thursday, Nov. 30 10:50AM - 11:00AM Room: S402AB

mpetranovic@partners.org

PURPOSE

To determine the follow-up course and clinical outcome of lung cancer screening exams for patients whose studies were designated as Lung-RADS category 3 and 4 on the initial screening exam.

METHOD AND MATERIALS

The reports of all initial lung cancer screening chest CT exams performed at a major tertiary center between 2/1/2013 and 12/31/2016 were reviewed. Detailed chart review was performed for all patients assigned as category 3 and 4, including reports of any subsequent imaging, diagnostic procedures and complications, pathology and microbiology. We compared our findings with those estimated and predicted by ACR Lung-RADS version 1.0.

RESULTS

Our IRB approved study included 1567 adult patients (M:F 826:741, Age:64±6) and identified 20% (317/1567) exams as Lung-RADS category 3 or 4. 18% (58/317) of category 3 and 4 patients underwent some type of invasive procedure (CT-guided biopsy (7), bronchoscopy (6), surgery (43), other (2)). 4% (7/181) of category 3 and 32% (43/136) of category 4 patients were diagnosed with malignancy. Median time from initial screening exam to tissue diagnosis for malignancy was 11 weeks (range 2-154weeks). Majority of patients who underwent an invasive procedure went directly to either wedge resection or lobectomy without prior tissue diagnosis. Complications were seen in 7% (4/58) of patients, all related to surgery and included air leak (3) and chyle leak (1). 2% (8/317) of patients who underwent an invasive procedure yielded benign pathology. 8% (26/317) patients did not have any imaging follow-up, including 6% (20/181) of category 3 and 2% (6/136) of category 4. 51% (93/181) of category 3 and 41% (56/146) of category 4 patients were downgraded to category 2. The average number of CT exams performed prior to downgrading was 1.3.

CONCLUSION

We found our patient population had greater percentage of category 3 and 4 patients than the estimated population prevalence. A

higher percentage of category 3 and 4 patients ultimately had a malignant diagnosis than predicted. A small proportion of patients had procedures performed for benign diagnosis. Complications among all groups were low.

CLINICAL RELEVANCE/APPLICATION

The high percentage of malignancy diagnosed in Lung-RADS category 4 and, to a lesser extent, category 3 patients emphasizes the importance of adhering to the guidelines in the management of these patients.

SSQ05-04 Assessment of the Vancouver Risk Calculator Compared to ACR Lung Rads Applied to National Lung Screening Trial Nodules

Thursday, Nov. 30 11:00AM - 11:10AM Room: S402AB

Participants
Charles S. White, MD, Baltimore, MD (*Presenter*) Consultant, Koninklijke Philips NV
Ekta D. Dharaiya, MS, Highland Heights, OH (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Sandeep Dalal, Cambridge, MA (*Abstract Co-Author*) Employee, Koninklijke Philips NV

For information about this presentation, contact:

cwhite@umm.edu

PURPOSE

To compare the efficacy of the Vancouver Risk Calculator (VRC) with ACR LungRADs in determining malignancy among solid nodules identified in the National Lung Screening Trial (NLST).

METHOD AND MATERIALS

The study received approval from the IRB and NCI CDAS system to use NLST data. All nodules detected in the CT arm of the NLST were considered for inclusion. After exclusions due to inability to determine malignant vs benign nodule status (no gold standard), incomplete data sheets preventing the use of the risk calculator, and subsolid nodule type, 4078 nodules were available for evaluation. The 4078 solid nodules were scored using the VRC consisting of 9 nodule and patient parameters (output = % likelihood of malignancy, malignancy threshold tested at >5% likelihood) and LungRADS (output = Category 2-4B, malignancy defined as 4A or 4B, malignancy defined as >5% likelihood as noted in LungRADS table on ACR website). Comparison was performed between LungRADS and the VRC to determine their respective sensitivity, specificity and accuracy to distinguish between benign and malignant solid nodules.

RESULTS

For ACR LungRADS category 2 (non-malignant), there were 2,141 nodules of which 3 were malignant. The VRC designated 0 malignant with 0 False Positives (FP) for the 5% threshold. For LungRADS category 3 (non-malignant) there were 1,136 nodules of which 7 were malignant. The VRC designated 3 malignant, with 31 false positives. For LungRADS category 4A (malignant), there were 630 nodules of which 26 were malignant. The VRC designated 25 malignant with 244 FP. For LungRADS category 4B (malignant), there were 171 nodules of which 64 were malignant. VRC designated 64 malignant with 107 FP. Overall sensitivity, specificity and accuracy for LungRADS was 90.0%, 82.1% and 82.3%, respectively and for VRC 5% threshold, it was 92.0%, 90.4% and 90.4%, respectively.

CONCLUSION

In comparison with ACR LungRads, the Vancouver risk model demonstrated higher sensitivity, specificity and accuracy in determining malignancy among solid nodules in the NLST.

CLINICAL RELEVANCE/APPLICATION

For solid nodules, risk models such as the Vancouver risk calculator may provide a superior assessment of the likelihood of malignancy than the ACR LungRads categories.

SSQ05-05 Management of New Solid Nodules at First Follow-Up after Detection in Incidence Screening Rounds of Low-Dose CT Lung Cancer Screening

PURPOSE

Low-dose CT (LDCT) lung cancer screening is recommended by US guidelines for high-risk individuals. New solid nodules detected after baseline screening have a high lung cancer probability and their management is crucial for the success of a screening program. Currently, there is no evidence for the management of nonresolving new solid nodules at first follow-up after detection.

METHOD AND MATERIALS

In this ongoing, multicenter, randomized controlled trial, 15,822 participants were randomly assigned to screening with LDCT (n=7,915) or no screening (n=7,907). In total, 7,557 individuals underwent baseline screening and 7,295 participants underwent subsequent screening rounds. We included all participants with solid non-calcified nodules, registered by the radiologists as new or

<15mm³ (study detection limit, ca. 3mm) at previous screens, that received a follow-up scan after detection. High-risk nodules (>500mm3) which led to immediate referral at first detection were excluded. Nodule volume was generated semiautomatically by software.

RESULTS

Overall, 680 participants with 1,020 low-intermediate risk new solid nodules were included. A total of 562 (55%) new solid nodules were resolving and in 321 (47%) participants all detected new solid nodules were resolving nodules. In 356 (52%) participants a new solid nodule persisted as solid nodule, with 25 (7%) participants being diagnosed with lung cancer in such a nodule. At follow-up, volume doubling time (VDT) (area under the curve [AUC]: 0.913, 95%CI 0.861-0.965), volume (AUC: 0.875, 95%CI 0.822-0.928), and VDT combined with a previously established >=200mm3 volume cutoff (AUC: 0.939, 95%CI 0.904-0.974) had high discriminatory power for lung cancer. The combination of <=590days VDT or >=200mm3 volume at follow-up provided 100% (95%CI 84-100%) sensitivity, 84% (95%CI 80-87%) specificity, and 27% (95%CI 19-37%) positive predictive value for lung cancer.

CONCLUSION

More than half of new solid nodules identified in LDCT lung cancer screening are resolving nodules. At first follow-up, a cutoff combination of <=590days VDT or >=200mm3 volume can be used for risk stratification.

CLINICAL RELEVANCE/APPLICATION

Management of new nodules detected after baseline determines the success of a screening program. Appropriate risk stratification by VDT and volume at follow-up could prevent delayed cancer diagnosis.

SSQ05-06 Use of a Risk Model Combining Clinical Information and CT Findings to Customize Follow-Up Intervals in Lung Cancer Screening

antoniusschreuder@gmail.com

PURPOSE

The U.S. has launched an annual CT lung cancer screening program, irrespective of individual participants' malignancy risk. We developed a risk model based on information from the baseline CT and clinical information to calculate the trade-off between cost savings by omitting one year follow-up scans in low risk individuals and the number of delayed cancer diagnoses.

METHOD AND MATERIALS

We used data from the National Lung Screening Trial. We selected all subjects who underwent a baseline scan and a one year follow up scan, those diagnosed with lung cancer after the baseline scan were excluded. Using baseline clinical data and baseline scan variables, various models were developed to estimate the risk of developing lung cancer after the one year follow-up scan, using backward stepwise regression. The full model included both clinical and scan variables. Additionally we tested a clinical-only model and a nodule-only model, the latter including the largest nodule diameter as the only variable. Furthermore, the published Brock and Patz models were validated on the same data set.

RESULTS

174 of 24,542 participants were diagnosed with lung cancer in the year after the first annual follow up. Best predictors included in the full model were older age, higher smoking duration and intensity, shorter smoking quit time, previous COPD and cancer diagnosis, emphysema, longest and perpendicular diameter of the largest nodule, presence of subsolid nodules, presence of an upper lobe nodule, and presence of a spiculated nodule. Using our full model, 9,972, 16,298, 19,726, and 21,158 of the cancer-free persons could have safely avoided the one year follow-up scan, at the expense of delaying the diagnosis of 17, 44, 70, and 88 of the lung cancer patients, respectively. The area under the ROC curve ranged from 0.79 with our full model to 0.73 with the Brock model to 0.67 in the Patz model.

CONCLUSION

Predictive models based on clinical and baseline scan information can be used to personalize follow up intervals in lung cancer screening, saving radiation and costs. Results differed substantially depending on the risk model used.

CLINICAL RELEVANCE/APPLICATION

Our model can be used to improve lung cancer screening efficiency by selecting a substantial proportion of participants for a two year follow-up interval, while delaying lung cancer diagnosis in only very few cases. This can greatly reduce costs, radiation burden and radiologist's work-load.

SSQ05-07 A Novel DeepWise CAD System for Detection of Pulmonary Nodules

qdqilinlin@163.com

PURPOSE

To validate a novel DeepWise computer-aided detection (CAD) system for automated detection of pulmonary nodules.

METHOD AND MATERIALS

The DeepWise CAD system designed by means of a specialized deep neural network is a novel and more intelligent CAD system to detect pulmonary nodules automatically. A public data set LIDC-IDRI and an in-house data set (a total of about 7,000 nodules) were used as the development data set. One hundred consecutive low-dose CT (LDCT) scans in a screening program and 100 specified and matched nodules in another 60 LDCT scans were independently evaluated by two radiologists (Radiologist *1, 2*) and the DeepWise CAD system to identify nodules larger than or equal to 2 mm in average diameter. All the nodules detected by both the radiologists and the system were reviewed jointly by another two chest radiologists, who were experienced in LDCT lung cancer screening, and a "true" nodule count was determined. The performance of the two radiologists and the DeepWise CAD system were compared.

RESULTS

Radiologist *1, 2* and the DeepWise CAD system detected 193, 115 and 271 nodules, respectively. Of the 325 separate nodules detected by the three techniques, 282 were classified as true nodules on consensus review. Of the true nodules present, the detection date of the Radiologist 1, 2 and the DeepWise CAD system were 66.3% (187/282), 40.8% (115/282) and 83.0% (234/282), respectively. And the 48 nodules missed by the DeepWise CAD included 41 solid nodules with an average diameter of less than 5 mm and 7 ground glass nodules. 187 (96.9%) of 193 Radiologist 1-detected nodules were true nodules, all 115 Radiologist 2-detected nodules were true nodules, and 234 (86.3%) of 271 of the DeepWise CAD-detected nodules were true nodules. The DeepWise CAD system identified 37 lesions that on consensus review were false-positive nodules, a rate of 0.23 (37/160) per patient.

CONCLUSION

The novel DeepWise CAD system detected 83.0% of true nodules, which was significantly superior to radiologists. And its false positive rate, 0.23 per patient, was significantly cut down.

CLINICAL RELEVANCE/APPLICATION

With the popularity of MDCT, the detection rate of lung nodules was significantly improved, which brought great pressure to radiologists. And the false positive nodules detected by traditional CAD software were so much that the clinical application was limited. So we need a more intelligent CAD system to detect pulmonary nodules accurately.

SSQ05-08 Lung-RADS Performs Well in a Diverse and Underserved Lung Cancer Screening Population

milchh@mskcc.org

PURPOSE

To evaluate the performance of Lung-RADS in a clinical setting that markedly differs from the Lung-RADS score derivation populations.

METHOD AND MATERIALS

Our low dose CT (LDCT) lung cancer screening program is referral based and relies on a bilingual coordinator. LDCTs were interpreted by subspecialized chest radiologists using Lung-RADS. 30% (356/1181) were interpreted prior to Lung-RADS release and assigned an internally derived 1-5 score that was later converted to Lung-RADS as follows: scores of 1 and 2 to Lung-RADS 1 and 2, scores 3 and 4 to Lung-RADS 3, scores 5a and 5b to Lung-RADS 4a and 4b. Data were obtained by patient interview and electronic medical records.

RESULTS

1181 patients were screened from December 2012- December 2016, median age was 63 [IQR 59-67], 49% (569) men, 75% non-white (31% black, 31% Hispanic, 13% other), 55% (651) Medicaid/Medicare insured, 71% current smokers (median pack-years 45), median socioeconomic status -2.26. Comorbidities: 69% overweight/obese (32%/37%), 68% hypertension, 67% chronic lung disease, 35% diabetes, 17% heart disease, 2.1% HIV positive. Lung-RADS performance: 87% (1030/1181) of baseline LDCTs were negative (Lung-RADS 1 or 2)- lung cancer rate 0.2%(2/1030); 10% (119) Lung-RADS 3- cancer rate 3.4%(4/119); 1.2% (14) Lung-RADS 4a- cancer rate 43% (6/14); 1.5% (18) Lung-RADS 4b- cancer rate 83% (15/18). The overall positive rate (Lung-RADS 3, 4a, and 4b) was 12.8% (151/1181), false positive rate 10.9%, and positive predictive value (PPV) 16.6% (CI 14.0-19.5). Sensitivity was 92.6%. Mortality in lung cancer patients was 27% vs 0.6% in non-lung cancer patients.

CONCLUSION

Although Lung-RADS was derived and retrospectively validated primarily via the NLST and I-ELCAP screening cohorts, it performs well clinically in a predominantly poor, ethnically diverse population, meeting or exceeding benchmarks.

CLINICAL RELEVANCE/APPLICATION

In clinical practice Lung-RADS increased the PPV of the LDCT exam to 16.6% versus 3.8% in the NLST and significantly exceeded ACR cancer diagnosis benchmarks for Lung-RADS 4a-43% and 4b-83% (benchmarks: 4a- 10-15%, 4b- >15%). .

SSQ05-09 Access to Lung Cancer Screening Services: Preliminary Analysis of Geographic Service Distribution Using the ACR Lung Cancer Screening Registry

Thursday, Nov. 30 11:50AM - 12:00PM Room: S402AB

Awards
Student Travel Stipend Award

Participants
Paniz Charkhchi, MD, Ann Arbor, MI (*Presenter*) Nothing to Disclose
Ruth C. Carlos, MD, MS, Ann Arbor, MI (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

panizcharkhchi@yahoo.com

PURPOSE

Lung cancer has the highest mortality rate among all types of cancer in the United States. NLST demonstrated low dose CT (LDCT) for lung cancer screening decreases both lung cancer related mortality and all-cause mortality. Currently, the only CMS approved lung cancer screening registry is the Lung Cancer Screening Registry (LCSR) administered by the American College of Radiology (ACR). We aim to show the availability of facilities, participated in the LCSR, in the each state to provide lung cancer screening services to those who are screen-eligible and to assess if facility availability is proportionate to state-level demographic and lung cancer related outcome.

METHOD AND MATERIALS

The ACR LCSR list of participating lung cancer screening facilities was used as a proxy for the availability of lung cancer screening facilities in each state. Additionally, we normalized the number of facilities by state by the number of screening-eligible individuals using BRFSS data. State-level demographics were obtained from the 2015 BRFSS: poverty level, insured population, unemployed, Black and Latino. We obtained data on lung cancer incidence and death, number of active physician per 100,000 and Medicare expenditure. We performed linear regression models to examine the influence of the covariates on state-level screening facility number by state using Stata 11.

RESULTS

As of 11/18/2016, 2,423 facilities participated in the LCSR, with a median number of 32 facilities per state (interquartile range 63) with highest number in the Florida (n=198) and the lowest number in the District of Colombia and Montana (n=3). Figure 1 graphically represents the location and distribution of lung cancer screening facilities by proportion of screen-eligible individuals. There was a positive independent effect (OR=12.90, 95% CI =11.01- 14.79) between state-level number of screening facility and rate of screen-eligible individuals rate per 100,000. There were no significant correlations between numbers of facility and lung cancer outcomes, state demographic characteristics, or physician supply and Medicare expenditure.

CONCLUSION

Although there was a positive relation between facility number and screening eligible rate, there is a further need to evaluate the geographic access of these facilities.

CLINICAL RELEVANCE/APPLICATION

Screen eligible by state remains additional work define if other access barriers exist.

PURPOSE

Whole body CT in non-severly injured patients is frequently a cause of dispute between referring trauma phisicyans and vetting radiologists. On the other hand, missing a potentially treatable injury is equally unacceptable and may lead to lawsuits. This study aims to determine whether the use of split bolus versus delayed arterial phase might be of value in the assessment of non-severely injured trauma patients.

METHOD AND MATERIALS

A retrospective sample of 72 polytrauma whole-body CT scans, performed from January 2015 to March 2017 at a major trauma centre was analysed. All patients with an ISS less than or equal to 16, represented our inclusion criteria. One pass poly trauma CT scans were performed by a delayed arterial phase acquisition (bolus-triggering technique starting after 20sec. from peak enhancement) or by the split bolus technique (1th bolus with 65ml of contrast at 2mL/s, following by 10sec. delay, 2th bolus with 85mL of contrast at 3.5 mL/s following by a flush of 40ml of saline at 3.5 mL/sec, initiate scan at 77 sec.). Differences in attenuation values of the liver, spleen, pancreas and kidneys between the two acquisition protocols were expressed in Hounsfield Units. Statistical comparison between the two groups was determined by using the Chi-square test.

RESULTS

Forty patients were scanned using the split bolus protocol, whereas the remaing 32 patients received the delayed arterial phase protocol. Overall, 10 patients had bone fractures, 3 had pneumothoraces , 3 had renal contusions, 1 had renal, adrenal, and hepatic contusions and 3 had vascular injuries. There was no significant statistical difference in regard to overall attenuation values of the liver in both groups: (117 vs 123 HU, p=0.18) and pancreas (112 vs 131 HU, p=0.46), whereas differences were statistically significant in regard to the spleen (143 vs 119 HU , p=0.04), and kidneys (205 vs 225 HU, p=0.03).

CONCLUSION

Our results show that split bolus acquisition technique is associated with more homogeneous contrast enhancement of the spleen and kidneys and can be implemented as a standard acquisition protocol in non-severely injured patients.

CLINICAL RELEVANCE/APPLICATION

The integration of a low radiation dose technique such as split bolus in daily clinical practice in patients in whom the indications for standard whole-body CT are 'borderline', can reduce disputes between referring trauma physicians and vetting radiologists and avoid lawsuits.

SSQ06-03 Imaging of Delayed Manifestations of Abdominopelvic Trauma

Thursday, Nov. 30 10:50AM - 11:00AM Room: S405AB

Participants
Mohammed F. Mohammed, MBBS, Vancouver, BC (*Abstract Co-Author*) Speaker, Siemens AG; Employee, X-Ray Teleradiology Services
Khaled Y. Elbanna, MBChB, FRCR, Vancouver, BC (*Presenter*) Nothing to Disclose

mohammed.f.mohammed@gmail.com

PURPOSE

Abdominal injuries presenting to hospital emergency departments often warrant an initial modality of imaging to screen for injuries from the initial traumatic incident.A handful of traumatic injuries may not be identified or fail to manifest on the initial CT, resulting in delayed manifestations of abdominal trauma. This may lead to subsequent readmission, delayed management, and possibly severe complications.No studies have investigated this topic in a holistic, whole-body approach. As such, our study aims to quantify the frequency and type of delayed abdominal injuries, and to determine the etiology behind the delayed manifestation and diagnosis.

METHOD AND MATERIALS

For this IRB-approved retrospective study, the hospital trauma registry was queried for patients with multi-trauma and ISS >= 16 between January 2010 and August 2016 and had initial Abdominopelvic CT on admission, yielding 3735 studies. Patients who received a follow-up abdominopelvic CT within 6 months from the initial scan were included in our study (203). The clinical indication and radiological findings were reviewed, clinical indications for repeating CT study, presence or absence of a new radiological finding, organ-related abnormality and clinical management accordingly.

RESULTS

203 patients (5.44%) received follow up CTs. The average elapsed time between the initial and follow-up CT was 15±27 days. Individual clinical indications (n=243) included evaluation for abdominal collection (n=97), 39.92%; solid organ injury (n=85), 34.98%; Bowel-Related abnormalities (n=31), 12.76% and miscellaneous indications (n=30), 12.35%. Delayed manifestations and complications of trauma were found in 41 cases (20.1 %) and were attributed to 46 abnormalities related to new abdominal collections and hematoma (n=17) ; solid organ injury (n=19); bowel and mesentery (n=6); diaphragmatic injury (n=3) and urinary bladder injury(n=1). Based on the radiological findings on follow up CT studies, 8 Surgical and 16 interventional procedures were performed.

CONCLUSION

A small percentage of traumatic injuries may not be identified on the initial CT, resulting in delayed traumatic manifestations, leading to an increase in morbidity.

CLINICAL RELEVANCE/APPLICATION

Understanding the frequency and pattern of delayed abdominal injuries increases the awareness of radiologists to injuries that require scrutiny on initial trauma imaging and closer follow up.

SSQ06-04 A 2017 National Survey to Assess Blunt Trauma CT Protocols at U.S. and Canadian Trauma Centers

Thursday, Nov. 30 11:00AM - 11:10AM Room: S405AB

aychoi@winthrop.org

PURPOSE

To our knowledge, there are no published societal or national guidelines for blunt trauma CT imaging protocols, including on the use of whole-body CT (WBCT). Our goal was to survey trauma radiologists in the United States and Canada in order to determine if there is any consensus on indications for WBCT, the algorithms used in blunt trauma patients, and the most common protocols used.

METHOD AND MATERIALS

With IRB approval, an anonymous 17 question survey was distributed via email link to 78 radiology departments at 78 trauma centers in the U.S. and Canada. The study was open for a two-week period in March 2017. A commercially available website that allows subscribers to create and analyze surveys was used for analysis.

RESULTS

31 respondents from 31 institutions completed the survey (response rate 40%). 52% use WBCT protocol for blunt abdominal trauma. For those that use WBCT, half report that a single radiologist interprets the entire scan. The most common blunt trauma chest CT protocol is single phase, contrast-enhanced arterial phase imaging (72%). The most common blunt trauma abdomen/pelvis CT protocol is a single IV contrast injection followed by portal venous phase imaging (48%). 76% reported not routinely obtaining delayed phase abdominal and pelvic images. Spine reconstructed images are always created at 52% of institutions. When asked if trauma CT images are routinely reviewed by a radiologist before the patient is moved from the CT table, the two most common answers were "no" (55%) and "yes, a majority are reviewed by a radiology resident" (28%). 86% of institutions routinely use filtered-back projection or iterative reconstruction with trauma CTs. When asked who interprets trauma CTs performed during what would be considered after hours, the most common answer was "after-hours interpretations are provided by an in-house or remotely situated attending radiologist who is a full-time staff physician at the institution" (72%). 50% of institutions do not routinely assess renal function prior to blunt trauma CT imaging.

CONCLUSION

There is substantial variation across U.S. and Canadian-based institutions regarding the current use of whole-body CT in blunt trauma, how trauma CT scans are protocoled, and who interprets them.

CLINICAL RELEVANCE/APPLICATION

There is a lack of uniformity in how patients with blunt trauma are currently scanned with CT across U.S. and Canadian trauma centers.

SSQ06-05 Traumatic Vascular Injuries of Abdominal Solid Organs: Is Split-Bolus Really That Bad?

Thursday, Nov. 30 11:10AM - 11:20AM Room: S405AB

Participants
Maarten J. Graumans, BSC, Amsterdam, Netherlands (*Abstract Co-Author*) Nothing to Disclose
Ferco H. Berger, MD, Toronto, ON (*Presenter*) Nothing to Disclose
Wietse Zuidema, MD, Amsterdam, Netherlands (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

m.graumans@vumc.nl

PURPOSE

To evaluate the accuracy of the single-pass split-bolus whole body CT protocol compared to the conventional segmented multi-pass protocol for traumatic vascular injuries of solid abdominal organs.

METHOD AND MATERIALS

745 trauma patients were retrospectively included; 350 patients in the conventional segmented multi-pass whole body CT group and 395 patients in the split-bolus single-pass whole body CT group. Radiology reports were analyzed for presence of contrast extravasation, hemorrhage and vascular injuries. Electronic patient records were analyzed for subsequent hemorrhagic events during follow-up either in clinical records or follow-up imaging radiology. Mortality analysis was performed on patients who died since their presentation in the hospital.

RESULTS

In total, 79 patients suffered hemorrhages of which 35(10%) in the conventional group and 44(11.1%) in the split-bolus group. There were no missed hemorrhages found in either group. There was no statistically significant difference of the incidence of vascular injuries between groups. No cases of mortality were found to be related to missed vascular injuries.

CONCLUSION

Using the split-bolus single-pass whole body CT protocol for the initial evaluation of trauma patients does not lead to clinically significant missed vascular injuries of abdominal solid organs.

CLINICAL RELEVANCE/APPLICATION

Our work suggests that the split-bolus protocol does not underperform compared to the conventional protocol and should be considered as a method of radiation dose reduction in the trauma population.

SSQ06-06 Emergency Department Imaging Super-users: Utilization Characteristics of the Most Resource Intense Patients

Thursday, Nov. 30 11:20AM - 11:30AM Room: S405AB

For information about this presentation, contact:

tarek.hanna@emory.edu

PURPOSE

To identify and characterize the most frequent users of emergency department (ED) imaging ("Super-users").

METHOD AND MATERIALS

All patients with at least 1 ED visit in 2016 within a four-hospital healthcare system were retrospectively identified. Characteristics of those encounters and all associated radiology examinations were then analyzed.

RESULTS

Overall, 126,940 unique patients presented for 187,603 separate ED visits which resulted in a total of 192,142 imaging examinations. Mean annual ED visits per patient were 1.48 ± 1.66 (range: 1-294). The top 0.32% (n=408) of patients visited the ED >10 times in the year and accounted for 3.8% of all ED visits; the top 1.7% (n=2,158) of patients visited the ED >5 in the year and accounted for 10.48% (n=19,667) of all ED visits. 73,672 ED patients (58%) underwent at least 1 ED imaging examination, with a mean of 2.6 exams per patient (SD 2.69; range: 1-60). 2,124 patients (1.67% of the total ED patients) underwent >=10 imaging examinations, and accounted for 15.01% of the total annual ED imaging volume. ED imaging volume consisted of CT (n=68,370; 35.6% of imaging volume; range per patient 0-21), radiography (n=67,409; 35.1%; range 0-39), ultrasound (n=29,985; 15.6%; range 0-27), MRI (n=15,433; 8.03%; range 0-13), with far fewer numbers of all other modalities.

CONCLUSION

A tiny fraction (1.67%) of all ED patients account for a disproportionately large percentage (15%) of all ED imaging volume. Further study of these Super-users may catalyze targeted interventions to control unnecessary ED imaging volume growth, contain costs, and decrease per-patient radiation exposure.

CLINICAL RELEVANCE/APPLICATION

Further characterization of this vulnerable patient population may facilitate informed targeted interventions to optimize ED imaging, restrain costs, and decrease per-patient radiation exposure.

SSQ06-07 Have We Gone Too Far? Active Arterial Bleeding: Not as Bad as We Thought

Thursday, Nov. 30 11:30AM - 11:40AM Room: S405AB

For information about this presentation, contact:

joaquinpatricio.moran@salud.madrid.org

PURPOSE

The presence of active bleeding in computed tomography (CT) is usually related to failure of conservative treatment in the context of a traumatic hemorrhage. Our goal is to evaluate if all patients with a traumatic active arterial extravasation should be managed aggressively or not, and if there is any predictor factor in the therapeutic decision-making.

METHOD AND MATERIALS

We performed a retrospective analysis of CT angiographies with active arterial extravasation ("blush") in adult trauma patients admitted from January 2013 to March 2017 at the emergency department. Patients with intestinal, aortic or spontaneous bleeding were excluded. All studies were review in a posterior second lecture. We reviewed the management performed and analyzed several clinical, laboratory, and radiological parameters before the treatment. We made a descriptive, univariant and multivariate study with the software SPSS Statistics v.20.

RESULTS

Out of 152 patients included in the study, 41 were remove in the review and the analysis was performed on a final population of 111 patients. We followed two different groups: patients who required surgical or radiologic intervention (75), and the remaining patients who were managed conservatively (36), both with a good outcome. Between the conservative and aggressive management groups, we found statistically significant differences in hemodynamic stability (83% vs. 42%; $p < 0.001$), lactate level (mean 2 vs.4.2 mmol / L; $p < 0.001$), arterial blush measurement (mean 12 vs.19 mm; $p = 0.05$) and localization (55% vs. 36% with peripheral location; $p = 0.03$). The area under the ROC curve for lactate level and arterial blush size like predictor factors was 0.7 in both cases. The combination of statistically significant variables had a sensitivity of 80%, a specificity of 64%, a positive predictive value of 86% and a negative predictive value of 52% to predict the need of agressive management.

CONCLUSION

Some patients with traumatic active arterial extravasation in a CT angiography can be managed conservatively based on clinical, laboratory and radiological data. We consider that lactate level and arterial blush size are good predictor factors. An exhaustive investigation that define solid criteria for therapeutic decision-making is necessary.

CLINICAL RELEVANCE/APPLICATION

Several of the traumatic active arterial extravsation detected in emergency CT angiography can be treated conservatively, without any intervention.

SSQ06-08 Unidentified Bright Objects of Spleen on Arterial Phase CT: Differentiating features of this Mimicker of

Splenic Vascular Injury in Blunt Abdominal Trauma

Thursday, Nov. 30 11:40AM - 11:50AM Room: S405AB

naren2705@gmail.com

PURPOSE

We describe Unidentified Bright Objects of Spleen (UBOS) as hyperdense areas around splenic lacerations on arterial phase (AP) CT which are isodense on portal venous phase and have no abnormal correlate on digital subtraction angiography (DSA). They need to be differentiated from splenic vascular injuries like active contrast extravasation (AE) and pseudoaneurysms (PA) as it has management implications. We describe a few signs and their diagnostic accuracy to differentiate PA/AE from UBOS

METHOD AND MATERIALS

Retrospective analysis of patients of blunt abdominal trauma who had undergone dual phase CT & DSA was done. All hyperdense lesions on AP were evaluated for their margins (well defined/ill-defined), presence of the lesion on adjacent/parallel walls of the laceration (wall sign), presence of normal parenchyma in relation to at least one side of the lesion (adjacent parenchyma sign) and string of beads appearance. The difference between the mean CT Hounsfield unit (HU) of the lesion and aorta was also noted in the AP. The diagnostic accuracy of these signs for distinguishing from UBOS was calculated with DSA as gold standard.

RESULTS

In the 43 patients included, 54 hyperdense lesions were detected on AP, which included 22 vascular injuries (11 PA, 11 AE) and 32 UBOS based on DSA. The presence of ill-defined margins had a low sensitivity and specificity (37%, 18% respectively). The adjacent parenchyma sign had a sensitivity of 84% and specificity of 77%. The wall sign and a beaded appearance had a sensitivity of 50% and 65% and a high specificity of 95% and 86% respectively. ROC curve analysis done for the difference in HU between the aorta and the lesion showed that a difference of over 50 HU had a sensitivity of 88.9% and specificity of 90.6% (AUC - 0.896).

CONCLUSION

A difference of over 50 HU between the lesion and aorta & the adjacent parenchyma sign had highest diagnostic accuracy while the wall sign and beaded appearance had a high specificity but a low sensitivity for identifying UBOS

CLINICAL RELEVANCE/APPLICATION

Accurate differentiation of unidentified bright objects of spleen from splenic vascular injuries has management implications and is possible with the above described signs

SSQ06-09 Radiology in the Midst of the Opioid Epidemic: 12-year Analysis of Imaging Findings, Mortality and Opioid Prescription History among Patients with Intravenous Substance Use Disorders (IV-SUDs) Presenting to Emergency Radiology

rralmeida@mgh.harvard.edu

PURPOSE

To assess the prevalence and type of IV-SUDs imaging complications, mortality rate, and history of opioid prescriptions (OP) and in patients presenting to Emergency Radiology (ER).

METHOD AND MATERIALS

HIPAA compliant-IRB approved retrospective study of 1031 patients who presented to ER (2005 to 2016) to assess IV-SUDs complications. Demographics, clinical symptoms, imaging diagnosis, history of OP, and dates of death were recorded. Exams were categorized by imaging diagnosis, modality and specialty. Analyses for significant differences were done.

RESULTS

In 1031 patients (65% men; mean age 36 yrs; 78% white; 95% English speakers), 1673 exams (779 X-rays, 544 CT, 292 MRI and 58 US) were performed (1-13 exams per patient, mean 1), accounting for 0.2% (1673/854299) of all ER studies in the same period. 52% of patients had 1 or more studies with IV-SUDs complications. The rates of positive imaging per imaging specialty were: GI 77% (113/146), MSK 52% (419/802), Vascular 48% (77/162), Neuro 47% (97/206), and chest 25% (90/356). Most frequent clinical symptoms were local complications of injections (27%, 450/1673), respiratory (15%, 251/1673) and back pain (13.4%, 224/1673). History of OP before the first imaging was present in 30% (310/1031) of cases (mean 10 prescriptions per patient); significantly more often in women (37%, 128/348), than men (27%, 182/673, p=0.008). Mean time from OP to first imaging was 51 months (SD

39); significantly shorter in men (45 months) than women (51 months, p=0.01). Overall death was recorded in 11.7% (121/1031) of patients; significantly higher in patients with positive imaging diagnosis of IV-SUDs complications (14%, 73/534) than in those without (10%, 48/449, p=0.04). 5-yr mortality rates were: 7% (73/1031) overall; higher in patients with prior opioid prescription (9%, 29/310) than in those without (6%, 44/721, p=0.06); higher in patient with imaging complications (6%, 33/534) than in those without (4%, 21/427, p=0.2).

CONCLUSION

There is a high prevalence of multisystem IV-SUDs imaging complications among patients presenting to the ER. Patients with positive imaging findings and prior OP have a higher overall mortality rate compared to patients with negative imaging.

CLINICAL RELEVANCE/APPLICATION

Understanding factors associated with IV-SUDS imaging complications is fundamental to designing responsive patient care models that can better support the health and survival of this vulnerable population.

Cameron Simmers, MD, Dunedin, New Zealand (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To determine the typical anatomical distribution of anterior ectopic gas resembling pneumoperitoneum and to determine the relationship of this finding with trauma and clinical outcomes using archival CT.

METHOD AND MATERIALS

In total, 492 consecutive trauma patients between two separate geographical centres were included to be screened. One hundred and eighty-six patients with recognised causes for ectopic gas were excluded, leaving 306 patients (211 male, mean age 44.5) for analysis by dual consensus between the two centres. A further 200 non-trauma CT scans were consecutively selected as a control group.

RESULTS

The pseudopneumoperitoneum was related to trauma (p=0.0001) and identified in 5.2% of patients after exclusions. Pseudopneumoperitoneum occurred bilaterally and consistently found to be adjacent to the lower 6 anterior ribs near the costochondral junction. Pseudopneumoperitoneum was independently associated with high velocity trauma. There were no significant differences between sides, gender or injury severity score. None of the patients with pseudopneumoperitoneum had evidence for hollow viscus perforation at laparotomy or clinical examination.

CONCLUSION

Pseudopneumoperitoneum is a post traumatic phenomenon centred near the costochondral junction of the lower 6 anterior ribs. These findings have potentially significant clinical implications and are therefore important to recognise in order to prevent unnecessary laparotomy in the trauma setting.

SSQ07-02 Misty Mesentery Is Not Associated With Baseline or New Diagnosis of Cancer: A Matched Cohort Study

PURPOSE

To compare the prevalence of a known diagnosis of cancer in patients with and without misty mesentery (MM) at baseline imaging, and to determine its association with the development of a new diagnosis of cancer.

METHOD AND MATERIALS

This was a retrospective, HIPAA compliant, IRB approved study of patients with and without MM on CT scans acquired from January 1, 2000 to December 31, 2010. We searched our RIS database for reports that included keywords associated with MM. All scans were reviewed to confirm the presence of MM. 4:1 age- and gender-matched controls without MM were identified. Medical records were reviewed and the following data noted: date of CT, use of iodinated IV contrast, CT protocol (noncon, single, or multiphase), baseline nonmalignant diagnoses, history of abdominal malignancy known at the time or identified on the CT scan, subsequent diagnosis of cancer, and date of the new diagnosis or last encounter. Data was analysed with Pearson's chi-square test, two-sample Student's t-test, and Cox proportional hazard models (only patients who did not yet have a baseline diagnosis of cancer). We used STATA® for statistical analysis. An a of 0.05 was considered statistical significance.

RESULTS

Our sample consisted of 148 patients with MM (60 women, 40.54%) and 600 patients without it (236 women, 39.3%) . The mean age of patients were 63.5 years and 61.9 years for patients with and without MM, respectively. No statistically significant difference in any non-malignant diagnoses. Patients with MM were less likely to have a malignancy at baseline (RR = 0.764, absolute difference 12.3% p=0.008). Patients with MM had a longer mean follow-up duration than controls (1742 days, standard deviation = 1545.0 versus 1391 days, standard deviation = 1467.4; P = 0.01). On survival analysis, we observed an increased risk of developing any cancer in MM patients, but this effect was not statistically significant (HR = 1.71, 95% CI 0.93-3.15, p=0.083)

CONCLUSION

We found no clear evidence that patients with MM are more likely to have cancer at the time of baseline imaging or to be later diagnosed with cancers previously thought to be associated with misty mesentery, such as lymphoma.

CLINICAL RELEVANCE/APPLICATION

Further testing is not necessary following the diagnosis of MM, and perhaps its identification on cross-sectional reports should be ommitted or at least not emphasized to minimize patient and provider anxiety.

PURPOSE

Component separation is a commonly used technique allowing for sufficient fascial approximation during complex ventral hernia repair (VHR). However, in certain cases, despite component separation, fascial apposition is not possible resulting in bridged VHR. Prior studies have suggested a role for computed tomography (CT) in preoperative planning for VHR. We hypothesized that CT characteristics of abdominal wall musculature may correlate with the defect size and outcomes of fascial approximation during surgery.

METHOD AND MATERIALS

Consecutive patients who underwent complex VHR using component separation technique and available operative note and pre-operative abdominal CT scans were retrospectively recruited in this IRB-approved study. Specific parameters such as defect size, abdominal wall fat thickness; thickness and mean attenuation of abdominal wall muscles including rectus abdominis (RA), external oblique (EO) and internal oblique (IO) were measured in multiple levels on axial planes using Osirix software (Pixmeo, Bemex, Switzerland) and used for further analysis.

RESULTS

Forty patients meeting inclusion criteria were included. Twenty patients had successful fascial approximation (unbridged group) while in the other 20 patients fascial bridging was used for hernia repair (bridged group). The defect width had a positive correlation with mean EO thickness (Correlation Coefficient (CC)= 0.43, p=0.006), IO thickness (CC=32, p=0.43), abdominal wall fat thickness (CC=0.35, p=0.03) and EO/IO mean attenuation ratio (CC=0.45, p=0.004). Mean defect width on axial plane (15.0±5.2 vs. 9.3±3.7 cm, p<0.001) and EO/IO mean attenuation ratio (1.17±1.9 vs. 0.24±1.12, p=0.02) were significantly higher for patients who

required bridging technique for fascial closure. However, abdominal wall fat thickness did not significantly differ between groups.

CONCLUSION

Characterization of abdominal wall musculature thickness and fat composition by computed tomography might predict the success of fascial approximation in patients undergoing complex VHRs.

CLINICAL RELEVANCE/APPLICATION

Upon validation in larger prospective studies, these findings might enable preoperative planning and intervening to improve the outcomes in this patient population.

SSQ07-04 Role of High Resolution Transperineal Sonography and Its Comparison with MRI in Peri-Anal Fistulous Disease

Thursday, Nov. 30 11:00AM - 11:10AM Room: E350

abhi.jnmc@gmail.com

PURPOSE

To describe the high resolution transperineal sonographic findings in perianal fistulous diseases and to compare its efficacy with MRI, considering surgical results as gold standard.

METHOD AND MATERIALS

This prospective study included 180 patients with clinical suspicion of perianal fistulous disease. These patients were subjected to 2-D high resolution transperineal sonography which was performed in lithotomy position using 8MHz linear array transducer, after which they underwent MRI of the perineum on 1.5T Magnet. The results of sonography and MRI were interpreted by two separate radiologists. The preoperative sonographic and MRI findings were compared with the findings of surgical exploration taken as reference standard and the sensitivity, specificity, positive predictive value and negative predictive values of sonography and MRI were calculated and compared.

RESULTS

Transperineal sonography showed a high sensitivity of 91.5%, specificity of 72% and positive predictive value of 92.7% in detection of primary tract. MRI had comparable sensitivity of 93.2% and specificity of 81%, with positive predictive value of 95.6%. MRI showed a higher diagnostic accuracy in detection of secondary tracts, supralevator extension, whist sonography and MRI had comparable results in detecting intersphincteric collection, crypto glandular abscesses and internal opening. In multiple fistulae, post operative recurrence and associated abscesses both sonography and MRI showed comparable diagnostic efficacy.

CONCLUSION

Transperineal sonography is a highly effective tool in pre-operative assessment and classification of perianal fistulous disease. It has a high sensitivity in detection of primary tract and can accurately identify the secondary tracts, abscesses and internal opening. It is also useful in assessing recurrence in post operative cases.

CLINICAL RELEVANCE/APPLICATION

Transperineal sonography, being a relatively cheap and time saving procedure, can be established as a highly useful alternative to MRI perineum, in view of comparable diagnostic accuracy in cases with perinanal fistulous disease.

SSQ07-05 An MR-Derived Standardized Visceral Adipose Tissue Index (VATI) for Prediction of Insulin Sensitivity

PURPOSE

Quantification of visceral adipose tissue (VAT) by MRI is currently performed in many cross-sectional, interventional and epidemiological studies and has shown to be of stronger metabolic relevance compared to other adipose tissue compartments in the human body. However, considering the absolute volume of VAT bears inaccuracies as this has to be interpreted different for subjects with different size. Thus, a VAT-index is introduced - comparable to body mass index, BMI - correcting the VAT-volume by

the square of body height.

METHOD AND MATERIALS

VAT volume was assessed between femoral heads and thoracic diaphragm by axial T1-weighted MRI on a 1.5T whole-body imager (Magnetom Sonata, Siemens Healthcare, Germany). Automatic segmentation of VAT and subcutaneous adipose tissue (SCAT) was performed by a fuzzy-clustering algorithm. In total 952 subjects (603f/349m, mean age 44.6 years) at increased risk for metabolic diseases were included in this prospective analysis. Anthropometrics and insulin sensitivity (IS, by oral glucose clamp) were determined immediately after the MR-session. VAT index (VATI) was calculated by dividing VAT volume (given in l) by the squared body height (cm^2).

RESULTS

VAT volume was in a range between 0.25l and 13.9l and the mean value was twice as much for males (5.6l) compared to females (2.8l). Mean BMI was comparable for males (30.6kg/m^2) and females (29.9kg/m^2). VATI was calculated to 1.76l/m^2 for males and 1.02l/m^2 for females and IS was in a broad range. By applying a stepwise multivariate linear regression analyses (IS as dependent variable) to adjust the effects of covariates (including age, BMI, WHR) and to identify independent relationships, VATI remained as the only significant predictive parameter for IS.

CONCLUSION

MRI has been established as a reliable tool for non-invasive phenotyping. In order to correctly interpret the amount of VAT in the framework of metabolic imaging, the absolute volume should be corrected for body height. It has to be mentioned that these results do not reflect the general population and cut-off values for VATI regarding differentiation of insulin sensitive and insulin resistant subjects remain to be determined.

CLINICAL RELEVANCE/APPLICATION

For a correct interpretation of visceral adipose tissue volume assessed by abdominal MRI, standardization and correction for body height - comparable to body mass index - is advisable.

SSQ07-06 Effect of Hepatobiliary MR Contrast Agent Administration on the Signal Intensity of Peritoneal and Pleural Fluid Effusions

maxime.ronot@aphp.fr

PURPOSE

To describe the effect of hepatobiliary-specific MR imaging contrast agent (HBCA) administration on the signal intensity of peritoneal and pleural fluid effusions on T1-weighted MR images.

METHOD AND MATERIALS

From October 2015 to May 2016 all consecutive patients with peritoneal or pleural effusions who underwent HBCA-MRI (Gd-BOPTA or Gd-EOB-DTPA) at 1.5T and 3T were retrospectively included from two centers. The signal intensity of peritoneal and pleural fluids was classified as hypo/iso/hyperintense compared to the splenic parenchyma, before and after HBCA administration. The relative signal enhancement (RE) and the signal-to-noise ratio (SNR) were calculated on pre and contrast-enhanced sequences.

RESULTS

139 patients with peritoneal/pleural effusions without biliary or vascular leakage (mean 60±10-yo, 96 males, 69%) were included. MR imaging was performed for chronic liver disease (n=105), cancer staging (n=21), and other causes (n=15). On T1-weighted hepatobiliary phase (HBP) MR images, the peritoneal fluid appeared hyper/isointense in 88-100%, and pleural effusions in 100% of the patients following Gd-BOPTA administration. On T1-weighted HBP images, all effusions remained hypointense following Gd-EOB-DTPA. The signal intensity of fluids increased with both types of HBCA but RE was significantly higher following Gd-BOPTA than Gd-EOB-DTPA ($p=0.002$ and <0.001 for peritoneal and pleural fluids, respectively), whatever the field strength. RE was significantly correlated with the HBP acquisition time ($r=0.42$, $p<0.001$ and $r=0.50$, $p = 0.033$ for peritoneal and pleural fluids, respectively). It was significantly higher in patients with chronic liver disease following Gd-BOPTA administration ($p=0.009$).

CONCLUSION

The signal intensity of pleural and peritoneal fluids progressively increases following HBCA administration, independently of field strength and in the absence of biliary or vascular leakage. Because most patients who underwent Gd-BOPTA enhanced MR imaging had hyperintense fluid effusion during HBP, we do not recommend this contrast agent to diagnose biliary leakage.

CLINICAL RELEVANCE/APPLICATION

Because most patients who underwent Gd-BOPTA enhanced MR imaging show hyperintense fluid effusion during HBP, we do not recommend this contrast agent to diagnose biliary leakage.

SSQ07-07 Utility of the MDCT Scan Measurement of Gas Distended Gastric Volume Pre and Post Sleeve Gastrectomy and Its Correlation with 1-Year Weight Loss

PURPOSE

Measure gastric volume pre and postoperatively, and see its evolution over time. Correlate these volumes with weight loss. Determine if the resected or the residual stomach are predictors of weight loss.

METHOD AND MATERIALS

80 patients with BMI >40 kg/m2 or >35 kg/m2 and medical comorbidities underwent LSG between January 2012 and November 2016 and were analysed prospectively. 207 multislice computed tomography data sets acquired in those patients (52 female and 27 male) were evaluated for gastric volume with a dedicated examination protocol In each CT scan, the patient took diluted oral gastrografin (Sodium Amidotrizoate) mixed with sodium bicarbonate, to produce the gastric distension (from liquid plus air), until they feel repleted. Then the CT scan is performed with a thickness of 2mm and a max FOV, a specific 3D software is used for the reconstruction. CT scans were performed preoperatively and 2 months and 1 year after surgery. Parameters were compared to percentage of excess weight loss (%EWL) at 1 year.

RESULTS

Mean preoperative BMI of patients was 47.25 kg/m2, and mean preoperative stomach volume was 690.5 ml. A significant correlation was observed between preoperative gastric volume and preoperative weight (p=0,019 , r=0,401). One year after surgery the mean %EWL was 63.1% and the mean BMI was 35.5kg/m2. A significant correlation was found between the differences in volume of the stomach (preoperatively and 2 months and preoperatively and 1 year) and the %EWL. At 2 months after surgery, the mean difference in gastric volume was 567.8 ml with statistical correlation with the %EWL at 1 year (p=0,013 and r=0,504). At 1 year after surgery the mean difference in gastric volume was 499.5 ml, also with statistical correlation with %EWL at that moment (p=0,021 and r=0,444). No differences were found between the %EWL at 1 year and the remnant volume at 2 months (p=0,467 and r=0,182) or at 1 year (p=0,309 and r=0.198).

CONCLUSION

1. CT Scan pre and postoperatively, proved to be usefull and of great utility measuring the volume of the gas distended stomach. 2. There is a correlation between the differences in the volume of the stomach and the %EWL 1 year after surgery. 3. Gastric remnant volume changes over time.

CLINICAL RELEVANCE/APPLICATION

MDCT Scan can demonstrate in a precise way the changes in gastric volume over time and this data can help the surgeon to decide the best surgical approach.

SSQ07-08 Imaging of Gangrenous Appendicitis: Do Dual Energy Iodine Overlay Images Add Clinical Value?

Thursday, Nov. 30 11:40AM - 11:50AM Room: E350

mohammed.f.mohammed@gmail.com

PURPOSE

Appendicitis remains the most common acute surgical condition of the abdomen. One unique form of this disease is gangrenous appendicitis. This form carries a very high perforation risk which leads to an increase in morbidity and mortality.There have been numerous publications on the role of CT in the diagnosis of acute appendicitis, however the accuracy of CT in diagnosing gangrenous appendicitis is less established. In our study, we propose that the use of Dual Energy (DE) and spectral imaging techniques can improve diagnostic accuracy of acute gangrenous appendicitis.

METHOD AND MATERIALS

For this retrospective, IRB-approved study, the hospital RIS was queried for all abdominopelvic CT scans performed in the emergency department between January 1, 2013 to December 31, 2016 that were positive for appendicitis on histopathology. Non DECT studies and those with frank perforation, phlegmon or peri-appendicular abscess formation were excluded. A total of 236

cases were included in our study. 120 kVp simulated images and iodine overlay (IO) images were reviewed by two abdominal radiologists in a randomized fashion who were blinded to the results of the histopathology for presence of gangrene. Sensitivity, specificity, positive and negative likelihood ratios and interobserver agreement were calculated for each set of images. Confidence was rated on a 5 point Likert scale with 1 being completely uncertain and 5 being absolutely confident.

RESULTS

59.7 % (141) of patients were male. The mean age of patients was 43.5 ± 1.2 years. 51 patients (21.6 %) were positive for gangrenous appendicitis on histopathology.The sensitivity, specificity, positive and negative likelihood ratios, confidence and interobserver agreement for IO images were 100 %, 79.5 %, 4.6, 0, 5 and 0.99 respectively ($p < 0.0001$), compared to 21.6 %, 95.1 %, 4.4, 0.82, 3.75 and 0.98 respectively ($p < 0.0001$) for 120 kVp simulated images.

CONCLUSION

Review of IO images adds significant clinical value to the DECT of the abdomen and pelvis for assessment of acute appendicitis as well as the presence of gangrene within the appendix.

CLINICAL RELEVANCE/APPLICATION

IO images should be reviewed along side the simulated 120 kVp in cases of suspected appendicitis to diagnose or exclude presence of gangrenous appendicitis.

SSQ07-09 Dual Energy and Spectral CT Utilization Rates in Acute Abdominopelvic Imaging

mohammed.f.mohammed@gmail.com

PURPOSE

The clinical applications of Dual Energy CT (DECT) in the abdomen and pelvis is well established. However, the actual utilization rates of DE/Spectral analysis are less well documented, specifically in the acute setting. Our study aims to assess the utilization rates of DECT in acute abdominopelvic imaging in the emergency department and the clinical value added by DE/spectral interrogation methods.

METHOD AND MATERIALS

For this retrospective, IRB-approved study, the hospital RIS was queried for all abdominopelvic DECT scans performed in the emergency department between January 1 to December 31, 2016. A total of 1238 studies were performed and were included in our study. The reports were reviewed for mention of DE/spectral interrogation as part of the interpretation of the study. Note was made of the number of times DE/spectral interrogation techniques altered management (by changing the diagnosis or detection of an unexpected, clinically relevant finding), confirmed an observation and increased confidence in the definitive diagnosis, provided additional relevant information or characterized an incidental finding - thus avoiding the need for further investigation.

RESULTS

DE/spectral analysis was utilized in 243 studies out of 1238 (19.63 %). DE/spectral analysis altered management in a significant way 10.3 % of interrogated cases, confirmed suspected observations and increased diagnostic confidence in 21 % of cases, provided relevant information on an observation in 66.7 % of cases and characterized an incidental finding in 18.1 % of cases.DE/spectral analysis was most commonly utilized in assessment of the genitourinary tract (68.5 %) followed by the gastrointestinal tract (20.6 %), the hepatobiliary system (7 %), the musculoskeletal system (2.25 %) and the vascular system (1.5 %).

CONCLUSION

There is good utilization of DE/spectral analysis in the acute setting, with nearly 1 out of 5 abdominopelvic DECT studies undergoing DE interrogation, adding clinical value to the examination by providing information that would have otherwise required additional imaging or other investigations. DE interrogation altered clinical management in 10 % cases.

CLINICAL RELEVANCE/APPLICATION

Routine utilization of DE/spectral techniques can impact management, improve diagnostic confidence and provide definitive clinically relevant diagnostic information only capable by DECT/spectral techniques.

Myeong-Jin Kim, MD, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To compare the diagnostic performance of multidetector CT (MDCT) among the guidelines based on the American Association for the Study of Liver Diseases (AALSD), the Liver Imaging Reporting and Data System (LI-RADS) 2014v, the Organ Procurement and Transplant Network (OPTN) system, and the Korean Liver Cancer Study Group-National Cancer Center (KLCSG-NCC) for the diagnosis of hepatocellular carcinoma (HCC) and allocation of liver transplantation (LT) candidates.

METHOD AND MATERIALS

From 2007 to 2014, 78 patients who underwent preoperative MDCT and subsequent LT for suspected HCC were included in this retrospective study. Two radiologists independently reviewed the CT images and evaluated focal hepatic lesions according to each guideline. Patients were allocated into one of three groups: beyond Milan criteria (MC), within MC with priority, or within MC without priority. The sensitivity and specificity of each guideline for detecting HCC, and accuracy of patient allocation were compared using logistic regression with the generalized estimating equation.

RESULTS

Fifty of 78 patients had 87 HCCs. For the detection of HCCs smaller than 1 cm (n = 24) and HCCs equal to or greater than 2 cm (n = 24), per-lesion sensitivity was not significantly different among four guidelines (P > 0.05). However, the sensitivity for detecting 1-2-cm HCCs (n = 39) was significantly higher when using the AASLD or the KLCSG-NCC guidelines (30.8-41.0%) than that using the LIRADS or the OPTN system (15.4-18.0%) (P = 0.030 for reader 1 and P = 0.005 for reader 2). Per-patient specificity was 92.3-96.2% using the AASLD or the KLCSG-NCC guidelines, and 92.3% using the LIRADS or the OPTN system without significant differences among four guidelines (P > 0.05). The accuracy for patient allocation was 74.4% in reader 1, and 71.8% in reader 2 without any difference among four guidelines in both readers.

CONCLUSION

The AASLD and the KLCSG-NCC guidelines can provide higher sensitivity than LIRADS and the OPTN system for the detection of 1-2-cm HCCs with MDCT. The accuracy for patient allocation was comparable among four guidelines.

CLINICAL RELEVANCE/APPLICATION

The AASLD and the KLCSG-NCC guidelines can improve the sensitivity for detecting 1-2-cm HCCs using CT compared with other two systems. Any of the four guidelines can be used for patient allocation.

SSQ08-02 Predicting HCC Microvascular Invasion (MVI) Using Imaging Morphological Criteria: Still a Lot to Know

Thursday, Nov. 30 10:40AM - 10:50AM Room: E353A

Participants
Andrea Prochowski Iamurri, MD, Ancona, Italy (*Presenter*) Nothing to Disclose
Roberto Montalti, Ancona, Italy (*Abstract Co-Author*) Nothing to Disclose
Andrea Agostini, MD, Ancona, Italy (*Abstract Co-Author*) Nothing to Disclose

Marco Vivarelli, Ancona, Italy (*Abstract Co-Author*) Nothing to Disclose
Andrea Giovagnoni, MD, Ancona, Italy (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Predicting HCC MVI using TC and MRI morphological criteria.

METHOD AND MATERIALS

This study received the necessary IRB approval. From September 2009 to December 2015, 208 patients underwent to curative resection for HCC at our institution. Subsequently we excluded 73 patients without imaging at PACS, 25 patients without MVI information at the pathology report and 18 patients that underwent to surgery more than 90 days after performing CT or MRI.The final cohort was made up of 92 patients that performed 56 CT and 36 MRI.For each patient we reviewed retrospectively the imaging studies evaluating number of lesions, size of the biggest lesions, lesions margin, presence of capsule and peripheral enhancement. Therefore we compared these characteristics with the presence or the absence of MVI stated in the pathology report.

RESULTS

Of the 92 patients 31(33.7%) presented MVI at the pathology report. The retrospective review of the imaging studies showed that the 92 patients presented 1.4±0.9 nodules, the average size of the biggest lesion was of 4.9±4.3cm, 48 (52,2%) had irregular margins, 45 (48,9%) had capsule and 45 (48,9%) had peripheral enchainment.Size (p=0.003) and capsule (p=0.004) demonstrated correlation, using a univariate analysis, with MVI. Other criteria like number of lesions, margins and peripheral enhancement didn't show any correlation with MVI.Multivariate analysis confirmed these results showing and odds ratio of 4.5 and 6.8 for capsule and size >6cm respectively.

CONCLUSION

Size >6cm and presence of capsule are associated with MVI.

CLINICAL RELEVANCE/APPLICATION

MVI is an important prognostic factor for recurrence in patients with HCC: its imaging prediction can be useful for identifying patients with better survival after liver transplant.

SSQ08-03 Multiparametric PET/MRI of Hepatocellular Carcinoma: Synergy of Redundancy?

PURPOSE

To quantify multiparametric FDG-PET/MRI parameters in hepatocellular carcinoma (HCC) and to assess the correlation between mpMRI and FDG-PET SUV parameter values in liver parenchyma and HCC lesions.

METHOD AND MATERIALS

This prospective study, approved by the institutional review board, enrolled 15 HCC patients (M/F 12/3, mean age 61 years). The mpMRI protocol, performed simultaneously with an 18F-FDG-PET examination, consisted of BOLD-MRI, IVIM-DWI and DCE-MRI measurements. Quantitative parameter maps were generated [BOLD: R2* pre and post O2, ΔR2* (post-pre); IVIM: pseudodiffusion coefficient D*, diffusion coefficient D, perfusion fraction PF, ADC; DCE-MRI: Ktrans (Tofts model TM and shutter-speed model SSM), ve (TM&SSM), kep (TM&SSM), arterial fraction ART (TM&SSM), mean intracellular water molecule lifetime τi (SSM) and ΔKtrans (SSM-TM), the latter two potentially reflective of tissue metabolism]. Mean mpMRI parameters and PET parameters (SUVmean and SUVmax) in HCC lesions and liver parenchyma and SUV tumor/liver ratios SUVmean T/L and SUVmax T/L were calculated. Differences between PET/MRI parameters in liver and HCC were assessed using Wilcoxon signed-rank tests. Spearman correlations between PET and mpMRI parameters in liver, all HCC lesions and FDG-avid (SUVmean HCC > SUVmean liver) HCC lesions were determined.

RESULTS

21 lesions were analyzed [mean size 4 (range 2-13) cm] of which 11 were FDG-avid. Significantly higher ART (TM and SSM) and lower R2* (pre and post O2) values were found in HCC vs. liver (P<0.008). PET and MRI parameters did not correlate in liver. In HCC, Ktrans TM and SUVmax (r=-0.467, P=0.033) and ΔR2* and SUVmax (r=0.586, P=0.013) showed significant correlations. IVIM parameters significantly correlated with PET parameters in FDG-avid HCC lesions [D and SUVmean (r=-0.767, P=0.021); ADC and SUVmean (r=-0.800, P=0.014)]. SSM parameter ΔKtrans showed significant correlation with SUVmean T/L and SUVmax T/L (r=0.438-0.536, P<0.047).

CONCLUSION

Multiparametric PET/MRI seems synergistic for liver parenchyma characterization, while quantitative mpMRI showed significant correlations with FDG-PET SUV values in HCC.

CLINICAL RELEVANCE/APPLICATION

Multiparametric PET/MRI can potentially provide improved characterization of HCC lesions compared to the individual modalities.

PURPOSE

New tumor response patterns to anticancer drugs have led to a response criteria shift from size to density. Choi criteria categorize response to anti-angiogenic therapies by a decrease in tumor density greater than 15% at the portal venous phase (PVP). We compared this threshold to the variability caused by both biology and image acquisition (improper PVP-timing) using liver metastases (LM) from colorectal cancer (CRC) as a paradigm.

METHOD AND MATERIALS

Pretreatment PVP CT images from a total of 291 LM-CRC patients from a single precision medicine trial were included. Four experienced radiologists independently scored the PVP timing and reached a consensus according to a 3-point scoring system: early/optimal/late PVP. Using radiologists' consensus, we trained a proprietary computer-aided quantitative quality control method to monitor PVP-timing. The reference standard was a computer-refined consensus. For each patient, we contoured target liver lesions and calculated their average density.

RESULTS

The PVP-timing was early, optimal and late in 52, 194 and 45 patients, respectively. The average (95CI) accuracy of the four radiologists for the detection of an optimal PVP-timing was 81.7% (78.3-85.2) and was outperformed by the 88.6% (84.8-92.4) computer-accuracy. The mean±SD LM-CRC density was 68±15HU overall and 59.5±14.9HU, 71.4±14.1HU, 62.4±12.5HU at early, optimal and late PVP-timing, respectively. LM-CRC density was thus decreased at non-optimal PVP-timing by 16.7% at early-PVP (p=8.9e-08) and 12.6% at late-PVP (p=1.8e-04) compared to that of optimal-PVP.

CONCLUSION

The 15%-threshold defined by Choi criteria is very sensitive for the detection of tumor response because non-optimal PVP-timing induces a similar decreased tumor density. Therefore, non-optimal PVP alters treatment response assessment and caution should be exercised in interpreting the significance of small density changes. Computer-aided quantitative PVP-timing scoring system outperforms radiologists' visual assessments and could improve the monitoring of anticancer therapy efficacy at patient and clinical trial level.

CLINICAL RELEVANCE/APPLICATION

Non-optimal PVP-timing causes variability in observed tumor density that can impact treatment response assessment defined by Choi criteria. We designed, by machine-learning, a computer-aided system for an optimized monitoring of anticancer drug efficacy.

SSQ08-05 One-Step Spectral and Perfusion CT Scan: Monitoring the Therapeutic Efficacy of VEGF Receptor Kinase Inhibitor AG-013736 in Rabbit VX2 Liver Tumors

PURPOSE

To develop a spectral contrast-enhanced CT protocol from perfusion CT data obtained with the same scan based on the time-attenuation curves and to evaluate its value in assessing the therapeutic efficacy of a vascular endothelial growth factor (VEGF) receptor inhibitor AG-013736 in rabbit VX2 liver tumors.

METHOD AND MATERIALS

The institutional animal care and use committee approved this study. In 31 VX2 liver tumor-bearing rabbits, a spectral CT protocol

The institutional animal care and use committee approved this study. In 31 VX2 liver tumor bearing rabbits, a spectral CT protocol was reconstructed to evaluate the maximum contrast of liver tumors by using time-attenuation curves from the perfusion CT data in the same scan. The iodine concentrations(ICs)of tumors derived from spectral CT normalized to aorta (nICs) at different time points (baseline, 2, 4, 7, 10 and 14 days after treatment) were compared within the treated group (n = 23) by using the Friedman test as well as between the control (n = 8) and treated groups by using the Mann-Whitney test. Correlations between nICs and perfusion parameters ,and between nICs and the tumor size, Bax,Bcl-2,VEGFR and VEGF mRNA were analyzed by using the Spearman rank test.

RESULTS

The optimal timing for maximum contrast of liver tumors in spectral CT was 15 seconds±2 in the arterial phase (AP) with the tumor CT values of 175-343HU. In AP, moderate correlations were found between nICs and time to peak (r=-0.588, P= 0.001) while substantial correlations were found between nICs and mean slope of increase (r= 0.672, P <0.001). The difference for nICs between each time point after treatment and baseline were significantly lower in the treated group than in the control group at 2 days after treatment. The greater decrease of nICs in tumors at 2 days in AP were positively correlated with smaller increase in tumor size at 14 days (r=0.69 , P<0.05). The tumor nIC values in AP had positive correlations with Bcl-2,VEGFR and VEGF mRNA (r values ranging from 0.58 to 0.76) and negative positive correlations with Bax (r= -0.56) (P<0.05 for all).

CONCLUSION

Iodine concentrations from spectral CT derived from perfusion CT data in AP were well correlated with perfusion CT parameter, which allowed early treatment monitoring the therapeutic effect of AG-013736 to liver tumors.

CLINICAL RELEVANCE/APPLICATION

Spectral CT can quantify the arterial tumor perfusion at a substantially lower radiation dose, and have good correlations with perfusion CT and histopathological findings.

SSQ08-06 Clinical Significance of T2* For Differentiating Tumor KRAS Mutation Status in Rectal Cancer

PURPOSE

To investigate the characteristics and potential differences of T2* in rectal cancers with different KRAS status.

METHOD AND MATERIALS

Totally, 119 patients, including 83 men and 36 women with histologically proved rectal cancer underwent pelvis MRI examination including T2 fast field echo (T2 FFE) sequence using five echoes. T2* values were automatically calculated after region of interest (ROI) being selected along the outline of whole tumor. Patients were stratified into two groups-KRAS wild-type and mutant by amplification refractory mutation system (ARMS) method. According to different mutation locations, patients with KRAS mutant were divided into codon 12 and codon 13 two subgroups. The T2* values between KRAS wild-type group and KRAS mutant group, codon 12 subgroup and codon 13 subgroup, were compared by using independent samples t test. Receiver operating characteristic(ROC) analysis of discrimination between KRAS wild-type and KRAS mutant rectal cancer was performed for T2* values. Intra- and interobserver agreement were evaluated using the intraclass correlation coefficient (ICC).

RESULTS

Our study included 76 KRAS wild-type, 43 KRAS mutant, and the latter group were then divided into 38 codon 12 patients and 5 codon 13 patients. Intra- and inter-observer reproducibility were relatively good to excellent for T2* (ICCIntra=0.8705, 95% confidence interval 0.8139~0.9099; ICCinter=0.7914, 95% confidence interval 0.7133~0.8501). T2* values were significantly higher in KRAS mutant group ([44.20±12.18]ms) than that in KRAS wild-type group ([36.27±11.96]ms) (t = -3.452, P = 0.001). However, T2* values showed no significant differences between codon 12 and codon 13 subgroups ([44.42±12.20]ms vs [36.27±11.96]ms; t =-0.325, P = 0.741). According to ROC curve, T2* values showed diagnostic significance with the AUC values of 0.706. The optimal cutoff values of 40.73ms for T2* resulted in (T2* valus of KRAS mutant rectal cancers were greater than this value) accuracy rate of 69.75%, sensitivity of 76.74%, specificity of 65.79%, positive predictive value of 55.93%, negative predictive value of 83.33%.

CONCLUSION

T2* values derived from T2 FFE sequence, as a promising biomarker, demonstrated potential clinical value in differentiating rectal cancers with different KRAS status.

CLINICAL RELEVANCE/APPLICATION

T2* values may be a useful imaging biomarker for differentiating rectal cancers with different KRAS status.

SSQ08-07 Preoperative N Stage Evaluation in Gastric Cancer Patients by MDCT: Can the Sum of the Short Axis Diameter of the Lymph Nodes be used for N Stage Evaluation?

PURPOSE

N staging is important in deciding the appropriate surgical treatment and in determining the prognosis of gastric cancer. In the N stage of gastric cancer, the accuracy of previous reports varies from 51% to 84%, because the definition of metastatic lymph node (LN) is different between studies using MDCT, and various cut-off values have been applied. In addition, the number of LNs seen in pathologic specimens tends to be higher than the number of LNs seen in CT. We have estimated that the sum of the sizes of LNs in CT can be proportional to the number of pathologic metastatic LNs. The purpose of this study was to compare the diagnostic performance of the sum of short axis diameter of lymph nodes (LN-sum) and the CT N stage of gastric cancer.

METHOD AND MATERIALS

Between January 2012 and December 2012, 127 consecutive patients who underwent preoperative MDCT and gastrectomy for gastric cancer were identified. We defined metastatic LN on MDCT as LN with a short axis >= 8mm. Regardless of size, LNs showing morphologic features such as central necrosis, heterogenous enhancement, nearly round shape (longitudinal/transverse diameter ratio <1.5), and clustered nodules were also considered as metastasis. We then calculated the LN-sum. The diagnostic value of LN-sum for distinguishing N stages was assessed by calculating the area under the receiver operating characteristic (ROC) curve. Sensitivity and specificity of N stage using LN-sum were generated using the optimal cut-off values. Also, conventional CT N stages of gastric cancer were made.

RESULTS

LN-sum showed significant correlation with the pathological N stage of gastric cancer (rho?=?0.70, p? **CONCLUSION**

Significant correlations exist among LN-sum in the N stage of gastric cancer. The LN-sum would be useful in the preoperative N staging of gastric cancer.

CLINICAL RELEVANCE/APPLICATION

The precise preoperative N stage in gastric cancer is of great importance in planning therapeutic strategies, so LN-sum could be used as a noninvasive imaging method for pre-operative N staging of gastric cancer.

SSQ08-08 Prediction of Intrahepatic Distant Recurrence after Radiofrequency Ablation of Hepatocellular Carcinoma: Role of CT Findings Indicating Portal Hypertension

PURPOSE

The purpose of this study is to determine whether the degree of portal hypertension(PH) assessed by CT findings could also predict intrahepatic distant recurrence(IDR) in patients with hepatocellular carcinoma(HCC) who received radiofrequency ablation(RFA).

METHOD AND MATERIALS

From August 2012 and April 2016, 78 patients who received RFA as initial treatment of HCC with available liver stiffness measurement(LSM) values prior to RFA were included, and the presence of IDR was reviewed. Two radiologists evaluate CT features : tumor size, multiplicity of tumors, and the sign of PH such as the diameter of main portal vein, splenic volume, the presence of gastroesophageal varices at risk of recurrence(GEV-R), and the amount of ascites. GEV-R was defined as the presence of esophageal varix and/or large gastric varix(>10mm) on CT. A LSM value and the fibrosis indices such as APRI and FIB-4 scores were also investigated. Recurrence free survival rate was calculated using Kaplan-Meier curve, and each parameter was evaluated using uni- and multivariate Cox proportion hazards regression analysis. For validation of model, we also performed the validation study with the patients who underwent RFA wihout the result of LSM during the same period(n=89).

RESULTS

During a median follow-up of 407 days, IDR was identified in 38.5% of the subject(30/78). On univariate analysis, tumor size, LSM, APRI score, and GEV-R were significantly associated with IDR. Subsequent multivariate analysis including all variables identified that tumor size and LSM were significant independent predictors of IDR. However, among the CT features only, GEV-R was significant independent predictor of IDR(HR=3.907; p=0.002) as well as tumor multiplicity(HR=2.790; p=0.030). On validation study, tumor multiplicity(HR=2.86; p=0.006) was the only significant independent predictor of IDR after RFA. GEV-R shows increased tendency of recurrence(HR=1.68; p=0.083).

CONCLUSION

GEV-R and tumor multiplicity on CT could be a non-invasive predictor of recurrence after RFA as well as LSM.

CLINICAL RELEVANCE/APPLICATION

Portal hypertension sign on CT scan, such as GEV-R, might be useful as non-invasive predictor for IDR after RFA for HCCs.

SSQ08-09 Quantitative Analysis of Diffusion-Weighted MRI and Contrast-Enhanced MRI for Estimating Histopathological Grade of Hepatocellular Carcinomas

Thursday, Nov. 30 11:50AM - 12:00PM Room: E353A

zhouwu787@126.com

PURPOSE

Diffusion-weighted MR images (DWI) and Contrast-enhanced MR images (CE-MR) have been reported to be helpful for estimating the histological differentiation of hepatocellular carcinoma (HCC). However, the clinical reverence of DWI and CE-MR for estimating histopathological grade of HCCs has not yet been comparatively assessed in a quantitative routine. The purpose of this study is to quantitatively assess the performance of the ADC value in DWI and the mean intensity value in arterial phase of CE-MR in estimating the grade of malignancy of HCC.

METHOD AND MATERIALS

Thirty-five pathologically confirmed HCC lesions from July 2012 to October 2015 were included in this retrospective study. Sixteen low grade tumor corresponds to Edmondson grade I and II, and nineteen high grade tumor corresponds to Edmondson grade III and IV. DWI and CE-MR were retrieved for each subject (Signa Excite HD 3.0T, GE Healthcare, Milwaukee, WI, USA) . Single-shot echo-planar DW imaging acquisitions were performed in the axial view with three b values (0,100,600 sec/mm2). ADC map was calculated by the mono-exponentially fitting model. The region of interest (ROI) extraction of HCCs in DWI and CE-MR was manually performed by an experienced radiologist (10 years of experience in abdominal radiology), using a free-form curve fitting technique. The performance of texture feature and ADC value in differentiating the biological aggressiveness of HCC was assessed using Receiver Operating Characteristic (ROC) analysis. $P<0.05$ was considered statistically significant.

RESULTS

Low grade HCCs showed a higher mean intensity value ($p=0.001$) and a comparable ADC ($p>0.05$), as compared with high grade HCCs. AUC, Accuracy, Sensitivity and Specificity were 0.714, 0.743, 0.688, and 0.789 for ADC in DWI, corresponding to 0.924, 0.914, 1.000, and 0.842 for the mean intensity value in CE-MR, respectively.

CONCLUSION

The Mean intensity of arterial phase images in CE-MR proves to be superior to the ADC value of DWI in the prediction of the histopathological grade of HCC.

CLINICAL RELEVANCE/APPLICATION

Our quantitative study indicates that the mean intensity in arterial phase of CE-MR is much better than the ADC value of current DWI in the performance of predicting the histopathological grade of HCC, which may aid clinical decisions and help with patient management in clinical practice.

ABSTRACT

LEARNING OBJECTIVES 1. To review the histological staging of liver fibrosis. 2. To discuss the classification of imaging-based techniques for assessment of liver fibrosis. 3. To highlight key unmet needs and potential future directions in liver fibrosis imaging. ABSTRACT Liver fibrosis is characterized by the accumulation of collagen and other extracellular matrix proteins as a result of repeated injury to the tissue due to chronic liver disease. In this keynote lecture, we will review challenges inherent to using liver biopsy for staging of liver fibrosis, including existence of numerous staging systems, sampling variability, and declining acceptance. We will provide a classification of imaging techniques implemented on US, CT, and MRI which evaluate changes in physical or physiological properties that accompany liver fibrosis. We will highlight key unmet needs in this field, including standardization of biomarkers across imaging systems, need for head-to-head comparison between techniques, and concomitant assessment of biological confounders (such as inflammation and steatosis).

SSQ09-02 Can "Simultaneous Multi-Angular Relaxometry of Tissue" and "Modified Look-Locker Inversion Recovery" T1 Mapping Magnetic Resonance Imaging Sequences Predict the Histopathologic Degree of Liver Fibrosis in Chronic Liver Disease?

PURPOSE

Determination of the severity of the chronic liver disease (CLD) has a great importance for the decision of the management plan and to predict the prognosis. In this study, we aimed to introduce new magnetic resonance imaging (MRI) sequences for T1 mapping, Modified Look-Locker Inversion Recovery (MOLLI) and Simultaneous Multi-Angular Relaxometry of Tissue (SMART) sequences to predict the degree of liver fibrosis in patients with histopathologically proven CLD.

METHOD AND MATERIALS

Ninety-one cases (51 CLD and 40 control group) were prospectively enrolled in the study, and an MRI of the liver was performed by using a 32-channel body coil with a 1.5T MRI scanner (MR 450w, GE, Chicago, USA). SMART and MOLLI sequences were acquired to create T1 maps. Following the MRI study, a percutaneous ultrasound-guided core biopsy was performed from the parenchyma of the liver to determine the histopathological grade of liver fibrosis in the patient group. T1 mapping values of the liver were measured separately by two different observers independently by using nine separate circular "region of interests" and compared with the histopathological fibrosis grades. Intraclass correlation coefficient (ICC) method was used to assess the variability on

SMART and MOLLI sequences statistically.

RESULTS

ICC for assessing T1 values of the liver on SMART and MOLLI MRI sequences were excellent, yielding 0.982 and 0.960, respectively. SMART and MOLLI values in patients with CLD were significantly higher than the control group ($p < 0.001$). SMART and MOLLI values were positively and significantly correlated with the grade of fibrosis (Table 1). Receiver operating curve analysis showed that SMART sequence was superior to MOLLI sequence for the determination of the grade of the fibrosis (Table 2). The difference between ROC analysis of SMART and MOLLI measurement of observers were statistically significant ($p = 0.042$ and $p= 0.003$).

CONCLUSION

Both SMART and MOLLI sequences can be used for predicting the liver fibrosis in patients with CLD. However, SMART sequence has better diagnostic performance and ICC when compared to MOLLI sequence values.

CLINICAL RELEVANCE/APPLICATION

SMART and MOLLI T1 mapping MRI sequences may have a role for the noninvasive determination of the degree of liver fibrosis which will improve the management plan.

SSQ09-03 Grading of Hepatic Fibrosis using Iodine Map of Spectral Liver CT

Thursday, Nov. 30 10:50AM - 11:00AM Room: E353C

Participants
Jeong Hee Yoon, MD, Seoul, Korea, Republic Of (*Presenter*) Grant, Bayer AG Speaker, General Electric Company Speaker, Koninklijke Philips NV Speaker, Bayer AG
Jeong Min Lee, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Grant, Bayer AG; Grant, General Electric Company; Grant, Koninklijke Philips NV; Grant, STARmed Co, Ltd; Grant, RF Medical Co, Ltd; Grant, Samsung Electronics Co, Ltd; Grant, Guerbet SA; Joon Koo Han, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To determine whether iodine map from spectral computed tomography (CT) is able to provide hepatic extracellular volume fractions (fECVs) for grading hepatic fibrosis (HF).

METHOD AND MATERIALS

A total of 57 patients (M:F=42:15, mean age, 54.3 ± 11.9 years) histologically diagnosed with HF underwent quadriphasic liver CT at the scanner with spectral detector (IQon, Philips Healthcare) at 120kVp. Delayed phase was obtained 3 minutes after standard dose of contrast media administration. On the generated iodine maps of iodine, approximately 0.8-1cm2 round regions of interest (ROIs) were drawn avoiding focal lesion and vessels in the liver, and aorta for calculating fECV as follows: fECV (%) = Iodine concentration liver (mg/ml*)/ Iodine concentration aorta (mg/ml*)x (100-Hematocrit [%]). Correlation between fECV and HF stage was evaluated using Spearman's correlation coefficient. fECVs, iodine concentration and effective Z were compared between F0-1 (n=7), F2-3 (n=17) and F4 (n=33), and between F0-3 and cirrhosis (F4).

RESULTS

fECVs showed a moderate correlation with pathologic HF staging ($r=0.55$, $P<0.0001$). fECV was higher in F4 than F2-3 (36.0±8.0% vs. 26.4±4.1, $P<0.01$) but there was no significant difference between F2-3 and F0-1 (28.8±3.7%, $P>0.05$). In comparison between F0-3 and F4, F4 showed significantly higher fECV than F0-3 (36.0±8.0% vs. 27.7±4.2%, $P<0.0001$). In addition, iodine density of the liver (mg/ml*) was significantly higher in F4 than F0-3 (1.87±0.28 vs. 1.63±0.33, $P=0.006$). Effective Z was also higher in F4 than F0-3 (8.42±0.16 vs. 8.31±0.20, $P=0.026$), but there was a substantial overlap of the values.

CONCLUSION

Iodine map of delayed phase from the spectral CT enables to estimate fECV and fECV increased as HF progressed and F4 showed significantly higher fECV than F0-3.

CLINICAL RELEVANCE/APPLICATION

Iodine map can be generated from single phase of routine exam at spectral CT, and it can provide quantitative information regarding HF, without additional contrast media use or scan acquisition.

SSQ09-04 Two-dimensional Shear Wave Elastography for Grading Liver Fibrosis using a Confidence Map: Are Liver Stiffness Measurements Accurate without Breath-holding?

Thursday, Nov. 30 11:00AM - 11:10AM Room: E353C

For information about this presentation, contact:

durot@stanford.edu

PURPOSE

Ultrasound elastography of the liver for grading liver fibrosis needs to be performed in a resting respiratory position as forceful inspiration or expiration can falsify values. However, in patients with comorbidities optimal breath-holding can be challenging despite coaching. The aim of this study was to assess whether liver stiffness measurements using two-dimensional (2D) shear wave

elastography (SWE) along with a novel confidence map yield similar results in patients with and without breath-holding.

METHOD AND MATERIALS

Liver stiffness measurements were performed in 25 consecutive patients with chronic liver disease (7 non-alcoholic fatty liver disease, 5 hepatitis B, 4 hepatitis C, 4 alcoholic cirrhosis, 2 hemochromatosis; 3 others) by using 2D SWE (prototype software ElastQ; EPIQ7; Philips). In the same imaging session and in each patient, two 6-sec cine loops were obtained each either in resting respiratory position or during free quiet breathing. For each data set, 10 circular regions of interest (ROI; 0.791cm2) were drawn at 2 cm below the liver capsule in the middle of the field of view. A confidence map that automatically highlights areas without breathing artifacts was used to guide ROI placements. The mean and median shear wave velocities obtained by the two methods were compared using the Bland-Altman methodology and concordance correlation.

RESULTS

In both groups, the median shear wave velocity was 1.23 m/s with a concordance correlation of 97% (95%CI; 94-98%) and Bland-Altmann 95% limits of agreement of -0.17 and 0.12. The mean velocity in the breath-hold group was 1.36 m/s and in the free-breathing group 1.34 m/s with a concordance correlation of 97% (95%CI: 94-99%) and Bland-Altmann 95% limits of agreement of -0.17 and 0.12.

CONCLUSION

In 2D SWE using a confidence map for ROI placements, liver stiffness measurements are comparable with and without breath-holding.

CLINICAL RELEVANCE/APPLICATION

The possibility of free breathing makes 2D SWE exams more robust and clinically practical, in particular in patients with difficulties holding their breath in a resting respiratory position.

SSQ09-05 A Prediction Model for Survival in Patients with Cirrhosis by Using Abdominal CT Findings: Compared with MELD Scoring System

Thursday, Nov. 30 11:10AM - 11:20AM Room: E353C

Participants
Ji Eun Lee, MD, Bucheon, Korea, Republic Of (*Presenter*) Nothing to Disclose
Woo Kyoung Jeong, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Young Kon Kim, MD, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Dongil Choi, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Won Jae Lee, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Model for End-stage Liver Disease (MELD) score was developed as a disease severity index for patients with liver cirrhosis (LC) awaiting liver transplantation. Although MELD score is known to be better than Child-Turcott-Pugh score for predicting survival, there are still some limitations. Imaging study contains important information of LC and portal hypertension, and there have been attempts to measure the related imaging parameters. We have tried to establish a new model with abdominal CT for prediction of survival in patients with LC and compare it with MELD score.

METHOD AND MATERIALS

145 patients diagnosed with LC and underwent abdominal CT were included retrospectively. Two radiologists measured the imaging parameters, such as maximum diameters of main portal vein (øMPV), superior mesenteric vein (øSMV), splenic vein (øSV), and estimated splenic volumes. The grade of esophageal, paraesophageal, gastric varices and amount of ascites were also evaluated. Statistically significant CT features related to overall survival were used to establish a model to calculate risk scoring system using multivariate Cox proportional hazard regression and validated this system with data (n=88) of another hospital. To compare the accuracy of two scoring systems, time-dependent C statistics was used.

RESULTS

øSMV/øSV, splenic volume, esophageal varices grade and amount of ascites were significant predictors of survival, and risk score was calculated by following formula: 0.79×øSMV/øSV + 0.001×splenic volume + 1.00×grade 1 esophageal varix(EV) + 0.57×grade 2EV + 1.32×grade 3EV + 1.45×moderate ascites + 2.16×large ascites - 2.07. Patients with same or higher risk scores than 1.74 had significantly poor overall survival rates ($p<0.001$), with median survival of 7 months. Also in validation set, patients with high risk scores (>= 1.74) had significantly poor overall survival rates ($p=0.02$). Time-dependent AUC showed MELD score was superior to imaging model for the first 20 months, but after 50 months, imaging model was better (c-index of imaging and MELD score, 0.768 and 0.735, respectively). Also, in validation set, imaging score was superior to MELD score after 20 months (c-statistics, 0.732 and 0.681, respectively).

CONCLUSION

In patients with LC, this imaging model may be useful in predicting long-term survival compared to MELD score.

CLINICAL RELEVANCE/APPLICATION

A prediction model with abdominal CT may be useful in predicting long-term survival in patients with LC.

SSQ09-06 Point Shear Wave Elastography for Grading Liver Fibrosis: Can the Number of Measurements be Reduced?

Thursday, Nov. 30 11:20AM - 11:30AM Room: E353C

For information about this presentation, contact:

durot@stanford.edu

PURPOSE

To assess whether the number of point shear wave elastography (pSWE) measurements of the liver could be reduced to 5 vs. the currently recommended 10 measurements in patients with chronic liver diseases.

METHOD AND MATERIALS

In 1412 patients with chronic liver disease (694 hepatitis B, 499 hepatitis C, 62 non-alcoholic fatty liver disease, 35 primary biliary cholangitis, 24 post liver transplantation, 18 autoimmune hepatitis, 15 alcoholic cirrhosis, 14 cardiac cirrhosis, 51 others) pSWE measurements were performed on a S2000 scanner (Siemens) following the protocol recommended by the Society of Radiologists in Ultrasound (SRU) with 10 consecutive valid measurements obtained in liver segment 8. Liver fibrosis grading using published cut-off values were compared using 10 vs. 5 measurements with Kendall's tau coefficient and the exact test of symmetry.

RESULTS

The median shear wave velocities using 5 measurements was 1.27 m/s compared to 1.26 m/s using 10 measurements. Overall fibrosis grading highly correlated when using 5 vs. 10 measurements (tau=0.96; P<0.001). Similarly, there was high correlation when grading clinically significant (>= F2) vs. non-significant (F0/1) fibrosis (tau=0.95; P<0.001). A change in grading was observed in 34/1412 patients (2.4%; 95%CI; 1.7-3.3%) of exams when classifying clinically significant from non-significant fibrosis. Changes in grading occurred primarily when velocities ranged between 1.1 and 1.5 m/s. When the median values from 5 measurements were either <1.1 or >1.5 m/s (in 794 patients; 56%), a change of grading was observed in 0/1412 measurements (0%; 95%CI; 0-0.4%).

CONCLUSION

Clinically significant changes in grading liver fibrosis using only 5 measurements was observed in only a small portion of patients. In patients with known F0 or F4 fibrosis, 5 measurements may be sufficient on surveillance ultrasound elastography exams.

CLINICAL RELEVANCE/APPLICATION

Five instead of 10 measurements may decrease scanning time, cost, and discomfort in both sonographers and patients.

SSQ09-07 Novel Mapping of Fibrosis and Hepatic Inflammation in NASH Patients with Dual R2 MRI Relaxometry

Thursday, Nov. 30 11:30AM - 11:40AM Room: E353C

hilton.filho@hc.fm.usp.br

PURPOSE

Hepatic inflammation and fibrosis are two of the most important factors for the stratification, treatment and prognosis of patients with liver disease. Our objective is to evaluate a MRI multi-component relaxometry (MCR) technique to map fibrosis and inflammation in patients with non-alcoholic steatohepatitis (NASH). The extracellular water fraction (ECWF) was investigated for fibrosis, and the ratio of the transverse relaxation rate (R2) between intra and extra-cellular water (R2I/E) was assessed for inflammation.

METHOD AND MATERIALS

101 NASH diagnosed patients with liver biopsy were selected within 6 months for MRI exam. A 3T Philips Achieva was used with a multi-spin echo sequence. The images were analysed by a radiologist and physicist with over 12 years experience in abdominal imaging. The biopsies were reviewed by a pathologist with 14 years experience using the NASH-CRN score. 15 volunteers with normal lab results and no known liver disease were used for control.

RESULTS

The mean ECWF for the 101 NASH patients was 24.5(±3.1)% and 18.7(±1.6)% for the 15 volunteers. There was a significant correlation between ECWF and fibrosis stage (rs=0.83, p<1.0-06). In distinguishing healthy from fibrotic patients we achieved an AUROC of 0.98, with a sensitivity of 93% and specificity of 94% for a threshold ECWF of 20.6%. There was a significant difference between all stages of fibrosis by ECWF (p<0.001).The mean R2I/E for the 101 NASH patients was 3.2(±0.6) and 2.4(±0.3) for the 15 volunteers. For distinction of normal parenchyma from any lobular inflammation we achieved an AUROC of 0.91, with sensitivity of 83% and specificity of 83% at an R2I/E threshold of 2.7.

CONCLUSION

ECWF demonstrated very good performance in quantifying all stages of fibrosis, whereas R2I/E correlated more strongly with inflammation. The maps and distributions of ECWF and R2I/E also allow assessment of heterogeneity in liver pathology.

CLINICAL RELEVANCE/APPLICATION

The excellent performance of MRI ECWF in quantifying the earliest stage of NASH promises better selection of patients for biopsy.

Assessing inflammation with R2I/E offers an additional tool for patient selection. ECWF and R2I/E offer biomarkers of liver fibrosis and inflammation that are independent of field strength, are obtained without contrast or radiation, and help in the diagnostic and follow-up of NASH patients.

SSQ09-08 Reversibility of HCV-Related Liver Disease and Sustained Virology Response after Interferon-Free Antiviral Therapy

PURPOSE

The aim of this study was to assess:the evolution of hepatitis C-related liver disease by comparing analytical and elastography data before and after treatment with new antiviral agents.

METHOD AND MATERIALS

For this prospective study, we conducted a:randomized sampling of patients with hepatitis C virus (HCV) who had completed treatment with new drugs between May 2015 and March 2016. It was required that all patients included had undergone blood tests, viral load, liver B-mode ultrasonography and ARFI elastography with the determination of shear wave velocity (SWV) before starting treatment. These tests were repeated after a year of the completion of treatment for comparing results. The criteria for exclusion were as follows: coinfection with other hepatitis viruses or human immunodeficiency virus, liver transplant, alpha-1 antitrypsin deficit, metal deposition diseases and alcohol consumption of greater than 20g/day. Finally, we obtained 100 patients. Comparisons of means were performed using Student t-test for matching data. A p value of <0.05 was considered significant.

RESULTS

It was verified:a significant decrease of liver ARFI values since the average shear wave velocity declined from 1.98 to 1.66 m/s ($p<0.01$), which meant an improvement of liver parenchymal injury associated to HCV.Furthermore, it was determined reversibility in METAVIR stages, specially in F>=3 and F>=4 levels, in which more than half of patients improved their METAVIR stage after treatment ($p<0.05$).Moreover, sustained viral response was confirmed in all patients as well as an improvement of analytical data with hepatic profile (Alanine aminotransferase- ALT-, Aspartate aminotransferase -ALT-) ($p<0.05$).:

CONCLUSION

It has been verified a significant improvement of analytical and structural liver parameters in patients with HCV-related hepatic fibrosis who underwent treatment with interferon-free antiviral therapies.

CLINICAL RELEVANCE/APPLICATION

Reversibility of liver stifness after treatment might be monitored with ARFI elastography and it is essential for prognosis and management of these patients.

SSQ09-09 A Deep Convolutional Neural Network for the Prediction of METAVIR Score Using B-Mode Ultrasonography Images

Thursday, Nov. 30 11:50AM - 12:00PM Room: E353C

sig.jhl@gmail.com

PURPOSE

Liver fibrosis is one of the most important prognostic factors in patients with chronic liver disease. We developed a deep convolutional neural network (CNN) for the prediction of METAVIR score using B-mode ultrasonography (US) images.

METHOD AND MATERIALS

Among 7,273 patients with 140,605 B-mode US images, who had undergone either histopathologic examination or transient elastography, 2,798 patients with 5,517 B-mode US images were used for training the CNN. METAVIR score of the specimens, determined by pathologists specializing in liver pathology, and estimated METAVIR score derived from transient elastography were used as reference standards. Our training model (S-Detect for liver quantification) was based on the Visual Geometry Group-16 neural network with image appearance normalization technique. Two-class (F0, F1, F2, F3 vs. F4) and four-class (F0 vs. F1 vs. F23 vs. F4) models were developed. After training, 675 patients' images were tested to evaluate the models' performance in classifying the images to the correct METAVIR score.

RESULTS

Performance of the two-class model was as follows: sensitivity 81.6%, specificity 96.4%, and accuracy 88.3%. Performance of the four-class algorithm was as follows: sensitivity 64.5%, specificity 89.0%, and accuracy 72.7%. The expected METAVIR score was

displayed in the application within 2 seconds of analysis on average.

CONCLUSION

The engineered deep CNN-based METAVIR score prediction system revealed remarkable diagnostic accuracy using B-mode US images.

CLINICAL RELEVANCE/APPLICATION

This technology can assist radiologists in identifying the degree of liver fibrosis in a convenient fashion, leading to reduction in time and labor costs, while also providing a means for objective evaluation of liver fibrosis.

sunhz@sj-hospital.org

PURPOSE

The present study aimed to evaluate the clinical value of PET/MR in the staging of cervical cancer and diagnosis of pelvic lymph node metastasis.

METHOD AND MATERIALS

Seventy patients with cervical cancer were prospectively enrolled. Pelvic PET/MR scan and whole-body PET scan were performed before treatment. All images were evaluated by two experienced radiologists using a randomized, double-blind method. The diagnostic consistency of PET/MR staging, clinical staging, and gold standard staging of cervical cancer was evaluated with the Kappa consistency test, and the diagnostic consistency between each two methods was calculated. The difference between PET/MR staging and clinical staging was evaluated with the paired chi-square test ($P<0.05$). The value of PET/MR in the diagnosis of pelvic lymph node metastasis of cervical cancer was analyzed using diagnostic consistent rate, sensitivity, specificity, positive predictive value, and negative predictive value. The statistical software SPSS 19.0 was used in the analyses.

RESULTS

The consistency between PET/MR staging and the gold standard method for the diagnosis of cervical cancer was 91.43%. Kappa analysis indicated that the consistency between PET/MR staging and gold standard staging was satisfactory (kappa = 0.908). The consistency between clinical staging and gold standard staging of cervical cancer was fair (Kappa = 0.542). There was a significant difference between pre-treatment PET/MR staging and clinical staging ($X2 = 9.278$, $P<0.05$). In the patient-based analysis, the accuracy of PET/MR diagnosis of pelvic lymph node metastasis was 95.71%, sensitivity was 95.65%, and specificity was 95.74%. In the lymph node-based analysis, the accuracy, sensitivity, and specificity of PET/MR diagnosis were 97.61%, 92.16%, and 98.13%, respectively.

CONCLUSION

The diagnostic value of PET/MR for the staging of cervical cancer is significantly superior to clinical staging, and the former can be used as a one-stop diagnostic method for cervical cancer by accurately diagnosing and identifying pelvic lymph node metastasis.

CLINICAL RELEVANCE/APPLICATION

PET/MR without gadolinium administration will stage cervical cancer and identify pelvic lymph node metastasis accurately, and is strongly recommended as a one-stop diagnostic method in cervical cancer.

SSQ10-03 How to Differentiate Benign Atypical Myomas from Malignant Uterine Sarcomas Using MR Imaging

PURPOSE

To retrospectively evaluate MRI charateristics to differentiate malignant uterine sarcomas from benign myomas with atypical presentation on MRI.

METHOD AND MATERIALS

IRB-approved monocentric case-control study including 113 women (51 sarcomas and 62 atypical myomas) with an atypical uterine mass on MRI were underwent before surgery. Clinical and MRI data (heterogeneity on T2-weighted and diffusion sequences, ADC and perfusion curves relative to outer myometrium) were collected and compared with pathological findings.

RESULTS

Only 50% of sarcomas presented as a single uterine mass. Predictive criterias for malignancy were age (64 vs 48 years, p <0.0001), menopausal status (84% vs 20%, p <0.0001, OR = 20.82), irregular contours (73% vs 5%, p <0.0001; OR = 46.69), intra-tumoral hemorrhage (38% vs 13%, p = 0.003), high signal greater than the endometrium on DWI (100% vs 16%, p <0.0001 OR = 12.01), ADC (0.7 vs 1, 2.10-3 mm^2 / s, p <0.0001). Conversely, the presence of a portion, even partial, with low T2 signal or a type I perfusion curve had a VPN of 100% (p <0.0001).

CONCLUSION

Beyond the previously known clinical and morphologic criteria, adding functional sequences on MRI better differentiates malignant sarcomas from atypical myomas.

CLINICAL RELEVANCE/APPLICATION

Diffusion and perfusion MRI sequences may allow better predicting malignancy when facing an atypical uterine mass, to guide optimal therapeutic management.

SSQ10-05 Accuracy of Time Intensity Curves Generated From 4-Point DCE MRI in Differentiating Benign and Malignant Adnexal Lesions

PURPOSE

To assess the accuracy of time intensity curves (TIC) generated from 4-point dynamic contrast-enhanced magnetic resonance imaging (DCE MRI) in differentiating benign and malignant ovarian lesions with solid tissue.

METHOD AND MATERIALS

Patient consent was waived by the Ethics Review Board for this retrospective study. From April 2006 to January 2017, 98 patients with ovarian DCE MRI studies with evidence of solid tissue at MRI were included (45 benign, 10 borderline and 43 malignant lesions). Semiquantitative analysis of signal intensity (SI) over time curves was performed using region-of-interest on the most enhancing solid tissue. TICs were classified according to three patterns of enhancement: a minimal increase with no well-defined shoulder "type 1, benign." A moderate initial rise in the SI of solid tissue relative to myometrium "type 2, borderline." An initial rise in the SI of solid tissue that was equal or steeper than myometrium "type 3, malignant". In patients with hysterectomy (n=11), the lesion SI was normalized to psoas and compared to a standard normalized myometrium curve. Standard of reference was histopathology in all patients.

RESULTS

Accuracy, sensitivity, specificity, PPV, and NPV of TIC for differentiating benign from malignant/borderline lesions was 85.9%, 96.2%, 74.5%, 80.6% and 94.6% respectively. TIC yielded comparable results to prospective clinical radiological diagnosis using standard morphological assessments (acc 85.7%, sens 93.9%, spec 80.0%, PPV 76.7%, NPV 94.9%). However, out of the 12 misdiagnosed patients during the clinical reads, (2 false negatives, 10 false positives), TIC was able to accurately reclassify 6 of them, resulting in an overall acc 93.9%, sens 100%, spec 87.5%, PPV 89.3%, NPV 100%.

CONCLUSION

The enhancement patterns of ovarian lesions on 4-point DCE MRI can help distinguish between benign and borderline/malignant tumors. Although pharmacokinetic parameters have been proposed by research-based groups, they have not been widely adopted or validated in the clinic. TIC based on 4-point DCE MRI can be a useful adjunct to standard qualitative morphological reads, with

the potential to improve diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

Time intensity contrast-enhanced curves generated from 4-point DCE MRI are a useful adjunct to standard morphological imaging and can improve the accuracy for discriminating between benign and malignant ovarian lesions.

SSQ10-06 Amide Proton Transfer Imaging of Early Radiotherapy Response in High-Risk HPV+ Gynecologic Cancer

avenkatesan@mdanderson.org

PURPOSE

HPV-associated gynecologic cancers are treated primarily with radiation, with cervical cancer being the most common cancer among women in the developing world. Anatomical MRI can be challenging to interpret following radiation when the morphological appearance of residual or early recurrent tumor tissue mimics post-radiotherapy inflammation and/or fibrosis. Amide proton transfer (APT) MRI, a subset of chemical exchange saturation transfer (CEST) MRI, has the potential to provide molecular information regarding tissue pH and mobile protein content, which may be beneficial in distinguishing radiation necrosis from recurrent disease. Necrotic lesions should demonstrate less cytosolic protein and peptide content as a result of the loss of cytoplasm compared to viable tumor tissue. We investigated the prognostic value of APT MRI following radiothearpy in a murine model of high risk HPV+ cervical cancer.

METHOD AND MATERIALS

A clinically relevant HPV+ orthotopic cervical cancer model was developed that expresses the E6 and E7 oncogenes of HPV-16 and the Ras oncogene. 4 animals received 9 Gy radiation and were imaged on days -1 and +1. A CEST-RARE pulse sequence was used with a 3 second saturation period consisting of a 2.0 uT continuous wave saturation pulse. 40 saturation frequencies between +5 and -5 ppm were acquired to generate a CEST spectrum in 8 minutes on a 7T Bruker MRI (Bruker Corporation, Billerica MA). Pixelwise analyses of magnetization transfer asymmetry (MTRasym) was performed to measure mobile protein content.

RESULTS

Preliminary results show that MTRasym measurements decreased the day after radiation treatment indicating a decrease in mobile protein content. This result supports the hypothesis that necrotic lesions have less cytosolic protein content than viable tumor, which can be detected with APT MRI.

CONCLUSION

Initial results indicate that as early as one day after radiation treatment, APT MRI can be used to distinguish necrotic tissue vs. viable tumor through a decrease in MTRasym. Additional mice will be imaged to confirm this trend and determine statistical significance.

CLINICAL RELEVANCE/APPLICATION

These findings may be beneficial to clinicians in identifying a new functional MRI technique to monitor early radiotherapy response of HPV+ gynecologic cancers.

SSQ10-07 Preoperative Tumor Texture Analysis from MRI Predicts High-Risk Status and Reduced Survival in Endometrial Carcinomas

PURPOSE

Tumor heterogeneity is a key feature of malignant disease. Heterogeneity at MRI can be quantified by texture analysis. We aimed to explore whether high-risk clinical and histological features in endometrial cancer are reflected in tumor texture parameters from preoperative MRI, and to assess the prognostic value of tumor texture parameters.

METHOD AND MATERIALS

Preoperative pelvic MRI (1.5T) including contrast-enhanced (CE) T1-weighted, T2-weighted and diffusion-weighted imaging was

Preoperative pelvic MRI (1.5T) including contrast-enhanced (CE) T1-weighted, T2-weighted and diffusion-weighted imaging was performed in 180 patients with histologically confirmed endometrial carcinomas. Using the software TexRAD, tumor regions of interest (ROIs) were manually drawn on the slice displaying the largest cross-section tumor area. Histogram based texture parameters (standard deviation, entropy, mean of positive pixels (Mpp), skewness and kurtosis) were calculated from these tumor ROIs on non-filtered and filtered images. The derived texture parameters were included in multivariate logistic regression models assessing their predictive value for identifying high tumor grade, deep myometrial invasion (DMI), cervical stroma invasion (CSI) and lymph node metastases. Preoperative histological risk from biopsy, conventional MRI findings and MRI-measured tumor volume were included as covariates, and the best cutoff values of texture parameters were determined by ROC curve analysis. Multivariate Cox regression was used for survival analysis.

RESULTS

High entropy in ADC-maps independently predicted DMI (OR 5.1, p=0.001), low Mpp in T2 images independently predicted CSI (OR 3.5, p=0.01) and high Mpp in CE T1 images independently predicted high grade (OR 3.5, p=0.005). High kurtosis in CE T1 images independently predicted reduced recurrence- and progression-free survival (HR 1.5, p<0.001). Different levels of filtration, including no filtration, were represented among the high ranked texture parameters.

CONCLUSION

MRI derived tumor texture parameters, reflecting tumor heterogeneity, independently predict high tumor grade, deep myometrial invasion, cervical stroma invasion and reduced survival in endometrial carcinomas. Thus, tumor texture parameters based on MRI represent promising biomarkers to aid preoperative tumor characterization for risk stratified surgical treatment.

CLINICAL RELEVANCE/APPLICATION

Tumor texture features at MRI are associated with high-risk phenotype and may aid preoperative risk classification for stratified surgery in endometrial cancer.

SSQ10-09 Machine Learning to Differentiate Uterine Sarcoma from Leiomyoma with High Signal Intensity on T2-Weighted Imaging Based on Multi-Parametric Magnetic Resonance Quantitative Imaging Features

PURPOSE

To determine whether a prediction model using machine learning based on quantitative multi-parametric magnetic resonance imaging (MRI) features has adequate diagnostic performance for differentiating uterine sarcomas from benign leiomyomas with high signal intensity on T2-weighted imaging (T2WI).

METHOD AND MATERIALS

This retrospective study was approved by the institutional review board. The need for informed consent was waived. We included 62 patients who underwent pelvic 3T MRI examination for evaluation of uterine myometrial smooth muscle masses with high signal intensity on T2WI. Of the 62 patients, 38 had benign leiomyoma and 24 had uterine sarcoma. Age, tumor size, and 12 histogram and texture parameters (minimum, mean, standard deviation of, and maximum normalized signal; skewness; kurtosis; homogeneity; energy; contrast; correlation; entropy; and dissimilarity) were assessed on T1WI, T2WI, ADC maps, and contrast-enhanced T1WI. We developed a prediction model with machine learning (extreme gradient boosting) and calculated the area under the receiver operating characteristic curve (AUC) of this model by 10-fold cross validation, and compared the performance of this model with two board-certified radiologists.

RESULTS

Age had the highest importance (myoma, 43.8±9.9; sarcoma, 59.2±15.5; p=0.0001), followed by the minimum normalized T2 signal (myoma, 0.35±0.45; sarcoma, 0.82±0.54; p=0.0009), ADC skewness (myoma, 0.33±0.85; sarcoma, 0.86±0.89; p=0.0237), mean ADC (myoma, 1.56±0.40; sarcoma, 1.29±0.33; p=0.0057), and T2WI correlation (myoma, 0.86±0.08; sarcoma, 0.91±0.04; p=0.0041). In the validation analysis, the AUC of the machine learning is significantly higher than two radiologists (0.92 vs. 0.75 and 0.64, respectively; p<0.001).

CONCLUSION

Age was the most important factor for differentiation of uterine sarcoma from myoma with high-signal intensity on T2WI. The performance of machine learning was superior to that of experienced radiologists.

CLINICAL RELEVANCE/APPLICATION

Machine learning based on patient age and the texture of multi-parametric MRI has adequate diagnostic performance for differentiating uterine sarcoma from myoma with high signal intensity on T2WI.

PURPOSE

Several open-source texture analysis software packages have recently been developed to address the increased need for quantitative image analysis. This study quantifies the variation in these features due to differences in algorithm implementation.

METHOD AND MATERIALS

Forty regions of interest (ROI) were extracted from digital mammography scans of 39 patients, and 39 ROIs were extracted from head and neck (HN) computed tomography (CT) scans of 39 patients. Mammography ROIs (256 x 256) contained normal breast parenchyma while each HN ROI (174 to 2819 total pixels) contained a manually delineated tumor. Two in-house software packages and two open-source packages (MaZda and IBEX) were used to calculate 6 first-order features (max, min, mean, standard deviation, skewness, kurtosis) and 4 gray-level co-occurrence matrix (GLCM) features (contrast, entropy, difference entropy, sum average) in each ROI. GLCM parameters (gray-level limits, binning, directionality) were modified to provide the greatest consistency across packages. The mean and standard deviation of each feature value across all ROIs were calculated. Non-parametric tests were used to compare feature pairs of corresponding features across software, and significance was determined using $p<0.001$ to correct for multiple comparisons.

RESULTS

For the mammography and HN cases, first-order features agreed to within 1.13±0.10% and 2.49±0.24%, respectively, except for kurtosis, which varied by 101±20% and 71.0±30.7%. Kurtosis was the only first-order feature to show statistically significant differences among the packages. The means of all second-order features differed significantly among all four packages by up to one order of magnitude and two orders of magnitude for the mammography and HN cases, respectively. Possible reasons for the increased differences in feature values for the HN cases include the reduced range in pixel values in the tumor and the non-rectangular ROIs, which warrant further investigation.

CONCLUSION

The large variation in calculated texture values among software packages as well as anatomic sites indicates that analysis should be customized to accommodate the imaging modality and clinical task of interest.

CLINICAL RELEVANCE/APPLICATION

Many research institutions have used open-source texture analysis software in a one-size-fits-all approach without considering the variations in the texture algorithms or their implementation.

PURPOSE

The Thyroid Imaging, Reporting and Data System (TIRADS) is designed to improve ultrasound characterization of thyroid nodules for effective clinical management of malignancy risk. The ACR TIRADS white paper identified six features for nodule categorization with diagnostic merit: composition, echogenicity, shape, size, margins, and echogenic foci. In this study, we present and validate method to quantify the echogenicity of solid nodules in order to predict malignancy risk.

METHOD AND MATERIALS

We evaluated 35 biopsy-proven malignant and 34 biopsy-proven benign solid thyroid nodules from thyroid ultrasound exams from 2013 to 2016. The nodules were segmented and the mean intensity of each nodule was calculated by averaging the mean intensities of representative sections in both the sagittal and transverse planes. The mean intensity of a sample of background thyroid parenchyma adjacent to each nodule was also obtained. A ratio was calculated between nodule intensity and adjacent thyroid parenchyma intensity. The resulting means were compared using a t test and the agreement between transverse and sagittal ratios was assessed with Bland Altman analysis.

RESULTS

The mean ratio of malignant nodule intensity to background thyroid intensity was 0.73. The mean ratio of benign nodule intensity to background thyroid intensity was 0.86. Two-tailed t-test demonstrated significance with a P value of 0.0015. Bland Altman demonstrated good agreement between sagittal and transverse ratios.

CONCLUSION

A ratio of thyroid nodule intensity to background thyroid parenchymal intensity is a useful predictor of malignancy in solid nodules, and calculating this ratio at the workstation may aid in accurate assessment of echogenicity.

CLINICAL RELEVANCE/APPLICATION

Quantification of solid thyroid nodule intensity at the workstation can help predict malignancy risk.

SSQ11-03 Diagnostic Accuracy of Radiomics-based Hepatic Venous Pressure Gradient for Clinically Significant Portal Hypertension

PURPOSE

To investigate whether a radiomics-based hepatic venous pressure gradient (rHVPG) could be as accurate as the direct HVPG measurement in diagnosing clinically significant portal hypertension (CSPH).

METHOD AND MATERIALS

A training cohort of patients with portal hypertension (n = 71) was retrospectively recruited in 3 high-volume liver centers in China between August 2016 and March 2017. Computed tomography (CT) images were analyzed for radiomic features extraction. A LASSO regression model was used for data dimension reduction, feature selection, and radiomics signature building. Besides, a predictive model, which combined the radiomic signatures, liver volume and spleen volume, was developed using the two-class logistic regression analysis. To assess the diagnostic performance of rHVPG for CSPH with the invasive HVPG measurement as reference standard, receiver operating characteristic (ROC) curves were constructed. A validation was conducted on another cohort consisting of 12 patients with portal hypertension.

RESULTS

A total number of 10324 imaging features were extracted [Figure 1A, 1B]. A radiomics signature that consisted of 34 selected features, was highly correlated to the presence of CSPH (P < 0.001 for both training and validation cohorts). The predictive model containing variables of radiomics signature, liver volume and spleen volume [Figure 1C], demonstrated high accuracy with an area under ROC curve (AUC) of 1.000 (1.000-1.000). Additionally, the model provided an excellent prediction in the validation cohort with an AUC of 0.778 (0.512-1.000).

SSQ11-04 Investigation of Arterial Enhancement Fraction (AEF) In Functional Imaging of Hepatocellular Carcinoma (HCC) and Its Correlation with Alpha-Fetoprotein (AFP)

maoxn@sj-hospital.org

PURPOSE

To investigate the correlations between AEF and AFP and to discuss the clinical application value of AEF in the functional imaging of HCC.

METHOD AND MATERIALS

IRB approval was secured for this prospective study with informed consent obtained. 25 patients with pathologically proved HCC who underwent tri-phasic contrast-enhanced CT exam between May 2015 and September 2016 were enrolled(21 males and 4 females, 46y~68y), and divided into "Positive" (P) and "Negative" (N)group based on AFP levels (P group: AFP>200ng/ml). All scans were performed on a 128 row multi-detector CT (iCT 256, Philips) with following parameters: tube voltage 100kVp, automatic tube current modulation, pitch 0.993, rotation time 0.5s, collimation 128×0.635, FOV 350×350mm, slice thickness 3mm. Tri-phasic enhanced CT was acquired with 1.2ml/kg body weight of Iodixanol (Visipague 270, GE Healthcare, Ireland) injection at a rate of 4.5ml/s, followed by 20ml saline flush. On the basic of unenhanced, arterial, portal venous and delay phases of CT images, AEF color map was obtained with CT-Kinetics software (GE Healthcare), the corresponding texture features were automatically generated after the regions of interest (ROIs) defined by two 11-year experienced radiologists. Mann Whitney U test and boxplot were used to compare the difference between P and N group. Spearman correlation test and linear regression were applied to evaluate the correlation between texture features with AFP.

RESULTS

Significant differences(P<0.05) were found between two groups in several parameters, including StdDeviation, Variance, Uniformity, Inertia, Cluster Prominence and Haralick Correlation with 0.080 vs 0.147, 0.007 vs 0.023, 0.855 vs 0.750, 3.715 vs 8.373, 3.808 vs 21.530, and 56.210 vs 122.500 in N and P group, respectively. While mean value of AEF showed no statistical difference(P=0.22). All above parameters had significant correlations with AFP (stdDeviance was taken for an example shown in Figure 1).

CONCLUSION

AEF texture features reflected the distribution of HCC's blood supply, which had strong correlation with AFP level, and would be regarded as an option to predict the biological activity of HCC.

CLINICAL RELEVANCE/APPLICATION

AEF texture analysis method which combined morphological with functional imaging without additional invasive procedure or radiation exposure, could promisingly reflect pathological AFP level and provide more scientific basis efficiently for clinicians.

SSQ11-05 A Size-independent Radiomics Model for Classification of Indeterminate Pulmonary Nodules Seen at CT

PURPOSE

While radiomic signatures to classify lung nodules as malignant or benign exist, an effective classifier that is independent of size features has not been established. We hypothesized that we could derive a parsimonious set of radiomic features useful for classification independent of nodule size.

METHOD AND MATERIALS

96 Nodules (33 benign; 63 malignant) in CT scans of patients (70 M; 26 F; mean age = 67, range = 47-85) from our institution were considered for this study. Inclusion criteria were: confirmed tissue diagnosis and nodule size of 4-30 mm. Patients with screen-detected nodules, ground glass opacities, metastatic lung nodules, contrast-enhanced scans or scans with slice thickness > 3 mm were excluded. Segmentations were created in the Definiens Developer XD™ environment, followed by generation of 222 radiomic features per nodule characterizing tumor size, shape, location, intensity and texture. We built two linear classifiers, one using the full set of radiomic features, and one excluding 13 size-related features, using a sparse linear regression technique (LASSO) and cross-validation.

RESULTS

Mean nodule size was 18 mm (interquartile range [IQR] 11-23 mm), 22 mm (IQR 17-26 mm) and 14 mm (IQR 9-15 mm) for all 96, with 63 malignant, and 33 benign nodules, respectively. Upper lobe nodules constituted 29% and 6% of malignant and benign nodules respectively. 19% of malignant nodules had a spiculated margin compared to 9% of benign nodules. For both models developed, two texture features were most frequently selected by LASSO, indicating the importance of nodule texture as a predictor. The size-independent classifier had an Area Under the ROC Curve (AUC) of 0.812 (Confidence Interval (CI)=0.73-0.91), while including size features added only a modest improvement (AUC: 0.838 (CI=0.755-0.92)). In contrast, a clinical risk calculator consisting of age, smoking status, nodule size and location gave inferior performance (AUC: 0.524 (CI=0.4-0.65)).

CONCLUSION

Texture features were most informative for differentiating between benign and malignant pulmonary nodules, independent of clinical information and size-based features.

CLINICAL RELEVANCE/APPLICATION

Size-independent radiomic-based models have the potential to separate benign from malignant nodules when nodule sizes are similar.

SSQ11-06 Comparison of RECIST 1.1, irRC, irRECIST and WHO Criteria in Patients with Renal Cell Cancer Receiving Immune Therapy

Thursday, Nov. 30 11:20AM - 11:30AM Room: S403A

Participants
Sukhbir Kaur, Stanford, CA (*Presenter*) Nothing to Disclose
Sandhya Srinivas, MD, Stanford, CA (*Abstract Co-Author*) Nothing to Disclose
Alice Fan, Stanford, CA (*Abstract Co-Author*) Nothing to Disclose
Viola Chen, Stanford, CA (*Abstract Co-Author*) Nothing to Disclose
Lijia Xie, Stanford, CA (*Abstract Co-Author*) Nothing to Disclose
Hans-Christoph R. Becker, MD, PhD, Stanford, CA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

While tumor response assessment by WHO and RECIST 1.1 have been broadly used to predict the outcome of patients under conventional chemotherapy, alternative criteria such as irRC and irRECIST have been designed to consider the specific response patterns of certain tumor entities treated with immunotherapy such as pseudo-progression and tumor flare. Therefore, this study aims to determine the difference between these criteria in a selected cohort of 32 patients with renal cell cancer treated with immunotherapy.

METHOD AND MATERIALS

MINT Lesion software (Mint Medical GmbH, Dossenheim, Germany) was used to assess tumor response in all cases. A total of 141 image studies were evaluated using the 4 response criteria. The software produced an assessment of Complete Response (CR), Partial Response (PR), Stable Disease (SD)/No Change (NC) or Progressive Disease (PD) for each image study. Cohen's unweighted kappa statistic was used to evaluate agreement between criteria assessments.

RESULTS

Comparison of irRC and WHO (kappa=0.6948, 95% CI: 0.5999-0.7897) showed substantial agreement and comparison of RECIST 1.1 and irRECIST criteria showed almost perfect agreement (kappa=0.8917, 95% CI: 0.8303-0.9531). In 20 cases irRC produced an assessment of SD when WHO produced an assessment of PD. In 11 cases irRC produced an assessment of PR when WHO produced an assessment of PD. Additionally, there were 5 cases where irRECIST produced an assessment of SD when RECIST 1.1 produced PD and 6 cases where irRECIST produced PR when RECIST 1.1 produced PD. Application of irRECIST produced the least number of cases assessed as PD (n=32), followed by RECIST and irRC (n=43) and WHO (n=74).

CONCLUSION

This study found variation between all criteria, especially regarding assessment of progressive disease. irRECIST led to the fewest assessments of PD, likely because these criteria best consider the phenomenon of tumor flare and pseudo-progression that has been observed under immunotherapy. Further studies are needed to confirm if irRECIST also best predicts clinical outcome.

CLINICAL RELEVANCE/APPLICATION

Since our study has shown that irRECIST criteria best consider pseudo-progression and flare of RCC under immunotherapy, they may be best suited to follow these patients.

SSQ11-07 Radiomics of Multi-parametric MRI for Pre-treatment Prediction of Progression-Free Survival in Advanced Nasopharyngeal Carcinoma

Thursday, Nov. 30 11:30AM - 11:40AM Room: S403A

Participants
Bin Zhang, MD , Guangzhou, China (*Presenter*) Nothing to Disclose
Shui Xing Zhang Sr, MD, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

xld_Jane_Eyre@126.com

PURPOSE

This study aimed to identify MRI-based radiomics for the pre-treatment prediction of progression-free survival (PFS) in patients with advanced nasopharyngeal carcinoma (NPC) (stage III-IVb) .

METHOD AND MATERIALS

One-hundred and eighteen patients (training cohort: n = 88; validation cohort: n = 30) with advanced NPC were enrolled. A total of 970 radiomics features were extracted from T2-weighted (T2-w) and contrast-enhanced T1-weighted (CET1-w) MRI. Least absolute shrinkage and selection operator (LASSO) regression was applied to select features for progression-free survival (PFS) nomograms. Nomogram discrimination and calibration were evaluated. Associations between radiomics features and clinical data were investigated using heat maps.

RESULTS

Eight MRI-based radiomics signature that significantly associated with PFS was identified from 970 features. The prognostic value of radiomics signature derived from joint CET1-w and T2-w images performed better than that from CET1-w or T2-w images alone. The TNM staging system yielded a C-index of 0.514 (95%CI: 0.432 to 0.596).The radiomics nomogram integrated radiomics signature from joint CET1-w and T2-w images with the TNM staging system showed a significant improvement of the TNM staging system in predicting PFS in the training cohort (C-index, 0.761 vs 0.514; $p < 2.68 \times 10\text{-}9$). The clinical nomogram yielded a C-index of 0.649 (95%CI: 0.552 to 0.746). The radiomics nomogram integrated radiomics signature with clinical data outperformed the clinical nomogram (C-index, 0.776 vs 0.649; $p < 1.60 \times 10\text{-}7$). The calibration curves showed the good agreements between nomogram-predicted and actual survival. These results were further confirmed in the validation cohort. Radiomics heatmaps suggested associations between radiomics features with tumor stages.

CONCLUSION

Multiparametric MRI-based radiomics nomogram shows more accurate than the traditional TNM staging system and clinical nomogram in predicting individualized PFS in advanced NPC, which epitomizes the pursuit of precision medicine and may affect patient treatment strategy.

CLINICAL RELEVANCE/APPLICATION

This present study developed and validated multi-parametric MRI- based radiomics as a convenient approach to predict individual PFS pre-treatment in patients with advanced NPC.

SSQ11-08 Radiophenomics: A Machine Learning Approach to Radiological Exploration of Atherosclerosis

dellalatta@ftgm.it

CONCLUSION

Radiophenomics results in a promising unsupervised stratification of atherosclerotic cardiovascular burden, with the promise of addressing the heterogeneity and the progression of the disease.

Background

Atherosclerosis is a complex, heterogeneous and multi-district disease, whose progression can be conveniently assessed by a plethora of radiological measurements. Aim of this work is the integration of a group of radiological measurements, in order to single out some meaningful phenotypes and explore the disease.

Evaluation

The considered sample was constituted by 1283 subjects from the asymptomatic general population of a screening study (age:

60.7 +/- 8.3 years; males=46%). For each subject, who underwent an MSCT examination, mitral and aortic valve volumetric calcium, cornary volumetric calcium, Agatston calcium score, left and right carotid intima thickness, number of carorid plaques, pulmonary trunk diameter and pulmonary artery diameter were computed. The lipidic profiles were also assessed by measuring total cholesterol, LDL and HDL cholesterol, triglycerides; age, gender and BMI were also reported. On the basis of the 9 considered radiological measurements, the similarity between each couple of subjects was evaluated by the proximities obtained with an unsupervised random forest approach. Successively, a multidimensional scaling procedure was used to map each subject on a plane. Finally, a fuzzy c-means algorithm was used to identify the clusters of subjects in the similarity map (optional figure); to identify the correct number of clusters, the Xie-Beni index was computed.

Discussion

Three distinct phenotipes were singled out: A (n=219), B (n=845), C (n=219). Passing from phenotype A to B and C: Agatson score, pulmonary diameters, intima thickness and number of plaques of carotid arteries significantly increased. Contemporaneously, HDC cholesterol significantly decreased, while age, percentage of male gender and triglycerides increased; moreover, phenotypes B and C showed a BMI value significantly greater than A.

SSQ11-09 Nodule Interface Sharpness Radiomics Distinguishes Benign From Malignant Nodules on Non-Contrast CT Scans

PURPOSE

Many people with benign lung nodules are subjected to unnecessary surgical procedures due to the inability in making confident diagnostic predictions regarding nodule pathology on routine non-contrast CT scans. Interestingly, many malignant nodules are associated with lymphocytic infiltration which may manifest in the perinodular space and hence result in a differential textural appearance between the interior to exterior of the nodule. The aim of this study is to evaluate the role of Nodule Interface Sharpness (NiS), a new radiomic feature that aims to capture the textural transition going from the inside to the outside of the nodule.

METHOD AND MATERIALS

Our study comprised of CT scans of 290 patients from multiple institutions, one cohort for training (N=145) and the other (N=145) for independent validation. All patients had previously undergone surgical wedge resection for a suspicious nodule. A set of 48 NiS features from the nodules margins on 2D slices were extracted. The features pertain to the spiculations and intensity transitions along the nodule interface going from the inside to the outside of the nodule. A Support Vector Machine (SVM) based classifier was trained to distinguish benign from malignant nodules using the most informative NiS features identified on the training set via the Minimum Redundancy, Maximum Relevance (mRMR) feature selection algorithm. The model then applied to predicting presence of malignancies on the validation set.

RESULTS

The most informative NiS features identified were mean gray profile and entropy of the gradient magnitude of the voxels along the margin. The SVM classifier yielded an AUC=0.83 on the independent validation set. In comparison, two human readers with 13 and 3 years of experience had AUC's of 0.69 and 0.73.

CONCLUSION

Our results appear to suggest that the NiS radiomic features associated with lung nodules interface on non-contrast CT scans capture the transitional intensity profiles from the intra- to the peri-nodular space and are thus able to distinguish between benign and malignant nodules on CT scans.

CLINICAL RELEVANCE/APPLICATION

The combination of radiomic features based off NiS with human interpretations could allow for improved discrimination of benign from malignancy nodules and could help reduce unnecessary surgical interventions for pathologic confirmation of nodule diagnosis and also reduce the number and frequency of follow on CT scans for indeterminate findings.

PURPOSE

Stroke is a leading cause of death and disability worldwide. Stem cell therapy has brought substantial benefits to patients as an important restorative therapeutics. However, its efficacy was limited by poor migration and survival ability. In this study, we aimed to enhance therapy efficacy of EPCs for ischemic stroke via PHD2 silencing using siRNA delivered by MRI visible nanoparticles.

METHOD AND MATERIALS

Human umbilical cord blood derived EPCs was transfected with siRNA targeting PHD2 delivered by MRI visible nanoparticles. Expression of CXCR4 and HIF-1a was detected by western blot 48h after siRNA transfection. In vitro transwell assay and H2O2 apoptosis assay was used to detect the migration and survival ability of EPCs respectively. 5×10^5 EPCs with or without PHD2 silencing (siPHD2-EPCs, siCON-EPCs) were transplanted intracardically 1 day after photothrombotic model of stroke was induced in nude mice. Functional recovery was assessed with mNSS and foot-faults test at 1 day before ischemic stroke induction and 1, 3, 7, 14 days after EPCs implantation. MRI and Bioluminescent imaging (BLI) were carried out at 1, 3, 7 days after EPCs transplantation. Prussian blue and GFP staining were carried out at 1 day and 7 day after EPCs transplantation. Angiogenesis, neurogenesis and white matter recovery were assessed at 7 days and 14 days respectively.

RESULTS

PHD2 silencing increased expression of CXCR4 and HIF-1a of EPCs. Both in vivo and in vitro results suggested that PHD2 silencing increased migration and survival ability of EPCs. Mice treated with siPHD2-EPCs showed significantly decreased infarct volume and increased fractional anisotropy (FA) in the ipsilesional corpus callosum than the other groups. Improved functional recovery was observed in the siPHD2-EPCs treated mice. At 7 days, increased BDFN expression was observed in the siPHD2-EPCs treated group. Histological analysis showed that angiogenesis, neurogenesis and white matter recovery were increased after siPHD2-EPCs treated than the other groups.

CONCLUSION

PHD2 silencing increased therapy efficacy of EPCs for ischemic stroke due to increased migration and survival ability.

CLINICAL RELEVANCE/APPLICATION

Our study provides an effective solution for the limitations of clinical stem cell therapy for ischemic stroke.

SSQ12-02 Tracking Stem Cell Transplants in Femoral Osteonecrosis of Pediatric Patients

PURPOSE

To monitor stem cell transplants in osteonecrotic lesions of pediatric cancer survivors with ferumoxytol-enhanced MRI and correlate T2* signal kinetics with outcomes.

METHOD AND MATERIALS

In an ongoing prospective clinical trial (NCT02893293), we performed serial MR imaging studies of seven hip joints of six cancer survivors before and after decompression surgery for osteonecrosis (ON) treatment. We injected ferumoxytol prior to the surgery to label mesenchymal stem cells (MSC) in the bone marrow before their transplantation into osteonecrotic bone. We hypothesized that MR tracking of stem cells in the osteonecrotic bone would enable differentiation of successful and failed cell therapies. We compared T2* values of cell transplants with presence or absence of joint collapse at 12 months using a Student t-test.

RESULTS

Pre-surgical MRI scans of the patients' hip joints confirmed an osteonecrosis (ON) in the epiphysis of the femur, with an intact joint surface (eligibility criteria for the decompression procedure). Ferumoxytol administration lead to hypointense bone marrow enhancement on pre-surgical T2-FSE sequences. Following decompression surgery and transplantation of iron labeled MSC from the iliac crest into the ON, iron-labeled cells could be seen in the access canal. Five ON remained stable over 12 months after decompression surgery. Two ON showed a decreasing volume over time, ultimately collapsed and required artificial joint replacement. At 1-3 weeks after decompression surgery, T2* values of cell transplants in stable ON (2.797 ± 0.07) were significantly shorter ($p<0.05$) compared to T2* values of cell transplants in ON that ultimately collapsed (3.498 ± 0.2383).

CONCLUSION

Stem cell transplants in pediatric cancer survivors can be monitored with ferumoxytol-enhanced MRI. T2* signal kinetics of MSC in osteonecrotic lesions predict clinical outcomes. This immediately clinically applicable stem cell imaging test could become a powerful tool to diagnose success or failure of stem cell transplants in osteonecrotic bone in pediatric patients, monitor engraftment non-invasively and predict bone repair outcomes.

CLINICAL RELEVANCE/APPLICATION

This is the first study that shows the feasibility of tracking in vivo labeled stem cells in patients. The rapid disappearance of the cell transplant, as indicated by the iron signal on MR images, correlates with unfavorable clinical outcomes.

SSQ12-03 Integrin-Targeted Quantitative Multispectral Optoacoustic Tomography with MRI Correlation for Monitoring a BRAF/MEK Inhibitor Combination Therapy in Experimental Human Melanoma Xenografts in Mice

PURPOSE

To investigate a multimodal imaging protocol of avß3-integrin-targeted multispectral optoacoustic tomography (MSOT) and MRI for monitoring a BRAF/MEK inhibitor combination therapy in a murine model of human melanoma.

METHOD AND MATERIALS

Human BRAF V600E-positive melanoma xenografts (A375) were implanted subcutaneously in the lateral flank of n=10 balb/c nude mice. Imaging was performed before (day 0) and after (day 7) a BRAF/MEK inhibitor combination therapy (encorafenib, 0.03 mg/d; binimetinib, 0.012 mg/d, Array BioPharma Inc., therapy n=5) or placebo treatment (control n=5), respectively. MSOT was conducted on a preclinical system (inVision 256-TF, iThera Medical GmbH) unenhanced and 5 h after i.v. injection of a avß3-integrin-targeted fluorescent probe (IntegriSense 750, Perkin Elmer, 4 nmol). For tumor volume assessments, T2w MRI data sets were subsequently acquired on a clinical 3 Tesla scanner (Magnetom Skyra, Siemens Healthineers). MSOT data acquired at multiple wavelengths was spectrally unmixed to derive the avß3-integrin-specific signal. Imaging results were validated by ex vivo immunohistochemistry with regard to microvascular density (CD31).

RESULTS

A significant decrease of avß3-integrin specific tumor signal was observed in the therapy group (-79 %, from 7.98±2.22 to 1.67±1.30, p=0.030), whereas no significant change was detected in the control group (-55 %, from 6.60±6.51 to 3.69±1.93, p=0.348). Immunohistochemistry demonstrated a significant decrease in microvascular density under therapy (CD31; therapy: 119±15, control: 312±62, p=0.008). Tumor volumes increased in both groups with no significant intergroup difference (therapy: +107±42 mm3; control +112±44mm3, p>0.05). Competitive in vivo blocking studies using avß3-integrin receptor antagonist cilengitide (Selleck Chemicals) confirmed the selective binding of the targeted fluorescent probe.

CONCLUSION

Quantitative MSOT allowed for the early non-invasive monitoring of a BRAF/MEK inhibitor combination therapy in BRAF V600E-

positive human melanoma xenografts in mice, adding molecular information on tumor avß3-integrin receptor status to morphology-based tumor response assessments.

CLINICAL RELEVANCE/APPLICATION

Quantitative MSOT with targeted probes may generate additional clinical imaging biomarkers of early tumor response in human melanoma under novel targeted treatment regimens.

SSQ12-04 Why Iron Oxide Labeling Matters for Stem Cell Mediated Cartilage Repair: Insights from a Large Animal Model

PURPOSE

The success or failure of matrix associated stem cell implants (MASI) in cartilage defects is evaluated on MR images at 6-12 months after MASI, based on the degree of cartilage repair. We evaluated if iron oxide nanoparticle labeling could accelerate this diagnosis based on different iron signal kinetics of successful and failed implants.

METHOD AND MATERIALS

Studies were performed in seven Göttingen minipigs with artificially created cartilage defects of the distal femur. We aspirated and isolated mesenchymal stromal cells from the iliac crest and labeled the cells with ferumoxytol (Feraheme), using a clinically translatable, transfection agent-free protocol. We implanted viable and apoptotic ferumoxytol-labeled MSCs into 22 cartilage defects and monitored the signal of the implants with a clinical 3T MRI scanner at week 1, 2, 4, 8, 12 and 24, using a proton density sequence (3700/34/90 TR/TE/alpha) and a multiecho spin echo sequence (3500/45 TR/TE). Implants without ferumoxytol label served as controls. Quantitative T2 relaxation times were compared for significant differences between labeled and unlabeled as well as viable and apoptotic MASI using Student t-tests.

RESULTS

Iron oxide labeled MASI showed significant T2 shortening compared to adjacent normal cartilage and unlabeled implants. At week 1, viable and apoptotic MASI did not show significant differences in T2 relaxation times (20.91±2.12 ms versus 20.97±2.07 ms). At week 2, T2 relaxation times of viable ferumoxytol-labeled implants (21.79±2.59) ms were significantly lower compared to apoptotic ferumoxytol-labeled implants (27.93±3.49 ms, $p<0.05$). The label disappeared in both groups at 4 weeks. Histological correlation at 24 weeks showed complete defect repair of viable MASI and incomplete defect repair of apoptotic MASI.

CONCLUSION

Rapid loss of iron signal early after MASI indicates cell death and predicts incomplete defect repair many weeks later. To our knowledge, this is the first study to detect early engraftment failure of MASI with MRI in a large animal model.

CLINICAL RELEVANCE/APPLICATION

MRI of ferumoxytol-labeled MASI represents an easily clinically translatable method for detection of early engraftment failure in arthritic joints.

SSQ12-05 A Case Series of NSCLC Patients Performing both C-11 Erlotinib and F-18 FDG PET/CT Comparing with EGFR Mutation Status

PURPOSE

To evaluate the ability of C-11 erlotinib PET/CT as a non-invasive approach to identify EGFR mutation status and to study various PET parameters that may serve as a potential proxy for selecting the patient who could benefit from erlotinib treatment.

METHOD AND MATERIALS

We performed PET/CT in 5 NSCLC patients, each with both C-11 erlotinib and F-18 FDG. All had EGFR mutation status of the

tumors. There were two patients who had wild-type EGFR and three patients who had EGFR mutation i.e., exon 21 mutation (L858R), exon 19 insertion and exon 19 deletion. Three experienced nuclear medicine physicians, unknown of the patients' EGFR status, read the C-11 erlotinib PET/CT by visual analysis and gave the result as positive or negative. PET parameters i.e., SUVmax, SUVavg, MTV, TLG, Tumor to background ratio were analysis in both C-11 erlotinib and FDG studies.

RESULTS

There was a wide range of C-11 erlotinib uptake in primary tumor and metastatic sites. By visual analysis, 67% correction was observed (10/15). The average SUVmax and tumor to background mediastinal blood pool ratio were 2.04±0.68 vs 2.18±1.45 (p = 0.77) and 3.44±1.63 vs 1.56±1.10 (p = 0.02) in EGFR mutation positive vs EGFR mutation negative, respectively. Sub-group analysis of SUV parameters in primary tumor, lymph node and distant metastases including adrenal, bone, brain and muscle showed no significant difference between each group. There was no significant correlation between FDG parameters (SUVmax, SUVavg, MTV, TLG) and C-11 erlotinib parameters as well as EGFR mutation status.

CONCLUSION

Our study confirmed the tumor heterogeneity of C-11 erlotinib binding in primary tumor and each metastatic sites. The tumor to mediastinal blood pool ratio of C-11 erlotinib uptake was the only parameter that seems to be significantly different between EGFR mutation positive vs negative group.

CLINICAL RELEVANCE/APPLICATION

C-11 erlotinin PET/CT confirmed the tumor heterogeniety of erlotib binding in primary NSCLC and metastastic sites in the same patient as well as different patients with different EGFR mutation status.

SSQ12-06 MR Molecular Imaging and Tumor Theranostic 2D Ultrathin MnO2 Nanosheets with Fast Responsibility to Endogenous Tumor Microenvironment and Exogenous NIR Irradiation

PURPOSE

To study the feasibility of using two-dimensional (2D) ultrathin MnO2 nanosheets with ultra-sensitivity to tumor microenvironment (TME) to enhance MR molecular imaging and photothermal therapy (PTT).

METHOD AND MATERIALS

The fabrication of ultrathin 2D MnO2 nanosheets were based on an exfoliation strategy. The surface of MnO2 nanosheets were modified by Soybean phospholipid (SP) to enhance stability in physiological environments without significant toxicity. The MnO2 nanosheets and MnO2-SPs were characterized by various methods. The murine breast cancer cell line (4T1) and Kunming mice were cultured to evaluate *in vitro* cell and *in vivo* biological toxicity. Importantly, we investigated *in vitro* and *in vivo* MR imaging evaluations and photothermal therapy on mice breast tumor xenografted tumor model.

RESULTS

These ultrathin 2D MnO2 nanosheets show the intriguing characteristic of disintegration and releasing of Mn2+ in response to the mild acidic and elevated reducing conditions of TME, which has successfully realized the pH- and reducing-responsive T1-weighted magnetic resonance imaging of tumor without obvious biological toxicity. *In vivo* MRI, it has been found that the positive T1-weighted MRI signal increased significantly after the intravenous administration of MnO2-SPs nanosheets into mice bearing the breast 4T1 cancer xenograft. Furthermore, the high PTT efficiency of 2D MnO2 nanosheets responsive to exogenous NIR irradiation have been systematically demonstrated both *in vitro* and *in vivo* for suppressing the tumor growth.

CONCLUSION

For the first time, we have successfully demonstrated that the exfoliated ultrathin 2D MnO2 nanosheets feature the high intrinsic photothermal-conversion capability for PTT against tumor, which are also the first paradigm of inorganic photothermal agents with the ultra-sensitivity to the endogenous TME, including mild acidic and reducing conditions. This tumor sensitivity could not only realize the pH- and reducing-responsive T1-weighted MR imaging, but also possibly facilitate the metabolism and excretion of the MnO2 nanosheets after the tumor theranostics.

CLINICAL RELEVANCE/APPLICATION

2D MnO2 nanosheets can serve as powerful MR imaging-guided photothermal agents for excellent tumor ablation.

SSQ12-07 Non-Invasive Imaging of Transplanted Therapeutic Cells in the Inflamed Rat Brain by Spectral Photon Counting Computed Tomography (SPCCT)

PURPOSE

Cell therapy holds promise for treatment of ischemic stroke in the chronic phase. To foster translation into the clinic, there is a need for non-invasive techniques that enable long-term follow-up of cell fate. Our purpose is to provide proof of concept of specific and quantitative in vivo imaging of therapeutic cells by an innovative, translational technique: K-edge imaging by spectral photon counting computed tomography (SPCCT).

METHOD AND MATERIALS

M2-polarized anti-inflammatory macrophages were labelled with gold nanoparticles (AuNPs, 0.1 mg/mL, 15 h) and gold/cell quantified by mass spectroscopy. Rats underwent intracerebral (IC) injection of lipopolysaccharide to induce chronic neuroinflammation. Two weeks after, the same rats were scanned in vivo using a pre-clinical SPCCT prototype after IC delivery of 5x105 AuNPs-labelled or control unlabeled cells. A phantom with a concentration range of AuNPs (0 to 8 mg/mL) was scanned for calibration of in vivo quantification. Anode tube voltage of 120 kVp and current of 100 mA were used. The same phantom and rats (ex-vivo) were then scanned by µCT and K-edge imaging by synchrotron X-rays (SXR) as gold standards for validation. Gold K-edge images were reconstructed and gold signal was manually delineated for quantification.

RESULTS

K-edge imaging of gold with SPCCT detected gold-labelled cells within the brain, in agreement with µCT and SXR. Mass spectroscopy detected an amount of 165 gold pg/cell, corresponding to 82.5 µg of gold injected within cells. The measured concentrations in phantom linearly correlated with the known concentrations (R2 = 0.99, slope: 0.82, intercept: 0.19), supporting the potential for accurate in vivo gold-cell quantification, which is currently in progress.

CONCLUSION

Our initial results provide proof-of-concept for non-invasive in vivo imaging of AuNPs-labelled therapeutic cells by SPCCT, which has the advantage of being specific and quantitative.

CLINICAL RELEVANCE/APPLICATION

SPCCT may be valuable to improve cell therapy in chronic stroke patients.

SSQ12-08 PET/CT Imaging of the Alkylphosphocholine Analog 124I-CLR1404 in High and Low-Grade Brain Tumors

PURPOSE

CLR1404 is a cancer-selective alkyl phosphocholine (APC) analog that can be radiolabeled with 124I for PET imaging, 131I for targeted radiotherapy and/or SPECT imaging, or 125I for targeted radiotherapy. Studies have demonstrated avid CLR1404 uptake and prolonged retention in a broad spectrum of preclinical tumor models. The purpose of this pilot trial was to demonstrate avidity of 124I-CLR1404 in human brain tumors and develop a framework to evaluate this uptake for use in larger studies.

METHOD AND MATERIALS

12 patients (8 men and 4 women; mean age of 43.9 ± 15.1 y; range 23 - 66 y) with 13 tumors were enrolled. Eleven patients had suspected tumor recurrence and 1 patient had a new diagnosis of high grade tumor. Patients were injected with 185 MBq ± 10% of 124I-CLR1404 followed by PET/CT imaging at 6-, 24-, and 48-hours. 124I-CLR1404 PET uptake was assessed qualitatively and compared with MRI. After PET image segmentation SUV values and tumor to background ratios were calculated.

RESULTS

There was no significant uptake of 124I-CLR1404 in normal brain. In tumors, uptake tended to increase to 48 hours. Positive uptake was detected in 9 of 13 lesions: 5/5 high grade tumors, 1/2 low grade tumors, 1/1 meningioma, and 2/4 patients with treatment related changes. 124I-CLR1404 uptake was not detected in 1/2 low grade tumors, 2/4 lesions from treatment related changes, and 1/1 indeterminate lesion. For 6 malignant tumors, the average tumor to background ratios (TBR) were 9.32 ± 4.33 (range 3.46 to

15.42) at 24 hours and 10.04 ± 3.15 (range 5.17 to 13.17) at 48 hours. For 2 lesions from treatment related change, the average TBR were 5.05 ± 0.4 (range 4.76 to 5.33) at 24 hours and 4.88 ± 1.19 (range 4.04 to 5.72) at 48 hours. PET uptake had areas of both concordance and discordance compared with MRI.

CONCLUSION

124I-CLR1404 PET demonstrated avid tumor uptake in a variety of brain tumors with high tumor-to-background ratios. There were regions of concordance and discordance compared with MRI, which has potential clinical relevance. Expansion of these studies is required to delineate the clinical significance of these PET findings.

CLINICAL RELEVANCE/APPLICATION

124-CLR1404 PET provides unique molecular imaging properties in brain tumors and may add complementary diagnostic information to MRI and thus has potential to improve diagnostic certainty.

SSQ12-09 Early Stage Detection of Stem Cell Transplant Rejection with a Ferumoxytol-Based Dual-Modality Imaging Probe

hnejadni@tanford.edu

PURPOSE

Limited survival of transplanted stem cells represents a significant bottleneck for successful tissue regeneration. The goal of this study was to develop a novel dual-modality imaging probe, composed of a superparamagnetic nanoparticle backbone for cell detection and a fluorescent apoptosis marker.

METHOD AND MATERIALS

We immobilized caspase-3 cleavable peptides (KKKKDEVD-AFC) on the surface of the FDA approved nanoparticle compound ferumoxytol to prepare ferumoxytol-AFC nanoparticles (Feru-AFC NPs). Size distribution and Zeta potential of Feru-AFC NPs were measured by Dynamic Light Scattering (DLS). Mesenchymal stem cells (MSCs) were incubated with Feru-AFC NPs or ferumoxytol (control group) and underwent Prussian blue stains and ICP mass spectrometry as well as in vitro fluorescent and MR imaging. Then, intravital microscopy (IVM) was performed on matched (syngeneic) or mismatched (porcine-derived) MSCs, implanted in skull defects of six C57BL/6J mice. The mice underwent MR and fluorescent imaging on day 1, 3, 6, and 9. T2 relaxation time and fluorescent signal of the two groups were compared with a Student's t-test, using a $p<0.05$.

RESULTS

Feru-AFC NPs could be efficiently internalized into MSCs, as confirmed by Prussian blue stains and ICP mass spectrometry. Labeled MSC showed a significantly shorter T2-relaxation time compared to unlabeled MSCs ($p<0.05$). Feru-AFC NPs did not show significant fluorescence, however, in the presence of recombinant human caspase-3 or extract of apoptotic MSCs, Feru-AFC NPs showed significant green fluorescence due to cleavage of DEVD and release of AFC fluorophores. Accordingly, viable Feru-AFC NP-labeled MSCs showed no detectable fluorescence, while apoptotic Feru-AFC NP-labeled MSCs showed significant green fluorescence. In vivo, MR imaging enabled localization of cell transplants in skull defects. Mismatched MSC implants showed significantly higher fluorescent signal compared to matched MSC implants three days after implantation ($p<0.05$).

CONCLUSION

Feru-AFC NPs represent a novel tool for long-term stem cell tracking through MRI and early diagnosis of cell apoptosis through simultaneous fluorescence imaging.

CLINICAL RELEVANCE/APPLICATION

The described dual-modality contrast agent could improve monitoring of the localization and early diagnosis of cell rejection/apoptosis and direct patients with failed implants to repeated interventions.

728295931@qq.com

PURPOSE

Objective: To investigate the value of dual-energy technology in the treatment of fracture healing after internal fixation of spinal fractures.

METHOD AND MATERIALS

Methods: 60 cases of spine (cervical spine 5 cases, thoracic vertebrae 25 cases, lumbar vertebrae 30 cases) were collected and examined by dual-energy X-ray absorptiometry (DXA).The bone mineral density (BMD) measurements were performed at the same time by gemstone spectral imaging (GSI) scan for patients with spinal fractures, before operation, after metal internal fixation, and after removal of metal internal fixation. The data used in the analyzing were obtained by the energy spectrum analysis software. The single energy images at different energy levels of 40-140 keV, the base substance diagram of calcium and water were obtained. The ROIs were measured by different parameters among 40-140 keV (with interval 10 keV) and the CT values of different energy levels, the calcium and water based material density, and the bone density values were calculated.

RESULTS

Results: The best single energy image was obtained at 60 keV. Before operation, there was statistical significance ($P < 0.05$) between the bone mineral densities getting from GSI (0.440 ± 0.056 g / cm3) and QCT (0.404 ± 0.069 g / cm3) , and the former was greater than that of the QCT. The GSI measurement was (0.360 ± 0.026 g / cm3) in the 6 patients healing well,(0.281 ± 0.032g / cm3) in the 8 patients delayed healing, and (0.121 ± 0.021g / cm3) in the 8 patients nonunion.

CONCLUSION

Conclusion: The energy spectrum CT scanning technique can effectively remove metal artifacts and ray beam hardening artifacts, and clearly show the fine structure after metal fixation for fracture, and the image quality is higher. The best single energy image was achieved at the 60keV. By using of calcium-water-based substance pairs, the bone density could be measured more accurately than by QCT, and can be used as a new bone density measurement method to predict the degree of fracture healing.

CLINICAL RELEVANCE/APPLICATION

can be used as a new bone density measurement method to predict the degree of fracture healing.

SSQ13-03 The Value of a New Single Energy Metal Artifact Reduction (SEMAR) Algorithm in Post-Surgery Follow-Up of Patients with Knee Tumor Prostheses

Thursday, Nov. 30 10:50AM - 11:00AM Room: E451A

Participants
Lei Ding, Guangzhou, China (*Presenter*) Nothing to Disclose
Fang-Ling Zhang, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

408021193@qq.com

PURPOSE

To evaluate the effect of a new single energy metal artifact reduction (SEMAR) algorithm with a 320 Multidetector computed tomography (MDCT) volume scanner in post-surgery follow-up of patients with knee tumor prostheses.

METHOD AND MATERIALS

From November 2015 to February 2017, 95 consecutive patients (59 males, 36 females; mean age, 24.2 years; age range, 9-64 years) with a tumor prosthesis of knee joint underwent a 320-MDCT scan. The images were reconstructed using two different methods: conventional iterative reconstruction (IR) alone and IR associated with SEMAR. Four radiologists visually graded the whole image quality at articular level on a 6-point scale from 0 (periprosthetic anatomic structures are completely obscured by metal artifacts) to 5 (periprosthetic structures are recognized with high confidence). Additionally, the readers assessed the presence of periprosthetic complication on a similar 6-point scale from 0 (extensive artifacts, prosthetic complications are unable to be recognized) to 5 (minimal artifacts, prosthetic complications are recognized with high confidence). Wilcoxon matched-pairs signed rank test and Intra-class correlation coefficients (ICCs) were used for the scores of image quality and prosthetic complications.

RESULTS

Visualization of periprosthetic structures were significantly improved by the SEMAR algorithm (3.8~4.3 vs. 1.2~1.6, $P<0.05$). In 66 of 95 patients, prosthetic complications were confirmed by other imaging examination, clinical or pathology. and prosthetic complications. The new algorithm also increased diagnostic confidence of prosthetic complications (4.3~4.7 vs 1.3~1.9, $P<0.05$). The sensitivity of diagnostic confidence of prosthetic complications was increased (98.5% vs. 45.5%, $P<0.05$).

CONCLUSION

The SEMAR visibly reduces the metal artifact and can increase diagnostic confidence of prosthetic complications in patients with knee tumor prostheses.

CLINICAL RELEVANCE/APPLICATION

The SEMAR can visibly reduces the metal artifact and increase diagnostic confidence of prosthetic complications in patients with knee tumor prostheses.

SSQ13-04 Cross-sectional Imaging of the Bone-Implant Interface of Total Ankle Arthroplasty Implants: CS-SEMAC MRI versus IMAR CT

PURPOSE

Imaging evaluation of the bone-implant interfaces of total ankle arthroplasty is helpful for the assessment of osseous implant integration; however, it is unclear which imaging modality performs best. Therefore, we evaluated the visibility of the bone-implant interface of total ankle arthroplasty implants by comparing two state-of-the-art metal artifact reduction MRI and CT techniques.

METHOD AND MATERIALS

After institutional review board approval, a total ankle arthroplasty system (TMTA, Titanium and Cobalt-Chromium alloy, Zimmer, Warsaw, Indiana) was implanted into 6 fresh frozen human cadaver ankles. Each specimen underwent cross-sectional imaging using Compressed Sensing (CS) SEMAC MRI at 1.5T and Iterative Metal Artifact Reduction (IMAR) CT at 120 keV. A total of 12 studies (6 CT, 6 MRI) were created, which consisted of axial, sagittal and coronal images with 3 mm slice thickness and similar slice orientations. The blinded and randomized data sets were subsequently independently analyzed by two experienced observers. After three months, both observers analyzed the data sets again. Using a four quadrant scheme, the visibility of the bone-implant

interface was evaluated on each slice orientation using equidistant 5-point Likert scales. Descriptive statistics, ICC, and Mann-Whitney U test were used for analysis. A p-value of <0.05 was considered significant.

RESULTS

The inter-observer agreement (kappa 0.815, 95%-CI 0.729-0.874) and intra-observer agreement (kappa intra-observer 1 0.904, 95% CI 0.859-0.934; kappa intra-observer 2 0.835, 95%-CI 0.758-0.887) were high with > 80% exact matching ratings for each image orientation, quadrant and imaging modality. The average 4-quadrant visibility score was 18 for CS-SEMAC MRI and 15 for IMAR CT ($p < 0.001$). Additionally, CS-SEMAC MRI consistently showed significantly higher scores for matched slice orientation and cadavers (axial: $p<0.001$, sagittal: $p<0.001$, coronal; $p<0.001$, cadaver 1: $p<0.001$, cadaver 2: $p=0.011$, cadaver 3: $p<0.001$, cadaver 4: $p=0.001$, cadaver 5: $p<0.001$, cadaver 6: $p<0.001$).

CONCLUSION

CS-SEMAC MRI is superior to IMAR CT for the visualization of the bone-implant interface of total ankle arthroplasty implants.

CLINICAL RELEVANCE/APPLICATION

CS-SEMAC metal artifact reduction MRI technique substantially improves the visibility of the host bone-implant interfaces of total ankle arthroplasty implants, suggesting a change of postoperative imaging from CT toward MRI.

SSQ13-05 Reduction of Metallic Artefacts from Spinal Fusions Using Virtual Monoenergetic Imaging by Dual Layer Spectral Computed Tomography

julia.dangelmaier@tum.de

PURPOSE

To evaluate the clinical potential of virtual monoenergetic images generated with a dual-layer spectral Computed Tomography (CT) system and determine the optimal settings for reduction of metallic artefacts from posterior spinal fusions.

METHOD AND MATERIALS

Twenty patients with posterior spinal fusion who underwent a spectral CT scan (IQon Spectral CT, Philips Healthcare, USA) for various clinical indications were included in this study. Two independent readers evaluated axial 0.9 mm slides with soft tissue and bone window settings. Image quality of the conventional scan was compared with virtual monoenergetic images at 40, 60, 80, 100, 120, 140, 160, 180 and 200 keV. A four point Likert-scale was used to document subjective impression of overall and specific diagnostic image quality for either the implant inheriting bone, muscle, spinal canal or retroperitoneal vessels. The Hounsfield Units of the area with the most pronounced streak artefact as well as the Hounsfield Units of a reference area containing fat and muscle was documented for every keV-setting.

RESULTS

Quantitative analysis showed statistically significant artefact reduction for higher monoenenergetic levels compared to conventional images ($p<0.05$). Analogously, qualitative analysis revealed significant improvement of overall image quality ($p<0.05$) and benefit for all:tissues separately compared:to the original images in the range from 80 to 200 keV ($p<0,05$). Optimal overall keV-setting was 180 keV and ranged from 160 to 200 keV for the implant inheriting bone, the spinal canal, adjacent muscle and retroperitoneal vessels. Our results reveal high inter-reader agreement for qualitative evaluations (ICCs >0.927; $p<0.05$).

CONCLUSION

Dedicated keV-settings to evaluate either the implant inheriting bone, the spinal canal, adjacent muscle or retroperitoneal vessels - structures which are frequently of peculiar interest after posterior spinal fusions - are recommended.

CLINICAL RELEVANCE/APPLICATION

Virtual monoenergetic images of higher energies provide significant reduction of metallic artefacts from posterior spinal fusions.

SSQ13-06 SMART (Sequences for Metal Artifact Reduction around a Tumor Prosthesis) MRI: Diagnostic Performance for Detection of Recurrence and Complications around a Tumor Prosthesis

Thursday, Nov. 30 11:20AM - 11:30AM Room: E451A

Participants
Laura M. Fayad, MD, Baltimore, MD (*Abstract Co-Author*) Nothing to Disclose
Adam Levin, Baltimore, MD (*Abstract Co-Author*) Nothing to Disclose
Carol Morris, MD, Baltimore, MD (*Abstract Co-Author*) Nothing to Disclose
Jan Fritz, MD, Baltimore, MD (*Presenter*) Research Grant, Siemens AG; Scientific Advisor, Siemens AG; Scientific Advisor, Alexion Pharmaceuticals, Inc; Speaker, Siemens AG

PURPOSE

To assess the feasibility and performance of an MRI protocol including conventional and fast metal-reduction anatomic (T1/STIR, contrast-enhanced) and functional (dynamic contrast-enhanced (DCE)) imaging for the surveillance of patients who have undergone limb-salvage reconstruction with a tumor prosthesis.

METHOD AND MATERIALS

Following IRB approval and informed consent, 15 subjects with tumor prostheses, underwent 17 MRIs at 1.5T. MRI included two-plane anatomic imaging (T1-weighted/STIR, post-contrast T1-weighted, subtraction of pre-contrast from post-contrast) with both conventional WARP and fast compressed-sensing (CS)-SEMAC sequences, and functional imaging (DCE-MRI with 7-second resolution). One observer recorded the quality of each sequence (1=>75%, 2=25-75%, 3=10-25%, 4=no substantial-artifacts) adjacent to and remote from the prosthesis, and the presence of recurrence by three interpretation sessions (WARP, WARP+CS-SEMAC, WARP+CS-SEMAC+DCE) using a 5-point confidence scale (definitely-not, probably-not, possibly-present, probably-present, definitely-present). ROC analysis was performed, using histology as the reference for positive recurrence, and minimum 6-month stability for absence of recurrence.

RESULTS

Of 17 studies, there were 4 histologically-proven intramuscular recurrences. Average image quality was different adjacent to the prosthesis compared with remote from the prosthesis on T1, STIR and contrast-T1 sequences (WARP:1.2 vs 3.9, CS-SEMAC: 2.9 vs 3.4, respectively). ROC analysis revealed improved diagnostic performance for the detection of tumor recurrence with the successive addition of CS-SEMAC and DCE imaging to WARP (area-under-the-curve: WARP=0.84, +CS-SEMAC=0.92, +DCE=1.0).

CONCLUSION

An MRI protocol including conventional metal reduction (WARP), and fast CS-SEMAC and DCE-MRI offers good diagnostic performance for the detection of recurrence in patients with a history of limb salvage surgery and tumor prostheses.

CLINICAL RELEVANCE/APPLICATION

Following resection and reconstruction with a tumor prosthesis, cross-sectional imaging has traditionally been limited. With the advent of SMART-MRI, surveillance imaging of patients with tumors prostheses is now possible with high diagnostic accuracy.

SSQ13-07 Minimizing CT Radiation Dose in Total Hip Arthroplasty Patients Using Model-Based Iterative Reconstruction and Orthopedic Metal Artifact Reduction

PURPOSE

To minimize CT radiation dose in patients with large metal-on-metal total hip prostheses using model-based iterative reconstruction (iMR) combined with orthopedic metal artifact reduction (O-MAR).

METHOD AND MATERIALS

Patients with a unilateral or bilateral metal-on-metal total hip prosthesis were included. Patients were scanned on a Philips iCT 256-slice CT scanner. Each patient received a conventional CT pelvis and a low-dose CT pelvis with respectively -20%, -43%, -60% or -80% lower CT radiation dose for patients in group 1, 2, 3 or 4 respectively. The conventional CT pelvis was reconstructed with iterative reconstruction, iDose4 level 4. The low-dose CT pelvis was reconstructed with iDose4 level 4 and model-based iterative reconstruction (iMR, levels 1, 2 and 3). All images were reconstructed with and without the use of O-MAR. CT numbers, noise or standard deviations (SDs) and contrast-to-noise-ratios (CNRs) were determined in muscle, fat, the bladder and background.

RESULTS

In this ongoing study, 23/80 patients were included for first analysis. In total 5, 6, 7 and 5 patients were included in group 1, 2, 3 and 4 respectively. Dose-length-products (DLPs) were reduced from 767.4 to 659.3 (-16%), 637.6 to 380.8 (-41%), 670.3 to 306.6 (-56%) and 840.1 to 199.6 (-77%) for group 1, 2, 3 and 4 respectively. While reducing radiation dose with 20%, 43%, 60% or 80%, CT numbers accuracy was maintained, SDs decreased ($p<0.01$) and CNRs ($p<0.001$) increased in iMR and O-MAR images compared to iDose4 and O-MAR images. In iMR level 1 and O-MAR images, CNRs between muscle and fat were on average 94%, 74%, 54% and 47% higher compared to iDose4 and O-MAR images while reducing radiation dose with 20%, 43%, 60% or 80%.

CONCLUSION

The use of iMR and O-MAR reduces standard deviations, increases CNRs and maintains CT number accuracy while reducing radiation dose in total hip arthroplasty patients up to 80% compared to iDose4 and O-MAR.

CLINICAL RELEVANCE/APPLICATION

Despite quantitative measurements show that the use of iMR enables a radiation dose reduction up to 80% compared to iDose4 in total hip arthroplasty patients, qualitative analysis is essential.

SSQ13-08 Evaluation of CT Metal Artifact Reduction Techniques in Patients with Total Shoulder Arthroplasties

PURPOSE

To determine the CT metal reduction technique that optimizes visualization of bone and soft tissue adjacent to a total shoulder arthroplasty.

METHOD AND MATERIALS

19 patients with TSA underwent dual energy CT (DECT). Post processing was performed for each study, creating 4 different image sets, each in soft tissue and bone kernels: (1) routine reconstruction (2) iterative metal reduction technique (iMAR) (3) DECT with virtual mono-energetic images at 130 keV and (4) combined iMAR and DECT virtual mono-energetic images at 130 keV. 2 experienced MSK Radiologists and 1 MSK Fellow blinded to processing data independently graded extent of artifact and image quality of one reconstruction for each patient, randomly ordered across 4 weekly reading sessions. A fifth reading session compared the 4 techniques side-by-side for each patient and a rank order preference was submitted. Attenuation measurements within bone and soft tissue at areas of greatest artifact near the hardware were collected for each reconstruction and compared to standard attenuation measurements collected from areas unaffected by artifact.

RESULTS

Of the four techniques utilized, iMAR combined with DECT with virtual mono-energetic images at 130 keV ranked best in overall image quality and in rank order preference by each of the 3 readers. The difference between attenuation measurements of bone and soft tissue in areas of greatest artifact and standard attenuation measurements was greatest in standard technique and lowest in iMAR combined with DECT Mono+.

CONCLUSION

In the setting of TSA, iMAR combined with DECT with virtual mono-energetic images at 130 keV objectively and subjectively decreases metal artifact when compared to standard reconstruction, iMAR alone and DECT with mono-energetic images at 130 keV alone.

CLINICAL RELEVANCE/APPLICATION

Orthopedic surgeons often utilize CT imaging to assess the necessity and nature of intervention. Metallic implants contribute to substantial artifact on CT imaging limiting visualization of adjacent structures. This is particularly relevant when trying to evaluate shoulder arthroplasties for evidence of loosening or fracture and to assess adjacent bone stock for revision surgery. This study demonstrates that utilization of iMAR with DECT with virtual mono-energetic technique in the setting of TSA provides optimal imaging quality of the adjacent osseous and soft tissue structures thus improving diagnostic evaluation.

SSQ13-09 Metal Artifact Reduction Using Spectral Dual-Energy CT with Virtual Monoengergetic Images for Patients with Metallic Orthopedic Implants of the Distal Radius

Thursday, Nov. 30 11:50AM - 12:00PM Room: E451A

Participants
Sun Jeong Moon, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Hye Jin Yoo, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

Ja-Young Choi, MD, San Diego, CA (*Abstract Co-Author*) Nothing to Disclose
Hee-Dong Chae, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the image qualities of virtual monoenergetic images obtained from spectral dual-energy CT (DECT) for patients with metallic orthopedic implants of the distal radius

METHOD AND MATERIALS

Forty-three consecutive patients with internal metallic implants for distal radius fracture underwent spectral DECT (33 women and 11 men, with a mean age of 50.7 ± 15.4 years (24-77 years). Sixteen virtual monoengergetic image sets ranging from 50 keV to 200 keV were generated at one single slice with the most pronounced hypodense streak artifacts of implants in axial plane. The image quality of sixteen monoengergetic images were assessed quantitatively and qualitatively by two independent musculoskeletal radiologists. Quantitative analysis included the density of most hypodense artifact and reference tissue, background image noise and artifact index (AI). Qualitative assessment included degree of artifacts, diagnostic image quality of peri-implent bones, and delineation of fracture lines if present. Friedman rank-sum test with post hoc tests and kappa analysis were used for the statistical analysis.

RESULTS

There was a statistically significant difference in CT number of most pronounced hypodense streak in peri-prosthetic region depending on monoenergy level ($p < 0.001$). There was a statistically significant difference in AI of most pronounced hypodense streak in periprosthetic region depending on monoenergy level ($p < 0.001$). AI of different monoenergy level was the lowest at 120-200 keV to provide the most significant metal artifact removal. The degree of artifacts, diagnostic image quality, and delineation of

fracture lines were significantly different among the keV settings (both $p < 0.001$). The hypodense streak in peri-prosthetic region was least pronounced at 110 keV and diagnostic image quality of peri-implant bones was best at 130 keV. Fracture lines were found in 22 patients, which was well delineated in all cases at 80~110 keV settings ($p < 0.001$).

CONCLUSION

Virtual monoenergetic images at high-energy levels have a well-concordant effect of reducing metal artifacts, and 110-130 keV monoenergetic images provided a least peri-implant artifact and best diagnostic image quality in patients with implants of the distal radius.

CLINICAL RELEVANCE/APPLICATION

Virtual monoenergetic images acquired from spectral DECT was useful to reduce metal artifacts caused by metallic implatns in patients with distal radius fracture

PURPOSE

Brown adipose tissue (BAT) is a promising target for anti-obesity interventions, which may entail induction of BAT volume expansion. Valid assessments of changes in BAT volumes require knowledge of intrinsic volumetric variability. Our aim was to determine the repeatability of cold-activated BAT volumes using [18F]FDG, the gold standard for detecting BAT activity, with both PET/CT and PET/MRI.

METHOD AND MATERIALS

To date, our study has enrolled 25 healthy volunteers (21 female, 4 male). As young, normal weight individuals are more likely to have detectable BAT, we included only subjects 18-35 y/o with BMI <= 25 kg/m2. A 5 mCi dose of [18F]FDG was injected midway through a 120 min cooling period, using a target temperature just above the shivering point. Subjects then underwent PET/CT immediately followed by PET/MRI. Imaging extended from the skull base to the upper abdomen, covering all common BAT areas. Repeat imaging occurred 2-7 days later per an identical protocol. BAT volumes were defined per BARCIST 1.0 criteria (Figure), incorporating a validated Dixon-based fat segmentation method for PET/MRI. Repeatability coefficients (RCs), based on percent differences between measurements (0% = perfect repeatability), were calculated.

RESULTS

Three subjects failed to complete the imaging protocol, and 6 had no detectable BAT. For the 16 evaluable subjects, RCs for BAT volumes (range, 24-315 ml) were 138.8% (PET/CT) and 98.8% (PET/MRI). Considering only the 8 subjects with the largest BAT volumes (range, 150-315 ml), RCs improved to 32.2% (PET/CT) and 36.4% (PET/MRI). The degree of BAT volume correlation between PET/CT and PET/MRI was significantly (p = 0.04) greater at baseline (R2, 0.96) than at repeat imaging (R2, 0.80). There was no difference (p = 0.88) in the degree of BAT volume correlation on serial PET/CT (R2, 0.85) compared with serial PET/MRI (R2, 0.87).

CONCLUSION

Volumetric repeatability was better for patients with more BAT. The higher degree of BAT volume correlation between PET/CT and PET/MRI on baseline imaging than between imaging sessions for either PET/CT or PET/MRI suggests that BAT activation factors (e.g., cooling protocol) may be a greater source of variability than imaging-related factors.

CLINICAL RELEVANCE/APPLICATION

Although repeatability of cold-activated BAT volumes on [18F]FDG-PET was acceptable for subjects with large amounts of BAT, further work is needed to improve the repeatability of small BAT volumes.

PURPOSE

Preliminary studies have shown choline-PET/CT to be of value in the preoperative localisation of parathyroid adenoma in primary hyperparathyroidism. Choline-PET/CT is used in our centre for patients with persistent hyperparathyroidism and in whom sestamibi scintigraphy, ultrasound, and either contrast enhanced CT or MRI, and venous sampling localisation investigations, and prior neck exploration have failed to identify the adenoma. This retrospective study aims to evaluate choline-PET/CT as a tool for localisation of parathyroid adenoma in a cohort of patients with repeatedly inconclusive conventional imaging.

METHOD AND MATERIALS

10 patients with biochemical hyperparathyroidism underwent choline-PET/CT. The findings were analysed and correlated with the prior localisation investigations. The reference standard was based on results of surgical exploration and histopathological correlation.

RESULTS

The patient cohort had undergone investigation for a mean of 5 years 3 months, had a mean of 9 previous localisation investigations (range 2-18) and a mean of 2 previous failed neck explorations (range 1-4), with 9/10 being symptomatic from their hyperparathyroidism. Choline-PET/CT identified likely causative lesions with relative certainty in 9/10 of cases. 7 cases had histologically-proven parathyroid adenoma following surgical exploration of the site identified by choline-PET/CT. A post-operative drop in serum parathyroid and/or calcium levels has been observed in all patients with positive histology.

CONCLUSION

In this challenging cohort of patients with persistent symptomatic hyperparathyroidism, with failed localization despite extensive non-invasive and invasive investigations, choline-PET/CT was able to accurately identify the location of the parathyroid adenoma in 70% cases, showing excellent promise as a second-line imaging tool.

CLINICAL RELEVANCE/APPLICATION

Choline-PET/CT shows initial promise at localising parathyroid adenoma in symptomatic patients with persistent primary hyperparathyroidism in whom conventional imaging has proved inconclusive.

SSQ14-03 Does the Risk of Development of Graves' Eye Disease after I-131 Therapy Depend On the I-131 Dosage?

PURPOSE

Graves' ophthalmopathy, or Graves' eye disease (GED) is sometimes a manifestitation of Graves' disease. It is controversial in the medical literature as to whether or not GED can be precipitated or worsened by Radioiodine therapy with I-131 (RAI). The aim of this study was to determine if there is a relationship between the dosage of I-131 administered and the onset of GED.

METHOD AND MATERIALS

We reviewed the cases of all patients receiving RAI for Graves' disease for the last 5 years. Those patients who already had GED prior to RAI were excluded from this study. Follow-up was achieved by review of medical records as well as follow-up notes of the patients' ophthalmologists. The I-131 dosage of each patient and whether or not GED later developed was then recorded. The I-131 dosage calculation was based on a desired dose of 160-200 microcuries of I-131 per gram of thyroid tissue, ranging from 10 mCi to 25 mCi of I-131.

RESULTS

A total of 82 patients received RAI for Graves' disease. Eight patients had known GED prior to RAI, and 20 patients were lost to follow-up; therefore these 2 groups were excluded. Of the remaining 54 patients, 17 (31.5%) developed GED. The remaining 37 patients thus far have not. There was no correlation between the incidence of GED and the dosage of I-131 dispensed. Statistical analysis indicates only a 1% chance to observe a correlation greater than 0.30, based on the observed incidence.

CONCLUSION

There is no relationship between the likelihood of the onset of Graves' eye disease and the dosage of I-131 in the range of 10-25 mCi dispensed.

CLINICAL RELEVANCE/APPLICATION

In RAI therapy for Graves' disease, the I-131 dosage contemplated should not be influenced by the concern for the development of Graves' ophthalmopathy.

SSQ14-04 Two Weeks' Withdrawal of Inorganic Iodine Therapy is Appropriate for Radioiodine Therapy for Graves' Hyperthyroidism

Thursday, Nov. 30 11:00AM - 11:10AM Room: S504CD

metnakada@yahoo.co.jp

PURPOSE

Inorganic iodine therapy has been getting wide popularity as an adjunctive to anti-thyroid drugs (ATDs) in treating hyperthyroidism in countries where dietary iodine intake is sufficient. The aim of this study was to investigate whether 2 weeks' withdrawal of inorganic iodine therapy was appropriate for radioactive iodine I-131 therapy (RAI) for Graves' hyperthyroidism (GH).

METHOD AND MATERIALS

We used potassium iodide (KI) pill which contains 38mg of iodine per pill. 37 patients with GH (M 5/F 32. Age 42.6 ±13.9yrs), who had been pretreated by combination of ATD and KI and were to undergo RAI, were enrolled. Thyroid weight ranged from 26 to 97g. Dose of KI (mg/day) ranged from 50 to 300mg/day (average:141). KI was withdrawn 14 days prior to RAI while ATDs were withdrawn 3 to 4 days prior to RAI. Patient were instructed to follow low iodine diet from 7days before to 3 days after administration of I-131. As a parameter for total body iodine, urinary iodine concentration normalized by urinary creatinine (UIC: μg/gCRE) was measured before withdrawal of KI (UIC1) and on the day of RIA UIC2). Thyroid function and TRAb(IU/ml) were determined on the day of RIA. 24hr uptake of radioiodine (RU; %) was determined using gamma camera and I-123. All patients were followed up for more than 2years after RAI. Results of UIC, RU, and efficacy of RAI in patients (KI group) were compared with those in 39 patients with GH, who underwent RAI with pretreatment by ATD alone (ATD group).

RESULTS

The average value of UIC2 in KI group was less than 0.1% of UIC1(147330 vs. 131.9. p=0.0008), but was higher than that in ATD group (131.9 vs.89.0, p=0.032). However, difference in RU was not significant between KI group and ATD group (64.9 vs. 71.0, ns). There was a inverse correlation between UIC2 in KI group and RI (r=-0.523, p=0.045). Additionally, successful rate of RAI in KI group was comparable to that in ATD group (78 vs.82%, ns). TRAb value in KI group was higher compared to ATD group (22.9 vs. 15.1, p=0.013).

CONCLUSION

Pretreatment by KI does not impair therapeutic efficacy of RAI for GH if the drug is discontinued 2 weeks before administration of I-131 and is combined with a low iodine diet.

CLINICAL RELEVANCE/APPLICATION

Combination therapy of KI and ATD seems feasible as a pretreatment for radioiodine therapy for Graves' hyperthyroidism.

SSQ14-05 The Relationship among FDG Uptake: Thyroglobulin Doubling Time and Behavior of Tumor in Radioiodine Negative Metastasis from Thyroid Cancer

Thursday, Nov. 30 11:10AM - 11:20AM Room: S504CD

metnakada`yahoo.co.jp

PURPOSE

Recent studies have suggested that doubling time of serum Tg (Tg-DT) under TSH suppression may better predict prognosis of

postoperative thyroid carcinomas. Aim of the present study was to investigate relationship between FDG uptake and Tg-DT in radioiodine- negative metastasis from differentiated thyroid cancer (DTC).

METHOD AND MATERIALS

66 patients with metastatic thyroid cancer (PCA/FCA 64/5) who had received total thyroidectomy followed by radioiodine ablation and had negative I-131 scan results underwent FDG PET/CT. TgAb was negative in all patients. Location of metastatic tumor was lymph nodes in the neck and/or the mediastinum in 29, lung in 21, and both lymph nodes and lung in 16. Intensity of FDG uptake in the tumor was visually compared with that of the mediastinum to be determined as positive or negative. Additionally, tumors with positive FDG uptake were classified into 2 subgroups based on SUVmax (high uptake: SUV max>=5.0, low uptake: SUV Max<5.0). When a patient had more than 2 tumors, the largest tumor was used for evaluation of FDG uptake. Tg-DT was determined as previously described (Thyroid 2011; 21:707-716). All patients were followed up for 36-85 months. Imaging modalities including US, CT, MRI and/or PET/CT were performed at a regular interval to investigate relationship among FDG uptake, Tg-DT, and behavior of tumor.

RESULTS

FDG uptake was negative (N) in 16 pts., was low (L) in 28 pts., and was high (H) in the remaining 22 pts. The average of Tg-DT(yrs) in N group, L group, and H group were 9.1, 4.7, and 1.7, respectively. There were significant differences in Tg-DT between H group and other 2 groups ($p<0.001$ for L group and $p<0.01$ for). Additionally, more than 20% increase in the short diameter of the largest tumor and/or appearance of new lesions during the follow up period were seen in 0/16 (0%) in N group, 6/21 (26%) in L group, and 17/22(77%) in H group. 2 patients in H group showed rapid growth of metastatic tumors despite of longer Tg-DT(>3 yrs.).

CONCLUSION

Negative FDG uptake in metastatic tumors may indicate longer Tg-DT and stable disease for long period while tumors with high FDG uptake tend to have shorter Tg-DT and aggressive clinical behavior. FDG PET/CT correlates well with Tg-DT and is a valuable predictor for prognosis of metastasis from DTC.

CLINICAL RELEVANCE/APPLICATION

FDG PET/CT has a positive role as an alternative to Tg-DT in management of metastasis from thyroid cancer.

SSQ14-06 I-131 Thyroid Dosimetry in Patients with Abnormal Renal Function

Thursday, Nov. 30 11:20AM - 11:30AM Room: S504CD

PURPOSE

Maximum permissible activity (MPA) of administered I-131 to treat thyroid cancer conventionally is estimated by combining whole body gamma camera & blood sample well counter measurements following oral administration of I-131. In attempting to simplify methodology by computing MPA from blood sample measurements, it is important to determine potential influence of various factors on methods used for estimating MPA. We retrospectively investigated the effects of previous treatment (PT) &/or abnormal renal function (AF) on MPA estimates derived from whole body counting and blood samples.

METHOD AND MATERIALS

Data were reviewed for 71 pts (age = 60±14 yrs; 38 female; 33 male) who previously had undergone total thyroidectomy for thyroid cancer and who were referred for pretreatment dosimetry to determine MPA. 30 pts (42%) had PT (PT+) & 41 pts (58%) did not (PT-), while 23 pts (32%) had AF (AF+) & 48 (68%) did not (AF-). Anterior & posterior whole body counts were measured by un-collimated gamma camera & blood samples were drawn & assayed in vitro by a well counter 1, 4, 24, 48, 72-96, & 96-144 hrs after 37-148 MBq I-131 administration to compute whole body γ & in-vivo ß dose contributions to compute conventional (Method1) total dose D, with MPA = 200 cGy/D. Linear regression comparing in-vitro blood sample measurements alone to conventional D yielded Method 2 predictions of D & MPA based on well counter blood measurements alone. Method 2 D & MPA were compared to conventional Method1 values by the paired t-test or Wilcoxon test & by linear regression.

RESULTS

MPA was similar for Method1 & Method2 for all 71 pts (21±14 versus 21±14 cGy/GBq, $p=0.97$), & for each pt subgroup: PT+ & AF- (N=24) MPA = 22±9 versus 22±9 GBq ($p=0.20$); PT- & AF- (N=24) MPA = 14±8 versus 14±8 GBq ($p=0.78$); PT- & AF+ (N=17) MPA = 8±2 versus 8±3 GBq ($p=0.92$); PT+ & AF+ (N=6) MPA = 7±3 versus 7±3 GBq ($p=0.29$). Correlation of Method2 to Method1 MPA was similar for PT-, PT+, AF- & AF+ subgroups ($r = 0.98, 0.99, 0.99$ & 0.94, respectively).

CONCLUSION

In pts with metastatic thyroid carcinoma or compromised renal function, MPA can be accurately estimated by measuring I-131 blood clearance, without the need to perform wholebody counting.

CLINICAL RELEVANCE/APPLICATION

Blood sampling alone suffices to estimate I-131 dose, regardless of renal function..

SSQ14-07 Utility of Fused Images by 99mtc-MDP SPECT and Low Dose CT in Detecting for Chronic-Infected Nonunion of the Lower Limb

Thursday, Nov. 30 11:30AM - 11:40AM Room: S504CD

Participants
Qitao Song, Tianjin, China (*Presenter*) Nothing to Disclose
Lei Long, Tianjin, China (*Abstract Co-Author*) Nothing to Disclose
Shuangshuang Cui, Tianjin, China (*Abstract Co-Author*) Nothing to Disclose
Chunyou Wan, Tianjin, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

15922234084@163.com

PURPOSE

To evaluate the benefits of using SPECT/CT fused images than using simple SPECT or CT in diagnosis and positioning of chronic-osteomyelitis nonunion of the lower limb.

METHOD AND MATERIALS

1.Patients are intravenous-injected typically 740-1110 MBq 99mTc-MDP. Images were acquired on a SPECT/CT (Dicovery™NM/CT670,GE) 2.The hybrid SPECT/CT system has a 16 slice multidetector CT. The SPECT was followed by CT examination with settings of 80-100 kV, 240 mAs, pitch-1. The CT images were reconstructed with 0.625mm slice thickness in multiplanar reformatting(MPR). 3.The author presents 36 cases of lower limb fracture nonunion, associated with or be suspicious of chronic osteomyelitis. For data analysis findings of three bone imaging models for every patients were categorized as yes(osteomyelitis), no(no osteomyelitis), or equivocal for the presence of osteomyelitis. Secondly, SPECT/CT fused imaging were compared to SPECT and CT with respect to localization ,extent of lesions, the body surface location consistency and the influence of internal and external fixed on each method.

RESULTS

The degree of interobserver agreement was evaluated by computing the kappa coefficient (κ=0.759 for SPECT/CT, κ=0.184 for CT, κ=0.192 forSPECT). Sensitivity of whole body bone scan for osteomyelitis was 52.2%, specificity 15.4%. Sensitivity of CT was 65.2%, specificity 23.1%. SPECT/CT fused images was sensitivity 91.3%, specificity 84.6%. It is the best choice in our study.Definition of anatomical localization of inflammatory foci was much easier by SPECT/CT fused images due to better description of anatomical details and concentration areas of eye-catching.

CONCLUSION

SPECT/CT fused images increased specificity than SPECT or CT.In distinguishing between soft tissue infection with osteomyelitis ,it is more accurate than only using SPECT. Hybrid SPECT/CT (With 16 row diagnositic CT)at the same time provide both anatomical and functions information. 99mTc-MDP SPECT/CT is more suitable for detecting osteomyelitis in China. Because it is more efficient, convenient(no special training), cheap than radiolabelled autologous white cells and 99mTc labelled monoclonal antibodies. Because of combination of SPECT and CT, radiation dose of patients has been increased. In order to reduce the radiation dose, the author adopts the method of low dose for lower limb CT scans(about 40% off).

CLINICAL RELEVANCE/APPLICATION

osteomyelitis

SSQ14-08 Correlation of Bone SPECT/CT and Plain Radiography with Clinical Findings in Painful Hip Prostheses

Thursday, Nov. 30 11:40AM - 11:50AM Room: S504CD

For information about this presentation, contact:

zyang@lsuhsc.edu

PURPOSE

The concomitant use of plain radiography (PR) and bone SPECT/CT scans (BSCS) have greater potential to accurately detect complications after hip arthroplasty compared to each modality alone. We aimed to correlate patient-reported sites of pain with findings on BSCS and PR in patients with painful hip prostheses.

METHOD AND MATERIALS

A retrospective review of 12 consecutive patients with painful hip prosthesis who received BSCS was performed. The pain location and duration and prosthesis type, treatment, and surgical pathology were noted from nuclear medicine and orthopedic clinic reports. Each BSCS was interpreted side-by-side with the most recent hip PR obtained prior to each BSCS. The Gruen zones and De Lee and Charnley zones were noted for sites with increased uptake on BSCS. For each zone, an uptake ratio (UR) was measured as uptake intensity in counts/1.8 cm3 divided by a background uptake value of half the average uptake at the iliac crests, and a pixel value ratio (PVR) was obtained from dividing the average pixel value by a background pixel value of the adjacent normal bone-prosthesis or cement-prosthesis (BPCP) interface. Qualitative and quantitative grades were applied to sites of increased uptake on BSCS and areas of increased bone formation on PR.

RESULTS

In each case, UR on BSCS and PVR on PR were increased at each patient-reported site of pain upon evaluation with both qualitative and quantitative grading. The pain location had concordance rates of 83.3% with the zone of greatest PVR (10/12 cases) and 83.3% with the zone of highest UR (10/12 cases). The concordance rate between the zone of greatest PVR and the zone of greatest UR was 83.3%. Focal areas of increased bone formation/density on PR in the BPCP interface were noted

contralateral to the side of the prosthesis with loosening with BSCS demonstrating increased uptake in a pattern of prosthesis loosening.

CONCLUSION

Each patient-reported site of pain demonstrated increased uptake on BSCS and increased pixel value on PR. Focal areas of increased bone density contralateral to periprosthetic loosening sites may suggest loosening in the absence of the characteristic greater-than-2-mm radiolucent zone at the BPBC interface and be an earlier radiographic indication of loosening.

CLINICAL RELEVANCE/APPLICATION

Correlations between findings on BSCS and PR may help overcome interpretive challenges on either modality alone, important when only one modality is available.

SSQ14-09 F-18 FDG PET Trumps MRI on PET MRI evaluation of Diabetic Pedal Osteomyelitis

Thursday, Nov. 30 11:50AM - 12:00PM Room: S504CD

Participants
Kavitha Yaddanapudi, MD, Stony Brook, NY (*Presenter*) Nothing to Disclose
Dinko Franceschi, MD, Stony Brook, NY (*Abstract Co-Author*) Nothing to Disclose
Robert Matthews, MD, Stony Brook, NY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The purpose of this study is to evaluate the relative senstivity of PET and MRI in diabetic osteomyelitis of foot as detected on PET MRI and confirmed by histopathological correlation.

METHOD AND MATERIALS

Retrospective evaluation of PET MRI imaging and correlation with histopathology was performed on 12 consecutive cases of suspected diabetic pedal osteomyelitis. On MRI imaging signal abnormalities were clasified as grade 0 (normal), grade I (edema) and grade II (confluent T1 hypointense signal).Grade II signal was diagnosed as osteomyelitis. Focal abnormal FDG uptake in the bones on PET was diagnosed as osteomyelitis. Of the 12 patients 10 (83.3%) had histopathological confirmation from surgery.

RESULTS

Ten of the twelve patients (83.3%) had osteomyelitis diagnosed on PET MRI which was confirmed at pathology (100% specificity). The two patients without evidence of osteomyelitis on PET MRI who were followed up were concluded not to have osteomyeltis according to clinical end points. Of the ten patients all ten had abnormal FDG uptake (100% senstivity FDG) localizing to bone. Only 7 of the 10 had MRI signal abnormalities Grade II represeneting osteomyelitis (70% senstivity MRI).Sites of pedal osteomyelitis included distal phalanges (N=6), tarsals (N=2), metatrasal (N=3) and calcaneus (N=1). Three of the ten patients had focal abscesses in the soft tissues.

CONCLUSION

FDG PET abnormalities on PET MRI are more senstive than MRI component for detection of diabetic osteomyeltis of the foot. Localisation to the bone however is only possible because of the simultaneous MRI accquistion which makes it an invaluable component of this modlaity.

CLINICAL RELEVANCE/APPLICATION

Diabetic osteomyelitis of the foot is a common problem that has significant clinical ramifications. Diagnosing osteomyelitis in diabetic foot especially on MRI and CT is complicated by preexisting chronic bony changes from neuropathy and non healing ulcers. Magnetic Resonance Imaging (MRI) is a useful modality for diagnosis of osteomyelitis and is more sensitive than CT. FDG PET is a very senstive modality for diagnosing osteomyelitis however in PET alone or PET CT anatomcal localisation to the bone is not optimal, a problem that is remedied by excellent anatomical detail on MRI. PET MRI serves as a one stop investigation for evaluation of osteomyeltis in diabetic foot.

PURPOSE

To investigate a new dual-energy computed tomography (DECT) technique with a modified 3-material decomposition algorithm for calcium removal in extracranial carotid artery stenosis.

METHOD AND MATERIALS

In this retrospective, IRB-approved study 30 calcified carotid plaques in 22 patients (15 males, mean age 73±10 years) with suspicion of stroke were included. DECT image data were obtained using second-generation dual-source CT with tube voltages at 80/140Sn kVp. Conventional CTA and virtual non-calcium (VNCa) images using the modified DECT algorithm were reconstructed. By assessing spectral characteristics, blooming-independent calcium removal was achieved. Two independent, blinded readers evaluated subjective image quality, blooming artifacts, amount of (residual) calcification, and performed stenosis measurements according to the NASCET-criteria. Differences were tested using a pairwise sign test. Paired sample t-tests with Bonferroni correction ($p<0.017$) and Bland-Altman analyses were used for assessing differences in stenosis measurements between VNCa and conventional CTA with digital subtraction angiography (DSA) as reference.

RESULTS

Subjective image quality was similar among conventional CTA and VNCa image datasets ($p=0.82$), while blooming artifacts were significantly reduced in VNCa images compared to conventional CTA ($p<0.001$). Residual calcifications in VNCa images were absent in 11 (37%), minor in 12 (40%), medium-sized in 2 (7%), and large in 5 (17%) arteries. Stenosis measurements differed significantly between VNCa (mean stenosis: 27±20%) and conventional CTA images (mean stenosis: 39±16%; $p<0.001$) and between conventional CTA and DSA (23±16%,$p<0.001$). No significant differences in stenosis measurements were observed between VNCa and DSA ($p=0.189$), with narrow limits of agreement (mean difference±1.96 SD,-4.7%; -35.13%; 25.71%).

CONCLUSION

The modified three-material decomposition DECT algorithm for blooming-independent calcium removal allows for an accurate removal of calcified carotid plaques in extracranial carotid artery disease.

CLINICAL RELEVANCE/APPLICATION

A novel, blooming-independent modified 3-material decomposition algorithm for calcium removal improves stenosis assessments by preventing overestimation of calcified stenosis in DECTA.

SSQ15-02 CT Texture of Carotid Arteries identifies Vulnerable Plaque in Stroke and Transient Ischaemic Attack: A Preliminary Outcome Study

PURPOSE

To assess the potential role of texture analysis in carotid arteries imaging.

METHOD AND MATERIALS

A retrospective case-control study. From a study population of 341 patients with CV risk factors that underwent whole-body CTA (detector configuration: 64x0.6mm; Iomeprol-400, 400mgI/ml; 70+50ml@4ml/s), 12 patients (age 63±10.29 yrs) with carotid atherosclerosis and a subsequent history of Transient Ischemic Attack (TIA) or Stroke were identified. These were age and sex matched with 12 control cases (age 62.9±10.16 yrs) with asymptomatic carotid atherosclerosis (follow-up 103.58±9.2 months). Stenosis and plaque composition were determined. Texture analysis was performed using a commercially available software (TexRAD, Somerset, UK) by a single operator blinded to clinical data. TexRAD uses a filtration-histogram based texture analysis technique to extract pixel size based (fine, medium, coarse) features and quantified histogram parameters including skewness (S) and normalized standard-deviation (SDn). A single axial slice was selected to best represent the carotid bifurcation for each side and a region of interest (ROI) was manually delineated in order to fully enclose the artery. Statistical analysis was performed using X2, t-test and Mann-Whitney test. ROC curves were constructed using TIA/Stroke as outcome.

RESULTS

Stenosis degree was greater at the right carotid bifurcation in the patient group (41.08 vs 12.08; p=.014), however no statistically significant differences were found at the left carotid bifurcation (p=.56); there were no differences in plaque composition for both sides (right p=.39, left p=.72). There was a statistically significant difference in Skewness at the fine and medium texture level (p=0.009 for spatial scaling factor (SSF) =2mm; p<0.001 for SSF=3mm and p=0.003 for SSF=4mm). SDn was statistically significant different between patients and control group for SSF=2mm (p=0.033). AUC values at SSF2 were .684 for SD and .723 for S (p values of .033 and .009 respectively); AUC values for S were .808 (p=.0001) at SSF3 and .075 (p=0.003) at SSF4.

CONCLUSION

CT texture identified vulnerable plaque in Stroke and TIA and may, therefore, have the potential to act as a new means of risk stratification in patients with carotid atherosclerosis.

CLINICAL RELEVANCE/APPLICATION

CT texture of carotid arteries may improve the identification of patients at risk for ischemic strokes.

SSQ15-03 Evaluation of Spectral Imaging in Craniocervical CT Angiography: Comparison with Conventional 120kVp CT Imaging

Thursday, Nov. 30 10:50AM - 11:00AM Room: N228

Participants
Shu Wang, Yancheng, China (*Presenter*) Nothing to Disclose
Fei Chen, Yancheng, China (*Abstract Co-Author*) Nothing to Disclose
Lizheng Yao, Yancheng, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

ycsyws@126.com

PURPOSE

To evaluate the application of gemstone spectral imaging (GSI) protocol in craniocervical CTA by comparing the image quality and radiation dose with a conventional 120-kVp protocol.

METHOD AND MATERIALS

40 patients were scanned on Discovery CT750-HD (GE Healthcare) with parameters of 40mm helical 0.984:1, 360 mA, 0.6s rotation time. 20 patients underwent conventional 120 kVp scan and the other 20 were scanned using GSI mode, with monochromatic images of 60keV and 70keV being reconstructed. Both groups received 60 ml contrast agent of 350 mgI/ml with an injection speed of 4.5 ml/s. Objective image quality of the two groups was compared in terms of arterial enhancement and contrast-to-noise-ratio (CNR), which were measured at seven ROIs placed respectively in bilateral carotid artery bifurcation, basal artery, bilateral internal carotid artery C2 segment, and bilateral middle cerebral artery proximal end. Subjective image quality was evaluated using a 5 grade scale (5-excellent; 1-fail). The effective radiation dose (ED) was also recorded and compared. Data were analyzed by using independent-sample t-test.

RESULTS

As compared to 120kVp group, 60keV monochromatic images had significantly higher arterial enhancement (120kVp: 355±64.2 HU vs. 60keV: 483±81.1 HU, p<.001), comparable CNR (120kVp: 29±7.7 vs. 60keV: 29±7.5, p=.933), and significantly higher subjective image quality (120 kVp: 3.7±0.80 vs. 60keV: 4.5±0.51, p<.001). In contrast, 70keV monochromatic images did not differ from the 120kVp group in image quality of arterial enhancement (352±57.0 HU, p=.549), CNR (25±6.1, p=.085), or subjective image quality (3.7±0.80, p=.547). Radiation dose in GSI group (2.61mSv) reduced 27.5% compared with 120 kVp group (3.60mSv).

CONCLUSION

Compared with conventional 120 kVp scan protocol, 60keV GSI could reduce radiation dose, maintain CNR and improve subject

Compared with conventional 120 kVp scan protocol, 60keV GSI could reduce radiation dose, maintain CNR and improve subject image quality.

CLINICAL RELEVANCE/APPLICATION

The application of GSI mode in craniocervical CTA with appropriate single energy level could significantly reduce radiation dose while maintaining image quality.

SSQ15-04 Feasibility of 70kV and Adaptive Statistical Iterative Reconstruction V Technique in Low Dose Craniocervical CT Angiography

xiaoxiao_8236@sina.com

PURPOSE

To investigate the feasibility of 70kV and adaptive statistical iterative reconstruction V (ASiR-V) to reduce radiation dose in wide-coverage craniocervical CT angiography , compared with 100kV

METHOD AND MATERIALS

This study was approved by the institutional review board. Written informed consent was waived. Twenty cases planned to craniocervical CT angiography was enrolled and randomly divided into two groups: A with 70kV and 40% ASiR-V(n=10), B with 100kV and 0%ASiR-V(n=10). Regions of interest (ROI) were placed on the thoracic inlet of carotid artery and cranial segment of carotid artery to measure the CT attenuation value and standard deviation (SD), the signal-noise-ratio (SNR) and contrast-noise-ratio (CNR) were calculated. Two experienced radiologists, who were blinded to the scan and reconstruction information, independently graded the CT images in terms of visibility and artifacts with a 4-grade rating scale. Dose length product (DLP) and effective radiation dose (ED) were recorded and calculated. Measurement data was compared with independent student T test, the concordance of image quality scores by the two radiologists was evaluated with kappa analysis, the image quality score was compared with Mann-Whitney U test.

RESULTS

The kappa value for the image quality scores from two radiologists was 0.618. The image quality score had no significant difference between two groups (3.80±0.42 vs 3.90±0.21, P=0.842). The effective radiation dose in group A was 59.5% lower that in group B (0.30±0.27mSv vs 0.74±0.15mSv, t=8.957, P<0.001). The CT value of carotid artery in group A was higher than that in group B (501.20±113.22HU vs 328.39±53.34HU,F=16.937,P=0.001). The SD value of of carotid artery in group A was higher than that in group B (25.53±3.01 vs 22.52±3.89 F=1.463,P=0.242). The SNR and CNR of carotid artery in group A was higher than that in group B(SNR, 19.84±4.87 vs 16.51±5.50, F=13.862,P=0.002; CNR, 32.22±10.01 vs 24.12±10.62, F=5.435,P=0.032).

CONCLUSION

Application of 70kV and adaptive statistical iterative reconstruction V (ASiR-V) can achieve approximate 60% radiation dose reduction and provide similar image quality compared with 100kV.

CLINICAL RELEVANCE/APPLICATION

Application of 70kV and adaptive statistical iterative reconstruction V (ASiR-V) can achieve approximate 60% radiation dose reduction and provide similar image quality compared with 100kV.

SSQ15-05 Who Is the Source of Redundant Imaging: Clinicians versus Radiologists?

PURPOSE

Redundant neurovascular imaging studies such as Carotid US, CTA, MRA, and DSA may add cost to healthcare in the evaluation of patients with new neurologic deficits. However there has been an assumption that this is due to clinicians' mismanagement. We sought to determine to what extend such redundant studies are generated by radiologists' recommendations.

METHOD AND MATERIALS

The study was considered a quality improvement analysis and therefore did not require an IRB submission and was HIPAA compliant. The Radiology Information System was queried for the presence of carotid ultrasound, CT angiography, Digital Subtraction Angiography (DSA) and MR angiography occurring within 48 hours, 72 hours, and 7 days of each other in the setting of new neurologic symptoms during calendar year 2016. The reports were reviewed to determine how often 1) there were redundant studies and 2) radiologists recommended the additional studies.

RESULTS

3,300 exams from 2,939 patients conducted at both inpatient and outpatient clinics at three affiliated institutions from January 1, 2016 to December 31, 2016 were included in this study. Redundant studies occurred in 86/2939 (6.7%) of these 2939 patients. Of these 86 redundant studies, the radiology report contained a recommendation for another vascular study in 35 out of the 86 (40.7%). This included 15 cases of recommending MRA after CTA, 15 cases of DSA after CTA, 3 cases of DSA after MRA and 2 cases of US after CTA. The remaining 51 of the 86 redundant studies were driven by the clinical services, not radiologists.Of the 35 instances in which the radiologist recommended a second study, that second study confirmed the first study in 24/35 (68.6%) cases and disagreed with the first study in 11/35 (31.4%). Of the 51 cases of redundant studies generated by clinicians, 36/51 (70.6%) of the subsequent studies agreed with the first study and 15/51 (29.4%) were discrepant.

CONCLUSION

Of cases of redundant neurovascular imaging, the majority (59.3% = 51/86) are generated by clinicians, but radiologists recommended additional imaging in 40.7% of cases. When radiologists at our institution recommend additional radiological studies, 32/35 (91.4%) occurred following a CTA. Most second studies (68.6%) confirmed the first study's findings.

CLINICAL RELEVANCE/APPLICATION

Clinicians generate most redundant neurovascular studies but radiologists are responsible as well.

SSQ15-06 Optimizing Image Quality in Head and Neck CT Angiography with Spectral CT Optimal Monochromatic Image Technique

Thursday, Nov. 30 11:20AM - 11:30AM Room: N228

Participants

772890021@qq.com

PURPOSE

To study the use of the optimal monochromatic image technique in dual-energy Spectral imaging to optimize the image quality in head and neck CT angiography (CTA)

METHOD AND MATERIALS

28 patients were selected to undergo head and neck CTA using Spectral scan mode with patient body mass index (BMI)-dependent scan protocols (GSI-51 for BMI<23kg/m2 and GSI-1 for BMI>23kg/m2). After scanning, 5 sets of monochromatic images at 60, 65, 70, 75 and 80keV were reconstructed. Images were transferred to AW4.6 workstation for MPR, VR and CPR reconstruction. Two experienced radiologists evaluated the subjective image quality with a 4-point scoring system with the consistency of the scores evaluated by Kappa test. The CT values and their standard deviations of the aortic arch, common carotid artery, internal carotid artery, middle cerebral artery, cleidomastoid, and brain parenchyma were measured. The signal-to-noise ratio (SNR) and contrast to noise ratio (CNR) of the cervical vessels were calculated. Measurements in the 5 groups were compared by using the single factor variance analysis

RESULTS

The differences of SNR, CNR and subjective image scores among the 5 groups were statistically significant ($P < 0.05$). The average subjective image quality scores were the highest at 60keV (3.64±0.49) and 65keV (3.61±0.50) and the two observers had excellent agreement (Kappa>0.8). The highest SNR and CNR values were also obtained at these two energy levels. The SNR at 60keV and 65keV levels were (66.42±18.84 and 68.04±13.67) for the common carotid artery, (42.42±13.08 and 12.98±43.10) for the internal carotid artery and (45.51±12.47 and 45.52±11.47) for the middle cerebral artery. The respective CNR values were (77.22±24.10, 75.92±24.04), (77.31±25.47, 25.04±76.03), and (39.97±11.99, 39.45±11.05). The CT values at these two levels were all greater than 300HU for adequate vessel display.

CONCLUSION

The optimal energy levels in Spectral CT for head and neck CTA were at 60-65keV to provide adequate enhancement and to improve image quality.

CLINICAL RELEVANCE/APPLICATION

The optimal energy level technique in Spectral CT imaging may be used in head and neck CT to provide adequate enhancement and to improve image quality.

SSQ15-08 The Ability of Whole-Body CT to Detect Blunt Cerebrovascular Injury in a Large Trauma Patient Cohort: A Prospective Evaluation

Thursday, Nov. 30 11:40AM - 11:50AM Room: N228

justedv@uw.edu

PURPOSE

The purpose of this study is to assess the ability of whole-body CT (WBCT) to detect blunt cerebrovascular injury (BCVI) in a trauma paitient population.

METHOD AND MATERIALS

All trauma patients presenting to our institution between 8/1/2013 and 10/31/2016 were retrospectively identified from a radiology report database. Patients were 18-years of age or older; had sustained blunt trauma causing BCVI; and underwent WBCT imaging with neck CTA reconstructions at presentation. A 64-detector WBCT consisting of a chest CTA extending through the circle of Willis with 2 mm thick axial slices was performed, and neck CTA reconstructions with 1 mm thick axial slices and coronal, sagittal, and oblique MIP reconstructions were generated from WBCT source data. A neuroradiologist blinded to clinical history prospectively evaluated each WBCT, noting injury presence, location, and grade using the Biffl scale for BCVI grading. Following a 7 day washout period, neck CTA reconstructions were evaluated by the same rater in identical fashion. Twenty-one normal WBCT and neck CTA were randomly inserted into each respective group, and the reviewer was told that an unknown number of normal studies were present prior to evaluation. Sensitivity, specificity, and positive and negative predictive values were calculated with neck CTA findings serving as the reference standard.

RESULTS

During this study period, 3,392 trauma patients presented for WBCT with 118 trauma patients diagnosed with BCVI. Six patients were subsequently excluded due to poor image quality, resulting in a final cohort of 112 (3.3%) BCVI patients who met all inclusion criteria and possessed 133 individual vascular injuries. WBCT correctly detected 115 BCVI. Eighteen BCVI were missed by WBCT whereas 5 vessels were incorrectly identified as having BCVI. The sensitivity of WBCT for detecting BCVI was 86.5%, and its specificity was 76.2%. The positive predictive value was 95.8% and the negative predictive value was 47.1%. Of the 18 missed BCVI, 8 (44.4%) were grade I injuries, 9 (50.0%) were grade II injuries, and 1 (0.6%) was grade III. No grade IV injuries were missed.

CONCLUSION

WBCT is sufficiently sensitive and specific for detecting BCVI, with grade I and II injuries accounting for the majority of missed lesions.

CLINICAL RELEVANCE/APPLICATION

WBCT is sensitive enough to detect the majority of BCVI and should be used as a first-line screening tool in trauma patients.

SSQ15-09 Improving the Accuracy of Quantifying Carotid Atherosclerotic Plaques with High Definition Acquisition and Reconstruction

Thursday, Nov. 30 11:50AM - 12:00PM Room: N228

593195886@qq.com

PURPOSE

To investigate the accuracy of quantifying carotid atherosclerotic plaques with high-definition (HD) acquisition and reconstruction model on a high-definition computed tomography (HDCT) system.

METHOD AND MATERIALS

20 Patients with carotid stenosis and plaques (9 males, 11 females, mean age 66±0.46y) underwent HDCT carotid arteries angiography with a high-definition acquisition mode. Images were reconstructed with the high-definition algorithm with the new adaptive statistical iterative reconstruction (ASIR-V) at 50% strength (50% ASIR-V) and standard algorithm with 40% ASIR-V. The axial images of the two reconstructions were further processed to generate the maximum intensity projection (MIP) and multi-planar reconstruction (MPR) three-dimensional images. CT values, standard deviation (SD) in arteries and muscle and the areas of plaques, calcifications and the degree of stenosis in vessels were measured. Contrast-to-noise ratio (CNR) for the carotid arteries was calculated (CNR= (CT carotid arteries -CT muscle) / SD muscle. All measured data were compared using paired sample t test for statistical analysis using SPSS software,a=0.05 indicating significant difference.

RESULTS

73 plaques, including 28 calcified plaques, 23 mixed plaques and 22 soft plaques were identified in both standard and HD reconstructions. CNR values of two reconstruction methods were statistically the same (P>0.05). However, the area measurement for the calcified plaques with the HD reconstruction (3.60±3.00mm2) was statistically smaller than that with the standard reconstruction (4.27±3.45mm2) (p=0.02). There was no difference between the two reconstructions in the vascular stenosis degree (P = 0.129) and plaque area measurement (P = 0.598) .

CONCLUSION

High-definition acquisition and reconstruction on a HDCT system improves the accuracy of quantifying calcified carotid atherosclerotic plaques.

CLINICAL RELEVANCE/APPLICATION

High-definition acquisition and reconstruction on a HDCT system improves the accuracy of quantifying calcified carotid atherosclerotic plaques.

Inseong Kim, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To reveal changes in neurotransmitters in internet and smartphone addicted youth compared with normal controls and after cognitive behavioral therapy, and to identify the correlations between neurotransmitters and affective factors related to addiction.

METHOD AND MATERIALS

Institutional review board approved this prospective study and informed consents were obtained. Nineteen young persons with internet and smartphone addictions consisted of 9 males and 10 females and their mean age was 15.47±3.06 years. Nineteen gender and age-matched healthy controls were also included. Nine weeks cognitive behavioral therapy was administered to 12 addicts ages 11 to 17 years. MEGA-press MRS was used to measure GABA and glutamate-glutamine (Glx) levels in the anterior cingulate cortex. GABA and Glx levels in the addicted group were compared to controls and after 9 weeks of cognitive behavioral therapy. GABA and Glx levels were correlated to clinical scales of internet and smartphone addictions, impulsiveness, depression, anxiety, insomnia and sleep quality.

RESULTS

Brain-parenchymal and gray-matter volume adjusted GABA to creatine ratios (p=0.028 and 0.016) and GABA to Glx ratios (p=0.031 and 0.021) were significantly increased in internet and smartphone addictions. After 9 weeks of cognitive behavioral therapy, brain-parenchymal and gray-matter volume adjusted GABA to creatine ratios (p=0.034 and 0.026) and brain-parenchymal volume adjusted GABA to Glx ratio (p=0.05) were significantly decreased. Glx was not statistically significant. Most brain-parenchymal and gray-matter volume adjusted GABA to creatine ratios and GABA to Glx ratios were significantly correlated with clinical scales of internet and smartphone addictions, depression and anxiety.

CONCLUSION

The increased GABA level and disrupted balance between GABA and glutamate in the anterior cingulate cortex may contribute to understanding the pathophysiology of and treatment for internet and smartphone addictions. Correlations between neurotransmitters and psychology tests in internet and smartphone addictions may reveal the relation and solution to their psychological comorbidities.

CLINICAL RELEVANCE/APPLICATION

The increased GABA in internet and smartphone addicted youth and its decrease after cognitive behavioral therapy will be useful to reveal the neurobiology of comorbidities and treatment.

SSQ16-02 Spontaneous Low-Frequency Fluctuations in Neural System for Emotional Perception in Major Psychiatric Diagnostic Categories: Amplitude Similarities and Differences across Frequency Bands

changmiao618@163.com

PURPOSE

Growing evidence indicates shared and distinct emotional perception in schizophrenia (SZ), bipolar disorder (BD), and major depressive disorder (MDD). The alterations of spontaneous low-frequency fluctuations have been increasingly reported in emotional perception neural system in these disorders. However, it is unknown what similarities and differences of their amplitudes (ALFF) are across SZ, BD, and MDD.

METHOD AND MATERIALS

ALFF and its signal balance between two frequency bands (slow-5 and slow-4) within emotional perception neural system were compared across 119 SZ, 100 BD, 123 MDD, and 183 healthy control (HC) participants. Exploratory analyses were performed to determine the relationship between an ALFF balance and clinical variables.

RESULTS

Commonalities in ALFF change pattern were observed across three disorders in emotional perception neural substrates, such as increased ALFF in the anterior cerebrum, including subcortical, limbic, paralimbic, and heteromodal cortical regions, and decreased ALFF in the posterior visual cortices. SZ, BD, and MDD showed significant decreased ALFF signal balance within emotional perception neural system in both slow-5 and slow-4, with greatest alterations in SZ, followed by BD, and then MDD. A negative correlation was shown between the ALFF balance and negative/disorganized symptoms in slow-4 across SZ, BD, and MDD.

CONCLUSION

Our findings suggest that the extent of observed commonalities herein further support the presence of core neurobiological disruptions shared among SZ, BD, and MDD. ALFF signal balance might be considered as an important neuroimaging marker for the future diagnosis and treatment in these major psychiatric disorders.

CLINICAL RELEVANCE/APPLICATION

Our major findings suggest that the extent of observed commonalities herein further support the presence of core neurobiological disruptions shared among SZ, BD, and MDD. The balance of ALFF signals within emotional perception neural system might be considered as an important neuroimaging marker for the future diagnosis and treatment in these major psychiatric disorders.

SSQ16-03 The Impact of Apolipoprotein E Gene Polymorphism on the Cerebral Blood Flow in Patients with Mild Cognitive Impairment

Thursday, Nov. 30 10:50AM - 11:00AM Room: N229

Participants
Lin Zhu, PhD, Nanjing, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

julinzz@163.com

PURPOSE

We sought to investigate whether the apolipoprotein E (APOE) genotype specifically modulates cerebral blood flow in patients with amnesic mild cognitive impairment (aMCI) by using the pulsed arterial spin labeling (ASL) data.

METHOD AND MATERIALS

83 aMCI and 130 healthy controls (HC) underwent neuropsychological battery assessments, genetic screening and MRI scanning. ASL data preprocessing was carried out using the ASLtbx toolbox. A voxel-wise two-way ANOVA was performed to examine the main effects of diagnosis (aMCI vs. HC) and APOE genotype (ε2 vs. ε3ε3 vs. ε4), and the diagnosis-by-genotype interactions on CBF maps. Then, we performed multiple linear regression analyses to examine the relationships between the neuropsychological test scores and CBF values in brain areas showing significant diagnosis-by-genotype interactions.

RESULTS

(1) Significant diagnosis-by-genotype interactions on CBF were observed in the left superior frontal gyrus , right anterior cingulate/medial prefrontal cortex and bilateral superior temporal gyrus. Post-hoc pairwise analysis revealed that compared with the ε2 carriers and ε3ε3 carriers, the ε4 carriers had significant higher CBF values in the above areas in the aMCI group, but there were no significant genotype differences in the HC group. (2) APOE ε4 carriers showed significant higher CBF values in the right anterior and posterior cingulate cortex than the ε2 carriers and ε3ε3 carriers respectively; (3) Compared with HC group, the aMCI group exhibited higher CBF values primarily in the left superior and middle frontal gyrus. (4) We found that the CBF values in the right anterior cingulate/medial prefomtal gyrus and superior temporal gyrus were negatively correlated with the similarity test scores ($r = -0.453$, $P = 0.014$; $r = -0.497$, $P = 0.006$).

CONCLUSION

The APOE genotype has diaease-specific effects on cerebral perfusion; the increased CBF within the lateral prefrontal and temperal cortex in the aMCI ε4 carriers may be interpreted as reflecting greater cognitive "effect" by aMCI ε4 carriers to achieve the same

level of performance as aMCI ε4 non-carriers (e.g., ε2 carriers and ε3ε3 carriers).

CLINICAL RELEVANCE/APPLICATION

(dealing with functional MR and cortical activation) ' fMRI may lay a foundation for the perfusion index of AD early diagnosis , disease severity, the following-up of AD and drug efficacy determination.'

SSQ16-04 Interaction of Systemic Oxidative Stress and Mesial Temporal Network Degeneration in Parkinson's Disease with and without Cognitive Impairment

Thursday, Nov. 30 11:00AM - 11:10AM Room: N229

Participants
Pi-Ling Chiang, MD, Kaohsiung, Taiwan (*Presenter*) Nothing to Disclose
Hsiu-Ling Chen, Kaohsiung, Taiwan (*Abstract Co-Author*) Nothing to Disclose
Yueh-Sheng Chen, Kaohsiung, Taiwan (*Abstract Co-Author*) Nothing to Disclose
Meng-Hsiang Chen, Kaohsiung, Taiwan (*Abstract Co-Author*) Nothing to Disclose
Wei-Che Lin, MD, Kaohsiung, Taiwan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Systemic oxidative stress is the well-investigated factor and contributes to neuroinflammation of Parkinson's disease (PD). Cognitive impairments in PD are strong-associated with mesial temporal lobe (MTL) dysfunction. In the present study, we sought to evaluate the relationship between systemic oxidative stress and MTL function by measuring the morphology and functional network alteration in PD patients with and without cognitive impairment.

METHOD AND MATERIALS

Forty-one patients with PD (subgrouping into 3 groups [PD-normal, PD-mild cognitive impairment, PD-dementia]) and 29 normal control volunteers underwent peripheral blood sampling to quantify systemic oxidative stress markers, and T1W volumetric and resting state functional MRI (rs-fMRI) scans. Rs-fMRI was used to derive the healthy intrinsic connectivity patterns seeded by the epicenter vulnerable to any of significant oxidative stress markers. The functional connectivity correlation coefficient (fc-CC) and gray matter volume (GMV) of the network seeded by the epicenter among groups were compared. The correlation analysis among fc-CC, GMV and cognitive impairment were performed.

RESULTS

The oxidative stress markers including leukocyte apoptosis and LFA-1 values were significantly higher in the PD group. Using whole brain VBM based correlation analysis, bilateral MTL were identified as the most vulnerable epicenters of lymphocyte apoptosis ($p < 0.005$). The following resting state functional connectivity analysis further revealed the MTL network seeded by the epicenter. The MLT network of normal connectivity profile was resembled the PD-associated atrophy pattern. The GMV of the MTL network also demonstrated the significant difference between groups. Reduced fc-CC and GMV were associated with the progressed cognitive impairment.

CONCLUSION

The epicenters vulnerable to lymphocyte apoptosis can be linked to an altered MTL network that modifies both architecture and functional connectivity, with relationship to cognitive impairment. The possible relations among them may represent consequent cognitive impairment processes of systemic oxidative stress and MTL network injuries in PD patients.

CLINICAL RELEVANCE/APPLICATION

The volumetric and re-fMR can demostrate damages of MTL network vulnerable to oxidative stress.

SSQ16-05 Effects of Mentally Stimulating Activities Training On Resting-State Network Functional Connectivity in Amnestic Mild Cognitive Impairment: A Pilot Controlled Trial

PURPOSE

To explore the resting-state network functional connectivity alterations in patients with amnestic mild cognitive impairment(aMCI)before and after mentally stimulating activities training.

METHOD AND MATERIALS

Cognitive diagnosis was made by an expert consensus panel based on previous published criteria. Thirty-eight elderly subjects with aMCI comprising of training group (18) and control group (18), with age-, sex- and MoCA score-matched participated in this study. Rest-state fMRI (rs-fMRI) and neuropsychological assessment were conducted at baseline and after 6-month following training/control program. The global functional connectivity of rs-fMRI was analysed based on the graph theoretical modeling and seed-based analysis. The changes of functional connectivity and neuropsychological scores were compared between the two groups.

RESULTS

After 6-month training/control program, the MoCA score was significantly increased in training group (25.53±2.51) compared with the control group (21.81±2.02). Based on the graph theoretical modeling, the bilateral angular gyrus presented positive connectivity with the global brain in training group. Seed-based analysis, functional connectivity between the hippocampus and a set of regions was decreased in training group, these regions are: the right angular, cingulate gyrus and praecuneus; While, the left supplement motor area showed increased connectivity to the hippocampus.

CONCLUSION

These findings would be helpful to aid our understanding of the neurofunctional mechanisms associated with effects of mentally stimulating activities training on the cognitive function in aMCI.

CLINICAL RELEVANCE/APPLICATION

The network functional connectivity analysis of resting-state fMRI maybe a potentially useful tool for exploring the mechanism of mentally stimulating activities in aMCI.

SSQ16-06 Multi-voxel Pattern Analysis with Large-scale Granger Causality to Investigate Brain Connectivity Changes in Resting-State Functional MRI of Patients with HIV-Associated Neurocognitive Disorder

PURPOSE

To develop and evaluate a novel machine learning framework using large-scale Granger causality (lsGC) for identification of subjects with HIV-Associated Neurocognitive Disorder (HAND) by capturing differences in resting-state functional MRI (rsfMRI) connectivity.

METHOD AND MATERIALS

Resting-state fMRI scans (3T, EPI sequence, TR=1.65s, 250 acquisitions) were acquired in a cohort of 45 age-matched subjects (20 healthy, 25 HIV+ of which 16 had HAND symptoms (HAND+)). After pre-processing, data was parcellated into regions defined by the Automated Anatomical Labeling (AAL) atlas. Regions were represented by their average time-series. A novel multivariate directional extension of Granger causality, lsGC, quantified the interdependence between time-series. Generalized matrix learning vector quantization, a method that combines supervised machine learning with embedded feature selection was used to classify HAND+ and healthy subjects from the resulting connectivity matrix in a Multi-Voxel Pattern Analysis (MVPA) framework. Strict data separation (90% train/10% test) was carried out in a 100-iteration cross-validation scheme. As a standard reference method, we used conventional multivariate Granger Causality (mGC) for comparative evaluation. Area Under the Curve (AUC) for Receiver Operator Characteristics (ROC) analysis and prediction accuracy were used to quantitatively evaluate the diagnostic quality of HAND+ subject classification.

RESULTS

Our novel lsGC rsfMRI connectivity analysis approach outperformed mGC in identifying HAND+ subjects, with AUC = 0.86 ± 0.29 and accuracy = 0.88 ± 0.17% for lsGC compared to AUC = 0.70 ± 0.35 and accuracy = 0.64 ± 0.25% for the conventional mGC method, respectively. Diagnostic quality differences between both methods were statistically significant ($p < 0.01$, Wilcoxon signed-rank test) for both AUC and prediction accuracy.

CONCLUSION

Our results suggest that the novel lsGC analysis method significantly improves the diagnostic quality for identification of patients with HAND. We conclude that, when compared to conventional mGC analysis, our MVPA framework is better suited to capture disease-related brain network connectivity changes based on rsfMRI neuroimaging.

CLINICAL RELEVANCE/APPLICATION

Our framework identifies HAND+ subjects by revealing disease-related changes in brain connectivity patterns, which can serve as a useful diagnostic biomarker in HIV-related neurologic disease.

SSQ16-07 The Altered Resting-State Functional Connectivity and Regional Homogeneity in Type 2 Diabetes with Mild Cognitive Impairment

Thursday, Nov. 30 11:30AM - 11:40AM Room: N229

bear1119xy@126.com

PURPOSE

Patients with Type 2 Diabetes Mellitus (T2DM) have considerably higher risk of developing cognitive impairment and dementia. This

Patients with Type-2 Diabetes Mellitus (T2DM) have considerably higher risk of developing cognitive impairment and dementia. This study aims to investigate the possible alterations in spontaneous neural activity of brain through resting state-functional MRI (rs-fMRI) in T2DM patients with and without mild cognitive impairment.

METHOD AND MATERIALS

Eighteen T2DM patients with mild cognitive impairment (DM-MCI) and 18 matched T2DM patients with normal cognition (DM-NC) were enrolled. On a 3 Tesla scanner, rs-fMRI data were obtained axially using a gradient-echo planar imaging sequence. Using the Brainnetome toolkit (BRAT) (www.brainnetome.org/en/brat) and SPM8 software, the regional homogeneity (ReHo) was calculated to represent spontaneous brain activity in different brain areas. ReHo changes were correlated with neuropsychological scores and disease duration. Based on the anatomically labeled (AAL) template, the whole-brain partitional analysis on functional connectivity was also applied to search for significant links.

RESULTS

Compared to DM-NC group, DM-MCI group exhibited decreased ReHo value in the right inferior, middle, and superior temporal gyrus; but increased ReHo value in the bilateral superior and medial frontal gyrus, the right orbital gyrus and the inferior frontal gyrus(fig.1). In the DM-MCI group, ReHo value was negatively correlated with Montreal Cognitive Assessment scores in the left medial frontal gyrus (R=-0.662, p=0.01), and positively correlated with diabetes duration in the right inferior and middle frontal gyrus (R=0.594, p=0.026)(fig.2). Correlation between ReHo and glycosylated hemoglobin A1c was not significant. The DM-MCI group showed 11 pairs of weaker functional connectivity between different brain areas (p<0.01, FDR corrected)(fig.3).

CONCLUSION

The abnormal brain activity reflected by ReHo measurements and the weaker functional connectivity of multiple brain regions could help uncover the susceptible regions of T2DM patients who progress into cognitive dysfunction, and may provide insights into the pathogenesis of T2DM related cognitive impairment.

CLINICAL RELEVANCE/APPLICATION

Resting state-fMRI may be able to track early progression of brain functional alterations, and can be an appropriate approach for studying the spontaneous brain activity in diabetes related cognitive impairment.

SSQ16-08 Early Volume Reduction of Hippocampus after Whole-Brain Radiation Therapy: Automated Brain Structure Segmentation Study

PURPOSE

It is well known that cognitive decline often occurs after whole-brain radiation therapy (WBRT), especially in the long survivors. Our hypothesis was that the hippocampus is vulnerable to radiation and may become atrophic even at early stage after WBRT. Therefore, using automated segmentation of brain structures, we assessed volume changes of the various brain structures including the hippocampus within 10 months after WBRT.

METHOD AND MATERIALS

Twenty patients with lung cancer who underwent both WBRT and chemotherapy were recruited as a WBRT group. As a control group, 18 patients with lung cancer who underwent only chemotherapy were also recruited. Pre-treatment MRI was performed within one month before radiation or chemotherapy, and post-treatment MRI were performed 6 to 10 months after the radiation or chemotherapy. Contrast enhanced high-resolution 3D T1-weighted images of pre- and post-treatment were analyzed using longitudinal processing of FreeSurfer. We calculated volume reduction ratios [{(volume of pre-radiation - volume of after radiation)/ volume of pre-radiation}x100] for the whole-brain cortex and white matter, hippocampus, and amygdala defined by Aseg atlas in FreeSurfer.

RESULTS

In the WBRT group, the hippocampus showed significant volume reduction (5.7%, $p < 0.01$), while the whole-brain cortex and white matter, and amygdala did not show significant volume reduction (4.9%; $p = 0.21$, 1.3%; $p = 0.19$, 1.3%; $p = 0.95$, respectively). The volume reduction ratio of the hippocampus was significantly higher than those of the whole-brain cortex and white matter ($p = 0.01$ and 0.02, respectively). In the control group, there was no significant volume reduction in any regions (the ratios: 0.3%, 1.0%, 1.0%, and 0.9% for the hippocampus, amygdala, whole-brain cortex and white mater, respectively).

CONCLUSION

Among the whole-brain cortex and white matter, hippocampus, and amygdala, only the hippocampus showed significant volume reduction within 10 months after WBRT suggesting its vulnerability to radiation.

CLINICAL RELEVANCE/APPLICATION

Our study may support the validity of the "hippocampus-sparing" WBRT to prevent the radiation-induced cognitive impairment.

SSQ16-09 Nonlinear Modulation of Interacting Between COMT and Depression on Brain Function

Thursday, Nov. 30 11:50AM - 12:00PM Room: N229

Participants
Cancan He, Nanjing, China (*Presenter*) Nothing to Disclose
Liang Gong, Nanjing, China (*Abstract Co-Author*) Nothing to Disclose

Chunming Xie, Nanjing, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

cche0919@163.com

PURPOSE

The catechol-O-methyltransferase (COMT) gene is related to dopamine degradation and has been suggested to be involved in the pathogenesis of major depressive disorder (MDD). However, how this gene affects brain function properties in MDD is still unclear.

METHOD AND MATERIALS

Fifty patients with MDD and 35 cognitively normal participants were underwent a resting-state functional magnetic resonance imaging scan. A voxel-wise data-drive global functional connectivity density (gFCD) analysis was used to investigate the main effects and interactions of disease states and COMT rs4680 on brain function.

RESULTS

We found significant group differences on the gFCD in bilateral fusiform area (FFA), postcentral and precentral cortex, left superior temporal gyrus (STG), rectal and superior temporal gyrus, right ventrolateral prefrontal cortex (vlPFC), and the abnormal gFCDs in left STG was positively correlated with depressive severity in MDD patients. Significant disease × COMT interaction effects were found in the bilateral calcarine gyrus, right vlPFC, hippocampus, and thalamus, and left SFG and FFA. Further post-hoc tests showed a nonlinear modulation effect of COMT on gFCD in the development of MDD. Interesting, an inverted U-shaped modulation was showed in the prefrontal cortex (control system), while U-shaped modulations were found in the hippocampus, thalamus and occipital cortex (processing system).

CONCLUSION

Our study manifested a nonlinear modulation of interacting between COMT and depression on brain function. This findings expand our understudying of the COMT effect underlying pathophysiology in MDD patients.

CLINICAL RELEVANCE/APPLICATION

The brain functional features detecting combined with COMT genotyping may provide a useful biomarker to the occurrence and development of depression.

pamela.bertolazzi@hotmail.com

PURPOSE

The aim of this work is to investigate the influence of childhood obesity on changes in anatomy and cerebral connectivity, using the DTI by Magnetic Resonance Imaging (MRI). The hypothesis is that the brain is an organ also affected by high adiposity, particularly the hypothalamus, which is a complex region involved in the regulation of appetite and hormonal homeostasis.

METHOD AND MATERIALS

The images were obtained on Achieva 3T Phillips Magnetic Resonance. The sample for statistical analysis consisted of 120 subjects: 59 obese adolescents and 61 healthy adolescents, aged 11 years to 18 years, and matched regarding gender, age, and schooling. The images were processed with the FSL-Tbss (Tract Based Spatial Statistics) program and analyzed statistically by the same program with Randomize.

RESULTS

Statistical analysis showed decrease in the values of Fractional Anisotropy (FA) of obese pediatric patients compared with healthy controls in amygdala, hippocampus, thalamus, cingulate gyrus, fornix, insula, putamen, orbital gyrus and bilateral hypothalamus. There was no region of higher FA in obese patients in relation to the control group.

CONCLUSION

The data reveal a pattern of involvement in important regions in the control of appetite and emotions. Limbic structures, such as amygdala, hippocampus, thalamus, cingulate gyrus, fornix and insula are altered. Important regions related to impulse control, reward and pleasure in eating (putamen and orbital gyrus) and autonomic appetite control (bilateral hypothalamus) were also shown to have decreased FA.

CLINICAL RELEVANCE/APPLICATION

Childhood obesity is a subject of high clinical importance, and presents data of ascent from 10 to 40% of the last 10 years in most countries. Previous studies have pointed to obesity as a risk factor for neurodegenerative disorders through DTI tractography. In this way, we investigated previous or early cerebral changes in obesity.

SSQ17-03 Voxel-Based Morphometry (VBM) and Tract-Based Spatial Statistics-Diffusion Tensor Imaging

(TBSS-DTI) in Rett Syndrome: Alterations in Visuomotor Areas and Limbic System

PURPOSE

Rett syndrome (RTT) is a neurodevelopmental disorder presenting with loss of motor and speech abilities, stereotypic movements, gait disturbance, autistic behavior and seizures. We aimed to investigate underlying morphometric and white matter (WM) changes in patients with RTT using MRI.

METHOD AND MATERIALS

IRB approved this study and all the participants/ parents gave signed consent form. T1-weighted 3D images (MPRAGE) (TR/TE/TI: 1910/3,5/1100ms) and diffusion tensor imaging (DTI) of the brain along 60 non-collinear directions (TR/TE: 5814 /98 ms, bmax:1000s/mm2) were obtained from 15 female patients with classical Rett syndrome and MECP2 mutation, and 14 healthy age and sex-matched subjects (median ages, 3.99 and 5.08 respectively; p>0.95). We used SPM12 for voxel-based morphometry (VBM) and TBSS, a part of FSL 4.0 software package for voxel-wise statistical DTI analysis. From VBM analysis, segmented GM, WM and CSF volume, total intracranial volume (TIV), and normalized volumes by diving to TIV were measured. Statistically significant clusters in VBM and TBSS-FA map (all, FEW correction, p<0.05) were determined using MNI atlas.

RESULTS

Although GM, WM, CSF volumes were significantly smaller in patients (p<0.02), the significance didn't remain in comparison of normalized volumes (p>0.1). Patients showed significantly reduced WM density in frontal and parieto-occipital areas related with visuomotor coordination, sensorimotor areas and cognition; also significantly less GM density in superior and middle temporal gyri and left prefrontal cortex (p<0.05). Patients showed reduced FA in the cerebellar hemispheres, corpus callosum, inferior frontooccipital fascicles, anterior thalamic radiations, thalami, external capsules, fornices, cinguli, superior longitudinal fascicles (p<0.05).

CONCLUSION

When normalized to TIV, no significant volume loss was observed in patients with RTT. VBM and TBSS-DTI revealed mostly WM density and FA reductions in bilateral visuomotor areas and limbic system components such as cingulum and fornices related with cognition, behavior and seizures.

CLINICAL RELEVANCE/APPLICATION

Multimodal neuroimaging link structural and connectivity alterations related with diverse clinical features in patients with RTT.

SSQ17-04 Preterm Neonates Show a 'Catch-Up' Pattern toward Term in Motor Development during the Neonatal Period: A Diffusion Tensor Imaging Study

Thursday, Nov. 30 11:00AM - 11:10AM Room: S103CD

PURPOSE

To detail the postnatal trajectory of neonatal sensorimotor functions by comparing the postnatal age-related changes of brain white matter (WM) microstructure and neurobehavioral abilities between preterm and term neonates during the neonatal stage.

METHOD AND MATERIALS

118 neonates (within 28 days after birth) with no abnormality who underwent conventional MRI and DTI were included (Table1). The DTI-derived fractional anisotropy (FA) and neonatal neurobehavioral assessment were separately used to characterize the brain WM microstructure and neurobehavioral development levels. The scatterplot with linear fitting was used to investigate the relations of FA and neurobehavioral scores (active tone and behavior) with postnatal age (day), setting gestational age (GA) as a covariate. Here, OR (optical radiation), AR (auditory radiation), CST (corticospinal tract), PTR (posterior thalamic radiation) and thal-PSC (thalamus-primary somatosensory cortex) were selected as regions of interest; active tone and behavior were used to separately evaluate the abilities of motor and integrated visual, auditory and sensory. All statistical analysis were performed by using Matlab; p<0.05 was considered as statistically significant difference.

RESULTS

Significant correlations of adjusted FA with postnatal age were found in preterm CST (p=0.042), term OR (p=0.018) and PTR

Significant correlations of adjusted FA with postnatal age were found in preterm CST ($p=0.042$), term OR ($p=0.018$) and PTR ($p=0.002$). Compared to term neonates, preterm showed an obviously higher correlation in CST (0.29 vs 0.08), while less correlations in visual, auditory and somatosensory-associated WMs (Figure 1). Being relatively consistent, neurobehavioral results indicated that preterm neonates presented relatively higher and lower correlations than term in active tone (0.48 vs 0.35) and behavior scores (0.36 vs 0.52), respectively (Figure 2).

CONCLUSION

Although being delayed, preterm neonates show a 'catch-up' pattern toward the term in motor development during the neonatal period.

CLINICAL RELEVANCE/APPLICATION

Postnatal trajectory of neonatal sensorimotor function e.g. preterm 'catch-up' motor development provide valuable references in guiding the early intervention and thus gaining more effective outcomes.

SSQ17-05 Visually Accessible Rembrandt Imaging (VASARI) Features Predict Survival and Identify Distinct Groups of Pediatric High Grade Glioma

John.Lucas@StJude.org

PURPOSE

To understand the relationship of Visually Accessible Rembrandt Imaging (VASARI) features to prognosis and disease subgroups in pediatric high grade glioma (pHGG).

METHOD AND MATERIALS

Seventy one consecutive cases of newly diagnosed pHGG were systematically reviewed and scored for VASARI features by two expert radiologists. Agreement between reviewers was scored for each VASARI feature. The inter-correlation between VASARI features and impact on hierarchical clustering of patients were evaluated. The distance between variables is as follows; Pearson correlation was used among the continuous variables, Kendall's correlation was used among binary/ordinal variables, and Spearman correlation was used between continuous variables and binary/ordinal variables. Pearson correlation was used to measure the distance between subjects. The number of clusters was determined using the hybrid method proposed by Langfelder and Zhang (2008). Patient clusters were evaluated for their subgroup specific survival. Analyses were completed in either SAS v9.3 or R 3.3.3.

RESULTS

The median concordance between reviewers for VASARI features was 60% (range, 29-79%). The most concordant features include tumor location, diffusion characteristics, and pial invasion, while the most discordant features were ependymal invasion, proportion of non-contrast enhancing tumor (nCET), and proportion of edema. Univariate cox proportional hazards analysis identified hemorrhage (HR 5.6, 95% CI 1.1-28.2, p=0.035), nCET crossing midline (HR 2.5 95% CI 1.2-5.2, p=0.048), and size (HR 1.15 95% CI 1.01-1.33, p=0.05) as features which increased the hazard for progression. Hierarchical clustering identified 5 patient subgroups with distinctive correlated imaging features and varied survival.

CONCLUSION

VASARI features require refinement in their definition before broad acceptance for pHGG. Some features may be prognostic at diagnosis, and may aid further risk classification beyond classic clinical and pathologic factors.

CLINICAL RELEVANCE/APPLICATION

VASARI features may be prognostic and identify distinct populations in pHGG.

SSQ17-06 Post Treatment DSC-MRI is Predictive of Early Treatment Failure in Children with Supratentorial High-Grade Glioma Treated with Erlotinib

johnthomas75@gmail.com

PURPOSE

The role of perfusion imaging in the management of pediatric high grade glioma is unclear. We evaluated the ability of DSC-MRI to determine grade, evaluate post-treatment response and predict treatment failure.

METHOD AND MATERIALS

Twenty-two patients with high-grade glioma underwent biopsy and were treated with concurrent and sequential radiotherapy and erlotinib as part of a phase I/II clinical trial (NCTXXXX). Pre-, immediate post-radiotherapy, 6-month, and treatment failure DSC MR images were reviewed, registered, and processed for the ratio of CBF and CBV. Processed, derived perfusion, and T1WI, T2WI, and FLAIR MRI sequences were used for segmentation and extraction of tumor perfusion parameters at all time-points. Patient, tumor, treatment, and outcome data were summarized and related to perfusion data.

RESULTS

Regional CBF in tumors increased from diagnosis to post radiotherapy, while they decreased to levels below those at diagnosis from post radiotherapy to 6-month follow up. At 6 months, the median regional CBF was higher in tumors that progressed (median, 1.16) than in those that did not (median, 0.95;P< .05). Patients with CBF ratios above 1.4 at diagnosis had shorter survival times relative to CBF ratios below 1.4 (P= .77). Tumors with a regional CBV above 1.15 at the post-radiotherapy (1- to 3-month) follow-up scan were associated with an earlier time to death than that of tumors with a CBV below 1.15 (P< .05).

CONCLUSION

Post-treatment perfusion characteristics are prognostic and may predict survival. Perfusion MRI is useful for managing pediatric high-grade glioma and should be incorporated into future trials.

CLINICAL RELEVANCE/APPLICATION

DSC-MRI is recommended in the evaluation of treatment response in pediatric patients with high grade glioma

SSQ17-07 Differentiation of Medulloblastoma and Astrocytoma in Children Using Histogram Analysis of Enhancement MRI

Thursday, Nov. 30 11:30AM - 11:40AM Room: S103CD

Participants
Weijian WANG, Zhengzhou, China (*Presenter*) Nothing to Disclose
Jingliang Cheng, MD,PhD, Zhengzhou, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To investigate the diagnostic value of the histogram analysis derived from enhancement MR imaging in differentiating medulloblastomas from astrocytomas.

METHOD AND MATERIALS

Retrospective analysis of 47 patients which were pathologically confirmed posterior fossa tumors, including 29 cases of medulloblastoma,18 cases of astrocytoma.Drawing the region of interest(ROI) on the maximum level of enhanced MR sagittal image and going on histogram analysis,these two steps are all performed on the software named Mazda.Performed a statistical analysis on the histogram parameters to find out the characteristics of the significant differences between the two groups.

RESULTS

In the 9 parameters which are extracted from histogram,C99 has the statistical significance.The maximum area under the ROC curve was 0.85.The optimum C99 to distinguish medulloblastomas from astrocytomas was 176.5(76% specificity and 61% sensitivity).

CONCLUSION

Histogram analysis of enhancement MR imaging can provide reliably objective basis for differentiating medulloblastomas from astrocytomas.

CLINICAL RELEVANCE/APPLICATION

Histogram analysis of enhancement MR imaging is a new method,can provide reliably objective basis for differentiating medulloblastomas from astrocytomas.

SSQ17-08 Diagnostic Accuracy of MRI Perfusion (DSC) to Determine Grades and Types of Pediatric Primary Brain Tumors: A Multiparametric Approach

Amato Infante, MD, Rome, Italy (*Abstract Co-Author*) Nothing to Disclose
Cesare Colosimo, MD, Rome, Italy (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The goal of this prospective study was to assess the diagnostic accuracy of multiple parameters from dynamic susceptibility contrast (DSC) perfusion, in the distinction of pediatric brain tumor grades and types.

METHOD AND MATERIALS

A retrospective blinded review of 53 histologically proven pediatric brain tumors with DSC perfusion was performed independently by two neuroradiologists. Tumors were categorized by grade and by histological. Maximum rCBV (rCBVmax), Percentage Signal Recovery (PSR) and Contrast Leakage Patterns (CLP) were measured from manual ROI placement for each reviewer and averaged. Results from all three analyses were compared to WHO grade and tumors type. Multivariate statistical analysis was performed to evaluate the diagnostic accuracy of single and combined perfusion parameters, and of single parameters to distinguish the different groups.

RESULTS

rCBVmax demonstrated a positive correlation with tumor grade, but limited specificity for tumors type. PSR and CLP demonstrated a positive correlation with tumor type when tumors were grouped by astrocytic and non-astrocytic. The highest diagnostic accuracy for tumor grading and typing was obtained using all three perfusion parameters. Pilocytic astrocytomas demonstrated a peculiar perfusional pattern: rCBV<1.6, high PSR and T1-dominant leak.

CONCLUSION

Multiparametric MR imaging can be accurate in determining tumor grades and types (mainly pilocytic astrocytomas and embryonal tumors) in children.

CLINICAL RELEVANCE/APPLICATION

Perfusion MRI is of utility to increase diagnostic accuracy for adult brain tumor. In pediatric population the heterogeneity of tumors need more than one perfusion parameter to gain an higher sensitivity and specificity for grading and distinguishing brain neoplasms

SSQ17-09 MRI Surrogates of Molecular Subgroups in Pediatric Atypical Teratoid / Rhabdoid Tumor

annika.hohm@stud-mail.uni-wuerzburg.de

PURPOSE

Recent research identified new molecular subgroups in atypical teratoid / rhabdoid tumor (AT/RT). MRI characteristics of AT/RT have not yet been analyzed according to molecular parameters. We aimed to identify morphological features that may help predict molecular subgroups by means of MRI.

METHOD AND MATERIALS

A total of 43 consecutive patients with known molecular subtyping (AT/RT-TYR n=16, -SHH n=17, -MYC n=10) were obtained from the EU-RHAB register. We analyzed epidemiologic and standardized imaging parameters as well as meningeal dissemination status. Statistical analysis between molecular subgroups was performed by Mann-Whitney U test and chi-squared test.

RESULTS

In contrast to distinct origin (supra-/infratentorial, p=.002) of molecular AT/RT subgroups, a midline/off-midline localization was not significantly different. Typical cysts in the tumor periphery were found most frequently in AT/RT-TYR (p=.012). There was a tendency (p=.052) to strong contrast enhancement in AT/RT-TYR and AT/RT-MYC, whereas enhancement was absent in almost one third of -SHH tumors. Patient age and gender as well as tumor volume and visible meningeal dissemination were not significantly different between molecular subgroups.

CONCLUSION

This is the first study that describes and compares MR imaging features according to molecular subgroups in pediatric AT/RT. In contrast to previous studies, we show that an off-midline location is not specific for infratentorial AT/RT. Peripheral cysts and/or a band-like 'wavy" enhancement, if present, are important characteristics to differentiate AT/RT from other tumor entities in children < 3 years of age. These findings could be observed throughout all molecular subgroups, but with different frequencies. Correlation of initial MR imaging features with clinical outcome might be of great interest for individual risk assessment and patient stratification.

CLINICAL RELEVANCE/APPLICATION

Beyond typical anatomical distribution of molecular subgroups, we identified morphological parameters that may help to differentiate pediatric AT/RT with MR imaging.

SSQ18-01 Feasibility of Multi-Reference-Tissue Normalization of T2-Weighted Prostate MRI

Thursday, Nov. 30 10:30AM - 10:40AM Room: S403B

Participants
Laura I. Stoilescu, Nijmegen, Netherlands (*Abstract Co-Author*) Nothing to Disclose
Henkjan Huisman, PhD, Nijmegen, Netherlands (*Presenter*) Shareholder QView Medical

For information about this presentation, contact:

henkjan.huisman@radboudumc.nl

PURPOSE

To explore a novel multi-reference-tissue normalization method applied to t2-weighted prostate MRI.

METHOD AND MATERIALS

Assuming the availability of a set of distinct reference tissue segmentations, the hypothesis is that it allows computing a patient specific sequence model that can normalize MRI. The normalization should produce similar scalar values in the same reference regions for different patients/scanners/sequences and interpolate in between reference values for other tissue areas. Regions of interest (ROI) were drawn in four distinct tissue types in a cohort of sixty-five t2-weighted images from regular multiparametric prostate MRI (mpMRI). The four reference tissue types were: skeletal muscle, body fat, femur head, bladder lumen. Four average ROI signals were computed per patient. Each reference tissue was assigned a fixed reference value (t2 relaxation found in literature). Per patient, a smooth sequence model was fitted to the (average, reference) pairs. The estimated sequence model was then inverted to map patients' raw t2-weighted image scalar values to normalized values. To test the method, the effect of normalization on observed variance and tissue discriminability was analyzed. A leave-one-out experiment was performed in which for each ROI its normalized value was computed using the sequence model estimate using the three remaining reference ROIs. The difference between original t2-weighted and normalized scalar MRI was analyzed by means of variability and ROC analysis.

RESULTS

Multi-reference-tissue normalization significantly ($p<0.05$) decreased variability and increased the area under the ROC curve for discriminating each reference tissue combination. The ROC curves in the figure show the effect of the normalization (T2-n) on the discrimination between body fat and femur head tissue.

CONCLUSION

Semi-automatic multi-reference-tissue normalization shows reduced inter-patient variability and may allow better quantitative discrimination between tissue types.

CLINICAL RELEVANCE/APPLICATION

Multi-reference-tissue t2-weighted MRI normalization seems feasible. In combination with automatic segmentation, this could be providing clinical quantitative imaging support to mpMRI diagnosis of prostate cancer. This result motivates us to continue to explore the ability of this novel method to help detect and discriminate prostate cancer in mpMRI.

SSQ18-02 Automatic Algorithm for Joint Morphology Measurements in Volumetric Musculoskeletal Imaging

PURPOSE

An automated algorithm was developed for measurements of bone morphology and joint alignment in volumetric musculoskeletal imaging. The algorithm was applied to evaluation of the weight-bearing tibiofemoral and patellofemoral joints using a dedicated extremity cone-beam CT (CBCT) system.

METHOD AND MATERIALS

Weight-bearing CBCT scans were acquired from 24 healthy subjects at ~12 mGy dose; reconstructed field of view was 20x20x30 cm3 with 0.56 mm isotropic voxels. Anatomical landmarks on tibia, femur, and patella were set by an expert radiologist for the following metrics: Medial Tibial Depth (MTD), Tibial Tuberosity-Trochlear Groove (TTTG) distance, and Insall-Salvati-Ratio (ISR). The automated algorithm uses three sets of atlas volumes, one for each of the bones. The atlases are annotated with pertinent anatomical landmarks according to expert reader consensus. The atlas volumes are first registered (individually for each bone) to the analyzed volume using Mattes mutual information and similarity transforms. The best fitting atlas images are then selected, and their bone surfaces are deformably registered to the corresponding bones in the analyzed volume. No segmentation of the analyzed volume is necessary. The transforms found in the registration are then applied to the atlas landmarks to compute the anatomical metrics.

RESULTS

The deviation of the anatomical landmarks found by the algorithm from the locations selected by the expert reader are within the range of intra-reader variability (~1 mm). The automated algorithm achieved high level of agreement with expert radiologist readings in leave-one-out evaluation of the anatomical metrics, with ICC of 1.0, 0.93, and 0.97 for TTTG, ISR, and MTD, respectively. The RMSE of the metrics sharply decreases with increasing number of atlas images, achieving RMSE of less than 0.5 mm for TTTG and MTD less than 0.2 [a.u.] for ISR when 15 atlas images are used for each bone.

CONCLUSION

The algorithm achieved high correlation with expert radiologist readings, providing quantitative assessment of the complex, multi-body anatomy of the joints in support of orthopedic diagnosis and surgical planning.

CLINICAL RELEVANCE/APPLICATION

An automatic algorithm for image-based anatomical measurements in musculoskeletal radiology supports quantitative assessment of joint morphology in diagnostic and surgical applications.

SSQ18-03 A Contrast-to-Noise Ratio for Clinical Mammographic Images

Thursday, Nov. 30 10:50AM - 11:00AM Room: S403B

melissa.hill@volparasolutions.com

PURPOSE

Image quality estimation directly from clinical mammograms rather than from phantom images would allow for patient-specific and 'real-time' monitoring of complete system performance. This study evaluates a novel method to estimate a contrast-to-noise ratio (CNR) directly from mammograms.

METHOD AND MATERIALS

The novel CNR uses a noise estimation from the compressed breast region that minimizes the influence tissue characteristics, while a signal difference between pixels with known tissue compositions serves as an alternative to the difference between a phantom contrast feature and uniform background. For initial validation, a phantom with 0.2 mm Al and 2-8 cm PMMA was imaged with technique factors to match automatic exposure control (AEC)-acquisition on the GE Senographe Essential, and in combo-mode (FFDM & DBT) on the Hologic Selenia Dimensions. CNR measured from phantom images per EUREF guidelines was compared to CNR determined using noise estimated by the proposed method. The novel CNR was calculated for AEC-acquired clinical images and plotted against compressed thickness following typical analysis of AEC performance. The dataset included 274 Hologic Selenia Dimensions combo-mode images and 80 GE Senographe Essential FFDM images. Phantom and clinical images were acquired on different machines. Version 1.5.3.0 of the VolparaDensity algorithm was applied to measure tissue composition.

RESULTS

The correlation was excellent between the EUREF-derived and novel CNR for phantom images, with Pearson coefficients over 0.99. The trends between mammographic image CNR and thickness correspond well to the phantom-verified relationships, with differences in phantom and mammographic CNR magnitudes largely resulting from the different contrast materials and methodologies, along with some variability from machine-specific performance.

CONCLUSION

A novel CNR measure was assessed using phantom and clinical mammographic images. The validation results show promise for the ability to avoid signal variations due to tissue structure, while extracting system-dependent data to make objective CNR estimates. Future work will assess clinical image CNR sensitivity to variations in acquisition parameters.

CLINICAL RELEVANCE/APPLICATION

To our knowledge this is the first description of an objective CNR measure that can be made directly from mammographic images, thereby enabling real-time and patient-specific image quality evaluation.

SSQ18-04 Framework for Automatic 3D Coronary Artery Vessel Wall Segmentation from Coronary CT Angiography

Thursday, Nov. 30 11:00AM - 11:10AM Room: S403B

Participants
Ahmed M. Ghanem, PhD, Bethesda, MD (*Presenter*) Nothing to Disclose
Ahmed H. Hamimi, MD , Chevy Chase, MD (*Abstract Co-Author*) Nothing to Disclose
Jatin R. Matta, Bethesda, MD (*Abstract Co-Author*) Nothing to Disclose

Ahmed M. Gharib, MBChB, Bethesda, MD (*Abstract Co-Author*) Nothing to Disclose
Khaled Z. Abd-Elmoniem, PhD, Bethesda, MD (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To develop a framework for automated 3D segmentation of the coronary vessel wall and atherosclerotic plaque in the three major coronary artery vessels using level sets and centerline as a guide. To overcome premature termination of coronary segmentation caused by poor contrast, motion artifacts, and severe stenosis.

METHOD AND MATERIALS

The proposed framework computes the vesselness and, with the original 3D coronary image, obtains an initial lumen contour via region growing. Next, a level set energy function is minimized to segment the lumen boundaries. Subsequently, the segmented lumen is utilized as the initial vessel outer boundaries. A second level set energy function segments the final outer wall using a specific sigmoid feature image. The lumen and vessel boundaries are joined to create the coronary wall. Once the wall is segmented, curved multiplanar reformation is used to straighten the segmented lumen and wall using the lumen centerline. Coronary CTA data were acquired from 41 asymptomatic CAD subjects. Images were read by a radiologist to identify the segments of adequate diagnostic image quality and the extent of atherosclerosis plaque burden therein including plaque presence, type, volume, and luminal stenosis severity. Wall and plaque volumes were segmented using the framework and compared to an expert radiologist's manual delineation. The evaluation dataset contained 122 plaques of different characteristics.

RESULTS

Agreement between automatic and radiologist segmentation improved was a function of plaque. For small, mild, medium, and large plaques, mean±SD similarity DICE coefficient between segmented and radiologist's delineation was 86±13%, 90±10%, 95±5%, and 95±6%, respectively. Relative volume difference was 7.3±7.3%, 5.2±5.2%, 4.9±3.9%, and 4.1±5.4%, respectively. The p-values from a paired t-test comparing the radiologist to framework segmentation volumes were $p=0.72$ for small, $p=0.76$ for mild, $p=0.89$ for medium, and $p<<0.93$ for large plaques.

CONCLUSION

Automatic CTA coronary wall segmentation that is highly similar to radiologist's manual delineation is feasible, which thus is promising for accelerated, reliable, and reproducible atherosclerotic plaque characterization.

CLINICAL RELEVANCE/APPLICATION

Automatic segmentation of CTA coronary wall improves objective quantification of coronary atherosclerotic plaque beyond subjective assessment of stenosis and potentially applicable for monitoring response to therapy.

SSQ18-05 CT Coronary Calcium Scoring with Tin Filtration Using Iterative Beam-Hardening Calcium Correction Reconstruction

PURPOSE

To investigate the diagnostic accuracy of CT coronary artery calcium scoring (CACS) with tin pre-filtration (Sn100kVp) using

To investigate the diagnostic accuracy of CT coronary artery calcium scoring (CACS) with tin pre-filtration (Sn100kVp) using iterative beam-hardening correction (IBHC) calcium material reconstruction compared to the standard 120kVp acquisition.

METHOD AND MATERIALS

In an IRB-approved, HIPAA compliant prospective study, 62 patients (56% male, age 63.9±9.2years) underwent a clinically-indicated CACS acquisition using the standard 120kVp protocol and an additional Sn100kVp CACS research scan. Datasets of the Sn100kVp scans were reconstructed using a dedicated spectral IBHC CACS reconstruction to restore the spectral response of 120kVp spectra. Agatston scores were derived from 120kVp and IBHC reconstructed Sn100kVp studies. Pearson`s correlation coefficient was assessed and Agatston score categories and percentile-based risk categorization were compared.

CONCLUSION

Low voltage CACS with tin filtration using a dedicated IBHC CACS material reconstruction algorithm shows excellent correlation and agreement with the standard 120kVp acquisition regarding Agatston score and cardiac risk categorization, while radiation dose is significantly reduced by 75% to the level of a chest x-ray.

CLINICAL RELEVANCE/APPLICATION

Low x-ray tube voltage third generation dual-source CT CACS paired with tin pre-filtration and iterative beam-hardening correction calcium material reconstruction allows for coronary artery calcium quantification in excellent correlation with standard protocols, albeit at a fraction of the radiation dose. This approach thus seems well suited for a screening test in a priori healthy individuals.

SSQ18-06 Robustness Evaluation of RA-950 Scoring in a Cohort of CT Lung Screening Patients Across a Large Range of CT Acquisition and Reconstruction Conditions

PURPOSE

Interest in quantitative evaluation of images is high, however variation in imaging protocols raises questions about the reliability of utilized metrics. In this study we investigate the multivariate effects of CT acquisition and reconstruction parameters on emphysema scoring in CT lung screening.

METHOD AND MATERIALS

30 clinical lung screening scans were selected from an in-house archive that contains raw projection data. Reduced dose acquisitions were simulated at 50%, 10%, and 5% of clinical dose (~2mGy CTDIvol) by adding noise to the raw data. Full-dose and reduced-dose acquisitions were then reconstructed using the open-source software "FreeCT_wFBP" at slice thicknesses of 0.6, 1, 2, and 5mm using smooth, medium and sharp kernels for a total of 48 reconstructions per patient. To score emphysema, a density mask was applied with -950HU as the threshold (RA-950 score), and for each parameter configuration, change in RA-950 relative to a reference (100% dose, 1.0mm slice thickness, medium kernel; chosen for similarity to clinical protocols) was calculated and averaged across the population.

RESULTS

Only 21 of 48 (44%) configurations produced scores within ±5% of the reference suggesting limitations to the range of acceptable parameters for quantitative emphysema evaluation. Configurations using the sharp kernel, the 0.6 mm slice thickness, or doses below 50% of the clinical reference consistently produced scores very different than reference. Protocols producing higher image noise resulted in higher RA-950 scores. With slice thicknesses >=1.0mm and the smooth or medium kernel, the 50% dose configuration results in RA-950 comparable to reference. Patient-specific surface plots revealed that change in RA-950 as a function of reconstruction parameter strongly depends on the amount of emphysema measured at reference.

CONCLUSION

As quantitative evaluation of COPD increases and efforts to reduce CT dose continue, changes in protocol are likely. This study shows that reliable quantitative emphysema evaluation is possible with further dose reduction (to ~1mGy) when combined with appropriate reconstruction parameters, however care must be taken to prevent parameter-dependent changes in the measured score.

CLINICAL RELEVANCE/APPLICATION

Establishing protocols for reliable quantitative metrics is critical for the use of clinical quantitative imaging. This study assesses and provides guidance on RA-950 scoring for the evaluation of emphysema.

SSQ18-07 Fully Automatic Measurement of the Splenic Volume in CT with U-Net Convolutional Neural Networks

PURPOSE

To develop a fully automatic deep learning method for 3D segmentation of the spleen on computed tomography (CT) scans and to compare the automatically measured spleen volume with the standard splenic index approximation formula that requires three 2D manual measurements.

METHOD AND MATERIALS

145 CT thorax-abdomen scans were collected from our institute. All scans were contrast enhanced and acquired with a slice thickness of 1 or 2 mm. The spleens were manually segmented in 3D by trained human observers in all scans. We used 100 scans for training and 45 scans as an independent test set. In the test set, the standard approximation formula was applied by a human observer to get an estimation of the splenic volume. The system fully analyzes the entire thorax-abdomen CT scan to segment the exact location of the spleen, without any need for pre-processing. Multiple U-net convolutional neural networks were trained for different orthogonal directions using the training data set. A validation set consisting of 30% of the training data was used to optimize the hyperparameters of the neural network. A dedicated hard mining selection strategy was employed to improve the learning process. The predictions of the U-nets were averaged and subsequently thresholded to obtain a 3D spleen segmentation. The mean absolute error of the splenic volume was used to measure the accuracy of the deep learning approach and the standard approximation formula in comparison to the manual reference standard. The performance of the deep learning approach was also evaluated by computing the Dice similarity coefficient on the test set.

RESULTS

The deep learning approach resulted in a mean absolute error of 8.5% (SD 11.6) in the splenic volume while the approximation formula gave a significantly higher ($p<0.01$) mean absolute error of 17.7% (SD 14.7). The average Dice score between the deep learning segmentations and the reference segmentations was 0.91 (SD 0.08).

CONCLUSION

Splenic volume can be fully automatically assessed using a U-net deep learning approach, with an accuracy that is substantially better than the clinically widely used approximation formula.

CLINICAL RELEVANCE/APPLICATION

An accurate splenic volume measurement can be used for assessing splenomegaly and for detecting changes in splenic volume over time.

SSQ18-08 Newly Developed 3D Computer-Aided Volumetry (CADv) with Pulmonary Nodule Component Evaluation: Capability for Quantitative Prediction of Malignancy and Postoperative Recurrence on Thin-Section CT

PURPOSE

To evaluate the quantitative capability of newly developed 3D computer-aided volumetry (CADv) with pulmonary nodule component assessment for predicting malignancy and postoperative recurrence on thin-section CT.

METHOD AND MATERIALS

59 consecutive patients with 101 pulmonary nodules underwent repeated thin-section CT, pathological examination, surgical resection and/ or follow-up examination. Then, all nodules were divided into malignant (n=64) and benign (n=37) nodule groups. In addition, all patients with operated as malignancy were also divided into postoperative recurrence (n=12) and non-recurrence (n=53) groups. In this study, CADv automatically assessed solid, ground-glass opacity, cavity and total nodule volumes from two serial CT data. Then, total volume change per day (TV/day), solid to total volume change ratio per day (S/T ratio/day) and doubling time (DT) were determined. Student's t-test was performed to compare all indexes between malignant and benign groups, and between recurrence and non-recurrence groups. Then, ROC analyses were performed to compare differentiation capabilities of indexes as having significant differences between malignant and benign groups, and between recurrence and non-recurrence groups. Finally, each diagnostic performances was compared by McNemar's test.

RESULTS

TV/day and DT had significant differences between malignant and benign nodule groups ($p<0.05$), although TV/day and S/T ratio/day had significant difference between recurrence and non-recurrence groups ($p<0.05$). On distinguishing malignant from benign groups, area under the curves (Azs) of TV/day (Az=0.94) was significantly larger than that of DT (Az=0.62, $p<0.001$). In addition, specificity (SP) and accuracy (AC) of TV/day were significantly higher than those of DT ($p<0.001$). For distinguishing recurrence from non-recurrence groups, Az of S/T ratio/day (Az=0.92) was significantly larger than that of TV/day (Az=0.68, $p=0.006$). Moreover, SP and AC of S/T ratio/day were significantly higher than those of TV/day ($p<0.001$).

CONCLUSION

Newly developed 3D CADv system has quantitative capability for prediction of malignancy and postoperative recurrence on thin-section CT.

CLINICAL RELEVANCE/APPLICATION

Newly developed 3D CADv system has quantitative capability for prediction of malignancy and postoperative recurrence on thin-section CT.

SSQ18-09 Quantitative Evaluation of Partial Obstruction of the Upper Urinary Tract by Analyzing Sequential Fluoroscopic Images from Antegrade Nephrostograms

Thursday, Nov. 30 11:50AM - 12:00PM Room: S403B

Participants
Isaac Leichter, PhD, Jerusalem, Israel (*Presenter*) Nothing to Disclose
Victor Neeman, PhD, Jerusalem, Israel (*Abstract Co-Author*) Nothing to Disclose
Ori Gleisner, Jerusalem, Israel (*Abstract Co-Author*) Nothing to Disclose
Jonathan Patao, Jerusalem, Israel (*Abstract Co-Author*) Nothing to Disclose

Mordechai Duvdevani, MD, Jerusalem, Israel (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Visual monitoring of fluoroscopy images, following PCNL does not allow for objective assessment of partial obstruction in the upper urinary tract. This study describes an algorithm for a quantitative evaluation of the urine flow rate, by analyzing sequential images from a routine nephrostogram.

METHOD AND MATERIALS

Following PCNL, contrast agent is introduced into the renal collecting system and serial fluoroscopic images of the renal pelvis are visually evaluated to ensure that contrast material is drained through the upper urinary tract. This study examined fluoroscopic images obtained retrospectively from nephrostograms of 40 subjects, 3 days following PCNL. In 16 cases, visual estimation of the images indicated partial obstruction. An algorithm was developed to calculate the amount of contrast agent in the renal pelvis, in each sequential image, by analyzing the integrated gray level values. As the contrast material is drained, its radio-opacity is decreased. The amount of contrast material in each image was calculated as a function of time, to yield a clearance curve of the contrast material from the renal pelvis. From this curve, the urine flow rate in the renal collecting system was calculated.

RESULTS

For each of the 40 cases, the obtained clearance curve highly fitted an exponential regression function with a mean correlation coefficient of 0.96 . The time constant - τ of the exponential decay was automatically calculated for each case. From the known value of τ, the time $t_{1/2}$ at which half of the contrast agent has drained from the renal pelvis was calculated. The mean value of $t_{1/2}$ for the 16 cases with suspected partial obstruction was 9.1 minutes, while for the 24 cases without suspected obstruction it was 2.4 minutes. The difference between the $t_{1/2}$ value of the two groups was statistically significant ($p<0.05$).

CONCLUSION

The described algorithm provides a quantitative assessment for the urine flow rate in the renal collecting system. The calculated time at which half of the contrast agent has drained from the renal pelvis following PCNL, was significantly longer in cases with partial obstruction.

CLINICAL RELEVANCE/APPLICATION

Measuring urine flow rate by processing fluoroscopic images from a routine nephrostogram examination may be used for diagnosing and quantitatively assessing partial obstruction in the upper urinary tract. This early diagnosis will improve patient care and management.

w007vg@yamaguchi-u.ac.jp

PURPOSE

Existing computer-aided detection (CADe) systems have not reached high enough sensitivity to be used as a first reader. In the computer vision field, deep learning achieved overwhelming success with substantially higher performance than existing methods. Our purpose was to develop a first-reader CADe system for distinguishing benign from malignant lung nodules in CT by using deep-learning models, namely, a CNN and our original NNC.

METHOD AND MATERIALS

We developed a CNN with 5 layers: 2 convolution layers and a pooling layer followed by a fully-connected soft-max layer, and NNC consisting of neural network regression (NNR) with 3 layers followed by a scoring layer. In NNC, convolution of the NNR was performed to process the entire 3D volume, but unlike CNN it was done outside the network. The NNC was trained with input volumes containing nodules and "teaching" maps for probability of malignancy. Namely, the desired output volumes for malignant and benign nodules contained a 3D Gaussian distribution and completely dark, respectively. Thus, the NNC was trained to enhance malignant nodules. To obtain a likelihood of malignancy, Gaussian weighting was performed on the output volume in the scoring layer. To test those 2 deep-learning models, we collected 94 lung nodules (34 malignant; 60 benign) from the LIDC-IDRI database. The malignancy and benignancy of the nodules were determined by 3 radiologists. The CT had slice thickness ranging from 0.5-3.0 mm. Tube voltage and current range from 120-140 kVp and 40-570 mA, respectively. We performed a two-fold cross-validation test. Receiver-operating-characteristic (ROC) analysis was used for evaluating the performance.

RESULTS

Our NNC achieved an area-under-the ROC curve (AUC) of 0.997, whereas the CNN achieved 0.986 (p=.083). Our NNC distinguished all malignant nodules correctly from 54 out of 60 benign nodules (10% false positive (FP) rate).

CONCLUSION

Our NNC classified 100% of malignant lung nodules correctly with 10% of FPs in CT. Our system could be used as a first reader where radiologists only check the cases suggested by our "screening" system.

CLINICAL RELEVANCE/APPLICATION

Our high-performance deep-learning-based system would reduce radiologists' workload thus improve the efficiency and potentially improve their diagnostic performance.

SSQ19-02 Development of a New Phantom to Measure Image Quality for Iterative Reconstruction in CT for Abdominal Scanning

Thursday, Nov. 30 10:40AM - 10:50AM Room: S404AB

Participants

Anne C. Martinsen, Oslo, Norway (*Presenter*) Nothing to Disclose
Hilde K. Andersen, MSc, Oslo, Norway (*Abstract Co-Author*) Nothing to Disclose
Kristin Jensen, Oslo, Norway (*Abstract Co-Author*) Nothing to Disclose
Hildur Olafsdottir, Salem, NY (*Abstract Co-Author*) Research funded, Image Owl, Inc
Ingvi S. Olafsson, BSc, Reykjavik, Iceland (*Abstract Co-Author*) Research supported, Image Owl, Inc
Joshua Levy, Salem, NY (*Abstract Co-Author*) Stockholder, The Phantom Laboratory President, The Phantom Laboratory Stockholder, Image Owl, Inc
David J. Goodenough, PhD, Myersville, MD (*Abstract Co-Author*) Consultant, The Phantom Laboratory

PURPOSE

To develop a novel phantom for abdominal CT image quality measurements feasible for iterative reconstructions.

METHOD AND MATERIALS

An anthropomorphic abdominal phantom, designed for ROC studies and quantitative image quality analyses was tested. The phantom consisted of 4 ROC inserts, one MTF insert, and two iodine test inserts. The iodine inserts contained 6 lesions of different sizes and density (1g and 5 g of iodine). The MTF insert contained two tungsten carbide beads. The ROC inserts contained 12 lesions (16 HU contrast to background difference). The phantom was scanned on Siemens Drive. The four ROC inserts were rotated and interchanged between scans. Scan parameters: 120 kVp, CTDIvol 10, 15 and 20 mGy, 3 mm slices, FBP B30f, Admire 2 and Admire 3 reconstructions. Three readers evaluated all images in a blinded, randomized order upon a 5 point scale, and area under curve (auc) was calculated. MTF, SNR and CNR were measured for all reconstructions and all dose levels, using ImageOwl. Spearman's rank correlation coefficient was used for evaluation of correlation between different image quality measurements.

RESULTS

For all dose levels, the iterative reconstruction techniques, Admire, had higher MTF and improved lesion detectability (significant for 10 and 15 mGy, derived from ROC studies) compared to FBP. Admire 3 had the highest score and FBP the lowest score for CNR and SNR for all dose levels. The Spearman's rank correlation coefficients for the correlation between auc and MTF, SNR and CNR were 0.26 (p=0.497), 0.81 (p=0.011) and 0.92 (p=0.001) respectively. The results indicate a strong correlation beween ROC lesion detectability and SNR and CNR. The correlation between lesion detectability and MTF was not significant.

CONCLUSION

The new phantom enabled a combination of quantitative and qualitative image quality measurements important for optimization of image quality for CT examinations. The correlation between the lesion detectability and SNR and CNR was good, indicating that both quantiative and qualitative measurements give meaningful results for both FBP and the iterative reconstruction, Admire, for abdominal CT.

CLINICAL RELEVANCE/APPLICATION

Optimization of iterative reconstruction demand phantoms designed for qualitive and quantiative image quality analysis. A new abdominal phantom designed for ROC studies showed promising results.

SSQ19-03 Motion Compensated CT Imaging of the Aortic Valve

PURPOSE

Cardiac CT imaging is used for the planning of transcatheter aortic valve implantation (TAVI). ECG correlated data acquisition and gated reconstruction enables imaging of the valve in the systolic and diastolic phase. Especially in the systolic phase, motion artifacts may occur and interfere with diagnosis and treatment planning. The purpose of the study was to analyze the efficiency of a second pass motion correction method to compensate cardiac motion.

METHOD AND MATERIALS

A time series of cardiac contrast enhanced CT volume images were first reconstructed atdifferent phase points with a temporal distance of 5% cardiac cycle. Edge features of the valve, thevalve leaflets and the neighboring vascular anatomy were enhanced in the reconstructed images by agradient based filter which uses non-maximum-suppression and hysteresis thresholding. Afterwards, a subsequent elastic image registration was applied to estimate dense motion vector fields for thedifferent cardiac phases. The resulting motion vector fields are included in the motion compensatedfiltered back projection and interpolated in the time domain to cover the temporal projection rangerequired for reconstruction. The method was applied to retrospective ECG-gated clinical datasetsacquired with a 256-slice CT scanner (Brilliance iCT, Philips Healthcare) and tested for systolic (30%R-R-interval) and diastolic (70%) imaging of the valve on ten data sets.

RESULTS

The method achieved motion artifact reduction in both heart phases. Especially in late systolea strong improvement in image quality and visibility of the valve leaflets and aortic boundaries couldbe observed, as well as reduced blurring compared to the gated reconstructions.

CONCLUSION

Motion compensated reconstruction of the aortic valve is feasible using edge filtering andimage based registration for motion estimation. Improved CT image quality and reduced motionartifact levels can be achieved thereby facilitating improved visualization

of the aorta as well asimproved planning and device selection for TAVI procedures.

CLINICAL RELEVANCE/APPLICATION

Improved CT visualization of the aorta by new image processing tools is crucial for optimized planning and device selection for TAVI procedures.

SSQ19-04 Body Position's Effect on the Subclavian Vein Artifact in Carotid Artery CT Angiography: Lateral Position vs Supine Position

Thursday, Nov. 30 11:00AM - 11:10AM Room: S404AB

13102233561@163.com

PURPOSE

Aim of this study was to assess the body position's effect on the subclavian vein artifact in carotid artery CT angiography by comparing lateral position with supine position.

METHOD AND MATERIALS

80 patients who underwent carotid artery CT angiography imaging were randomly separated into two groups: group A with patient lying with lateral position and B with patient lying with supine position (n=40 for both groups). The other scanning parameters were the same for both groups, including tube voltage of 120kV, tube current of 260mA, pitch of 1.375:1, slice thickness of 5.0mm, large FOV. 70ml contrast agent (omnipaque, 350mgI/ml), 4.0ml/s of flow rate and smart contrast agent monitoring with a threshold of 200Hu were used for both groups. Image noise and CT value of subclavian artery (at the level of subclavian artery origin, vertebral artery origin and subscapular artery origin) and adjacent muscle (trapezius) were measured. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) for subclavian artery were calculated, according the formulas: SNR=CTartery/SD and CNR=(CTartery-CTmuscle)/SD. Subjective image quality was evaluated by two radiologists with a 5-point scale. Measurement data was compared with independent student T test, the image quality score was compared with Mann-Whitney U test.

RESULTS

The SD of group A were lower than that of group B (35.03±14.09 vs 208.21±35.78, $p<0.05$). The SNR and CNR of group A were both higher than those of group B (SNR, 14.19±4.30 vs 6.40±2.3; CNR,10.76±3.62 vs 4.86±1.88, both$p<0.05$). The subjective image quality was also higher in group A than group B (4.30±0.47 vs 3.17±0.70, $p<0.05$).

CONCLUSION

Changed velocity vector of flowing blood via changed body position, could removed the subclavian vein artifacts during carotid artery CT angiography imaging. This technique is useful and very feasible.

CLINICAL RELEVANCE/APPLICATION

Through changed body position to changed velocity vector of flowing blood is a useful and very feasible way to removed the subclavian vein artifacts during carotid artery CT angiography imaging.

SSQ19-05 The Visibility of Peripheral Pulmonary Arteries in Pulmonary Embolism Patients by Free-breathing Combined with High-threshold Bolus Triggering Technique in CT Pulmonary Angiography

Thursday, Nov. 30 11:10AM - 11:20AM Room: S404AB

llpldl@163.com

PURPOSE

To investigate the visibility of peripheral pulmonary by computed tomography pulmonary angiography (CTPA) under free breathing mode and to explore the feasibility of this technique in pulmonary embolism patients who can't hold breathing.

METHOD AND MATERIALS

200 patients who were suspected PE underwent CTPA on GE Revolution CT. They were randomly assigned into two groups: free-breathing group (n=100) and breath-holding group (n=100). CTPA were performed with pitch 0.992:1, rotation time 0.28s and 16cm-detector. Automatic bolus-tracking was used with a monitor ROI placed on main pulmonary artery(MPA). For the free-breathing group, scan started immediately as the CT value reached a 250 HU threshold; for the breath-holding group, scan started 5 seconds after reaching an 80 HU threshold. The reconstruction slice thickness and interval were 0.625 mm with standard lung

algorithm and all images were transferred to the ADW 4.6 workstation for diagnosis and evaluation. Mean scanning time was recorded and analyzed by independent-sample t-test; the displayed distal branches of pulmonary artery was recorded and chi-square test was used for statistical analysis.

RESULTS

All CTPA were performed successfully and all the farthest branches reached of 6 or farer. There was no significant difference between the two groups in mean scanning time(0.67±0.09s vs 0.67s±0.10s, p=0.367). The order of distal pulmonary arteries of 6, 7 and 8 in the free and holding groups were 25, 57, 18 vs 17, 61, 22 respectively.There was no significant difference between the two groups ($\chi 2=2.059$, p=0.357), and there was no significant statistical significance ($p > 0.5$).

CONCLUSION

Compared with breath-holding mode, the free breathing mode CTPA by 16cm-wide detector scanner has the same ability to display the peripheral pulmonary arteries.

CLINICAL RELEVANCE/APPLICATION

Free breathing CTPA can be successfully applied in PE patients, especially valuable for the patients who can't hold their breath.

SSQ19-06 Patient Dose Reduction in Tomosynthesis Imaging: Application of a New Computerized Reconstruction Technique

Thursday, Nov. 30 11:20AM - 11:30AM Room: S404AB

Participants
Ryohei Fukui, Yonagoshi, Japan (*Presenter*) Nothing to Disclose
Junji Shiraishi, Kumamoto, Japan (*Abstract Co-Author*) Research Grant, FUJIFILM Holdings Corporation; Research Grant, Nihon Medi-Physics Co, Ltd

PURPOSE

A high radiation dose is one of the problem in tomosynthesis examination. Generally, an increase in the number of projected images results in high image quality of reconstructed tomosynthesis images, but also increases the patient dose. In this study, we developed a new interpolation technique for improving the image quality of reconstructed tomosynthesis images with a reduced number of projection images.

METHOD AND MATERIALS

A full projected images (73 projections) were acquired with Safire17 (Shimadzu Co.) as the original data set (Orig-set). Partially projected image data sets (Sub-set) with 37, 19, and 11 projections were selected from the Orig-set with intervals of 1, 3, and 7 projections. In this study, the Path Framework (PF) method, which was originally developed for a video interpolation technique, was applied to interpolate interval projection images of Sub-set images. The pixel value of the interpolated image was estimated from one of the two input images before and after the target phase; this pixel value was determined using the shifted value between the target phase and the two input images. Using this technique, the frequency content of the original image could be preserved without blurring. Three image data sets with 73 projection images were consisted with real projection images and their interpolated projection images obtained by the PF method (PF-set). Tomosynthesis images were reconstructed by these data sets using filtered back-projection. In order to evaluate the image quality, we adopted the wire method and the two-dimensional fast Fourier transformation method for spatial resolution and noise property, respectively.

RESULTS

Spatial resolution and noise property of tomosynthesis images reconstructed from the PF-set were equivalent to those obtained from the Orig-set., whereas the spatial resolution of tomosynthesis images was clearly degraded by using a conventional interpolation technique.

CONCLUSION

The number of projected images can be reduced more than 50% by using the PF method without degradation of image quality. We believe this proposed method would be utilized for the reduction of patient dose in tomosynthesis.

CLINICAL RELEVANCE/APPLICATION

This proposed method would be applied for various tomosynthesis systems without any modification of system hardware and can realize patient dose reduction effectively.

SSQ19-07 Ex-Vivo Neuro-Imaging of Human and Animal Spinal Cords via X-Ray Phase Contrast CT: Detection of Full Organ Anatomy, Micro-Vessels and Single Motor Neurons

PURPOSE

Achieving non-invasively both full-organ visualization and cellular-resolution in the imaging of anatomical and pathological CNS tissue structure is beyond both current clinical and preclinical cutting-edge neuroimaging techniques. In fact, the study of vascular and neurodegenerative disorders still relies heavily on sample-invasive imaging protocols, which involve dissections, staining or labeling of nervous tissue, and which in most cases fail to capture complete volumetric information on cell populations and microvasculature within a full-organ sample. In this ex-vivo study, we used a staining- and dissection-free imaging technique, X-ray phase contrast tomography (PCI-CT), to visualize full-organ vascularization and concurrent detection of single neuronal cells in excised spinal cord samples from both human donors and animals.

METHOD AND MATERIALS

Lumbar spinal cord samples, extracted from both healthy rats and human donors, were imaged using a synchrotron PCI-CT setup. We used 20-40 keV monochromatic coherent X-rays, a sCMOS-sensor PCO camera and an optics system with isometric voxels of sizes from 46^3 micron^3 down to 0.3^3 micron^3.

RESULTS

PCI allowed recognition and differentiation of full-organ spinal cord anatomy, including anterior/posterior gray horns, the dorsal/ventral roots and ganglions, the central canal and the meninges. Superficial as well as deep vessel architecture could be extracted without the need of any contrast-agent. Moreover, at the highest resolutions used, single neuronal cells perfused by surrounding vasculature could be recognized: distinct bundles of nerve fibers, single motor neurons and neuro-glial cells, cell bodies and axons, as well as intra-cellular structure (cell nuclei and nucleoli) were successfully detected.

CONCLUSION

CNS PCI micro-CT, with the unique detection of single cells and of single micro-vessels within full-organ samples, enables a volumetric histology-like analysis of neuronal cell populations and micro-vascular networks in extracted spinal cord samples of both human donors and animals.

CLINICAL RELEVANCE/APPLICATION

Non-invasive visualizations of full-organ CNS micro-vascularization and of neuronal cell populations are fundamental in the preclinical study of vascular and neurodegenerative diseases.

SSQ19-08 Evaluation of a New Nonrigid-Registration Method Using Non-Local Spatio-Temporal Priors on Liver Perfusion CT in Patients with Hepatic Cellular Carcinoma

Thursday, Nov. 30 11:40AM - 11:50AM Room: S404AB

For information about this presentation, contact:

wqg98@126.com

PURPOSE

To evaluate the feasibility of the Nonrigid-registration method on free-breathing liver CT perfusion in comparison with standard Rigid-registration method.

METHOD AND MATERIALS

Six studies of three patients with hepatic cellular carcinoma underwent free-breathing liver CT perfusion scanning by using a 128-row CT scanner (Revolution CT, GE Healthcare, Milwaukee, WI). The original axial CT images of all studies were registered by Nonrigid-registration method using Non-local Spatio-temporal Priors (GE Healthcare, Milwaukee, WI) and standard Rigid-registration method (ANALYZE software supplied by Mayo Clinic, Rochester, MN) respectively. The CT perfusion maps (BF, BV, MTT, PS, HAF, HAP and PVP) and motion in tumor regions on images registered by Nonrigid-registration and Rigid-registration were compared.

RESULTS

The Nonrigid-registration method significantly reduced respiratory motion on whole liver region, whereas only focused tumor region can be registered well by using standard Rigid-registration in our study. All the perfusion parameters had no statistically difference between Nonrigid-registration and Rigid-registration (all P values > .05)

CONCLUSION

The new Nonrigid-registration method using Non-local Spatio-temporal Priors gained better alignment on whole liver region than Rigid-registration. The Nonrigid-registration method promotes the application of free-breathing liver CT perfusion in clinical practice.

CLINICAL RELEVANCE/APPLICATION

Nonrigid-registration with non-local spatio-temporal can achieve a stable perfusion CT data and is a powerful method as a first step for image post-processing after CT perfusion scanning.

SSQ19-09 Improved Visibility of Guidewires and Devices for Interventional X-Ray Procedures Using a New Approach to Automatic Exposure Control

michiel.dehairs@uzleuven.be

PURPOSE

Current automatic exposure controls (AEC) of fluoroscopy systems adjust acquisition parameters to achieve a constant signal level in the image receptor. This study investigates a new AEC approach that sets parameters which optimize the visibility of specific materials quantified using a figure of merit (FOM). The clinical motivation is to increase efficiency and clinical outcomes in the angio suite while reducing dose.

METHOD AND MATERIALS

A Siemens Artis Q interventional system was used to image a phantom composed of 4, 8 and 12 composite plates, each of 20mm PMMA and 2mm Al, approximating the attenuation of 10, 20 and 30cm human tissue. Seven materials were studied, including iron, iodine contrast and platinum, covering a range of clinically relevant devices and contrast media. Samples were placed at the phantom center and imaged using a new AEC approach based on an FOM composed of a spatial frequency dependent signal difference to noise ratio (SDNR(u)). Standard SDNR was corrected for the influence of focal spot size and object motion blurring by multiplying with MTF based correction factors, which were calculated with access to unprocessed data. The FOM was defined as $SDNR^2(u)$/entrance air kerma rate. The FOM was measured for all samples using a total of 10 new AEC regulation curves, each optimized for a specific material, and the current standard curve. The FOM of the curve matching the correct insert was then compared to the FOM data of the other curves: taking the ratio gave an estimate of the efficiency change.

RESULTS

The new AEC improved the imaging efficiency of metals such as iron, tantalum and platinum: for the 20cm phantom the FOM increased by 16%, 165% and 164% respectively compared to the conventional AEC. There was little or no gain for the 30cm phantom, with increases of 0%, 7% and 4%, respectively, due to restricted parameter selection at large patient thicknesses. The FOM for iodine contrast increased between 15% and 20%, for the 20cm phantom.

CONCLUSION

The new AEC approach shows great potential for increasing the imaging efficiency of a wide range of materials. For a typical patient thickness of 20cm, increases between 15% and 165% were seen compared to the conventional AEC.

CLINICAL RELEVANCE/APPLICATION

Selecting AEC factors by optimizing an FOM instead of keeping X-ray detector signal constant can increase visibility of devices, guidewires and contrast media used during interventional procedures.

Stefan O. Schoenberg, MD, PhD, Mannheim , Germany (*Abstract Co-Author*) Institutional research agreement, Siemens AG
Steffen J. Diehl, MD, Mannheim, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate a robotic assistance device for cone beam CT guided IRE probe placement in a liver phantom with regard to ability of parallel probe placement, precision and intervention time.

METHOD AND MATERIALS

16 IRE probes, covering eight lesions, were placed in a liver phantom (CIRS liver phantom 71a) using a preclinical robotic assistance device and a multi axis c-arm system. Cone beam CT was performed for intervention planning and probe position verification.

RESULTS

Parallel probe placement was achieved in all eight cases. Mean angular deviation of the needle pair was only 1.52°(±0.65°). The mean distance delta (planned distance- actual distance) of the needle pairs was only 1.05mm (±1.65mm). Mean intervention time including planning scan, needle path planning, needle placement and verification scan was 10 min 41s (± 1min 27s).

CONCLUSION

Our preclinical data shows that IRE probes can be placed precisely within an acceptable time when cone beam CT and robotic assistance is used.

CLINICAL RELEVANCE/APPLICATION

Precise and time efficient IRE probe placement is possible when combining cone beam CT and robotic assistance. This approach has great potential to expand the spectrum of possible hybrid interventions and therapeutic strategies.

SSQ20-02 Utility of the 2015 American Thyroid Association (ATA) Guidelines for the Prediction of Clinically Significant Thyroid Cancer: A Review of 1,947 Consecutive Thyroid Biopsies

Thursday, Nov. 30 10:40AM - 10:50AM Room: N227B

Participants

Elaine M. Caoili, MD, MS, Ann Arbor, MI (*Abstract Co-Author*) Nothing to Disclose
Matthew S. Davenport, MD, Cincinnati, OH (*Abstract Co-Author*) Royalties, Wolters Kluwer nv; ;

For information about this presentation, contact:

amitpand@med.umich.edu

PURPOSE

To determine if the 2015 American Thyroid Association (ATA) Guidelines effectively stratify the risk of clinically significant thyroid cancer

METHOD AND MATERIALS

We retrospectively reviewed 1947 thyroid nodules which underwent us guided Fine needle aspiration from Oct 2009 to Feb 2016 Each nodule was assigned an ATA category based on sonographic features Each pt underwent a dedicated thyroid US and US guided fine needle aspiration performed by our cross-sectional interventional team

RESULTS

We aspirated 14 category 1 lesions which have a < 1% risk of malignancy. These are thyroid cysts. None of these were found to be malignant. We aspirated 249 category 2 lesions which have a < 3% risk of malignancy. These are described as spongiform or partially cystic lesions. One malignancy was associated with each of these appearances We had 733 ATA category 3 lesions which have a 5-10% risk of malignancy. These can be described as hyperechoic nodules, isoechoic solid nodules with regular margin partially cystic with eccentric solid nodule or partially cystic with peripheral nodules. Zero to up to 2% of cancers were found with each imaging appearance We had 850 ATA category 4 lesions which have a 10-20% risk of malignancy. These can be described as solid hypoechoic nodules. 7% were found to be malignant We had 101 ATA category 5 lesions which have a greater than 70-90% risk of malignancy. These can have microcalcifications. They be hypoechoic with irregular margins or hypoechoic and be taller than wide. 31% of the hypoechoic nodules with calcifications were malignant where as 19% were found to be malignant if the nodule was hypoechoic with irregular margins.

CONCLUSION

2015 ATA guidelines; Overestimate the risk for malignancy , ephasize papillary over non-papillary cancers and may contribute to the ongoing over-diagnosis of thyroid nodules Improved risk stratification will help identify patients who will benefit from active surveillance rather than immediate fine-needle aspira

CLINICAL RELEVANCE/APPLICATION

The rapid increase of thyroid cancer is related to over-diagnosis ,87% are well differentiated (papillary) sub-clinical small cancers < 2 cm, majority progress slowly or not at all In 2015, the American Thyroid Association (ATA) presented guidelines for the management of this increasingly common clinical problem with an indolent prognosis

SSQ20-03 Propensity Score-Matched Comparison of Oncologic and Functional Mid-Term Outcomes Following Robotic Partial Nephrectomy and Percutaneous Radiofrequency Ablation for T1a Renal Cell Carcinoma

Thursday, Nov. 30 10:50AM - 11:00AM Room: N227B

Participants
Byung Kwan Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

1436park@gmail.com

PURPOSE

To compare oncologic and functional mid-term outcomes following RPN and RFA using propensity score-matching.

METHOD AND MATERIALS

This retrospective HIPPA-compliant study was approved by institutional review board. Between December 2008 and April 2016, 287 and 80 patients underwent RPN or RFA for T1a RCC, respectively. Each treatment was performed by a single urologist or radiologist. Sixty-three patients from each treatment group were propensity score-matched for age, sex, American Society of Anesthesiologists score, tumor size, tumor laterality, tumor histology, R.E.N.A.L. nephrometry score, and preoperative estimated glomerular filtration rate (eGFR). RCC in RPN and RFA groups was histologically confirmed via surgery and biopsy, respectively. Posttreatment follow-up periods for RPN and RFA ranged from 1-90 months (median, 24.6 months) and 1-65 months (21 months), respectively. Tumor location, percentage of eGFR preservation, local recurrence rate, and 2-year recurrence-free survival rate were compared between groups.

RESULTS

Exophytic and endophytic RCC occurred in 73.0% (46/63) and 27.0% (17/63) of the RPN group, and in 52.4% (33/63) and 47.6% (30/63) of the RFA group, respectively (p=0.017). There was 91.7% preservation of eGFR in the RPN group and 86.8% in the RFA group (p=0.088). Local recurrence rates in the RPN and RFA groups were 0% (0/63) and 4.8% (3/63), respectively (p=0.244). However, two-year recurrence-free survival rate was 100% in the RPN group and 95.2% in the RFA group (p=0.029).

CONCLUSION

RPN may provide a higher recurrence-free survival rate than RFA. However, RFA can be a treatment option for an endophytic RCC that is difficult to treat with RPN.

CLINICAL RELEVANCE/APPLICATION

Increased likelihood of recurrent tumor should be informed to patients when RFA instead of RPN is chosen for treating T1a RCC.

SSQ20-04 Irreversible Electroporation in the Proximity of Surgical Clips is Safe

Thursday, Nov. 30 11:00AM - 11:10AM Room: N227B

Participants
Martin Liebl, MD, Aachen, Germany (*Presenter*) Nothing to Disclose
Maximilian F. Schulze-Hagen, MD, Aachen, Germany (*Abstract Co-Author*) Nothing to Disclose
Federico Pedersoli, MD, Aachen, Germany (*Abstract Co-Author*) Nothing to Disclose

Philipp Bruners, MD, Aachen, Germany (*Abstract Co-Author*) Nothing to Disclose
Peter Isfort, MD, Aachen, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Irreversible electroporation (IRE) is a minimal-invasive treatment option for hepatic malignancies close to vessels or bile ducts, due to its non-thermal ablation effect. Materials with good electric conductivity within the ablation zone could generate unwanted heating effects due to the induced electric current. Our aim was to evaluate the heating effects during IRE and the possible influences of surgical clips within the ablation zone.

METHOD AND MATERIALS

19 IRE procedures were performed in ex-vivo bovine liver tissue using the NanoKnife device (Angiodynamics) with 2 applicators. In each experiment three consecutive treatment cycles (each 90 pulses; pulse length 90 µs, 3000 Volt/cm) were performed immediately after each other. The electrode distance was fixed at 1.7 cm. At the midpoint between the electrodes, 4 points of interest (POI) for temperature measurements were established on a line perpendicular to the line connecting the electrodes (interelectrode line): 6 and 12 mm on both sides of the interelectrode line. On one side, a titanium surgical clip was placed at the 6 mm-POI. Temperature was measured every second at all 4 points during the electric pulse application. The mean temperature curve for all 19 ablations was calculated for each POI. After the IRE, the liver was dissected to evaluate possible tissue alterations.

RESULTS

IRE could be successfully performed in all 19 liver specimens. In the experiments an amperage of 15-20 A was reached. The titanium clip had no significant influence on the ablation temperature. The mean temperature increases at the 2 inner POI were 11.7 ± 4.5 °C (SD) and 10.3 ± 5.7 °C (SD), with a maximum of up to 20.4 °C. The mean temperatures at 6 mm to the interelectrode line were significantly higher compared to the temperatures on the same sides at 12 mm at all times during ablation with a maximum difference of 7.6 °C at the end of the energy deposition. ($p<0,00002$). Macroscopic evaluation of treatment zones showed no signs of heat-induced tissue alterations.

CONCLUSION

Titanium surgical clips have no influence on the ablation temperature during IRE. However, during pulse application a significant temperature increase was measured.

CLINICAL RELEVANCE/APPLICATION

IRE is a safe treatment option, even near surgical resection sites containing surgical clips. Substantial heating effects can occur in the center of IRE ablations, challenging the theory of a non-thermal ablation modality.

SSQ20-05 Heat Stress and Thermal Ablation Induced Expression of Nerve Growth Factor Inducible (VGF) in Hepatocytes and HCC Cells: Pre-Clinical and Clinical Studies

PURPOSE

Prior studies have shown that 1) sublethal heat stress of hepatocytes and HCC cells stimulates accelerated proliferation of HCC cells *in vitro* and 2) that thermal ablation of liver induces accelerated HCC tumor growth *in vivo*. The aim of the present study was to identify candidate growth factors induced by heat stress and thermal ablation *in vitro* and *in vivo* and in HCC patients undergoing thermal ablation.

METHOD AND MATERIALS

Hepatocyte and HCC cells underwent sublethal heat stress and were assessed for growth factor expression using expression microarray, qRT-PCR, western immunoblotting and ELISA. In an IACUC approved study, laser thermal ablation or sham ablation was performed in normal rat liver following HCC cell implantation. Rat liver and serum were harvested at 0-7 days post-ablation and analyzed for VGF expression using western-immunoblotting, immunohistochemistry and ELISA. Following IRB approval and informed consent, serum was collected from 16 patients undergoing thermal ablation for HCC at baseline, 3-6 hours and 18-24 hours post-ablation and analyzed for VGF using ELISA.

RESULTS

Sublethal heat stress induced a time-dependent significant increase in VGF mRNA (3-15 fold; $p<0.05$) and protein expression in both hepatocytes and HCC cells. Additionally there was a significant 3-fold increase in VGF concentration in the supernatant 48-72 hours following sublethal heat stress of HCC cells ($p <0.05$). Thermal ablation induced increased protein expression of VGF at the liver ablation margin 1-3 days post ablation and in HCC tumor 7 days post-ablation. There was no significant increase in serum VGF concentration following liver thermal ablation in rats or HCC thermal ablation in patients ($p>0.05$).

CONCLUSION

Sublethal heat stress and thermal ablation induce increased VGF expression in hepatocyte and HCC cells *in vitro* and in liver and HCC tumor *in vivo* but not in serum, thereby suggesting that heat stress induced VGF expression may be localized within the liver near the ablation zone. VGF warrants further investigation as a novel candidate growth factor mediating thermal ablation induced

accelerated intrahepatic HCC tumor growth.

CLINICAL RELEVANCE/APPLICATION

Nerve growth factor inducible (VGF) is induced by thermal ablation in the liver and may represent a novel growth mechanism mediating thermal ablation induced accelerated HCC tumor growth.

SSQ20-06 Irreversible Electroporation (IRE) for the Treatment of Recurrent Prostate Cancer (PCa) after Prostatectomy, Radiation Therapy and HiFU

Thursday, Nov. 30 11:20AM - 11:30AM Room: N227B

Participants
Michael K. Stehling, MD, PhD, Offenbach, Germany (*Abstract Co-Author*) Investor, InterScience GmbH; Shareholder, InterScience GmbH
Enric Guenther, DIPLPHYS, Frankfurt, Germany (*Abstract Co-Author*) Shareholder, InterScience GmbH
Stephan Zapf, Frankfurt, Germany (*Abstract Co-Author*) Nothing to Disclose

Ross E. Schwartzberg, MD, San Diego, CA (*Presenter*) Nothing to Disclose

PURPOSE

Over the last 7 years we have successfully treated over 500 patients with primary prostate cancer with Irreversible Electroporation (IRE). Here we present our experience with IRE for the treatment of recurrent prostate cancer in 36 men with a minimum follow-up of 1 year. We discuss indication, technique, efficacy, toxicity, limitations and potential pit falls.

METHOD AND MATERIALS

36 men with recurrent prostate cancer (PCa) were treated with IRE. Initial treatments consisted of: radical prostatectomy (RPE; N=9), external beam radiation (RT; N= 14), RPE and RT (N=4), high energy focal ultrasound (HiFU; N=7) and brachytherapy (N=2). Initial PCa stages were T1 (N=4), T2 (N=12), T3 (N=8), T4 (N=6) and NA (N=6), respectively. Mean follow-up time after IRE was 25.7 months (min. 13, max. 72 months). Follow-up was performed in with PSA and multi-parametric (mp)MRI in all and PSMA-PET/CT and re-biopsy in selected cases. Erectile function and urinary continence were assessed by IIEF5 and ICIQ questionnaires; all other adverse events were recorded and classified by CTCAE criteria.

RESULTS

In all cases mpMRI (DCE-sequences) showed complete ablation. Grade 0 to 1 adverse events were observed in 29 cases. Grade 2 (moderate) adverse events were observed 4 cases (urinary tract infections). A Grade 3 (severe) adverse events was observed in 3 cases (urinary retention). No Grade 4 or 5 events were noted. There was no statistically significant change in the recorded ICIQ (urinary continence) nor IIEF5 scores before and 6 months after IRE.

CONCLUSION

IRE is a suitable technique for the treatment of recurrent PCa after RPE, RT, brachytherapy and HiFU. It can be employed with lower toxicity than other second line treatments such as salvage RPE and/or RT. This could establish IRE as a 'problem solver' technology for recurrent PCa.

CLINICAL RELEVANCE/APPLICATION

Irreversible Electroporation (IRE) is a suitable treatment for recurrent PCa. Its low toxicity affords local tumor control without damage of crucial anatomical structures, particularly after RT.

SSQ20-07 Contrast-enhanced Ultrasound as an Assessment Method During Microwave Ablation for Benign Thyroid Nodules: A Prospective Study

Thursday, Nov. 30 11:30AM - 11:40AM Room: N227B

PURPOSE

The major goal of ultrasound - guided microwave ablation (MWA) procedure is to reduce the volume and eliminate the activity of benign thyroid nodules. The purpose of our present study is to observe the value of contrast-enhanced ultrasound (CEUS) during both pre- and post-treatment evaluation of MWA for benign thyroid nodules.

METHOD AND MATERIALS

Between June 2016 and February 2017, 86 patients with a total of 86 benign thyroid nodules who were admitted to our hospital for WMA treatment were included. A microwave system including a microwave generator, a flexible low-loss coaxial cable and an internally cooled shaft antenna was used. The generator is designed with a frequency of 2450 MHZ and a maximum output power of 100W. The MWA antenna is 16-gauge (10cm in total length, 1.6mm in diameter, 3 mm in length of the active tip). The ablation procedures were monitored by real-time ultrasound. Before MWA, dynamic CEUS examinations were performed to make pre-treatment assessment, including blood perfusion of nodules and their relationship with surrounding large vessels. One day and six month after ablation, the post-treatment CEUS were conducted to evaluate whether the original nodule was completely ablated.

RESULTS

During pre-ablation CEUS evaluation, peripheral hyperenhanced rings were detected during arterial phase of all nodules, with mean thickness 1.4 ± 0.6 mm. Fifteen nodules were located very close to superior or inferior thyroid artery. MWA were conducted successfully in all 86 thyroid nodules. Post-ablation CEUS showed that 82 (95.3%) nodules with complete ablation had no enhancement. The peripheral hyperenhanced ring disappeared in all nodules. The volume reduction of 91 ± 7.3 % was achieved with benign thyroid nodules after six months by ultrasound guided MWA. No major complications occurred.

CONCLUSION

Microwave ablation with real time ultrasound guidance is an effective and safe method in treatment of benign thyroid nodules. CEUS is a sensitive and effective method to make both pre-treatment evaluation and post-treatment efficacy of MWA.

CLINICAL RELEVANCE/APPLICATION

With application of CEUS both pre-and post-treatment of WMA, we can guarantee the effective and safety of treatment.

SSQ20-08 Percutaneous Cryoablation of Lymph Node Metastases

Thursday, Nov. 30 11:40AM - 11:50AM Room: N227B

Parvinian.Ahmad@mayo.edu

PURPOSE

To assess the safety and efficacy of percutaneous computed tomography (CT)-guided cryoablation for local control of lymph node metastases in patients with oligometastatic malignancy.

METHOD AND MATERIALS

In this single-institution study, a retrospective search of the institutional cryoablation database identified 39 unique patients (mean age 64 ± 14 years; 33 men, 6 women) treated with 45 cryoablation procedures targeting a total of 48 lymph nodes between October 2006 and March 2017. Patient demographics, disease characteristics, and procedural details were recorded. Primary endpoints were technical success and complications. The secondary endpoint was time to local progression. Technical success was defined as complete coverage of the target node by the ablation zone. Complications were graded according to the Society of Interventional Radiology consensus guidelines. Time to progression was calculated using the Kaplan-Meier method.

RESULTS

Technical success was achieved in 100% of cases. Targeted nodes measured 1.8 ± 1.6 cm (mean short axis diameter). Adjunctive maneuvers performed to protect adjacent structures included hydrodissection (n=28) and preprocedural ureteral stenting (n=2). There were no major complications. One patient developed a subcutaneous hematoma following ablation of an axillary lymph node and required thrombin injection to control bleeding. Another patient developed a tiny apical pneumothorax following ablation of a supradiaphragmatic node, prompting temporary chest tube placement and overnight observation. Mean imaging follow-up duration was 17.3 months. Local recurrence occurred in 9/48 cases (19%) with a mean time to progression of 18.8 ± 3.1 months.

CONCLUSION

Percutaneous cryoablation is a safe and effective therapy for achieving local control of lymph node metastases in the setting of oligometastatic malignancy. Further investigation is warranted to determine long-term efficacy.

CLINICAL RELEVANCE/APPLICATION

Percutaneous image-guided cryoablation is safe and effective for treatment of limited nodal metastases and may be a useful adjunct to other oncologic therapies for achieving local control of oligometastatic disease.

SSQ20-09 Tumor Response Assessment in Unresectable Hepatocellular Carcinoma (HCC) Patients: Functional MRI as a Substitute for Traditional Anatomic Sized Based Tumor Response Assessment

PURPOSE

The aim of this study was to evaluate superiority of functional MRI biomarkers to traditional sized based criteria in assessing tumor response in unresectable HCC patients who had trans- arterial chemoembolization (TACE).

METHOD AND MATERIALS

One hundred and seventy HCC patients with unresectable lesions were enrolled in this retrospective HIPAA- compliant study. Informed consent was waived. All patients had baseline MRI, 3-4 weeks and 6 months' follow-up MRI after TACE therapy. Change in functional MRI biomarkers (Apparent diffusion coefficient (ADC), artriovenous enhancement (ENH) and tumor volume) were measured on 3-4 weeks MRI using a semiautomatic volumetric software package (Onco Treat, 3.1.1, Siemens). Anatomic response variables including Response Evaluation Criteria in Solid Tumors (RECIST), modified RECIST (mRECIST), and European Association for the Study of the Liver (EASL) were measured on 6 months' follow-up MRI. Patients were stratified into responder and non-responder groups based on median survival (20 months). Change in functional variables (ADC, ENH, tumor volume) at 1 month and change in anatomic variables (RECIST, mRECIST, EASL) at 6 months were measured for each group. Hazard ratio (HR) was calculated for all variables with Cox proportional hazards model.

RESULTS

Mean volumetric change in ADC, ENH, tumor volume, RECIST, mRECIST and EASLE were summarized in Table 1. ADC and ENH change were significantly different between responder and non- responder group ($p= 0.0007$ and 0.001; respectively) whereas tumor volume, RECIST, mRECIST and EASLE were not ($p= 0.6$, 0.23, 0.34, 0.4; respectively). Patients with greater than 15% increase in ADC demonstrated better overall survival (OS) compared with those with <15% increase in ADC; hazard ratio for predicting increased OS was 0.59 (95% CI: 0.3- 0.8; $p= 0.01$) (Fig 1-A, B). Also, patients with greater than 23% decrease in ENH demonstrated better OS than those who did not; HR: 0.60 (95% CI: 0.4-0.5; $p= 0.01$) (Fig 1-C, D).

CONCLUSION

ADC and ENH changes precede and are superior to anatomic criteria is assessing treatment response to TACE.

CLINICAL RELEVANCE/APPLICATION

Functional MRI biomarkers provide early and more accurate prediction of tumor response in HCC patients undergoing TACE. These metrics can potentially be used in future clinical trials.

PURPOSE

Patients with breast imaging often seek second opinion review at tertiary care centers. The goal of our study is to evaluate the impact of these second opinions on patient management.

METHOD AND MATERIALS

A retrospective chart review was conducted on 504 consecutive patients with second opinion radiology interpretations performed by six sub-specialized breast radiologists at a cancer center from January 1st through September 1st of 2014. Outside imaging reports were compared to second opinion reports to categorize interpretation discrepancies. Interpretations were considered discrepant in cases with a clinically relevant BI-RADS category change or identification of previously undiagnosed additional extent of disease greater than 5 cm. The frequencies of discrepant BI-RADS categorizations, clinically significant alterations in surgical management, and incremental cancer detection were measured. Statistical analyses were performed with Fisher's exact test with a p-value <0.05 considered significant.

RESULTS

Presenting diagnoses at second opinion interpretation included invasive malignancy (356), Ductal Carcinoma in Situ (78), high risk lesions (16), suspicious findings (21), probably benign findings (4), BI-RADS 0 (1), and negative or benign findings (28). Second opinions resulted in interpretation discrepancies in 287 patients (57%) and percutaneous image-guided biopsies in 94 (19%). Additional sites of cancer were detected in 48 (10%), including 13 ipsilateral and 8 contralateral breast malignancies, and 27 axillary metastases. Another 5 biopsies yielded high-risk pathology. Second opinion interpretations altered surgical management in 58 (12%) due to the detection of additional cancer, a high risk lesion at biopsy, additional extent of disease, or stage 4 disease. Factors associated with increased discrepancy frequency included diagnosis of invasive or in situ cancer at presentation (p=0.003), dense breasts (p=0.005), and the absence of prior studies available for comparison (p=0.007).

CONCLUSION

Though additional imaging and resources are required, pre-operative second opinion radiology review by subspecialized radiologists increases cancer detection and results in clinically relevant changes in patient management.

CLINICAL RELEVANCE/APPLICATION

Second opinion interpretation of breast imaging by subspecialized breast radiologists resulted in additional cancer detection in 10% and altered surgical management in 12% of patients.

SST01-02 Radiomics Signature on 3T DCE-MRI for Estrogen Receptor-Positive Invasive Breast Cancers: Preliminary Results in Predicting Oncotype DX Test Recurrence Score

kj-violet@hanmail.net

PURPOSE

To evaluate the ability of quantitative computer extracted imaging features on 3T dynamic contrast-enhanced (DCE) magnetic resonance imaging (MRI) to distinguish estrogen receptor (ER)-positive invasive breast cancers between the low and non-low Oncotype DX risk categories.

METHOD AND MATERIALS

Between May 2011 to March 2016, we retrospectively enrolled 67 ER-positive invasive breast cancer patients who performed preoperative 3T breast DCE-MRI and Oncotype DX assay. We divided the patients into low (Oncotype DX recurrence score [RS] <18) and non-low risk (RS >= 18) groups. Extracted radiomics features included morphological, histogram-based, and higher-order texture features. The least absolute shrinkage and selection operator (LASSO) method was used for feature selection, and radiomics signature (Rad-score) was calculated via a linear combination of selected radiomics features. Logistic regression analysis was performed to investigate the association between Oncotype DX risk groups and clinicopathologic, MR imaging, and Rad-score. Receiver operating characteristic analysis and the area under the receiver operating characteristic curve (Az) were used to assess classification performance.

RESULTS

The Rad-score was constructed for each tumor by extracting thirteen of 158 radiomics features (8.2 %). Multivariate regression analysis showed that there was a significant difference in the Rad-score between the low and non-low Oncotype DX risk groups (P = 0.001). The Rad-score was able to differentiate between low and non-low risk Oncotype DX groups with an Az of 0.822 . The significant pathologic factors in univariate analysis achieved an Az of 0.574. Addition of Rad-score to the significant pathologic factors in univariate analysis showed an Az of 0.889.

CONCLUSION

The Rad-score that incorporates the radiomics features of DCE-MRI was highly associated with the low and non-low Oncotype DX risk classifications in patients with ER-positive invasive breast cancers.

CLINICAL RELEVANCE/APPLICATION

The Rad-score could allow for non-invasively predicting which ER-positive patients might have little to no benefit from adjuvant chemotherapy.

SST01-03 Volume-Based Metabolic Parameter of Tumor on Preoperative 18F-FDG PET/CT May Predict Axillary Lymph Node Metastasis

Friday, Dec. 1 10:50AM - 11:00AM Room: E450B

Participants
Seon Young Park, MD, Suwon-si, Korea, Republic Of (*Presenter*) Nothing to Disclose
Youngjin Yoo, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Hye Lin Kim, MD, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Doo Kyoung Kang, MD, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Taehee Kim, MD, PhD, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The purpose of our study was to evaluate the association between metabolic parameters on FDG PET/CT and axillary lymph node metastasis (ALNM) in patients with invasive breast cancer.

METHOD AND MATERIALS

From January 2012 to December 2012, we analyzed 173 patients with invasive ductal carcinoma (IDC) who underwent both initial breast MRI and 18F-FDG PET/CT examinations. All metabolic parameters were measured from the tumor volume segmented by a gradient-based method. Once the primary target lesion was segmented, maximum standardized uptake value (SUVmax), mean standardized uptake value (SUVmean), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were calculated automatically by the MIMvista software.

RESULTS

Mean age of 173 patients was 49 years old. Of 173 patients, 45 (26%) showed axillary lymph node metastasis. On univariate analysis, larger tumor size (> 2.2 cm; p=0.002), presence of lymphovascular invasion (p < 0.001), higher SUVmax (> 2.82; p=0.038), higher SUVmean (> 1.2; p=0.027), higher MTV (> 2.38; p < 0.001) and higher TLG (> 3.98; p = 0.007) were associated with a higher probability of axillary lymph node metastasis. On multivariate analysis, presence of lymphovascular invasion (adjusted odds ratio [OR], 11.053; 95% CI, 4.403-27.751; p < 0.001) and higher MTV (> 2.38) (adjusted OR, 2.696; 95% CI, 1.079-6.739; p=0.034) maintained independent significance in predicting ALNM. In subgroup analysis of T2/T3 breast cancer, lymphovascular invasion (adjusted OR, 20.976; 95% CI, 5.431-81.010; p < 0.001) and higher MTV (> 2.38) (adjusted OR, 4.906; 95% CI, 1.616-14.896; p=0.005) were independent predictors of ALNM. However in T1 breast cancer, lymphovascular invasion (adjusted OR, 16.096; 95% CI, 2.517-102.939; p=0.003) and larger SUV mean (> 1.2) (adjusted OR, 13.275; 95% CI, 1.233-142.908; p=0.033) were independent predictors while MTV was not.

CONCLUSION

MTV may be associated with ALNM in patients with invasive breast cancer, particularly T2 and T3 stages. In T1 breast cancer, SUVmean was associated with ALNM.

CLINICAL RELEVANCE/APPLICATION

Metabolic tumor volume in 18F-FDG PET/CT may be associated with axillary lymph node metastasis in patients with invasive breast cancer, particularly T2 and T3 stages.

SST01-04 Visibility of Mammographically Occult Breast Cancer on Diffusion-Weighted MRI versus Ultrasound

PURPOSE

There is widespread interest in identifying an effective and affordable breast cancer screening exam that can supplement mammography. While dynamic contrast-enhanced (DCE)-MRI is highly sensitive and currently recommended for high-risk women, cost and gadolinium-related safety concerns limit its wider use. Screening ultrasound (US) can identify some mammographically-occult malignancies but is time consuming and associated with low specificity. Diffusion-weighted MRI (DWI) is emerging as a promising non-contrast technique for breast cancer detection. We sought to investigate the visibility of mammographically-occult cancers on DWI versus US.

METHOD AND MATERIALS

This IRB-approved study retrospectively evaluated patients with 3T DCE-MRI detected mammographically-occult cancers who underwent pre-biopsy targeted US (12/2010 to 12/2013). DWI was performed during clinical breast MRI exams (b= 0, 100, and 800 s/mm2). Lesion visibility on DWI was scored visually (1=isointense to 5=focal hyperintensity) by three independent readers (not blinded to DCE). DWI visibility was defined as a mean score of >=2.5. US visibility was determined from imaging reports. Clinical factors (age, breast density, lesion size, morphology, and histology) were collected, and DWI and US lesion visibility were compared across and within subgroups using McNemar's Test.

RESULTS

During the study period, 60 mammographically-occult cancers (53 invasive; 7 DCIS) were imaged by both DWI and US in 53 women (median age 53 years, range 23-75 years). Cancers ranged in size from 4 to 102mm (median, 12mm) and included 39 masses, 20 non-masses, and 1 focus. More cancers were visible on DWI (47/60, 78%) than on US (38/60, 63%; p=0.049), with 32 (53%) visible on both modalities and 7 (12%) not visible on either. Subanalyses suggested better visualization by DWI versus US in particular for larger cancers (>=1cm; p=0.011), which had a higher proportion of non-masses than smaller cancers (51% vs. 8%), and for cancers in younger women (<50years; p=0.06, trend).

CONCLUSION

Mammographically-occult breast cancers may be more visible on DWI than ultrasound. DWI continues to show promise as a cost-effective supplemental screening tool, and warrants further investigation.

CLINICAL RELEVANCE/APPLICATION

Diffusion-weighted MRI may be more sensitive than ultrasound for detecting mammographically occult cancer, and may provide a safe, fast, and affordable supplemental tool for screening women.

SST01-05 Outcomes in Patients with a Focal Area of Clinical Concern Assessed as Probably Benign on Diagnostic Imaging

emblaschke@gmail.com

PURPOSE

The American College of Radiology (ACR) Appropriateness Criteria support either short-term follow-up or biopsy for women presenting with a palpable solid breast mass demonstrating probably benign (BIRADS category 3) features on imaging. To support

decision-making in this clinical scenario, we measured outcomes of BIRADS 3 cases in a large population of women presenting with a focal area of clinical concern.

METHOD AND MATERIALS

Following IRB approval, review of the electronic medical records identified 15,548 cases of diagnostic mammography with ultrasound that evaluated a focal area of clinical concern from 3/2006 to 3/2014. Each breast with one or more focal areas of clinical concern was designated as a case. Outcomes were determined by imaging, biopsy or any pathology in our hospital tumor registry at 24-month follow-up. Performance measures were defined according to the ACR BIRADS atlas, 5th edition.

RESULTS

Of the 15,548 cases, 965 (6.2%) were assessed as BIRADS 3 in 861 women (average age 47.7, range 24-89). During the 24-month follow-up, only one cancer, an invasive ductal carcinoma, was diagnosed with a cancer yield of 0.1% (1/965). In addition to the one biopsy-proven malignancy, another 29 cases underwent biopsy/tissue sampling for a positive predictive value (PPV3) of 3.3% (1/30) within the follow-up period.

CONCLUSION

The risk of subsequent breast malignancy diagnosis in patients presenting with focal areas of clinical concern assessed as BIRADS 3 is extremely low (0.1%). These findings strongly support the current ACR guidelines suggesting surveillance as a safe alternative to biopsy in these patients. Given the high likelihood of benignity and the low PPV3 (3.3%), additional research may facilitate reclassification of a subgroup of probably benign lesions as benign by imaging (BIRADS 2) with recommendation for clinical follow-up.

CLINICAL RELEVANCE/APPLICATION

Follow-up of symptomatic probably benign lesions has a low rate of malignancy, supporting the ACR guidelines with opportunity to improve stratification of benign vs. probably benign palpable masses.

SST01-06 Deep Learning through Convolution Neural Networks Using a Breast MRI Tumor Dataset Can Predict Oncotype Dx Recurrence Score

Friday, Dec. 1 11:20AM - 11:30AM Room: E450B

PURPOSE

We hypothesize that CNNs can be used to predict Oncotype Dx Recurrence Score (RS), which is a validated, gene-expression-based, aggressiveness assay using a breast MRI tumor dataset.

METHOD AND MATERIALS

An IRB approved retrospective review of our database from 1/2010 to 6/2016 identified 134 patients with ER+/HER2- invasive ductal carcinoma who underwent both breast MRI and Oncotype Dx RS evaluation. Patients were classified to 3 groups: Low risk (group 1, RS < 18), intermediate risk (group 2, RS of 18- 30) and high risk (group 3, RS > 30). For deep learning, 134 cases were separated into 80% (107/134) training set and 20% (27/134) test set. For each breast MRI, tumor was identified on first T1 post contrast dynamic images and underwent 3D segmentation using an open source software platform 3D Slicer. Then, 32x32 patch was extracted from the center slice of the segmented tumor data. A CNN was designed for Oncotype DX class prediction based on each of these cropped images. In brief, CNN consisted of 4 convolution layers, max-pooling layers and dropout of 0.25 after each convolution layer. Two models were created, one for three class Oncotype Dx prediction (group 1, group 2 or group 3) and a second for two class prediction (group 1 vs. group 2 and group 3). Code was implemented in open source software Keras with TensorFlow on a Linux workstation with NVIDIA GTX 1070 Pascal GPU.

RESULTS

Three class Oncotype Dx prediction model was evaluated in 3 groups consisting of 77, 40 and 17 patients in groups 1, 2 and 3. The CNN achieved an overall accuracy of 80% in three class prediction. Two class Oncotype Dx prediction model was evaluated in 2 groups consisting of 77 and 57 patients (group 1 vs. groups 2 and 3). The CNN achieved an overall accuracy of 92% in two class prediction.

CONCLUSION

Current deep CNN architectures can be trained with relatively small MRI data set to achieve useful performance at predicting Oncotype DX RS. Research is underway with a larger dataset to improve our prediction model.

CLINICAL RELEVANCE/APPLICATION

Deep learning through convolution neural networks (CNNs) have demonstrated strong performance in various image classification tasks in recent years and may be used to predict patients' likelihood of breast cancer recurrence.

SST01-07 Classifying Breast Lesions with Initial Enhancement Kinetics from High Temporal-Resolution DCE-MRI

Friday, Dec. 1 11:30AM - 11:40AM Room: E450B

Participants

fdp@uchicago.edu

PURPOSE

To identify parameters descriptive of initial lesion enhancement on high-temporal resolution breast DCE-MRI that may aid in ruling out malignancies

METHOD AND MATERIALS

46 patients with dense breasts and BIRADS 4 or 5 on screening mammograms were enrolled. Participants received an MRI prior to biopsy, including high temporal resolution DCE-MRI ('ultrafast') during the first minute after contrast administration, followed by a standard high-spatial resolution acquisition. Patients were scanned on 1.5T and 3T scanners with temporal resolutions from 3.5 to 10 seconds. Relative signal enhancement was calculated on a voxel-by-voxel basis. Signal enhancement was fit to an empirical model with 3 parameters: upper limit of enhancement, uptake rate, and time of initial enhancement (TIE). Initial slope and initial area under the curve (iAUC) were calculated from the fit parameters. The time of initial arterial enhancement was measured in the internal mammary arteries and lesion enhancement times were calculated relative to this time

RESULTS

65 lesions were included in this analysis (27 benign, 38 malignant). Two cases showed no abnormal enhancement (on ultrafast or standard DCE); both biopsy results were benign. Benign and malignant lesions had average TIEs of 9.5 ± 12.8s and 5.7 ± 3.3s, respectively. the difference was not significant but 10 benign lesions (37%) had higher TIEs than the maximum TIE for all malignant lesions (12.1s). Initial slope and iAUC were significantly different ($p<0.005$) between benign and malignant lesions, with average malignant-to-benign ratios of 1.96±0.06 and 1.49±0.04. The negative predictive value of iAUC was 93%

CONCLUSION

These preliminary results suggest that IAUC, initial slope, and TIE from ultrafast DCE-MRI have strong negative predictive value, and may be used to rule out cancer and reduce unnecessary biopsies. This type of analysis requires only 1 minute of high-temporal resolution imaging. Ultrafast imaging allows reliable measurements of initial kinetics that are less sensitive to global variables (e.g., cardiac output) and descriptive of lesion physiology

CLINICAL RELEVANCE/APPLICATION

High-temporal resolution DCE allows accurate measurements of very early enhancement kinetics, when differences between benign and malignant lesions may be largest, and may provide strong negative predictive power

SST01-08 A Reader Study of MARIA Radiowave Breast Imaging Compared with X-Ray Mammography for the Symptomatic Breast

Friday, Dec. 1 11:40AM - 11:50AM Room: E450B

PURPOSE

MARIA is a new, non-ionising, non-compressing radiowave breast imaging modality with good dense breast performance which has early potential as an adjunct to x-ray mammography (MMG). This study presents a sensitivity comparison of MARIA and MMG using offline reads of the respective images.

METHOD AND MATERIALS

Females attending a symptomatic breast clinic at one of 3 UK symptomatic clinics (Southmead - Bristol, Thirlestaine - Cheltenham, Great Western - Swindon), were identified by clinicians as having a palpable lump. Following informed consent, eligible patients meeting inclusion criteria were scanned in the prone position with MARIA, a non-ionising, multi-static radar system (Yorkshire & The Humber and South Yorkshire REC 15/YH/0084) ClinicalTrials.gov NCT02493595. Patients had ultrasound scan (US) and/or mammography (MMG). Cytology/ histology was conducted as necessary as part of normal clinical procedure and final diagnosis was determined. Both MARIA and MMG were read offline by independent readers who had no knowledge of the clinical outcome. Features identified in either modality were subsequently compared to the diagnosis on discharge (including histology/ cytology where available) to determine a sensitivity score.

RESULTS

145 single breast studies were analysed. MMG sensitivity, defined as successful detection of the symptomatic index lesion, was 79% (42/52) in lucent (BI-RAD a,b) while MARIA sensitivity in lucent was 71% (37/42). For dense breasts (BI-RAD c, d), sensitivity for MMG was 54% (50/92) while for MARIA it was 77% (71/92).

CONCLUSION

Initial results suggest that the MARIA system offers the provision of a safer (non-ionising), more comfortable (no breast

Initial results suggest that the MARIA system offers the provision of a safer (non-ionising), more comfortable (no breast compression) and inexpensive breast screening alternative compared to other modalities, which has been shown to be effective at detecting cancers in younger, pre-menopausal women with dense breasts. MARIA may also overcome some of the challenges posed by trying to optimise the balance between benefit and harm of MMG screening in women of younger age.

CLINICAL RELEVANCE/APPLICATION

The sensitivity of MMG is low for women with dense breasts (DB). MARIA shows great promise as a whole-breast adjunct offering a benign, more comfortable, sensitive diagnostic for women with DB.

SST01-09 Quantitative Assessment of Breast DCE-MRI BPE and Mammographic Breast Density Changes over Time

PURPOSE

Breast DCE-MRI background parenchymal enhancement (BPE) has been reported associated with breast cancer risk, potentially independent of the established mammographic breast density (MBD). We investigated quantitative characteristics and temporal changing patterns of BPE and MBD on a large (1792) set of MRI scans and mammogram examinations acquired from breast cancer-free women.

METHOD AND MATERIALS

We retrospectively identified 886 longitudinal breast DCE-MRI scans (2006-2015) and 886 mammogram examinations acquired in the same year with the MRI from 266 high-risk screening women (each with 2-9 sequential scans). For the 886 MRIs, the average age-at-scan was 50.4±9.3 YO, average between-scan time was 419±165 days, and 552 (62%) were post-menopausal with the rest pre-menopausal. All 266 women remain breast cancer-free at the time of this study. Fully automated computerized methods were applied to quantify BPE and area-based MBD (an average on CC and MLO view), both at unilateral and bilateral levels. BPE was computed from the first post-contrast sequence as the volumetric percentage of enhanced voxels over the fibroglandular tissue. Descriptive statistics, nonparametric regression, and linear mixed effects modeling were used to assess distributions and changing patterns of BPE and MPD over time.

RESULTS

Mean BPE was 22.2%±13.5 for all scans, and was 25.3%±14.8 for pre- and 20.4%±12.4 for post-menopausal scans (unpaired t-test $p<0.0001$). Likewise for MBD, mean was 29.7%±16.6 for all mammogram examinations, 31.9%±16.5 for pre- and 28.4%±16.7 for post-menopausal ($p=0.0027$). The Pearson's correlation coefficient between left and right BPE (or MBD) was 0.85 (or 0.90). Both BPE and MBD change over time in a roughly linear decreasing trend and both statistically significant ($p<0.05$) with respect to the evaluation of accumulated-years-since-first-scan, but the rate of change for MBD (0.7 percentage point/year, 95% CI 0.2-1.2) is somewhat less than for BPE (0.9 percentage point/year, 95% CI 0.5-1.3).

CONCLUSION

In longitudinal imaging scans of breast cancer-free women, both BPE and MBD are higher among pre- than post-menopausal women. They both decrease roughly linearly over time, but the trend of MBD is less pronounced than BPE.

CLINICAL RELEVANCE/APPLICATION

Quantitative assessment of temporal changing characteristics of BPE and MPD in cancer-free women can help determine their performance and mechanisms as independent breast cancer risk biomarkers.

PURPOSE

Increased volume of thoracic fat surrounding the heart (TFV) is predictive of major adverse cardiovascular events, however, its measurement has previously relied on time-consuming manual quantification which is prone to variability. We developed a fast and robust algorithm to automatically quantify TFV using deep learning methods.

METHOD AND MATERIALS

The Deep Learning method was divided into two parts: (i) a convolutional network used for heart segmentation for non-contrast CT axial slices and (ii) a second convolutional neural network used to identify superior and inferior heart limits. These two networks, implemented with the standard Caffe library on graphics display cards for fast training performance, were combined to provide a binary mask of the heart and thoracic fat. Standard fat range attenuation (-190 to -30 HU) was then applied and allowed for fat segmentation. Deep Learning was validated using 10-fold cross validation in 250 non-contrast coronary calcium scoring CT datasets, with expert fat and heart identification as the reference standard.

RESULTS

Median TFV was 130.354 cm3 (Inter-quartile range [IQR]: 89.121-198.183) and 130.936 cm3 (IQR: 87.244-193.696) for expert and automatic quantifications, respectively, with no significant difference ($p>0.99$). An excellent correlation was obtained between the two measures ($R=0.944$, $p<0.00001$), with a non-significant bias of -0.003 cm3 (95% confidence interval: -3.287 to 3.280) according to Bland-Altman analysis. The algorithm is now implemented in our homemade visualization software and allows for automatic TFV quantification of a new case within 20 seconds on a standard personal computer compared to approximately 10 minutes of expert measurement.

CONCLUSION

Using deep learning methods, we developed a fast, fully automated algorithm to segment the heart and quantify TFV from non-contrast CT data sets, with high correlation and agreement with expert measurement. This algorithm may allow for routine, efficient TFV quantification to aid cardiovascular risk assessment and improve the prediction of major adverse cardiovascular events.

CLINICAL RELEVANCE/APPLICATION

Deep Learning algorithm can perform fast and robust quantification of fat surrounding the heart in non-contrast CT data sets and allow for clinical routine quantification and prediction studies.

SST02-02 Use of 18-F FDG PET/CT for Diagnosis of Cardiac Device Infections

Friday, Dec. 1 10:40AM - 10:50AM Room: E450A

mahmood.maryam@mayo.edu

PURPOSE

Cardiac device infections can be challenging to diagnose, there is growing evidence to support the role of 18-F fluorodeoxyglucose (FDG) PET/CT imaging as a complementary diagnostic tool in patients with suspected cardiac device infections. We hypothesize that nuclear imaging will be useful in excluding cardiac device infections, particulary in cases with a low or intermediate pre-test probability of infection.

METHOD AND MATERIALS

Patients with possible cardiac device infection who underwent 18-F FDG PET/CT as part of the evaluation for possible cardiac device infection at a tertiary institution from 2006-2016 were retrospectively reviewed to evaluate the utility of PET/CT as an adjunctive diagnostic tool. We collected clinical, microbiologic, echocardiographic, imaging and outcomes data for at least 90 days following imaging. PET/CT and echocardiograms were reviewed again for the purposes of the study by independent investigators.

RESULTS

Thirty patients with possible cardiac device infection who underwent 18-F FDG PET/CT were reviewed. The most common presenting symptoms were fever in 60% and generator pocket site skin changes or tenderness in 40%. Blood cultures were positive in 59%; the most common organisms identified were coagulase negative Staphylococcus (23%), *Staphylococcus aureus* (23%) and Enterococcus (23%). Average maximum standardized uptake values (SUVmax) were 4.81 for positive PET/CT and 1.38 for negative PET/CT scans. Positive PET/CT was correlated with presence of generator pocket signs (p=0.0027) and positive generator pocket cultures (p=0.0145). PET-CT results were not correlated with fever (p=0.06), leukocytosis (p=0.70), elevated ESR or CRP (p=0.10), positive blood cultures (p=0.26) or positive echocardiographic findings (p=0.39). Overall 18-FDG PET/CT demonstrated senstivity of 86.67% (95% confidence interval [CI] 59.54% to 98.34%) and specificity of 93.33% (95% CI 68.05% to 99.83%) for diagnosis of cardiac device infections.

CONCLUSION

18-F FDG PET/CT is a valuable adjunctive diagnostic tool with a high sensitivity of 86.67% and specificity of 93.33% for diagnosis of possible cardiac device infections.

CLINICAL RELEVANCE/APPLICATION

18-F FDG PET/CT is a useful adjunctive diagnostic tool in challenging cases of cardiac device infections.

SST02-03 Reliability and Homogeneity of the CT Attenuation at Different Contrast Medium Concentration on 16cm Wide-Detector Revolution CT: A Phantom Experiment Study

xueyunjing@126.com

PURPOSE

To evaluate CT attenuation homogeneity and reliability of 16cm wide-detector revolution CT at different contrast medium concentration with a phantom experiment study.

METHOD AND MATERIALS

A phantom (QSP-1, FUYO) with nine cylindrical tubes of 18-mm-diameter and16-cm-length placed into water tank was used. One was in central region filled with saline and other eight tubes were in periphery region filled with contrast medium concentration of 2.0, 5.0, 10.0, 15.0, 20.0, 25.0, 30.0mg/mL. The phantom was scanned on revolution CT at 120 kVp using both axial 16cm protocol and helical 4cm protocol with 5mm thickness, respectively. Circular regions of interest of the same area were placed at the center of each tube to measure the CT attenuation value and the standard deviation. CT attenuation homogeneity of each tube was evaluated by variation range (VR: maximum attenuation-minimum attenuation) and degree of dispersion (DD:defined as percentage of variance range divided by mean attenuation), and coefficient of variation (CV: defined as percentage of standard deviation of CT attenuation divided by mean attenuation). Data were analyzed by using paired t test.

RESULTS

The variation range(VR) of CT attenuation ,degree of dispersion(DD) and coefficient of variation(CV)) of each tube filled with different density of iodine contrast medium was (5.65HU ,9.99%, 2.47%), (5.99HU,4.68%, 1.15%), (6.66HU,5.02%, 1.12%),

(12.46HU ,3.30%, 0.79%), (15.04HU,3.06%, 0.77%), (16.86HU, 2.86%, 0.81%), (20.07HU (2.87%, 0.77%) for axial 16-cm mode whereas those values for helical 4-cm mode were (7.17HU, 12.07%, 2.78%), (9.97HU ,7.75%, 2.21%), (13.78HU ,10.43%, 3.20%), (17.07HU ,4.56%, 1.16%), (8.88HU ,1.8%, 0.51%), (7.73 HU, 1.31%, 0.32%), (8.51HU ,1.21%, 0.31%). There were no significant differences between axial 16-cm mode and helical 4-cm mode in VR of CT attenuation, DD and CV (P = 0.642,0.343,0.332, respectively).

CONCLUSION

Axial 16-cm wide-detector scanning protocol on revolution CT at different density of iodine contrast medium can provide the same CT attenuation homogeneity and reliable CT value with helical 4-cm standard-detector scanning protocol.

CLINICAL RELEVANCE/APPLICATION

The wide-detector scanning technique with VHD reconstruction can provide excellent CT attenuation homogeneity which is comparable to standard-detector scanning technique. It will have good potential applications and clinical feasibility for TAG and FFRCT of coronary CT imaging

SST02-04 Analysis of Raw High Speed Myocardial Perfusion SPECT Images by Deep Convolutional Networks Improve Prediction of Potentially Significant Ischemic Defects

PURPOSE

We aimed to assess the abilities of deep convolutional neural networks (CNN) for automatic prediction of obstructive coronary stenosis from raw fast myocardial perfusion SPECT imaging (MPI) data.

METHOD AND MATERIALS

1468 patients (67% males) undergoing stress-first high speed SPECT in 7 national and international sites were studied. All patients were assessed for obstructive stenosis >= 70% by invasive coronary angiography (ICA). Left ventricular myocardium was segmented using standard Cedars-Sinai Quantitative Perfusion SPECT (QPS) and verified by one expert reader. Stress total perfusion deficit (TPD) was also automatically computed by statistical comparison to normal limits. The CNN approach was evaluated in a stratified 10-fold cross-validation procedure using supine stress raw polarmaps exported from QPS (10° angle resolution), and implemented using the Caffe Deep Learning Framework. CNN comprised three consecutive convolutional units, followed by two dense fully connected layers with a rectified linear unit activation, and a final softmax loss function for the optimization of the network. Area under the curve (AUC) comparison by Delong test was used to compare the performance of the CNN score and TPD to predict potentially significant ischemic defects. Net reclassification improvement (NRI) for TPD at 5% threshold and for the CNN score was also computed. Two-graph ROC technique was used to compute the optimal CNN score cutoff for NRI comparison.

RESULTS

From the total 1468 patients, 882 (60%) had obstructive stenosis >= 70%. 864 (60%) out of 1448 (99%) patients with no suspected coronary artery disease had ICA stenosis. The left ventricular contour assigned by standard QPS was adjusted in 323 (22%) stress images. AUC for CNN score was significantly higher than for stress TPD (0.81 vs 0.78, P<0.01 by Delong test). The optimal CNN score cutoff was found to be 0.7. A net reclassification improvement of 6.6% [95% CI: 2.2%-11%] (P<0.01) was significant for the optimal CNN cutoff as compared to stress TPD at 5%.

CONCLUSION

CNN improved the prediction of potentially significant ischemic defects and has the potential to enhance automatic interpretation of MPI studies. CNN combination of multiple polarmaps and patient information may bring further improvement.

CLINICAL RELEVANCE/APPLICATION

Automatic CNN interpretation of SPECT MPI may provide improved automatic scan interpretation without the needing of normal databases as for TPD.

SST02-05 Evaluation of Coronary Artery Calcium using Dual Energy Chest X-rays: Digital Phantom Study

bxz141@case.edu

PURPOSE

Despite proponents of CT coronary artery calcification (CAC) score, which provides proof of disease and predicts future events, it is not recommended for screening because of cost and radiation. Previously, we have demonstrated ability to identify CAC using 2-shot, dual energy (DE) chest x-rays, giving an opportunity to screen CAC from an already ordered exam. Here we will use digital simulations, backed up by measurements, to characterize DE calcium signals and the role of potential confounds such as beam hardening, xray scatter, cardiac motion, and pulmonary artery pulsation. For the DE calcium signal, we will consider quantification, as compared to CT calcium score, and visualization.

METHOD AND MATERIALS

We created stylized and anatomical digital 3D phantoms which included CAC. We simulated high and low kV x-ray acquisitions with xray spectra, energy dependent attenuation, scatter, ideal detector, and automatic exposure control (AEC). Phantoms allowed us to vary CAC size and density, adipose thickness, cardiac motion, etc. We used specialized dual energy coronary calcium (DECC) processing that includes corrections for scatter, beam hardening, and motion correction.

RESULTS

With DECC processing, beam hardening over a wide range of adipose thickness (0-30 cm) reduced CAC signal (ΔICAC) by <3%. Scatter correction errors of ±50% affected ΔICAC by ±9%. If a simulated pulmonary artery fills with blood between exposures, it can give rise to a residual signal in DECC images, explaining pulmonary artery visibility in some clinical bone images. Residual misregistration can be mostly compensated by integrating signals in an enlarged region encompassing registration artifacts. DECC calcium score compared favorably to CT mass score over a number of phantom perturbations.

CONCLUSION

Simulations indicate that proper DECC processing can faithfully recover coronary calcium signals. Beam hardening, errors in scatter estimation, cardiac motion, calcium residual misregistration, are all manageable. Simulations are valuable as we continue to optimize DE coronary calcium image processing and quantitative analysis.

CLINICAL RELEVANCE/APPLICATION

CAC detection from already ordered chest xrays would give benefits of CT CAC without its costs (patient charge and radiation), and lead to patients' adoption/adherence to lifestyle/drug therapies.

SST02-06 Diagnostic Performance of Computed Tomography Area Measurements of the Suprahepatic Segment of the Inferior Vena Cava to Predict Central Venous Pressure and Mortality in Patients Undergoing Transcatheter Aortic Valve Implantation

Friday, Dec. 1 11:20AM - 11:30AM Room: E450A

PURPOSE

To evaluate correlation of computed tomography (CT) area measurements of the suprahepatic segment of the inferior vena cava (IVC) with central venous pressure (CVP) and its performance to predict CVP and mortality in patients with severe symptomatic aortic stenosis.

METHOD AND MATERIALS

We retrospectively analyzed 153 consecutive patients (median age 84, 78 females) undergoing transcatheter aortic valve implantation (TAVI) at the University Hospital Zurich between January 2010 and December 2014. Only patients undergoing right heart catheterization (RHC) and CT within 1 consecutive day as part of preinterventional TAVI assessment were included. Patient baseline characteristics and outcome data after one year were recorded. Area measurements of the suprahepatic IVC were performed on axial CT slices. Correlations were assessed with Pearson's correlation coefficient. The optimal cutoff point for IVC area measurements to predict an elevated CVP (>=10mmHg) or mortality was determined using receiver operating characteristics (ROC) analysis.

RESULTS

RHC showed elevated CVP in 34 patients (25%) at baseline. IVC area measurements indicated a moderate correlation with CVP ($r=0.47$; $p<0.001$). For area measurements ROC analysis showed an AUC of 0.77 ($p<0.001$) to predict elevated CVP and an AUC of 0.77 ($p<0.001$) to predict one year mortality. A cutoff of 639mm2 for IVC area had a specificity of 80% and a sensitivity of 64% to predict a CVP >= 10mmHg. Whereas a little higher cutoff of 665mm2 for IVC area showed a specificity of 80% and a sensitivity of 60% to predict one year mortality. Indexing area measurements to body surface area did not lead to better diagnostic performance. Multivariate logistic regression analysis controlling for age, sex, body surface area and logistic EuroSCORE II indicated that an IVC area >= 665mm2 is a significant predictor of one year mortality with an odds ratio of 6.8 (95%CI: 2.2-21.1).

CONCLUSION

Our study suggests that area measurements of the suprahepatic segment of the IVC has the potential to non-invasively predict elevated CVP with moderate sensitivity but good specificity. Furthermore, an enlarged IVC seems to be a predictor of one year mortality in TAVI patients.

CLINICAL RELEVANCE/APPLICATION

Assessing the inferior vena cava to predict central venous pressure is an established method in ultrasound but has not been assessed in CT as a robust and reproducible examination modality, so far.

SST02-07 Lower Annual Cardiac Events in Diabetics with a Normal Exercise GMPI and aFunctional Capacity >=7 METS on Treadmill

Friday, Dec. 1 11:30AM - 11:40AM Room: E450A

maseeh.uzzaman@aku.edu

PURPOSE

Good exercise capacity has a high negative predictive value (NPV) in patients with known or suspected coronary artery disease (CAD) similar to a normal gated myocardial perfusion imaging (GMPI). However, previous studies have suggested that diabetic patients undergoing single photon emission computed tomography (SPECT) myocardial perfusion imaging (MPI) are at greater risk for cardiac events than non-diabetic patients with both normal and abnormal MPIs. Aim of this study was to evaluate NPV of functional capacity during treadmill exercise in diabetics with normal GMPI in Pakistani population.

METHOD AND MATERIALS

This was a prospective study which included 338 diabetics with normal exercise GMPI. On the basis of metabolic equivalents (METS) achieved during exercise, these patient were divided into Group A: >=7 METS (140 patients) and Group B: <7METS (198 patients). These patients were followed up on telephone (for 18 ±3 months) for fatal or non-fatal myocardial infarction (FMI and NFMI respectively). Regarding risk factors in Group A and B, like obesity (50 vs. 54%), hypertension (61 vs. 60%), smoking (14 vs. 15%), dyslipidemia (32 vs. 42%) and family history (32 vs. 30%), no significant difference was found.

RESULTS

The mean age predicted HR (MAPHR) achieved in group was significantly higher than Group B (86% vs. 83%). No significant difference was found between LV functional parameters (like ejection fraction, end diastolic and systolic volumes) of two groups. During follow up period, the overall all cardiac events reported in Group A was 03 (all NFMI and no FMI) while in Group B 16 events (15 NFMI and 01 FMI) were reported. Annualized event rate for overall events, NFMI and FMI in two groups were 1.43 vs. 5.39%, 1.43 vs. 5.05 and 0% vs. 0.3% respectively.

CONCLUSION

We conclude that NPV of a normal GMPI is higher in diabetic patients with a functional capacity >=7 METS than their counterparts who could achieve <7 METS on treadmill.

CLINICAL RELEVANCE/APPLICATION

Gated MPI has comparable diagnostic accuracy for CAD in diabetics but its prognostic strength is very high. Effort tolerance >7 METS with a negative MPI enhances the NPV in diabetics who are found to have high event rate despite of a normal MPI with vasoldilator or worklaod <7 METS

SST02-08 Increased Epicardial Fat Volume is Related to Diabetes Mellitus, Early Subclinical Atherosclerosis and Serum Levels of Inflammatory Biomarkers in Asymptomatic Patients

PURPOSE

We aimed to investigate whether increased epicardial fat volume (EFV) is related to inflammatory serum biomarkers, diabetes mellitus (DM) and early atherosclerosic disease in asymptomatic patients.

METHOD AND MATERIALS

We evaluated 456 asymptomatic patients from the EISNER (Early Identification of Subclinical Atherosclerosis using Non-invasivE Imaging Research) registry. EFV was quantified using semi-automated QFAT version 2.0 software from non-contrast CT data sets. EFV was assessed in patients with a coronary calcium score (CCS) of 0, early atherosclerosis (CCS 1-99) and advanced atherosclerosis (CCS >=100). EFV was examined in relation to CCS, serum levels of inflammatory biomarkers and presence of DM.

RESULTS

Mean EFV was lowest in 144 patients with a CCS of 0 [74 cm^3, interquartile range (IQR): 53-91] and was significantly higher in 144 patients with early atherosclerosis [87 cm^3, IQR: 56-111, p=0.016] and in 168 subjects with advanced atherosclerosis [89 cm^3, IQR: 61-112, p=0.002]. In multivariable analysis, log-transformed EFV was strongly associated with DM [Odds Ratio (OR) 4.6 (95% CI: 2.1-9.8), p<0.001], over hypertension (p=0.023), family history of coronary artery disease (CAD) (p=0.026), CCS (p=0.042) or other risk factors (p>0.05). EFV was correlated with serum biomarkers endothelial plasminogen activator inhibitor 1 (PAI-1) (r=0.29, p<0.001), monocyte chemoattractant protein 1 (MCP-1) (r=0.20, p<0.001), vascular cell adhesion molecule 1 (VCAM-1) (r=0.12, p=0.026) and inversely correlated with adiponectin (r=-0.18, p<0.001), while CCS was not correlated with serum levels of biomarkers (p>0.05). In multivariate regression analysis adjusted for age, cardiovascular risk factors and CCS EFV remained independently associated with PAI-1, MCP-1 and VCAM-1 (all p<0.05).

CONCLUSION

EFV is significantly increased in patients with coronary calcium compared to those with a CCS of 0; with no significant differences in patients with early atherosclerosis or advanced atherosclerosis. Increased EFV is associated with DM and serum levels of inflammatory biomarkers, suggesting that it may be linked to early plaque formation, metabolic abnormality and plaque inflammation.

CLINICAL RELEVANCE/APPLICATION

As a metabolically active fat depot increased epicardial fat volume predicts adverse cardiac events, however, its relationship to early coronary atherosclerosis, inflammatory biomarkers and diabetes mellitus remains unknown.

PURPOSE

Specific ventilation (SV) is defined as a dimensionless quantity of inhaled gas ventilation that occurs during tidal breathing and is calculated as tidal volume divided by functional residual capacity (Lewis *et al*, 1978). 1H MRI was previously proposed to regionally quantify SV, using inhaled O2 as a contrast agent (Sa *et al*, 2010). Our objective was to develop a novel and rapid way to measure whole lung and regional SV using free-breathing 1H MRI without exogenous contrast agents and over a short tidal breathing scan using conventional equipment. We also aimed to directly compare 1H MRI SV with hyperpolarized inhaled noble gas MRI ventilation and ventilation percent (VP).

METHOD AND MATERIALS

We evaluated 10 asthmatics (50±12yrs) and two healthy volunteers (27±6yrs) who provided written informed consent to MRI, spirometry and whole body plethysmography. Pulmonary hyperpolarized noble gas MRI (Kirby *et al*, 2012) and dynamic 2D multi-slice, whole lung coverage, free tidal-breathing 1H MRI using a bSSFP sequence (Capaldi *et al*, 2015) were acquired on a 3T system (GEHC). Free-breathing 1H MRI was retrospectively gated to generate tidal inspiration/expiration lung volumes that were co-registered using optical flow deformable registration (Lucas *et al*, 1981). 4DMRI SV maps were generated on a voxel-by-voxel basis using the co-registered volumes to generate local SV distribution maps. MRI ventilation percent (VP=ventilation volume normalized to thoracic cavity volume) and whole lung mean 4DMRI specific ventilation were determined and compared using Pearson correlation coefficients (r).

RESULTS

In Figure 1, 4DMRI SV and 3He MRI for an asthmatic (27yr female FEV1=74%pred, SV=0.08, VP=97.4%) shows qualitative agreement in the right-upper-lobe. For all subjects, there was a significant relationship for MRI specific ventilation and inhaled noble gas MRI ventilation percent (r=.67, p=.02), FEV1/FVC (r=.74, p=.007) and plethysmography SV (r=.77, p=.003).

CONCLUSION

In asthmatics, 4DMRI ventilation defects were spatially related with hyperpolarized inhaled noble gas MRI ventilation defects; 4DMRI SV also strongly correlated with experimentally measured SV and inhaled gas MRI ventilation percent.

CLINICAL RELEVANCE/APPLICATION

Free-breathing 4DMRI was exploited to generate specific ventilation maps that strongly correlated with experimentally acquired specific ventilation and inhaled noble gas MRI ventilation percent.

SST03-02 Preoperative Assessment of Localized Pleural Adhesion: Utility of Software-Assisted Analysis on 4-Dimensional Ultra-Low-Dose CT (4D-ULDCT)

PURPOSE

To assess the usefulness of software analysis using 4-dimensional ultra-low-dose CT (4D-ULDCT) for localized pleural adhesion (LPA).

METHOD AND MATERIALS

Twenty-four consecutive patients scheduled to undergo surgery underwent both 4D-ULDCT during a single respiration and conventional high-resolution chest CT as preoperative assessments. Four radiologists, who were blinded to patient status, independently evaluated the presence and severity of LPA in 3 grading-scale (non-LPA, mild LPA and severe LPA) for 6 measurement points (MPs) (upper and lower area on ventral, lateral and dorsal aspects) on the chest CT by 2 different methods: (i) observing conventional high-resolution CT images (static), reconstructed in the axial, coronal, and sagittal directions; (ii) observing 4D-ULDCT images (movie), while another radiologist similarly evaluated the presence and severity of LPA by the other method: (iii) observing adhesion map (A-map), which is colored gradient map created by research software using 4D-ULDCT that suggested the absence/presence of LPA based on the difference in the movements between the lung surface and chest wall. The presence and severity of LPA was confirmed in an identical fusion by their intraoperative thoracoscopic findings. Diagnostic accuracy in 3 grade scaling and the LPA presence were conducted between (i) and (iii), between (ii) and (iii) using t-test for a single sample, and between (ii) and (iii) using Wilcoxon signed-rank test.

RESULTS

The presence of LPA was surgically confirmed on 23MPs in 8 patients: 20MPs with mild LPA, 3MPs with severe LPA. For the LPA assessment, A-map method (iii) achieved significant better diagnostic performance with higher accuracy in 3-grade scaling of 78.5%, and higher sensitivity of 73.9%, PPV of 44.7% and NPV of 94.3%, comparable specificity of 82.6% for the LPA presence, in comparison with the other methods ((i), (ii)) ($p<0.05$). No significant difference in diagnostic performance were showed between conventional CT (i) and 4D-ULDCT (ii) ($p >0.05$)

CONCLUSION

Four-D ULDCT in combination with A-map method could be useful as a novel imaging approach for accurate preoperative analysis of LPA.

CLINICAL RELEVANCE/APPLICATION

This is the first study to demonstrate the clinical usefulness of software-aided, 4D-ULDCT images for the preoperative diagnosis of the presence and severity of LPA.

SST03-03 Quantification of Lung Perfusion and Ventilation in Patients with Chronic Thromboembolic Pulmonary Hypertension (CTEPH) Before and After Pulmonary Endarterectomy Using Phase Resolved Fourier Decomposition MRI

Friday, Dec. 1 10:50AM - 11:00AM Room: E451B

PURPOSE

To evaluate Fourier decomposition (FD) imaging of the lung as a radiation free, non-contrast-enhanced method for detection of perfusion and ventilation changes in CTEPH patients before and after pulmonary endarterectomy (PEA).

METHOD AND MATERIALS

We investigated 27 patients with diagnosed CTEPH before and 2 weeks after PEA. All patients underwent DCE time-resolved angiography with stochastic trajectories (TWIST) in one breathhold and a 2D fast low-angle shot (FLASH) sequence in free breathing in supine position, on a 1.5 T MRI. Coronal acquisition of FD imaging of the lung was performed. After nonrigid image registration (ANTS), and manual segmentation, perfusion and ventilation maps were generated using a image-sorting algorithm.

Histograms were calculated to visualize the distribution of ventilation and perfusion. Ventilated, but not perfused lung voxels were defined as perfusion defect, perfused, but not ventilated lung voxels were classified as ventilation defect.

RESULTS

Using DCE MRI as reference, the median PBF increased from 30,1ml/min/100ml (25-75% quartile range: 26-50) to 54,5ml/min/100ml (25-75 quartile range: 49-71, p<0,0001). Using FD MRI, the median perfusion defect percentage of the whole lung decreased from 46% (25-75% quartile range: 39-50%) to 33% (25%-75% quartile range: 27 -39%) after PEA (p<0.0001). The ventilation defect percentage of the whole lung was minimal and did not change (pre and post procedural median: 1% (25-75% quartile range: 0-3%). There was a significant difference of the perfusion defect percentage in the right lower lobe (median: pre 42%, median post: 17%, p<0,0001), the right upper lobe (median: pre 53%, median post: 28%, p=0.0005) and in the middle lobe (median: pre 46%, median post: 25%, p=0.0002). No significant difference of perfusion defect percentage was observed in the left lower (median: pre 48%, median post: 52%, p=0.48) and upper (median: pre 35%, median post: 41%, p=0.13) lobes.

CONCLUSION

Phase resolved Fourier Decomposition MRI is a feasible method to monitor regional ventilation and perfusion in CTEPH patients pre and post PEA. Especially left lower lobe results may be influenced by cardiac motion, which could interfere with the phase measurements of the parenchymal blood flow.

CLINICAL RELEVANCE/APPLICATION

These promising results may enable a proton-based, radiation and contrast free monitoring option of therapeutic effects after PEA in CTEPH patients in the future.

SST03-04 Blood Volume-Based MR Imaging with Ultra-Short TE vs Quantitatively and Qualitatively Assessed CT vs Perfusion SPECT: Capability for Prediction of Postoperative Lung Function in Non-Small Cell Lung Cancer Patients

Friday, Dec. 1 11:00AM - 11:10AM Room: E451B

PURPOSE

To directly compare the capability of contrast-enhanced (CE-) pulmonary thin-section MR imaging with ultra-short TE (UTE) as semi-quantitatively assessed blood-volume based MR imaging (BV-MRI with UTE) for prediction of postoperative lung function in non-small cell lung cancer (NSCLC) patients as compared with quantitatively and qualitatively assessed CT and perfusion SPECT.

METHOD AND MATERIALS

29 NSCLC patients (16 men and 13 women) underwent unenhanced and contrast-enhanced pulmonary thin-section MR imaging with UTE at a 3T system, thin-section CT, perfusion SPECT, and measurements of FEV1% before and after lung resection. In each patient, BV MRI was generated as percent signal change between unenhanced and CE-pulmonary thin-section MR imaging by pixel-by-pixel analyses after non-rigid registration. On BV-MRI with UTE, postoperative FEV1% (poFEV1%) was predicted from semi-quantitatively assessed blood volumes within total and resected lungs. Quantitatively predicted poFEV1% using CT was determined from the functional lung volumes within total and resected lungs by commercially available software. Qualitatively predicted poFEV1% using CT was determined from the number of segments of total and resected lungs. On perfusion SPECT, poFEV1% was predicted from uptakes within total and resected lungs. Then, each predicted poFEV1% was correlated with actual poFEV1%, and the limits of agreement between actual and each predicted poFEV1% were also evaluated by Bland-Altman analysis.

RESULTS

poFEV1%s predicted by BV-MRI with UTE (r=0.82, p<0.0001) and quantitative CT (r=0.86, p<0.0001) had better correlation with actual poFEV1%, when compared with qualitatively assessed CT (r=0.79, p<0.0001) and SPECT (r=0.78, p<0.0001). The limits of agreement between predicted and actual poFEV1% by BV-MRI with UTE (4.3±12.7 %) and quantitatively assessed CT (3.5±10.8 %) were smaller than those by qualitatively assessed CT (5.1±13.9 %) and SPECT (4.2±14.5 %).

CONCLUSION

BV-MRI with UTE can more accurately predict postoperative lung function than qualitatively assessed CT and perfusion SPECT, and is at least as valuable as quantitatively assessed CT in NSCLC patients.

CLINICAL RELEVANCE/APPLICATION

Blood volume-based MRI with UTE can more accurately predict postoperative lung function than qualitatively assessed CT and perfusion SPECT, and is at least as valuable as quantitatively assessed CT in NSCLC patients.

SST03-05 Correlation between Diaphragmatic Excursion and Decrease in Lung Volume on Expiratory Phase Imaging in Asthma Patients

Lea.azour@nyumc.org

PURPOSE

Inspiratory and expiratory phase imaging is often requested in asthma patients to evaluate air trapping, however, there is no radiographic measure of optimal expiration. Diaphragmatic excursion may be a reliable surrogate for lung volume assessment to gauge adequacy of expiration, particularly as the trachea may not change in configuration despite decrease in tracheal and/or lung volume.

METHOD AND MATERIALS

Between January 1, 2016 and December 31, 2016, a total of 226 CT exams with inspiratory and expiratory phase imaging were performed, 63 in individuals with asthma. Patients with supine imaging acquired with the same parameters in each phase were included (n= 33, mean age = 62, M=15, F=15). Diaphragmatic excursion was calculated as the difference between axial slices through the lungs on inspiration and expiration, using the lung apex and the cranial bound and diaphragm caudally. Lung and tracheal volumes were measured for each patient at inspiration and expiration.

RESULTS

Average inspiratory (I) and expiratory (E) lung volume was greater for men (I=5007 mL, E=3122 mL) than women (I=3122mL, E=1503mL). Similarly, average tracheal volumes were higher in men (I=61mL, E=45) than women (I=44, E=30). Average change in lung volume was 1500mL (range -564mL to 4109mL). Diaphragmatic excursion was found to range from -0.6cm to 6.8cm, with an average change in diaphragmatic excursion of 2.5 cm between inspiratory and expiratory scans (2.3 cm in women, and 2.7 cm in men). There was a very strong positive correlation between diaphragmatic excursion and change in lung volume between inspiratory and expiratory scans (r=0.83), and strong positive correlation with change in tracheal volume (r=0.79). A strong correlation was also found between change in tracheal volume and change in lung volume (r=0.67).

CONCLUSION

Diaphragmatic excursion is a strong quantitative measure of actual expiratory effort as validated by both lung and tracheal volumes, and may be more reliable than qualitative features such as tracheal morphology.

CLINICAL RELEVANCE/APPLICATION

Diaphragmatic excursion is a reliable quantitative surrogate for lung volume, and is an easily applicable clinical tool to assess the adequacy of expiratory phase image acquisition.

SST03-06 Pulmonary Function Diagnosis Based On Temporal Changes in Lung Density with Dynamic Flat-Panel Detector (FPD) Imaging: An Animal-Based Study

PURPOSE

X-ray translucency of the lungs changes with respiration. This is caused by relative increases and decreases in the volume of the lung vessels and bronchi per unit lung volume; pulmonary function can be evaluated based on temporal changes in the image density of the lung regions. The aim of the present study was to investigate the diagnostic performance of dynamic chest radiography for pulmonary function diagnosis based on respiratory changes in lung density.

METHOD AND MATERIALS

Sequential chest radiographs of six domestic pigs (body weight ca. 20-30 kg) were obtained during respiration using a dynamic flat-panel detector system (100 kV; 0.25 mAs/pulse; 15 frames/s; Test model, Konica Minolta). The pigs were intubated under

anesthesia, and respiratory control was ensured with a ventilator (100, 200, 300, 400, and 500 mL). We created porcine models of atelectasis using a catheter procedure, and analyzed the correlation between the inspired volume and changes in the pixel value measured in the lungs. To facilitate visual evaluation, differences in pixel values between an image taken at maximum expiration and those during respiration were sequentially calculated and then superimposed on the original images as a color display, employing a color table in which higher X-ray translucency (increased air) is shown in cold colors, creating functionally colored images.

RESULTS

Average pixel values in the lung regions changed according to forced respiration. High linearity was seen between changes in pixel value and inspired volume ($r = 0.9$). Changes in pixel value related to the inspired volume were successfully visualized as changes in color intensity on the functional colored images. In addition, areas of atelectasis were revealed as decreased changes in pixel values. Trapped air and airflow restriction were detected as higher and lower color intensity on functionally colored images, respectively (Fig. 1).

CONCLUSION

Dynamic chest radiography allowed for the evaluation of pulmonary function based on temporal changes in lung tissue image density. Inspired volume is quantified as changes in pixel value, and ventilation defects are detected as reduced changes in pixel value even without the use of contrast media.

CLINICAL RELEVANCE/APPLICATION

The method presented here is a simple and cost-effective functional imaging technique that can be performed as an adjunctive examination for conventional chest radiography.

SST03-07 CT Measurement of Atrioesophageal Adipose Tissue and Correlation with Metabolic Syndrome: Preliminary Results

Friday, Dec. 1 11:30AM - 11:40AM Room: E451B

Participants
Dennis P. Gilroy, DO, Rochester, NY (*Presenter*) Nothing to Disclose
Hakan Sahin, MD, Rochester, NY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Epicardial adipose tissue measurements on cardiac imaging planes have demonstrated association with atrial fibrillation and coronary artery disease. We wanted to investigate the utility of adipose measurements between the left atrium and esophagus on conventional axial and sagittal planes of routine chest CTs performed with ECG-gating in predicting the presence/complications of metabolic syndrome.

METHOD AND MATERIALS

The study protocol has been approved by the IRB. In this preliminary analysis, 50 patients with cardiac-gated CT performed for cardiac morphology or suspected aortic dissection were included, prospectively recorded, and retrospectively analyzed. The size of the atrioesophageal adipose tissue was measured on axial and sagittal images. Clinical conditions associated with metabolic syndrome were also recorded (hypertension, diabetes mellitus, BMI, dyslipidemia and atrial fibrillation). The association between the size of the adipose tissue and the clinical conditions was investigated.

RESULTS

Preliminary analysis reveals statistically significantly larger atrioesophageal fat in patients with dyslipidemia, compared with those who did not (p value 0.006). Additionally, this relationship extends to those with elevated systolic blood pressure (p value 0.05). The optimal threshold within the atrioesophageal fat measurement was determined to be greater than 4.1 mm in the sagittal plane (72.7% sensitivity and 62.5% specificity for the presence of dyslipidemia). Additional correlation exists between the axial measurement of atrioesophageal fat and BMI, albeit not statistically significant with the current data.

CONCLUSION

CT based epicardial fat quantification, using conventional imaging planes, is a simple tool that can be applied in everyday practice to identify patients with components of metabolic syndrome and possibly predict complications. While these results are preliminary, it is felt that the correlation between atrioesophageal fat measurement and additional various clinical parameters of metabolic syndrome will exist at statistically significant levels with a larger population.

CLINICAL RELEVANCE/APPLICATION

CT-based identification of patients with metabolic syndrome during routine CT evaluation using conventional imaging planes can serve as a value-added service leading to prediction of complications such as atrial fibrillation and alter therapeutic management due to known subsequent recurrence.

SST03-08 Effect of New Model-Based Iterative Reconstruction on Computer-Aided Detection for Quantitative Analysis of Airway Tree in Low-Dose Chest CT: Comparison with Adaptive Statistical Iterative Reconstruction in Routine Dose

Friday, Dec. 1 11:40AM - 11:50AM Room: E451B

Participants

PURPOSE

To evaluate the new model-based iterative reconstruction (MBIRn) with balanced setting (MBIRSTND) and spatial resolution preference (MBIRRP20) and adaptive statistical iterative reconstruction (ASIR) in low-dose and ASIR in routine dose on the performance of computer-aided detection (CAD) for quantitative airway analysis.

METHOD AND MATERIALS

30 patients had follow up scan for pulmonary disease on a GE Discovery CT750 HD system. Image acquisition was performed at routine dose and reduced dose level by increasing noise index (NI) from 14HU to 28HU using automatic tube current modulation. Tube voltage was fixed at 120kVp. Data of routine dose were reconstructed with ASIR, while low-dose were reconstructed with ASIR, MBIRSTND and MBIRRP20. Airway dimensions measured from the four reconstructions using an automated, quantitative software that was designed to segment and quantify the bronchial tree, and a skeletonization algorithm to extract the center-line of airway trees automatically (Figure 1). For each patients and reconstruction algorithm chose the right middle lobe bronchus with the least tortuous and bifurcation to measure the bronchial length of the matched airways. Two radiologists used a semi-quantitative 5-point scale (-2: inferior; 0, equal to ASIR in routine dose; 2: superior) to rate subjective image quality of airway trees on the low-dose images reconstructed with ASIR and MBIRn. Using paired t and Wilcoxon signed-rank tests for comparison.

RESULTS

Median effective dose was 3.01±1.89mSv at routine dose and 0.88±0.83mSv at 71% dose reduction. Algorithm impacts the measurement variability of the length of bronchus in low-dose chest CT, and MBIRSTND and MBIRRP20 were better than ASIR for the airway trees, while MBIRSTND displayed longer bronchus than ASIR in routine dose ($P<0.05$) (Table 1,Figure 2). MBIRSTND for the low dose chest CT also had higher subjective scores for the airway trees than ASIR in routine dose (Table 2,Figure 2).

CONCLUSION

The quantification accuracy of airway is strongly influenced by reconstructions. MBIRSTND and MBIRRP20 algorithms allow the desired airway quantification accuracy of CAD for chest to be achieved for 71% radiation dose reduction.

CLINICAL RELEVANCE/APPLICATION

Compare ASIR,MBIRSTND and MBIRRP20 from MBIRn algorithm potentially allows the desired airway quantification accuracy to be achieved on the performance of CAD with low-dose chest CT, especially for MBIRSTND.

SST03-09 Modified CT Fluoroscopy-Guided Lung Nodule Biopsy versus Conventional CT-Guided Biopsy: A Prospective Controlled Study to Assess Radiation Doses and Complication Rate

Friday, Dec. 1 11:50AM - 12:00PM Room: E451B

Participants
Ting Liang, Xian, China (*Presenter*) Nothing to Disclose
Gang Niu, MD, Xian, China (*Abstract Co-Author*) Nothing to Disclose
Jin Shang, Xian, China (*Abstract Co-Author*) Nothing to Disclose
Jian Yang, MD, PhD, Xian, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

liangting31500@126.com

PURPOSE

The aim of the study was to evaluate complication rate and radiation doses of lung nodule biopsy by the CT modified fluoroscopy-guided and conventional CT-guided methods.

METHOD AND MATERIALS

A total of 100 patients in single radiology unit were prospectively enrolled to receive CT-guided lung biopsy. 50 patients were undergoing modified CT fluoroscopy-guided (CTF) biopsy (Group 1), and other half was checked by traditional CT-guided methods (Group 2). The modified biopsy plan referred to the method of using axial scan with step by step for the nodule. 2 experienced chest radiologists performing thoracic biopsies performed CT-guided biopsy. 64 slice spiral CT (Toshiba) were performed with CT-guided pulmonary biopsy with the Japan 16G cutting biopsy needle. Radiation dose and diagnostic accuracy of patient were outcome measurements. Differences between proportions were analyzed with the chi-square test. Dose-length product (DLP) was compared between 2 groups. Sensitivity, specificity and accuracy were calculated based on 80 patient's results.

RESULTS

There were no significant between the two groups for the pulmonary nodules characteristics : size, group 1: 34±18mm (mean±standard deviation) vs. group 2: 38±20 mm ($p=0.845$); depth from pleura, 13±12 mm vs. 12±9 mm ($p=0.595$) (Table 1). The total DLP of the study group (median 3.8 mSv) was significantly reduced compared to that of the comparison group (median 11.1 mSv, p?0.05).

CONCLUSION

CT modified fluoroscopy-guided lung nodule biopsy provides high diagnostic accuracy and more lower radiation doses compared to conventional methods, and may be alternatively used for appropriate lung nodule.

CLINICAL RELEVANCE/APPLICATION

The CT modified fluoroscopy-guided pulmonary biopsy which can significant reduce the radiation dose and complication rate should be selected in clinical practice.

Devaki-Surasi@ouhsc.edu

PURPOSE

The purpose of the study is to retrospectively compare the longitudinal measurement of the liver on ultrasound (US) with liver volume as measured on CT.

METHOD AND MATERIALS

This IRB approved retrospective study with prospective image analysis included adult patients with US examinations of the liver or abdomen and CT examinations of the abdomen or abdomen/pelvis performed within 2 weeks of each other from 1/1/2010 to 4/30/2016. We recorded the longitudinal length measurement of the right lobe of the liver on the US study. The liver volume was calculated using manual 3D segmentation (AW suite). Hepatomegaly was defined as a liver volume of 2000 cc or greater. SPSS software was used for statistical analysis which included Receiver operating characteristic curve (ROC) analysis.

RESULTS

The sample had 130 patients including 64 males and 66 females. Liver length measured on US had a moderate positive correlation with liver volume measured on CT, with a Pearson correlation coefficient of 0.71. ROC curve was generated with area under the curve (AUC) of 0.78 (95% CI of 0.70-0.86/Standard error of 0.04). Based on this, an US cutoff of 16.4 cm was found to be an optimal threshold to identify hepatomegaly. Using this cutoff, the sensitivity for hepatomegaly was 83.3% (95% CI of 71.3 - 91%) and the specificity was 63.2% (51.9% - 73.1%). Using a maximum ultrasound liver length of 17 cm, the sensitivity for hepatomegaly was 81.5% (95% CI of 69.7% - 90.3%) and the specificity was 76.3% (65.6% - 84.5%). Using a maximum ultrasound liver length of 18 cm, the sensitivity was 63.0% (49.6%-74.6%) and the specificity was 84.2% (74.4% - 90.7%).

CONCLUSION

Liver length measured with US has only a moderate correlation with liver volume. Commonly used US liver length maximum values of 17 cm and 18 cm produce a significant number of false negatives and false positives. US length of 16.4 cm was found to be an optimal threshold to identify hepatomegaly. Improved methods for measuring liver size with US are needed.

CLINICAL RELEVANCE/APPLICATION

There is only a moderate correlation between liver length measured with US and liver volume measured on volumetric CT, potentially resulting in incorrect liver size estimates with US.

SST04-03 Acute Cholecystitis: Implications of Ultrasound Findings on Surgical and Clinical Outcomes

Friday, Dec. 1 10:50AM - 11:00AM Room: E353B

For information about this presentation, contact:

daniel.vanroekel2@bmc.org

PURPOSE

To identify sonographic signs of acute cholecystitis that predict surgical and clinical outcomes.

METHOD AND MATERIALS

The Institutional Review Board approved this HIPAA-compliant retrospective study. Informed consent was waived. 380 patients who underwent cholecystectomy between 06/22/2014 and 03/01/2016 and received abdominal ultrasound (US) prior to surgery were included. Individual US signs, including the presence of stones, gallbladder distention (> 4 cm transverse or > 10 cm long), wall thickening (> 3 mm), pericholecystic fluid, and abscess were graded in a blinded fashion. Outcomes included operating room (OR) duration, drain placement, surgical pathology, bile leak and surgical site infection. The US signs and outcomes were analyzed using an ANOVA or Chi square test.

RESULTS

Of 380 patients, 366 had documented OR times, of which 155 showed gallbladder distention on US. Patients with distention had increased OR times (22.7 minutes longer, p< 0.0001), increased rate of partial cholecystectomy (odds ratio 5.9, 95% CI: 1.22 to 28.01; p= 0.0192), surgical drain placement (odds ratio 2.7; 95% CI: 1.278-5.629, p=0.0071) and pathology diagnosis of acute and chronic cholecystitis (odds ratio 4.3; 95 % CI: 2.60 to 7.12, p <0.001) when compared with the non-distended group. Of 380 patients, 144 showed wall thickening. Patients with wall thickening had increased OR times (18.7 minutes longer, p=0.0008), increased rate of partial cholecystectomy (odds ratio 4.0; 95 % CI: 1.01 to 15.60, p=0.0455), drain placement (odds ratio 3.2; 95% CI 1.52-6.70, p =0.0014), and pathology diagnosis of acute and chronic cholecystitis (odds ratio 2.7, 95 % CI: 1.66 to 4.35, p <0.0001) than the group with normal wall thickness. US findings including gallstones, pericholecystic fluid and abscess were not positively associated with any of the studied clinical outcomes. Likewise, bile leak, site infection and pathology diagnosis of acute or chronic cholecystitis did not show a positive association with any of the US parameters.

CONCLUSION

Gallbladder distention and wall thickening on US are predictive of extended operating room times, partial cholecystectomy and surgical drain placement in patients presenting with acute cholecystitis.

CLINICAL RELEVANCE/APPLICATION

Gallbladder distention and wall thickening are important sonographic findings that can help the surgeon to predict difficult cholecystectomy cases.

SST04-04 Improved Detection of Small Liver Metastases Located Adjacent to Vessels Using Single Shot 2-Dimensional (2D) Magnetization-Prepared Gradient-Echo (MPGRE) Images Acquired at Hepatocytic Phase (HP) of Liver-Specific Contrast Agent (LSCA)

Friday, Dec. 1 11:00AM - 11:10AM Room: E353B

Awards

ajp8x@virginia.edu

PURPOSE

MRI with LSCA (Gadoxetic-Disodium, Gd-EOB-DTPA) performed 20-40 mins after intravenous administration has become the standard for assessing liver metastases. Image acquisition is typically done with a 3D fat saturated gradient echo (FSGRE) technique. At HP metastases display low signal intensity (SI) and are well seen against the high SI liver background. Since vessels also display low SI, detection of small lesions may be difficult, particularly when adjacent to vessels. MPGRE, also known as TurboFLASH (Siemens), IR FSPGR (GE), or TFE (Philips), with use of a slice selective MP pulse, provides high SI of the vessels from inflowing unsaturated blood. The goal was to investigate the use of HP-MPGRE for improved lesion detection, especially those adjacent to vessels.

METHOD AND MATERIALS

Thirty-eight consecutive patients with known liver metastases had HP FSGRE (3mm slice thickness) and MPGRE (4mm) at 20 min after LSCA dosing; 23 were imaged at 1.5T and 15 at 3T. Regions of interest were drawn in each case to measure the signal of the largest lesion, the normal liver tissue while avoiding the major vessels, the inferior vena cava representative of vessels, and the

background noise. Contrast-to-noise ratios (CNR) were calculated using the formula (S1-S2)/SD, where S1 was the SI of tissue 1, S2 the SI for tissue 2, and SD the standard deviation of background noise.

RESULTS

Mean (SD) lesion/vessel CNR for the 23 cases imaged at 1.5T and the 15 at 3T were -61.2 (24.4) and -169.3 (75.9) for MPGRE, and 5.3 (53.4) and -9.6 (11.3) for FSGRE, respectively, which, in absolute value, was greater for the former technique than the latter ($p<0.05$ for both). Mean (SD) lesion/liver CNR for the 23 at 1.5T and the 15 at 3T were 24.4 (18.7) and 51.2 (52.2), and 43.8 (18.9) and 60.2 (21.4), respectively, which is greater for the latter than the former ($p<0.05$ for both). While both MPGRE and FSGRE yielded high CNR for lesions compared to liver, only MPGRE provided consistently high CNR for lesions compared to vessels.

CONCLUSION

Lesion/vessel CNR on HP-LSCA-enhanced MRI was significantly and substantially greater for MPGRE than FSGRE, indicating visualization of liver metastases adjacent to vessels was markedly improved using the former technique.

CLINICAL RELEVANCE/APPLICATION

The addition of HP-MPGRE in a LSCA-enhanced liver metastasis MRI protocol is recommended as it markedly facilitates the detection of lesions, particularly those adjacent to vessels.

SST04-05 Abbreviated Liver-MRI vs Full Protocol Liver-MRI Including Hepatobiliary Phase Imaging to Screen for Liver Metastases in Patients with Solid Tumors: Preliminary Results

Friday, Dec. 1 11:10AM - 11:20AM Room: E353B

abarabasch@ukaachen.de

PURPOSE

To investigate whether an abbreviated liver-MRI protocol (AP), consisting of axial T2w-TSE, DWI and pre-contrast T1w-GRE in- and opposed phase (IP/OP) is appropriate to detect and classify liver metastases.

METHOD AND MATERIALS

Ongoing reader study on so far 71 consecutive patients with solid tumors who underwent liver-MRI to search for metastatic disease. All patients underwent a standardized full protocol (FP) hepatic MRI at 1.5T with axial and coronal T2w-TSE ± fat-saturation (fs), axial T1w-GRE (IP/OP), axial and coronal DWI (b=0, 50, 800), multi-phase T1w-dynamic GRE before and after i.v. gadoxetate disodium, and axial T1w-GRE + fs in the hepatobiliary phase. Body radiologists with between 9 and 12 years of experience first reviewed only the abbreviated protocol, and made their diagnosis regarding the presence or absence of focal liver lesions, as well as to the likelihood of malignancy on a 5-point scale. Results of the full MRI-protocol as well as imaging follow-up or histopathology of liver lesion was used as ground truth.

RESULTS

Acquisition time for the AP was 10.3 min., vs 39.8 min. for the FP. Based on the interpretation of the AP images, reader 1 identified all 56 patients with focal liver lesions that were also identified by reading images of the FP; reader 2 identified 54 of the 55 patients with focal liver lesions identified by the respective FP readings. Accordingly, the sensitivity to identify patients with focal liver lesions based on the AP- vs. the FP-readings was 100% (for reader 1) and 98.2% (for reader 2). Regarding characterization of focal liver lesions (positive predictive value), reader 1 had one additional false-positive diagnosis with AP compared to FP, for a PPV of 92% vs.. 94% (35/38 vs. 34/36); 95%-CI: 79 %-98 % vs 81% -99%. Reader 2 had 3 additional false-positive diagnoses with AP vs. FP, for a PPV of 88% vs. 97% (30/34 vs. 33/34); CI: 73%-97% vs. 85%-100%). Average time to read the AP was 43sec. for reader 1 and 72sec. for reader 2.

CONCLUSION

An MRI acquisition time of 10.3 min. and a reading time between 43 and 72 sec. is sufficient to identify patients with malignant focal liver lesions; it offers identical sensitivity and similar specificity and PPV as does a full, dynamic contrast enhanced liver MRI protocol that included hepatobiliary phase imaging.

CLINICAL RELEVANCE/APPLICATION

Abbreviated liver MRI seems useful to allow fast MRI-screening for metastatic spread to the liver in cancer patients.

SST04-06 Diagnostic Performance of an Abbreviated Gadoxetic Acid-Enhanced MRI Protocol for Colorectal Cancer Liver Metastases Surveillance

Friday, Dec. 1 11:20AM - 11:30AM Room: E353B

Participants
Rodrigo Canellas, MD, Boston, MA (*Presenter*) Nothing to Disclose
Aoife Kilcoyne, MBBCh, Boston, MA (*Abstract Co-Author*) Nothing to Disclose
Dushyant V. Sahani, MD, Boston, MA (*Abstract Co-Author*) Research support, General Electric Company; Medical Advisory Board, Allena Pharmaceuticals, Inc

For information about this presentation, contact:

rcsouza@partners.org

PURPOSE

To evaluate the diagnostic performance of an abbreviated gadoxetic acid-enhanced MRI protocol in colorectal cancer (CRC) liver metastases surveillance.

METHOD AND MATERIALS

In this IRB approved retrospective study, gadoxetic acid-enhanced (Eovist, Bayer healthcare) MRI scans of 43 patients with histologically proven liver metastases from colorectal cancer (mCRC) were assessed. Two readers independently assessed two sets of images of each patient. The first set consisted of T2WI + 15-20 min delayed T1-WFS followed by DWI (b values ranging from 50 to 800 s/mm2) and ADC maps. Readers evaluated liver lesions and characterized them as being or malignant. A maximum number of 10 lesions per patient were recorded. Malignant classification was based on low signal on the 15-20 min T1-FS, high signal on the DWI and low signal on ADC. Benign diagnosis was based on T2 bright, hypo-intense 15-20 min T1-FS and no restricted diffusion. The full MRI protocol (set 1 + set 2 + dynamic study + other sequences) was used as our reference standard. Cohen kappa analysis was used to assess the agreement between the readers.

RESULTS

Reader 1 characterized 184 lesions as malignant and reader 2 characterized 200 lesions as malignant with a good inter-reader agreement. Although useful in lesion characterization, DWI did not add much in terms of lesion detection compared to hepatobiliary phase T1-WFS. Full MRI exam with dynamic study was found useful in characterizing previously treated 3 small metastatic lesions, but did not improve the detection of metastatic liver lesions nor the characterization of few small lesions deemed indeterminate by the abbreviated protocol. The mean time for an abbreviated protocol takes around 15 minutes to be completed compared to 35 minutes of the the full MRI protocol.

CONCLUSION

An abbreviated gadoxetic acid-enhanced MRI protocol (T2WI, DWI and 15-20 min delayed T1FS) is faster, has robust quality and provides high diagnostic performance in detection and characterization of liver lesions in mCRC surveillance.

CLINICAL RELEVANCE/APPLICATION

MRI is a scarce resource and has high demand due to the clinical benefits in variety of clinical settings. Workflow strategies need to be engineered to meet the clinical demands without compromising the diagnostic performance of MRI. An abbreviated liver MRI protocol can serve as potentially faster and lower-cost alternative to conventional MRI protocol.

SST04-07 Multiparametric Imaging Correlations with Pathology in a HCC Rat Model

PURPOSE

To correlate multiparametric MR imaging with histopathological features of tumor response using a computer-implemented predictive model. This work quantifies MR imaging and pathology correlations in a hepatocellular carcinoma (HCC) rat model treated with sorafenib. Correlations of characteristic tissue hypoxia and nuclear crowding pathology features with MRI enable a non-invasive 'virtual biopsy' for understanding HCC response to sorafenib.

METHOD AND MATERIALS

Rat HCC McA-RH7777 cells were orthotopically implanted in the liver of 22 male Bufallo rats, and after 2 weeks, the animals were assigned to receive 7.5 mg/kg of sorafenib daily for 2 weeks (n=12) or to remain untreated (n=10). MR Imaging at 4.7 T was performed weekly, including anatomic, dynamic contrast-enhanced (DCE) and blood oxygenation level-dependent (BOLD) sequences. Pathology was co-registered with imaging using anatomical landmarks. Pimonidazole (PIMO) and Haemotoxylin and Eosin (H&E) staining were segmented using Gaussian mixture model to identify hypoxia, viable, and necrotic tissue. Tumor heterogeneity on pathology was quantified using the entropy of the hypoxic, viable, and necrotic tissue. The Maurer distance of each tissue type was compute to characterize the necrotic core and hypoxia relative to the HCC tumor boundary.

RESULTS

Lower entropy of the necrotic tissue was observed in the control group ($p<.05$) than the treatment group. For the PIMO stains, the distance of the hypoxic tissue in the treatment group was closer ($p=.1$) to the tumor boundary than the control group. Entropy in the pathology staining was also strongly correlated with T2star imaging ($r=.29$) but weakly correlated with BOLD effect.

CONCLUSION

Initial results demonstrate the feasibility of establishing quantitative correlations of imaging and pathology in this HCC rat model. Significant differences in entropy between groups can be used to evaluate treatment effect. Our analytical modeling platform has the potential to help predict response to sorafenib.

CLINICAL RELEVANCE/APPLICATION

Sorafenib is the only approved systemic therapy for advanced hepatocellular carcinoma. Disease control rate is achieved in less than 50% of advanced HCC patients, while nearly 10% experience grade 3-4. Therefore, imaging biomarkers are needed to identify

patients most likely to respond to sorafenib therapy.

SST04-08 Magnetic Resonance Imaging Biomarkers in Hepato-cellular Carcinoma: Correlation to Outcomes in Liver Transplant Candidates

punlee77@gmail.com

PURPOSE

To determine hepatocellular carcinoma (HCC) magnetic resonance imaging (MRI) biomarkers that enable prediction of delisting from tumor progression versus successful orthotopic liver transplantation (OLT).

METHOD AND MATERIALS

With IRB approval and HIPPA compliance, from a database of 1108 OLT listed patients with HCC from 2006-2015, patients who were delisted due to tumor progression and who had MRI at HCC diagnosis were identified. A comparison cohort of patients who went on to successful OLT without tumor recurrence matched for tumor stage and bridging therapies were then identified. Patient characteristics and MRI features upon consensus read by 3 abdominal radiologists were compared between the groups by bivariable and multivariable analsyis. The significant features were used to generate a prediction model based on MRI. Statistical analyses were performed using SAS version 9.4 (SAS Institute Inc., Cary, NC).

RESULTS

There were 53 patients included in each cohort (delist-ed vs OLT with no recurrence). Significant ($p< 0.05$) MR features associated with tumor progression resulting in delisting were: T2 hyper-intensity (odds ratio [OR]= 16; 95% confidence interval [CI]: 2.49, 670.95), internal rim enhancement (OR=23.32; 95% CI: 3.42, inf), infiltrative margins (OR= 22.45; 95% CI: 4.37, 115.22), corona enhancement (OR= 4.0; 95% CI: 1.13, 14.18), and bileduct dilatation (OR= 8.17, CI: 1.54, inf). A significant favorable MR features associated with successful OLT was intralesional fat, (OR=0.36, 95% CI: 0.13, 0.99). A prediction model derived from theses variables showed an area under the receiver operating characteristic curve (AUC) of 0.86 in the prediction of delisting versus successful transplantation.

CONCLUSION

MRI findings are significantly associated with risk of tumor progression in patients awaiting liver transplantation.

CLINICAL RELEVANCE/APPLICATION

MRI features of HCC has the potential to be included in an integrated liver transplantation selection model as biomarkers of tumor biology.

SST04-09 CT Attenuation of Liver Metastases before Chemotherapy is a Predictor of Overall Survival in Colorectal Cancer: Results from the Randomized, Open-Label FIRE-3/AIO KRK0306 Trial

matthias.froelich@med.uni-muenchen.de

PURPOSE

To investigate the prognostic value of pretherapeutic computed tomography (CT) attenuation values of liver metastases for overall survival (OS) in metastatic colorectal cancer (mCRC).

METHOD AND MATERIALS

In the open-label, randomized, prospective phase III FIRE-3 trial, 592 patients with histologically confirmed mCRC received 5-fluorouracil, leucovorin, and irinotecan (FOLFIRI) with either EGFR-antibody cetuximab or VEGF-antibody bevacizumab. Mean baseline attenuation [Hounsfield units (HU)] of up to five liver metastases was retrospectively measured in contrast-enhanced CT

scans of the abdomen (n=338, portal venous phase, slice thickness <=5 mm) using semi-automated volumetry. We analyzed the prognostic value of baseline HU values on overall survival (OS) using Kaplan-Meier estimate, log-rank statistics, and Cox proportional hazard regression. In addition, Receiver Operating Characteristic (ROC) analysis was employed to determine the optimal cutoff for baseline HU as predictor of prolonged OS.

RESULTS

Median baseline CT attenuation of liver metastases was 59.49 HU (IQR 49.08-68.73). In ROC analysis, baseline attenuation >61.66 HU was determined as optimal cutoff for increased OS (649 (95%-CI 587-730) days vs. 931 (777-1128), $p < 0.01$). This result was confirmed in univariate parametric Cox-regression (per 1 HU: HR=0.984, 95%-CI 0.975-0.993, $p < 0.01$). Results were consistent for subgroups based on quartiles with higher HU values being consistently associated with longer OS (median OS Q1 588 (95%-CI 460-806) days vs. Q2 663 (578-853) vs. Q3 800 (663-1096) vs. Q4 990 (777-1198)).

CONCLUSION

Increased baseline CT attenuation values >62 HU are a predictor of prolonged OS in mCRC. Measurements of CT attenuation are fast- and easy-to-perform in clinical routine and may serve as valuable prognostic imaging biomarkers in mCRC patients. Higher CT attenuation values may be the radiological representation of better vascularization of lesions. As a result, these lesions may be better to reach by and therefore more susceptible to systemic treatments.

CLINICAL RELEVANCE/APPLICATION

Liver lesions are the most common metastatic site in colorectal cancer. This work provides insights on the predictive value of the routinely assessed baseline attenuation of liver lesions on overall survival in patients from a large phase III trial.

kseehdr@dsmc.or.kr

PURPOSE

To retrospectively determine nondiminutive upper tract urothelial carcinomas (UTUCs) prospectively detected by using CT urography (CTU) but not confirmed with subsequent nonblinded ureterorenoscopy (URS).

METHOD AND MATERIALS

The institutional review board approved our study. Between 2003 and 2016, 8250 consecutive patients (mean age, 58 years±10.3) underwent 9133 CTU, which yielded 450 unique nondiminutive suspected UTUC lesions. Of 425 lesions that underwent subsequent nonblinded URS with knowledge of CTU findings-including size, location and morphology, 75 (17.7%) discordant lesions were not found at the initial unblended URS. After discordant lesions review, 30 lesions were classified as likely CTU false-positive findings without the necessity of further follow-up, and 45 lesions were classified as possible URS false-negative (FN) findings.

RESULTS

Nineteen of 75 (25.3%) of all discordant lesions after initial nonblinded URS were confirmed to be actual URS FN results, including 57.5% (19 of 33) of lesions with URS and/or CTU follow-up assessment. The average size of lesions with URS FN results was 7.5mm±3.2 and were identified with higher confidence at the prospective CTU by using the three-point scale (2.7±0.4 vs. 2.0±0.3, P=0.002). URS FN lesions were significantly more likely than concordant lesions in the calyceopelvis (73.6%, 14 of 19 vs. 41.4 %, 145 of 350; P=0.015). Eight lesions missed by using URS but confirmed by subsequent URS with surgical resection revealed adherent blood clot in one lesion and benign disease in seven lesions, and five lesions (62.5%) located in the calyceopelvis.

CONCLUSION

A priori knowledge of CTU for lesions missed at URS is more likely to have higher diagnostic confidence of the initial CTU.

CLINICAL RELEVANCE/APPLICATION

A priori knowledge of CTU for lesions missed at URS is more likely to have higher diagnostic confidence of the initial CTU.

SST05-02 Does Split-Bolus Injection Truly Influence the Ability of Renal and Urinary Lesion Detection at CT Urography? Multi-Center Prospective Randomized Comparison between Split-Bolus and Single-Bolus Injection Techniques

PURPOSE

To determine if split-bolus injection influences the ability of CT urography (CTU) for diagnosing the lesions in the kidney and the urinary tract.

METHOD AND MATERIALS

Institutional review board approved this multicenter prospective study. 299 patients from 11 institutions (male: female = 211: 88) had been randomly assigned to undergo CTU with split-bolus (n=148) or single-bolus (n=151) injection of CM. The degree of the renal enhancement was assessed with 3-point scale, and presence of renal cystic or solid lesion were evaluated. The urinary tract was divided into four regions (renal pelvis, upper, middle, and lower ureter), and the degree of opacification, as well as the suspicion of lesions were evaluated for each region. CT values of the renal parenchyma, renal lesions, and the renal pelvis were measured in each phase [nephrographic (NP) and excretory (EP) for single-bolus; mixed (MP) for split-bolus] and contrast ratio (CR) were calculated.

RESULTS

Although there were no differences in CTDIvol between single- and split-bolus injection, total DLP of split-bolus was significantly lower than those of single-bolus (1,425±60 vs. 2,013±59 mGycm; p<.0001). There was no difference in the degree of the urinary tract opacification between single- and split-bolus (p>.05). The renal parenchymal enhancement in NP of single-bolus achieved significantly better qualitative score than those in MP of split-bolus (p<.05), and significantly greater CT values than MP of split-bolus (162±31 vs. 128±22 HU; p<.0001). Nevertheless, there was no statistically significant difference in CR of renal lesion between in NP of single-bolus and MP of split-bolus (0.72±0.21 vs. 0.68±0.26; p>.05). CT values of the renal pelvis were significantly higher in EP of single-dose than MP of split bolus (730±505 vs. 560±421HU; p=.0009). The AUC, Sens, Spec, and Accu of urinary tract lesions were; 0.99, 100%, 94.6%, 94.7% for split-bolus, 0.99, 100%, 95.8%, 95.8% for single-bolus without NP, 0.97, 92.3%, 94.7%, 94.7% for single-bolus including NP.

CONCLUSION

CTU with split-bolus injection technique can accurately depict the lesions in the renal parenchyma and the urinary tract as single-bolus injection with reduced radiation dose.

CLINICAL RELEVANCE/APPLICATION

Split-bolus technique should be applied for the CTU considering radiation dose.

SST05-03 Analysis of Treatment Response of Bladder Cancer on CT Scans: Improved Assessment by Synergistic Combination of Radiomic Features and Clinically Estimated Feature

PURPOSE

To evaluate the accuracy of automatically extracted radiomic features from CT scans and clinically estimated feature in treatment response assessment of bladder cancer.

METHOD AND MATERIALS

Our Auto-Initialized Cascaded Level Set (AI-CALS) system is designed to extract 3D lesion boundary based on level sets. 47 radiomic features (RF) based on pre- and post- treatment changes in volume (V), 5 gray level (GL) and 9 shape (S) descriptors and 32 texture features (RLS) were extracted from the segmented lesions. A clinically estimated feature, the bimanual exam under anesthesia (EUA), was also collected from the clinical reports. Linear discriminant analysis was used to generate two combined response indices: one by the RFs alone (CRI-RF), and the other with both RFs and EUA (CRI-RF-EUA). With IRB approval, pre- and post-chemotherapy treatment CT scans of 98 patients with bladder cancers were collected. For all cases, cystectomy was performed after treatment and the disease outcome was available as reference standard of treatment response. 25% of patients had pT0 disease (complete response) at cystectomy. A radiologist marked 122 temporal pairs of primary site cancers. Stepwise feature selection and leave-one-case out cross-validation and receiver operating characteristic (ROC) analysis were performed. The area under the ROC curve (AUC) was calculated to estimate the accuracy for predicting pT0 stage (complete response) at cystectomy by V, CRI-RF and CRI-RF-EUA methods. Two radiologists also provided the likelihood of pT0 stage of the tumor by reading the pre- and post-treatment paired CT scans.

RESULTS

For the 122 cancers, the AUC for prediction of pT0 disease at cystectomy was 0.70±0.05 for V. The AUC for CRI-RF based on 2 Contrast and 2 RLS features was 0.74±0.05 and increased to 0.78±0.05 when EUA was added (CRI-RF-EUA). Prediction of pT0 disease by radiologists resulted in AUCs of 0.77±0.05 and 0.75±0.05, respectively. The differences did not reach significance (p>0.05).

CONCLUSION

Both CRI-RF and CRI-RF-EUA performed similar to the radiologists and better than V for estimation of treatment response. The addition of EUA further improved the accuracy of treatment response assessment.

CLINICAL RELEVANCE/APPLICATION

The combined response index using both the radiomic features and clinically estimated EUA has the potential to provide accurate treatment response assessment and is superior to volume change alone.

SST05-04 Quantification of Microvascular Changes to Predict ypT1N0 in Chemotherapeutic Response in Bladder Cancer

PURPOSE

To apply a parametric MRI methodology to quantify the microvascular changes in bladder tumors at the mid-treatment point of neoadjuvant chemotherapy (NAC) to predict the response with ypT1N0 endpoint.

METHOD AND MATERIALS

Thirty-eight muscle-invasive bladder cancer patients were included. Each patient had a pre-chemotherapy, a mid-chemotherapy (after 2 cycles), and a post-chemotherapy MRI, followed by radical cystectomy. The pathological findings of cystectomy specimens were used as reference standard. A patient with <=ypT1N0 was defined as a responder. MRI was performed with T2W-MRI prior to DCE-MRI on a 3T multi-transmit system (Ingenia CX, Philips Healthcare). Two pharmacokinetic parameters (Amp - signal enhancement amplitude, and kep - the exchange rate between the interstitial space and the plasma space) were estimated. For each patient, the k-means clustering of a voxel-wise Amp and kep data matrix was performed to segment their bladder tumor in 3 clusters. The volume fraction (VF) changes of 3 clusters from pre- to mid-chemotherapy MRIs were calculated and correlated with NAC response. P<0.017 was considered statistically significant for tri-parametric analysis. ROC curve analysis was performed when significant difference was found.

RESULTS

Based on pathological findings, nineteen patients with <=ypT1N0 were classified as responders, and the other nineteen patients as non-responders. The k-means clustering segmented a tumor in 3 clusters: Cluster 1 contained voxels with both low Amp and kep; Cluster 2 had voxels with high Amp and low kep; Cluster 3 had voxels with low Amp and high kep. The correlation with chemotherapeutic response showed that responders had significantly higher VF change of cluster 2 (P<0.001) and lower VF change of cluster 1 (P<0.005). There was no correlation found in the VF change of cluster 3. The ROC curve analysis calculated that AUC values were 0.81 for cluster 1 VF change and 0.78 for cluster 2 VF change.

CONCLUSION

The quantitative MRI methodology can quantify the complex microvascular changes in bladder tumor at the mid-treatment point to characterize the tumor response. The quantitative assessment can provide valuable information to predict pT1N0 endpoint before the end of NAC.

CLINICAL RELEVANCE/APPLICATION

Accurate prediction of NAC response can make substantial impact on treatment stratification to improve the outcomes of bladder cancer patients.

SST05-05 Bladder Cancer Staging in CT Urography Using Radiomic Biomarkers

PURPOSE

To evaluate the accuracy of a decision support system for staging of bladder cancers based on automatically extracted radiomic biomarkers from CT urography (CTU) merged in a predictive model by machine learning techniques.

METHOD AND MATERIALS

Bladder cancers at stage T2 or above are recommended for neoadjuvant chemotherapy treatment clinically. Correct staging is crucial for the decision of neoadjuvant chemotherapy and minimizing the risk of under- or over-treatment. Pre-treatment CTUs of 84 patients with bladder cancers were retrospectively collected with IRB approval. 43 cancers were below stage T2 and 41 cancers were at stage T2 or above. Our Auto-Initialized Cascaded Level Set (AI-CALS) system was used to extract 3D lesion boundary from all lesions. 87 radiomic biomarkers including 55 tumor heterogeneity and 32 morphological features (volume (V), 23 gray level (GL) and 8 shape (S)) were extracted from the segmented lesions. Linear discriminant classifier (LDA), support vector machine (SVM), and backpropagation neural network (NN), with stepwise feature selection based on F-statistics, as well as a random forest (RAF) classifier were used to combine the biomarkers into 4 predictive models for comparison. The dataset was partitioned into independent Set 1 and Set 2 for two-fold cross validation. The predictive models including feature selection were trained on one partition set and tested on the other partition set and vice versa. The area under the receiver operating characteristic curve (AUC) was calculated for each model to estimate its performance in predicting cancer stage (>= T2 or < T2).

RESULTS

The test AUC on Set 1 was 0.89, 0.92, 0.91, and 0.86 for LDA, SVM, NN and RAF, respectively. The test AUC on Set 2 was 0.90, 0.89, 0.95, and 0.96 for LDA, SVM, NN and RAF, respectively. The differences between the models did not reach statistical significance. The useful biomarkers included 2 heterogeneity features, 2 gray level features, and a contrast feature.

CONCLUSION

The machine learning techniques are promising in selecting effective radiomic biomarkers and merging them into predictive models that may provide useful decision support for bladder cancer stage assessment.

CLINICAL RELEVANCE/APPLICATION

An objective decision support system that merges computer-extracted radiomic biomarkers in a predictive model may assist clinicians in making more accurate and consistent cancer staging assessment.

SST05-06 Prospective Study of DWI and Intravoxel Incoherent Motion (IVIM) MRI as Biomarkers to Predict Clinical Aggressiveness in Bladder Cancer

Friday, Dec. 1 11:20AM - 11:30AM Room: E351

Participants
Miaomiao Zhang, beijing, China (*Presenter*) Nothing to Disclose
Yan Chen, MD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
Xinying Cong, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

zmm110408@126.com

PURPOSE

To evaluate the utility of the DWI and IVIM-MRI derived parameters in prediction of aggressiveness in bladder cancer.

METHOD AND MATERIALS

Fifty-eight patients (49 men, 9 women, mean age 61 years) were inspected through DWI and IVIM MR examination from April 2016 to March 2017. Bladder cancer (BC) was categorized in three different aggressiveness levels according to the classification criterion proposed by Kobayshi et al. The aggressiveness was classified as low- (including stage Ta and histological low-grade T1), intermediate- (high-grade T1) or high-aggressiveness (stage T2 or greater). Spearman Correlation Analysis was adopted to assess the correlation between aggressiveness and all parameters (apparent diffusion coefficient ADC, true diffusion coefficient D, pseudodiffusion coefficient D*, and perfusion fraction f). Comparisons of ADC value and IVIM parameters in different aggressiveness levels were performed using One-way analysis of variance (ANOVA). Diagnostic performance was calculated by means of receiver operating characteristics (ROC) analysis.

RESULTS

Aggressiveness of bladder cancer was negatively correlated with ADC value(r=-5.99, P < 0.001), D value(r=-5.07, P < 0.001) and f value(r=-3.64, P < 0.05). ADC, D, and f values in high-aggressive BC were significantly lower than both those in low-aggressive BC(P < 0.05) and those in intermediate-aggressive BC(P<0.05). There was not any significant difference between values of low- and intermediate-aggressive BC. The ROC analysis provided an AUC for ADC value to differentiate high-aggressive BC from low- and intermediate-aggressive BC(AUC=0.858, cut-off value =1.38mm2/s) with a sensitivity of 63.16%, a specificity of 100% and an accuracy of 75.87%, an AUC for D value(AUC=0.818, cut-off value =0.877mm2/s) with a sensitivity of 65.79%, a specificity of 95% and an accuracy of 75.86%, and an AUC for f value(AUC=0.782, cut-off value =0.33) with a sensitivity of 84.21%, a specificity of 70% and an accuracy of 79.3%.

CONCLUSION

ADC value and IVIM-derived parameters are promising biomarkers to predict aggressiveness in BC.

CLINICAL RELEVANCE/APPLICATION

(dealing with ADC value and aggressiveness)"The ADC value in DW-MRI can serve as a biomarker to predict the clinical aggressiveness of bladder cancer."

SST05-07 Comparison between Conventional Cystourethrography and MRI with Voiding MR-Cystourethrography in the Evaluation of Male Urethral Strictures

digirolamomarco@hotmail.com

PURPOSE

To evaluate the accuracy of conventional retrograde and voiding cystourethrography and MRI together with voiding MR-cystourethrography in the evaluation of male urethral strictures.

METHOD AND MATERIALS

We evaluated 39 male patients with urethral strictures diagnosed with urine flow velocity recording and conventional retrograde and voiding cystourethrography. All these patients underwent MRI and voiding MR-cystourethrography using a 1.5T superconductive magnet. The patients had urine-filled bladders and high-resolution sagittal TSE T2-weighted scans were performed (TR:6250ms; TE:90ms;sl.thick.:3mm; acq.time:3'38"). Voiding MR-cystourethrography was performed with T1-weighted spoiled 3D gradient-echo acquisitions on sagittal plane (TR:12ms; TE:2,7ms; flip-angle:40°; sl.thickness: 2mm; acq.time:12s) after the filling of bladder lumen with contrast-material-enhanced urine obtainded by the i.v administration 20 mg of furosemide followed by ¾ of the normal dose of a paramagnetic contrast agent (Magnevist, Bayer Pharma, Germany). After micturition high-resolution coronal TSE T2-weighted scans were performed at the level of the stenosis. Two radiologists in consensus evaluated the morphology and length of the urethral stenosis with the two modalities and with MRI the entity and the site of spongio-fibrosis was assessed.

RESULTS

6 patients were not able to perform voiding MR-cystourethrography. In 33 patients evaluated with two imaging modalities 42 urethral strictures were detected. The measurement of the stenosis length was equal or superior with voiding MR cystourethrography and the analysis of 3D sagittal scans allowed a better evaluation of the morphology of the urethral strictures in comparison with conventional cystourethrography. 32 strictures with Spongio-fibrosis were found (76%). The site of spongio-fibrosis was always assessed with MRI (dorsal, ventral, dorsal and ventral and circular fibrosis).

CONCLUSION

MRI with voiding MR-cystourethrography shows the morphology and the length of the urethral strictures better than conventional cystourethrography and allows the detection and site of spongio-fibrosis, avoiding radiation exposure to the gonads and urinary catheterization.

CLINICAL RELEVANCE/APPLICATION

MRI could be proposed as all-in-one technique for the evaluation of urethral stenosis, allowing their detection and length assessment and determining the presence and site of spongiofibrosis.

SST05-08 Diagnostic Accuracy of MRI for T-Staging of Urothelial Bladder Cancer: Systematic Review and Meta-Analysis

mmcinnes@toh.ca

PURPOSE

To determine the diagnostic accuracy of MRI for T-staging (≥T2) of urothelial bladder cancer (UBCa). Multi-disciplinary panel determined *a priori* that a sensitivity of >95% was necessary to obviate the need for re-resection of tumor after initial TURBT identifying

METHOD AND MATERIALS

Search of multiple databases was performed on Jan 26, 2017. Inclusion criteria: humans with UBCa who underwent pelvic MRI (>1.5T) for local staging; reference standard (surgical pathology); no chemo- or radiotherapy prior to imaging. Inclusion and data extraction was performed independently. Risk of bias was assessed using QUADAS-2. Summary estimates for diagnostic accuracy

were generated using bivariate random effects model and subgroup analyses evaluated for sources of heterogeneity.

RESULTS

13 studies (979 patients) were included. Pooled sensitivity and specificity for: A) 7 studies using only T2-W MRI = 89% (95%CI 78-95) and 55% (95%CI 45-65) and B) 8 studies using DWI = 78% (95%CI 69-85) and 78% (95%CI 70-84). Area under ROC curve (AUC) for T2WI was 0.71 and for DWI was 0.84. Summary ROC curve (SROC) is depicted in Figure 1; 95% prediction regions for T2WI and DWI do not overlap. Moderate risk of bias was identified in patient selection (3/13 studies), index test (4/13) and, reference standard (12/13); all primarily from lack of clear reporting.

CONCLUSION

MRI for T staging of UBCa demonstrates higher specificity and overall accuracy for DWI compared to only T2W-MRI. Caution is warranted; most comparisons were indirect and the majority of studies had moderate risk of bias in at least one domain.

CLINICAL RELEVANCE/APPLICATION

T-staging accuracy of UBCa (>T2) with MRI demonstrates variability with higher accuracy identified using DWI compared to T2W-MRI alone. Neither DWI nor T2W-MRI met our pre-specified criteria of >95% sensitivity suggesting that MRI is not an appropriate replacement test for re-resection of tumor following initial TURBT identifying

SST05-09 Bladder Cancer: MRI as an Alternative to Repeat Transurethral Resection of Bladder Tumor for Local Staging

PURPOSE

Transurethral resection of bladder tumor (TURBT) frequently understages muscle invasive bladder cancer and needs to be repeated. The purpose of this study was to determine test characteristics of multiparametric MRI (mpMRI) for the local staging of bladder cancer following TURBT, using cystectomy as the reference standard.

METHOD AND MATERIALS

This retrospective study was institutional review board approved and is HIPAA compliant. Between August 2011 and October 2016, 45 consecutive patients (median age 73 years) met inclusion criteria, which included a TURBT procedure followed by mpMRI then cystectomy without intervening neoadjuvant or intra-vesical therapies. Median time between TURBT and MRI was 43 days (SD 130, range 17-627 days). Two fellowship-trained abdominal radiologists, blinded to cystectomy staging, reviewed each mpMRI independently to document tumor T stage and regional nodal disease using all available sequences and each sequence in isolation. Sensitivity and specificity for the presence of muscle invasion (>=T2) and peri-vesical invasion (>=T3) were calculated on a stage-by-stage basis. Sensitivity and specificity for presence of regional nodal disease was assessed. Inter-observer agreement was measured using Cohen's Kappa coefficient.

RESULTS

Sensitivity/specificity for presence of muscle invasion was 92%/74% for reader 1 and 88%/84% for reader 2. Sensitivity/specificity for presence of peri-vesical invasion was 72%/92% for reader 1 and 67%/92% for reader 2. Sensitivity/specificity for regional nodal disease was 45%/93% for reader 1 and 45%/90% for reader 2. T2-WI was the most sensitive sequence for both readers for determining the presence of muscle invasion and peri-vesical invasion, while DWI was the most sensitive for regional nodal disease. The most specific sequence varied between readers. Inter-observer agreement was substantial for presence of muscle invasion, peri-vesical invasion and regional nodal disease when all sequences were used.

CONCLUSION

mpMRI is sensitive and specific at determining bladder cancer muscle and peri-vesical invasion in patients who have undergone prior TURBT. mpMRI was specific but not sensitive for assessing regional nodal disease.

CLINICAL RELEVANCE/APPLICATION

Multiparametric MRI is sensitive and specific at bladder cancer local staging following TURBT. Current bladder cancer management guidelines could consider mpMRI as an alternative to repeat TURBT.

N/A

PURPOSE

To compare the accuracy of a) CT based structural analysis protocol (CT-SAP) b) bone mineral density (BMD) and c) lesion size in predicting vertebral strength in a lytic lesion model of human vertebral metastatic disease.

METHOD AND MATERIALS

We created lytic defects in the middle vertebra of 40 cadaver thoracic and lumbar 3-level spinal segments from donors aged 48-57 years (Fig 1). The segments were imaged using a clinical CT spine protocol (field of view = 16cm, voxel dimensions: (0.31*0.31*0.625)mm . The segments were then tested to failure in either compression or in compression + torsion (3Nm). Linear regression models (JMP 9, SAS, NC) tested the correlations of a) defect size, b) BMD and c) CT-SAP predicted failure load with measured vertebral strength.

RESULTS

- Compression loading: Within an intentionally small range of defect diameters, lesion size was not correlated with vertebral strength (Fig 2.C). CT-SAP showed significantly higher prediction accuracy for vertebral strength than did BMD (Fig 2.B), (ANCOVA, $p<0.01$), Fig 2.A. - Compression + torsion loading: Lumbar vertebrae showed 12% reduction in mean strength than in pure compression Thoracic spines showed 34% higher strength than in compression alone ($p<0.05$). CT-SAP again had significantly higher prediction accuracy than BMD (Fig 2.C), $p<0.05$, but both measures showed lower prediction accuracy compared to the compression-only tests.

CONCLUSION

CT-SAP is superior to lesion size and BMD in predicting the strength of human vertebrae with lytic defects. These results are achieved by modeling the material properties and spatial distribution of the bone throughout the vertebral volume. Incorporation of a more realistic loading regime (compression + torsion) brings this in vitro model closer to actual stresses applied in vivo. The novel finding of regional differences in the effect of torsional loading on vertebral strength highlights the need to incorporate local variation in facet geometry in intervertebral kinematics, effecting local load transfer, in order to improve CT-SAP prediction accuracy.

CLINICAL RELEVANCE/APPLICATION

There are no objective and precise methods for predicting fracture risk in patients with spinal metastases. Subjective protocols such as SINS have limited accuracy. CT-SAP appears to provide more reliable objective predictions.

SST06-03 The Differential Diagnosis of Benign and Malignant Vertebral Compression Fracture with MR Fat-Water Separation Dixon Technique at 3.0T: A Retrospective Study

Friday, Dec. 1 10:50AM - 11:00AM Room: E451A

PURPOSE

The purpose of our study was to explore the value of fat-water separation Dixon technique in differential diagnosis of benign and malignant vertebral compression fractures.

METHOD AND MATERIALS

We retrospectively analyzed 76 patients with vertebral lesions who scanned at a CT scanner, and can not confirm the diagnosis. Then all patients underwent fat-water separation Dixon T1WI sequence on a MAGNETOM Skyra 3.0T MR scanner (Siemens AG, Erlangen, Germany). The patients were identified as either benign compression fractures (35 osteoporotic fractures,5 traumatic fractures, 3 infective fractures;age,28-76 years) or malignant compression fractures (28 metastatic fractures,3 multiple myeloma, 2 non-Hodgkin lymphoma; age,34-81 years) based on clinical follow-up or pathologically results. Besides general protocols for vertebral disease, the water-fat separation Dixon T1-VIBE protocol was included with the following parameters, TR/TE= 600/9.5ms, slice thickness=3mm, FOV= 340mm, matrix =384x384, iPAT = 2, Number of slices=16, and Average= 1. Four series of images (in/opposed phases, fat/water only) generated by the system were used for FF analysis. The signal intensity ratio was defined as SIR= SIopp-phase/ SIin-phase and the fat fraction was defined as FF= SIfat/ SIin-phase×100%.

RESULTS

The value of FF (27.43±6.77) in the benign group was significantly higher than that in the malignant group (11.88±4.23) (P<0.01).The SIR (0.72±0.28) in the benign group was significantly lower than that in the malignant group (1.38±0.21) (P<0.01).Through drawing ROC curve used the FF and SIR of benign and malignant vertebral compression fractures, the diagnostic critical value of benign and malignant vertebral compression fractures was12.75 and 0.86. The AUC of FF and SIR were 0.75 and 0.86.

CONCLUSION

The vertebral signal intensity and fat fraction through 3.0T MR fat-water separation Dixon technique can reflect the change of the vertebral body fat content in patients, and is helpful in differentiation in between benign and malignant vertebral compression fractures.

CLINICAL RELEVANCE/APPLICATION

(dealing with MR Dixon technique) '3.0T MR fat-water separation Dixon technique can demonstrate alterations in vertebral body fat content and this exam is recommended when the underlying cause of vertebral lesion is unclear.'

SST06-04 Validation of T2 Weighted Images for Assessing Fat Infiltration in Paraspinal Muscles Using an Osirix Application

suribe@med.puc.cl

PURPOSE

Fat infiltration in paraspinal muscles has shown to be related to low back pain risk and it has been quantified using a manual thresholding yielding to quantification errors. Moreover, although the segmentation is typically done in T2w images, this has not been validated. We proposed a software to automatically segment FI in PM using T2w images. The software was validated against manual segmentations using Dixon images as a gold standard since they do not contain water nor B0 inhomogeneities.

METHOD AND MATERIALS

We used T2w and Dixon images from 10 healthy volunteers and 10 patients, acquired in a Philips Ingenia 3.0T scanner (TE 110ms, TR 4160ms for T2w) with an acquisition matrix of 324x324 and a pixel resolution of 0.4x0.4x4mm. To segment fat, we developed an Osirix plugin based on PyOsirix, which allows for running Phyton scripts over the Osirix database. We manually define 4 ROIs per slice for the erector spinae and multifidus muscles and from L1-L2 to L5-S1. An automatic threshold is determined for each ROI. For the gold standards, we copy the same ROIs into the Dixon images and then we found a threshold manually. For the statistical analysis, we performed two-tail paired t-test, Pearson correlation, Bland Altman analysis and linear regression.

RESULTS

Two-tail paired t-test of the segmented areas showed that there is not significant difference between gold standard and our method (P=0.61). Linear regression showed the good agreement between the two methods (Y=0.91X+0.21 cm2). Pearson correlation was 0.89 and Bland Altman plots showed a low bias (-0.016 cm2) and limits of agreement of [-1.270, 1.238] cm2. Fortin and Batiié (2012) reported 9 minutes for manually finding the threshold for fat segmentation in T2w images. Our Osirix plugin performs the segmentation in a fraction of second per ROI.

CONCLUSION

We developed an Osirix plugin to automatically quantify FI in PM using T2w images. Our plugin showed an excellent agreement and no significant difference with manual segmentation using Dixon images. Our plugin reduces the processing time from minutes to a few seconds. As future work, we are developing techniques for facilitating the PM delimitations to define the ROIs.

CLINICAL RELEVANCE/APPLICATION

We validated a software to automatically segment the fat infiltration in paraspinal muscles using T2w images. We used manual segmentation in Dixon images as a gold standard.

SST06-05 Quantitative T2 Magnetic Resonance Imaging Compared to Morphological Grading of the Early Cervical Disc Degeneration in Asymptomatic Volunteers by T2 Relaxation Mapping

Friday, Dec. 1 11:10AM - 11:20AM Room: E451A

wscupiter@163.com

PURPOSE

The purpose of this study was to assess cervical disc degeneration quantitatively by using T2 Relaxation mapping.

METHOD AND MATERIALS

22 asymptomatic young subjects (11 men and 11 women; 21.73±2.01 years) were enrolled in this study. All date were collected on a 3.0 T MRI(Skyra,Siemens Healthcare, Erlangen, Germany);Therefore, the morphological date of 132 cervical disc covering C2 to T1 were obtained (Cervical sagittal T2-weighted, sagittal and axial T2 relaxation MRI) covering discs C2-C3 to C7-T1. All MR images in this study were acquired in the afternoon to minimize the diurnal variation of T2 values in the discs. All the discs were morphologically assessed according to the Miyazaki grade. Morphological evaluation of images were carried out by 2 radiologists with 10 years experience of musculoskeletal radiology in consensus. Six discs (C2-T1) of the cervical spine were put Regions of interest (ROIs) over axial T2 mappings images, including nucleus pulposus (NP),anterior and posterior annulus fibrosus (AF). To minimize the error in identifying nucleus pulposus (NP) anatomic structure, free hand ROIs were put carefully matched to the NP shape.The value of AF was calculated by the average between AAF and PAF. Mean T2 values were recorded using Siemens SyngoVIA workstation.Wilcoxon signed rank test, Kruskal-Wallis test, and Spearman rank correlation were performed. Correlations were considered as strong for r>0.7, moderate for 0.5< r<0.7, and weak for r<0.5. All statistical analysis was performed by SPSS software (v16.0, SPSS Inc., Chicago, IL, USA), P<0.05 was considered statistically significant.

RESULTS

The difference in T2 values between NP and AF were highly significant (P<0.001). The trends of decreasing T2 mapping values of both NP and AF with increasing Miyazaki grades was significant (P<0.01), particularly between Miyazaki grade I and II (P<0.001). Miyazaki grades were inversely significantly correlated with T2 values in the NP (r=-0.8901, P<0.001) and AF (r=-0.7446, P<0.001).

CONCLUSION

The process of cervical disc degeneration can be detected by T2 mapping, particularly at early stage. It displays comparable trends as Miyazaki grades does.

CLINICAL RELEVANCE/APPLICATION

Quantitative, objective and non-invasive evaluation of T2 mapping in intervertebral disc degeneration can prevent, diagnose and evaluate the clinical effect of spinal diseases.

SST06-06 Value of Psoas Proximal Insertion for Numbering Lumbar Vertebrae

Friday, Dec. 1 11:20AM - 11:30AM Room: E451A

Participants

Marc Garetier, MD, Brest, France (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the value of psoas muscle proximal insertion for correct numbering of the lumbar vertebrae in MRI, in particular in case of lumbosacral transitional vertebra (LSTV).

METHOD AND MATERIALS

Two radiologists assessed independently 477 MRI of the lumbar spine with coronal STIR sequence and a sagittal localizer sequence on the whole spine. The last lumbar vertebra was by counting caudally from C2, and its morphology was evaluated according to Castellvi classification as modal lumbosacral junction (N) or LSTV (C). The proximal insertion level of psoas muscle was assessed on coronal STIR sequence. It was named as the most proximal vertebrae with psoas over half of its body. The same parameters were assessed on 207 PET-CT of other patients including the whole spine to compare MRI and CT data with a Fisher's exact test, considering CT as gold standard for anatomical consideration, due to millimetric slices and possibility of multiplanar reconstructions.

RESULTS

Among the 477 patients, 405 patients (84,9%) had a modal last lumbar vertebra (L5N), 43 patients (9%) a LSTV (L4/5/6C+) and 29 patients (6,1%) a missing or supernumerary lumbar vertebra without LSTV (L4/6N). The psoas proximal insertion was L1 in 449 patients (94,1%), T12 in 8 patients (1,7%) and L2 in 20 patients (4,2%). It was L1 in 98,5% in case of L5N, 81,0% in case of LSTV, and 81,3% and 15,4% in case of L4N or L6N respectively. The interreader agreement for determination of psoas proximal insertion was excellent (Kappa = 0.96). There was no statistically significant difference between MRI and CT data ($p<0,05$).

CONCLUSION

Coronal STIR sequence has a high-performance for the determination of the psoas proximal insertion. Determination of psoas proximal insertion is an accurate, valuable and easy way for correctly number lumbar vertebrae. In case of a modal anatomy (L5N), it's almost always L1 (98%). Controversely, this insertion is not necessarily T12 or L2 according to the presence of missing or supernumerary lumbar vertebrae, with or without LSTV. In these situations, psoas even keeps an insertion on L1 in the majority of cases, except in L6N group.

CLINICAL RELEVANCE/APPLICATION

Radiologists should have a look on psoas proximal insertion in lumbar spine MRI. If this insertion is not 5 vertebral bodies above the lumbosacral joint, there is a high probability of variation in the number of lumbar vertebrae.

SST06-07 The Value of Golden-Angle RAdial Sparse Parallel (GRASP) Imaging for Differentiation between Infectious Degenerative Modic Type 1 Changes of the Spine

Friday, Dec. 1 11:30AM - 11:40AM Room: E451A

Participants
Meritxell Garcia, Basel, Switzerland (*Presenter*) Nothing to Disclose
Kai Tobias Block, PhD, New York, NY (*Abstract Co-Author*) Royalties, Siemens AG
Oliver Bieri, PhD, Basel, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Dorothee Harder, Basel, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Bram Stieltjes, MD,PhD, Basel, Switzerland (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The aim was to assess whether a T1w3D sequence with contrast for dynamic MR imaging, Golden-angle RAdial Sparse Parallel (GRASP) was able to distinguish between benign and pathologic vertebral compression fractures.

METHOD AND MATERIALS

Twelve patients with non-necrotic metastases in non-fractured VBs (mean 66 years), 11 patients with VB compression fractures without a history of a malig-nancy (mean 74 years), and 8 patients with VB compression fractures caused by osseous metastases (63 years) were examined by conventional MRI and GRASP at 1.5 or 3T (Siemens). Imaging parameters of the GRASP sequence were: TA 4:20 min, TR/TE 5.92/1.78 msec, slice thickness 2.5 mm, voxel size 1x1x2.5 mm. A region of interest (ROI) was placed in the pathologic-appearing VB and in a normal-appearing VB, whereby the latter served as a reference. The ROIs of metastatic non-fractured VBs served as a further reference.

RESULTS

The three patients groups did no show any difference in the maximum contrast-enhancement intensity, and all showed a higher contrast-enhancement than the normal-appearing VBs. In all VB fractures without malignancy the time-contrast-enhancement intensity course was almost parallel to that of the normal-appearing VB consisting of a fast increase of contrast enhancement (at 40-85 sec) shortly afterwards reaching a plateau (80-175 sec). On the other side, all metastases without fracture manifested a slightly earlier and very fast increase of contrast-enhancement (at 30-55 sec) immediately fol-lowed by a prolonged and weak decrease of enhancement towards a late plateau (>175 sec). The time-intensity contrast-enhancement curves of the pathologic fractures were quite similar to that of the metastatic non-fractured VBs (slope 35-65 sec, plateau >175 sec).

CONCLUSION

Pathologic VB fractures, however, can be distinguished from benign compression fractures by a different time intensity contrast-enhancement curve, whereby the dynamic differences can be attributed to differences in cellularity, edema, and vascularity of the bone. We conclude that GRASP imaging may be a promising sequence for the differentiation between benign and pathologic fractures, which may be of great value in patients in which the primary cause for the fracture cannot be evaluated by conventional MRI.

CLINICAL RELEVANCE/APPLICATION

GRASP imaging may be a promising tool for the differentiation between benign and pathologic fractures with MRI.

SST06-08 Texture Analysis of Paraspinal Musculature in MRI of the Lumbar Spine: Analysis of the Lumbar Spinal Outcome Study (LSOS) Data

Friday, Dec. 1 11:40AM - 11:50AM Room: E451A

Participants
Manoj Mannil, Zurich, Switzerland (*Presenter*) Nothing to Disclose
Jakob Burgstaller, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose

Arjun Thanabalasingam, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Sebastian Winklhofer, MD, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the clinical impact of fatty infiltration in paraspinal musculature on Spinal Stenosis Measure (SSM) Score and Walking Distance, at baseline and regarding changes after 12 months in patients suffering from lumbar spinal stenosis (LSS) using the qualitative Goutallier staging and quantitative Texture Analysis (TA) in Magnetic Resonance Imaging (MRI).

METHOD AND MATERIALS

In this retrospective, institutional review board approved study, TA was performed on axial T2 weighted MR images at level L3/4 using dedicated software (MaZda) in 62 patients with LSS. The association between Goutallier and TA findings with two clinical outcome measures, Spinal Stenosis Measure (SSM) Score and Walking Distance, at baseline and regarding changes after 12 months were assessed using machine learning algorithms (Random Forest) for TA feature reduction, followed by multiple logistic regression models.

RESULTS

Quantitative assessment of fatty infiltration using the histogram TA feature „mean" showed higher interreader reliability (ICC 0.83-0.97) compared to the Goutallier staging (κ = 0.69 to 0.93). No correlation between Goutallier staging and two clinical outcome measures at baseline and after 12 months was observed. Among 151 TA features in all paraspinal muscle groups, only TA feature "mean" of the spinotransverse group showed a significant but weak correlation with worsened SSM (p = 0.046) and TA feature "S(3,3) Entropy" as a measure of altered microarchitecture showed a significant but weak association with worsened walking distance over 12 months (p = 0.046). However, after correction for multiple testing no clear association can be observed.

CONCLUSION

MR TA is a reproducible tool to quantitatively assess paraspinal fatty infiltration, but its association with clinical outcomes in LSS patients is very limited.

CLINICAL RELEVANCE/APPLICATION

MR TA is a reproducible tool to quantitatively assess paraspinal fatty infiltration and mircoarchitectural changes, but its association with clinical outcomes in Lumbar Spinal Stenosis patients is limited.

SST06-09 Optimization of 2nd TE with Subtraction Image Using Ultra-Short TE for the Lumbar Cartilaginous Endplates in Human in Vivo

mika.yanagida@sapmed.ac.jp

PURPOSE

Dual echo acquisition with later echo subtraction has been used for suppressing long T2 signals in ultra-short TE (UTE) imaging.In this study, we evaluated the optimal 2nd TE with subtraction images using UTE for lumbar cartilaginous endplates (CEP) in human in vivo.

METHOD AND MATERIALS

The subjects were 20 patients who had low back pain and degenerative lumbar disorders (12 males, 8 females; average age: 41.3±8.7 years). All subjects were performed with a 3-tesla MR system (Ingenia, Philips Healthcare, The Netherlands) using a dS Torso coil. We used a 3D sequence (TR, 23ms; flip angle, 15°) with fat suppression that UTE was acquired with a phased-encoded stack of spirals trajectory as the first TE and four gradient echoes as the second TE following the first echo. TEs were set at 0.16, 4.6, 9.2, 13.8, and 18.2ms. Scanning was performed around lumbar spine, sagittal slice orientation, 60 slices, 0.94mm×0.94mm×4.8mm voxel size, and 17-minute scan time. Signal intensity of CEP and intervertebral discs (IVD) and vertebral bodies (VB) at the level of L3/L4 in region of interests (ROIs) were measured on the subtraction images (first TE minus second TEs). The ROIs were measured by a research scientist analyzing MR images and a spine surgeon. Furthermore, we calculated the contrast ratio (CR) of CEP/IVD and CEP/VB. To calculate the inter measurers variability, we expressed an intraclass correlation (ICC) with CR. The Friedman test was used for statistical significance, which was set at a p-value of <0.05. All statistics were performed in SPSS version 20.0 (IBM, SPSS Inc.).

RESULTS

CR for CEP/IVD was 47.9±15.5 for 4.6ms, 62.6±21.6 for 9.2ms, 65.8±20.4 for 13.8ms, and 48.5±22.0 for 18.2ms. CR of 9.2 and 13.8ms was significantly higher than that of 4.6 and 18.2ms (p<0.01). Furthermore, CR for CEP/VB was 9.3±4.1 for 4.6ms, 9.5±3.5 for 9.2ms, 18.7±4.3 for 13.8ms, and 22.3±5.8 for 18.2ms. CR of 13.8 and 18.2ms was significantly higher than that of 4.6 and 9.2ms (p<0.01). ICC of two measurers was 0.939 for CEP/IVD and 0.924 for CEP/VB.

CONCLUSION

The optimal 2nd TE with subtraction image was 13.8ms in human CEPs.

CLINICAL RELEVANCE/APPLICATION

Dual echo acquisition with UTE is useful for diagnosing degenerative changes of CEPs such as Modic changes.

PURPOSE

To directly and prospectively compare the TNM staging capability among whole-body co-registered FDG-PET/MRI, MRI with diffusion-weighted imaging (DWI), integrated FDG-PET/CT and conventional radiological examination in patients with malignant pleural mesothelioma.

METHOD AND MATERIALS

23 consecutive pathologically diagnosed malignant mesothelioma patients (14 men, 9 women, mean age 69.2 years old) underwent whole-body MRI including DWI, integrated PET/CTs, conventional radiological examinations, pathological examinations and surgical reports as well as follow-up examinations. TNM staging was evaluated by three different reader groups including radiologists with more than three year experiences of whole-body MRI and PET/CT and nuclear medicine physicians. Kappa statistics were determined for evaluations of agreements of each factor and the clinical stage between each of the methods and final diagnosis. Finally, the diagnostic accuracy of each factor and of determination of the clinical stage was statistically compared with each other by using McNemar's test.

RESULTS

T factor agreements were determined as substantial (PET/CT and conventional examination: kappa value=0.61) or almost perfect (PET/MRI and MRI: kappa value=0.86). N factor agreements were also determined as substantial (PET/CT: kappa value=0.73, conventional examination: kappa value=0.61) or almost perfect (PET/MRI and MRI: kappa value=1.00). M factor assessment, agreements were also determined as moderate (conventional examination: kappa value=0.47), substantial (MRI: kappa value=0.78) or almost perfect (PET/MRI and PET/CT: kappa value=1.00). In addition, clinical stage agreements were determined as substantial (PET/CT and conventional examination: kappa value=0.70) or almost perfect (PET/MRI and MRI: kappa value=0.87). Finally, accuracies of N factor evaluation on PET/MRI and MRI (100 [23/23] %) were significantly higher than that of conventional examination (73.9 [17/23] %, p=0.03).

CONCLUSION

Whole-body PET/MRI and MRI with DWI are potentially more useful for TNM stage assessment than conventional radiological examination, and can be considered at least as effective as PET/CT.

CLINICAL RELEVANCE/APPLICATION

Whole-body PET/MRI and MRI with DWI are potentially more useful for TNM stage assessment than conventional radiological

examination, and can be considered at least as effective as PET/CT.

SST07-02 Prognostic Value of Metabolic Variables of [18F]FDG PET/CT in Surgically Resected Stage I Lung Adenocarcinoma

Friday, Dec. 1 10:40AM - 10:50AM Room: E353C

Participants
Xiaoyi Wang, MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

The objective of this study was to assess the prognostic value of metabolic tumor burden measured by positron emission tomography/computed tomography (PET/CT) in patients with stage I lung adenocarcinoma.

METHOD AND MATERIALS

We reviewed 127 consecutive patients with pathologically proven stage I lung adenocarcinoma who underwent pre-treatment [18F]FDG PET/CT scans in our hospital from 2005 June to 2012 June. The maximum, mean and peak standardized uptake value (SUVmax, SUVmean and SUVpeak), metabolic tumor volume (MTV), total lesion glycolysis (TLG) and computed tomography volume (CTV) were measured. The Kaplan-Meier and Cox proportional hazards model were used with age, gender, TNM stage, clinical stage, histological grade, nodule type, tumor size and metabolic parameters to predict progression-free survival (PFS). The cut-off point was determined through ROC curve.

RESULTS

In univariate analysis, the histological grade, nodule type, diameter (cut-off value of 2.0cm), CTV (6.56cm3), SUVmax (3.25g/ml), SUVmean (1.58g/ml), SUVpeak (1.84g/ml), MTV (4.80cm3) and TLG (10.40) were significantly associated with PFS (all P value <0.05). Patients with poorly differentiated adenocarcinoma, solid nodule type, large size, high metabolic tumor burden were associated with poor prognosis. In multivariate analysis, only histological grade was independent prognostic factors for progression with a P value of 0.005 (RR, 0.355; 95 % CI, 0.173-0.728). Among five PET/CT metabolic parameters, only MTV was independent prognostic factors for progression with a P value of 0.031 (RR, 1.118; 95 % CI, 1.010-1.237).

CONCLUSION

Histological grade was an independent predictor for progression in patients with stage I lung adenocarcinoma. Among five PET/CT metabolic parameters, only MTV was an independent predictor for progression.

CLINICAL RELEVANCE/APPLICATION

Owing to the high heterogeneity, there is quite a limitation in treatment planning and prognosis predicting only based upon TNM stage and pathological type. Recently, several researches have already proved that SUVmax, MTV and TLG had prognostic and predictive value in NSCLC patients. Howerer, previous studies focused primarily on advanced stage disease, few studies have reported the role of those parameters in early stage adenocarcinoma. This study was conducted to document the prognostic role of metabolic tumor burden parameters in patients with stage I lung adenocarcinoma.

SST07-03 Comparison of Different Automated Lesion Delineation Methods for Metabolic Tumor Volume of 18F-FDG PET/CT in Patients with Stage I Lung Adenocarcinoma

Friday, Dec. 1 10:50AM - 11:00AM Room: E353C

Participants
Xiaoyi Wang, MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Defining metabolic tumor volume (MTV) of small and/or low uptake lesions using positron emission tomography/ computed tomography (PET/CT) is usually challenging since the variation is generally high. The aim of this paper is to investigate the suitable segmentation method in small, low uptake and heterogeneous stage I lung adenocarcinoma.

METHOD AND MATERIALS

One-hundred and thirty-three stage I lung adenocarcinoma patients with 2-deoxy-2-[18F]fluoro-D-glucose PET/CT scans were enrolled in this retrospective study. All lesions were divided into different groups according to nodule density (16 non-solid, 30 part-solid and 87 solid), nodule size (53 small lesions with longest diameter <= 20 mm; 80 large lesions with longest diameter >20 mm) and the maximum standard uptake value (SUVmax) level (57 low uptake lesions with SUVmax <= 2; 76 high uptake lesions with SUVmax > 2). The MTVs of the four different PET segmentation methods were evaluated and compared with CT volume (CTV). Percentage volume error (%VE) compared to CTV was calculated and the correlations between MTVs and CTV were analyzed.

RESULTS

The adaptive iterative algorithm (AT-AIA) had the highest accuracy in large, high uptake and solid nodules (72.5%, 72.4% and 65.6%, respectively). The method of adaptive thresholding at 40% SUVmax (AT40%) had the highest accuracy in small, low uptake and non-solid nodules (56.6%, 56.1% and 62.6%, respectively). In part-solid nodules, the accuracy of AT-AIA (60.0%) and AT40% (56.7%) were higher than that of the other two methods. The MTV of AT-AIA was in excellent consistent with the CTV in solid nodules (R=0.831, P=0.000) and in high uptake nodules (R=0.830, P=0.000). The MTV of AT40% was in good consistent with the CTV in non-solid nodules (R=0.686, P=0.003) and in part-solid nodules (R=0.731, P=0.000).

CONCLUSION

AT40% showed best performance in small, low uptake, non-solid and part-solid lesions. AT-AIA was suitable for large, high uptake and solid lesions.

CLINICAL RELEVANCE/APPLICATION

Up to now, defining metabolic tumour volume of small and/or low uptake lesions is still challenging since the variation is generally high. The aim of this study is to investigate the suitable segmentation method in small, low uptake and heterogeneous stage I lung

adenocarcinoma.

SST07-04 Decrease in SUV Max of a Solitary Pulmonary Nodule (SPN) in Dual-Time FDG-PET/CT Imaging: Does it Reliably Exclude Malignancy?

Friday, Dec. 1 11:00AM - 11:10AM Room: E353C

Charles.intenzo@jefferson.edu

PURPOSE

FDG-PET/CT is a well established modality for evaluating indeterminate solitary pulmonary nodules (SPN). Although the sensitivity for detecting malignancy is considered quite high, the specificity is lower. By adding delayed imaging (Dual-Time PET/CT), the specificity for malignancy improves, since malignant SPN increase glucose utilization over time, i.e. an increase by > 10% in the maximum standardized uptake value (SUV Max). By contrast, a decrease or no significant change in SUV Max suggests benign etiology. We observed, however, that it was not uncommon for biopsy-proven malignant nodules to show either no significant change or a decrease in SUV Max on delayed imaging. Our aim was to (1) determine the frequency of this pattern and (2) to correlate with histopathology.

METHOD AND MATERIALS

From 2007 through 2016, we collected all cases of FDG-PET/CT scans used for SPN evaluation in which the final diagnosis was lung malignancy, yet the SUV Max either did not significantly change, or decreased by 10% or more on delayed imaging.

RESULTS

A total of 86 patients met the above criteria, 50 men and 36 women. In 40 of the patients (Group A), the SUV Max decreased by $\geq$ 10%, which was considered a significant decrease. Of these, 23 patients had adenocarcinoma, 4 had squamous cell, 4 had small cell, and 13 had bronchoalveolar (BAC). The remaining 46 patients (Group B) demonstrated either no significant change in SUV Max, or a decrease less than 10%; 15 had adenocarcinoma, 13 had small cell, 7 had BAC, and 11 had squamous cell cancer.

CONCLUSION

(1) Although a significant increase in SUV Max in dual-point FDG PET/CT imaging generally indicates SPN malignancy, a decrease or lack of change in SUV does not necessarily mean a benign etiology. (2) Adenocarcinoma is the most common cell type in which SUV Max decreases or does not significantly change, likely a reflection of tumor differentiation.

CLINICAL RELEVANCE/APPLICATION

A lack of change or a significant decrease in SUV Max over time of an SPN does not exclude malignancy and this pattern is unreliable in SPN evaluation.

SST07-05 18FDG Uptake Patterns by Mediastinal Lymph Nodes and EBUS in the Nodal Staging of Patients with Non-Pulmonary Malignancies

Friday, Dec. 1 11:10AM - 11:20AM Room: E353C

Participants
Socrates Angelides, MBBS, Westmead, Australia (*Presenter*) Nothing to Disclose
Andrew Markewycz, BMedSc, Westmead, Australia (*Abstract Co-Author*) Nothing to Disclose
Josh Escabach, BMedSc, Westmead, Australia (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To retrospectively compare 18FDG-PET scans and EBUS findings in patients with documented mediastinal lymphadenopathy and non-pulmonary primary malignancies.

METHOD AND MATERIALS

25 patients with documented mediastinal lymphadenopathy and non-pulmonary primary malignancies underwent 18FDG-PET scintigraphy followed by EBUS within the ensuing 3 weeks. One-two nodes (n = 29) were assessed in each patient, determined by 18FDG-PET findings and accessibility of the 18FDG-positive nodes. The mediastinal nodal status from each procedure was compared.

RESULTS

EBUS resulted in mediastinal nodal status downgrading in 60% patients. No upgrading was noted. Downgrading most likely occurred when there several non-enlarged lymph nodes of similar 18FDG-avidity distributed randomly and bilaterally in the mediastinum, often with bilateral hilar uptake (~80% of patients). 100% patients with positive EBUS findings for malignant disease demonstrated discrete 18FDG-avid lymph nodes ipsilaterally, with minimal-to-no 18FDG-avid nodes contralaterally. EBUS findings in 20% of patients were inconclusive, despite multiple sampling. Enlarged, rounded lymph nodes with avid FDG uptake (SUV>4) were also more likely to harbour metastatic disease.

CONCLUSION

The pattern of mediastinal 18FDG uptake was highly predictive of metastatic disease, and may circumvent the need for EBUS

evaluation. Prospective analysis of these parameters will be undertaken.

CLINICAL RELEVANCE/APPLICATION

Patterns of 18FDG uptake in mediastinal lymph nodes may circumvent the need for EBUS assessment.

SST07-06 Short TE and Low Flip Angle VIBE Sequence for Lung Evaluation in PET-MRI

Friday, Dec. 1 11:20AM - 11:30AM Room: E353C

PURPOSE

Low-dose CT in standard PET/CT offers a better morphological lung characterization when compared with Dixon sequences in PET/MRI. Our aim is to improve diagnostic accuracy for lung lesions detection with PET/MRI avoiding a significant increase in the acquisition time, adding a short TE (Echo Time) and low FA (Flip Angle) T1-weighted sequence (gradient-echo volumetric interpolated breath-hold examination [VIBE]) to the standard acquisition protocol.

METHOD AND MATERIALS

We enrolled 21 oncological patients (11 M and 10 F) who underwent both thoracic CT scan and 3T PET-MRI (Siemens Biograph mMR) including lung dedicated short TE and low FA VIBE (inspiration, 3 mm slice thickness, axial plane). Time interval between the two examinations was < 2 weeks. VIBE sequences were retrospectively and independently evaluated by two radiologists for the detection of pulmonary nodules, parenchymal consolidations and dense bands; to assess inter-observer agreement Cohen's kappa coefficient (κ) was calculated. Results were then compared with CT scans findings, considered as the gold standard. Sensitivity and specificity were calculated.

RESULTS

VIBE sensitivity in lung nodules evaluation was 80% (8/10 patients) for nodules >5 mm and 57,1 % (4/7 patients) for nodules <= 5 mm, compared to CT imaging. In both cases specificity was 100%. All dense bands and parenchymal consolidation were found both with CT scan and VIBE. Inter-observer agreement was 95 % for nodules >5 mm (κ =0.90, $p<0.001$), 85% for nodules <= 5 mm (κ=0.44 $p<0.005$), 90% for dense bands (κ =0.56, $p<0.001$) and 100% for parenchymal consolidations.

CONCLUSION

VIBE showed high sensitivity in the evaluation of lung nodules > 5 mm; sensitivity was less satisfactory for smaller nodules. This sequence obtained also a very good inter-observer agreement, resulting a very reproducible imaging technique in pulmonary lesion investigation. Considering also the short acquisition time (15-18 s), it seems be reasonable to integrate PET/MRI protocols with a short TE and low FA VIBE, improving its diagnostic performance in lung evaluation.

CLINICAL RELEVANCE/APPLICATION

Short TE and low FA VIBE sequence can improve PET-MRI diagnostic performance in pulmonary lesions detection, without a significant increase in the acquisition time.

SST07-07 Relative Effect Size of Different Clinical & PET Variables on NSCLC Patient's Survival Estimated with Random Survival Forest Model

Friday, Dec. 1 11:30AM - 11:40AM Room: E353C

PURPOSE

To assess relative effect size of the different clinical & PET variables on the overall survival (OS) in patients with non-small cell lung cancer (NSCLC), using permutation Variable Importance (VIMP) measure with a Random Survival Forest (RSF) model.

METHOD AND MATERIALS

A RSF model, which can address right censored data problem, was constructed based on 952 Consecutive NSCLC patients with baseline PET/CT studies, but no brain metastasis or other type of primary cancer (separated into 604 for training and 348 for testing, according to their PET/CT study acquisition scanners). The RSF model included gender, age, race, smoking status, TNM stage (according to the 8th edition of the clinical TNM staging system), histology type, treatment types (with surgery, without surgery and no treatment), and maximum standard uptake value of whole-body tumor (SUVmaxWB) and whole-body metabolic

tumor volume (MTVWB) measured on the PET/CT studies. The overall survival (OS) time served as independent variable. The VIMP, which is a measure of relative importance of parameters on survival (the higher value indicates higher importance), was calculated using permutation method included in the RSF R package (randomForestSRC). The trained RSF model was used to predict the survival rate for the patients in the test dataset and the results were compared to the standard Cox model.

RESULTS

The top 3 highest VIMP coefficients of 0.047, 0.036 and 0.032, were from treatment type, clinical TNM stage and MTVWB, respectively. The coefficient of SUVmaxWB was 0.011. The histology type, race, smoking status and gender had similar coefficients of about 0.003, while age had the smallest VIMP of 0.001. When predicting the test patients' survival rate with the identical variables, our RSF model achieved moderate performance with C-index (a measure of predictive ability of a model) of 0.73, compared to 0.71 by the Cox model.

CONCLUSION

Our model suggests that treatment types, TNM stage and MTVWB are relatively important variables on NSCLC patient's survival, among the commonly used clinical prognostic and PET tumor variables. SUVmaxWB has a moderate effect, while the histology type, race, smoking status, gender and age have small effect on patients overall survival.

CLINICAL RELEVANCE/APPLICATION

This work suggests that treatment type, TNM stage, MTVWB and SUVmaxWB are important prognostic factors useful for the treatment decision making and prognosis of NSCLC patients.

SST07-08 Active Contour-Based Segmentation for 18F-FDG PET Thoracic Oncology: A Powerful Alternative to the Clinical State-of-the-Art Expert-Based Segmentation

PURPOSE

The aim of this study was to assess the performances of an active contour-based user GUI approach for the PET segmentation of complex-shaped lung tumours, in comparison to an optimized expert-based manual reference standard.

METHOD AND MATERIALS

In this retrospective study, 75 complex-shaped lung tumours were blindly segmented using the same graphical user interface (GUI) ITK snap software. For each tumour, four independent raters semi-automatically segmented the 75 tumours twice (sessions 1 and 2) using the active contour based-procedure of the GUI software. A probabilistic estimate of each tumour ground truth was also computed from the set of six independent expert-based manual segmentation results using the Simultaneous Truth And Performance Level Estimate (STAPLE) algorithm. Accuracy of the semi-automatic procedure was assessed by measuring the spatial overlap between the raters segmentation outputs and the corresponding expert probabilistic reference standards, using the DICE similarity coefficient (DSC). Interrater and intrarater reliability analyses were also performed using the intra class correlation coefficients (ICC) estimates of the output volumes,(two-way mixed-model, individual-rating, absolute-agreement). For all tumours segmentation procedures, average time per procedure was also estimated.

RESULTS

Overall accuracy of the user GUI active contour-based procedure was excellent with a DSC of 0.835 (95%CI = 0.775-0.895). Interrater reliabilities provided the following results: ICC = 0.941 (95%CI = 0.913-0.961) for the first session and ICC = 0.935 (95%CI = 0.906-0.956) for the second session. Intrarater reliabilities provided the following results: ICC = 0.993 (95%CI = 0.990-0.996) for the rater 1; ICC = 0.987 (95%CI = 0.976-0.993) for the rater 2; ICC = 0.972 (95%CI = 0.956-0.982) for the rater 3; and ICC = 0.977 (95%CI = 0.964-0.985) for the rater 4. Average time was 631 seconds for manual segmentation procedure, and 130 seconds for active contour-based procedure.

CONCLUSION

Compared to the state of the art expert-based manual segmentation, the GUI-based active contour procedure provided excellent accuracy and reliability, with a mean procedure duration almost five-times faster than the manual reference standard.

CLINICAL RELEVANCE/APPLICATION

Active contour-based segmentation from ITK-snap software is robust, fast, and easy enough to be routinely applied to segment

Active contour based-segmentation from ITK snap software is robust, fast, and easy enough to be routinely applied to segment heterogeneous and complex-shaped lung tumours.

SST07-09 FDG-PET/CT Predicts Development of Thyroiditis due to Immunotherapy for Lung Cancer

PURPOSE

Determine if PET/CT parameters of FDG uptake in the thyroid gland pre-and post-immunotherapy with nivolumab for advanced lung cancer could predict the development of the immune-related adverse event, thyroiditis.

METHOD AND MATERIALS

An IRB-approved retrospective chart review over 2 years found 18 patients with advanced lung cancer treated with nivolumab and with FDG-PET/CT scans pre and post therapy. The post-treatment FDG-PET/CT was performed approximately 6-9 weeks after the first dose of nivolumab. The standardized uptake value (mean and max) and total lesion glycolysis (TLG) of the thyroid gland were measured. Patients obtained monthly thyroid function testing as standard of care while receiving nivolumab. Results of the thyroid testing separated the patients into two groups, patients who developed new hypothyroidism (thyroiditis) and those who did not. Statistical t-test analysis used the FDG-PET/CT parameters to compare the two groups.

RESULTS

In the hypothyroid group, 7 patients developed hypothyroidism after immunotherapy. In the euthyroid group, 9 patients remained euthyroid and 2 patients had a pre-existing history of hypothyroidism (including these 2 did not significantly affect statistics). T-test analysis demonstrated statistically significant higher post-therapy SUVs in the hypothyroid versus euthyroid group. The differences in average values between the two groups were SUV mean 0.77 ($p<0.04$), SUV max 0.96 ($p<0.04$) and TLG 0.96 ($p<0.02$). Pre-therapy SUVs showed no statistical difference. 4 out of 7 patients in the hypothyroid group were euthyroid at the time of the post-therapy PET scan and developed hypothyroidism months later.

CONCLUSION

Nivolumab is an immune checkpoint inhibitor which works by activation of T cells against tumors and is associated with immune-related adverse events like thyroiditis. Increases in FDG uptake in the thyroid gland after immunotherapy indicate inflammation from thyroiditis and therefore predict the development of immunotherapy-induced hypothyroidism, potentially before laboratory testing or development of symptoms.

CLINICAL RELEVANCE/APPLICATION

FDG-PET/CT can predict the development of immunotherapy-induced hypothyroidism and therefore the necessity for thyroid hormone replacement.

jhirsch@umm.edu

PURPOSE

Conductive hearing loss due to ossicular abnormalities occurs from many causes, including trauma, infection, cholesteatoma, surgery and congenital anomalies. Surgical reconstruction of the ossicular chain is a well-established procedure for repair of ossicular defects, but is still plagued by high failure rates. Underlying disease and proper sizing of prostheses are two challenges that lead to component failure. Three-dimensional (3D) printing has been used successfully to solve a number of medical prosthesis problems. Custom 3D printing an individualized ossicular prosthesis would be a potential solution for the wide range of anatomic variation encountered in the pathological middle ear, and could decrease the rate of post-operative prosthesis displacement by increasing the likelihood of a proper fit, in addition to decreasing surgical time.

METHOD AND MATERIALS

The incus was removed from three formalin-fixed cadaveric human temporal bones with no macro- or microscopic evidence of pathology. Imaging of the cadaveric bone was obtained using a standard temporal bone CT protocol. A custom prosthesis for each cadaveric human temporal bone was designed using the Mimics Innovation Suite software (Materialise, Belgium) and fabricated on a Form2 3D printer (FormLabs, Somerville, Massachusetts). Four surgeons then performed insertion of each prosthesis into each middle ear, blinded to the bone from and for which each was designed. The surgeons were asked to match each prosthesis to its correct parent bone.

RESULTS

Each prosthesis had unique measurements. Each of the four surgeons was able to correctly match the prosthesis model to its intended temporal bone. The chances of this occurring randomly are 1:1296.

CONCLUSION

A custom 3D printed ossicular prosthesis is a viable solution for conductive hearing loss due to ossicular chain defects. Commercially available CT scanners can detect significant anatomic differences in normal human middle ear ossicles. These differences can be accurately represented with current 3D printing technology and, more significantly, surgeons can detect these differences.

CLINICAL RELEVANCE/APPLICATION

This process overcomes a common technical challenge of properly sizing the prosthesis, as each model is custom made for an exact fit which should lead to an improved result and decreased operative time.

SST08-02 Assessment of Microvascular Compression for Facial-Acoustic Nerves: Role of Combined Isotropic 3D T2-DRIVE and 3D TOFMRA

Friday, Dec. 1 10:40AM - 10:50AM Room: E353A

jiang_raphael@hotmail.com

PURPOSE

To evaluate the application value of isotropic 3D T2-DRIVE combining isotropic 3D TOFMRA in detecting microvascular compression for facial-acoustic nerves.

METHOD AND MATERIALS

Thirty-six patients were enrolled in the study with clinically suspected vascular compression of facial-acoustic nerves, of which both 3D T2-DRIVE and 3D TOFMRA sequences images were obtained of isotropy and identical voxel size at 0.7 mm×0.7 mm×0.7 mm. Source images and reformatted images were observed to evaluate the effects on demonstration of facial-acoustic nerves and culprit vessels, which was scored from 0 to 3 points in the order from poor to excellent. The differences were compared of effects on displaying both the facial-acoustic nerves and culprit vessels among the three approaches of 3D T2-DRIVE, 3D TOFMRA, and 3D T2-DRIVE+3D TOFMRA. The Kruskal-Wallis H test was employed in data processing, with $P<0.01$ for the statistically significant difference.

RESULTS

In displaying facial-acoustic nerves, 3D T2-DRIVE+3D TOFMRA and T2 3D-DRIVE were superior to 3D TOFMRA (H=58.78, P=0.0000. H=53.18, P=0.0000.respectively), and no statistically significant difference existed between 3D T2-DRIVE+3D TOFMRA and T2 3D-DRIVE (H=2.28, P=0.1313). In displaying culprit vessels, 3D-T2-DRIVE+3D TOFMRA was superior to T2 3D-DRIVE and 3D TOFMRA (H=54.12,P=0.0000. H=62.42, P=0.0000. respectively), and no statistically significant difference existed between 3D T2-DRIVE and 3D TOFMRA (H=0.0083, P=0.9274). Of 36 patients, 32 were detected with arteriolar compression for facial-acoustic nerves by the approach of 3D T2-DRIVE combining 3D TOFMRA, and 4 with no compression. The results were confirmed by surgical findings or clinical follow-up, respectively. The sensitivity and specificity was 100%, 100% of 3D T2-DRIVE+3D TOFMRA in diagnosing microvascular compression for facial-acoustic nerves, respectively.

CONCLUSION

The combination of isotropic 3D T2-DRIVE and isotropic 3D TOFMRA provides a precise and accurate diagnostic approach in identifying micorvascular compression for facial-acoustic nerves.

CLINICAL RELEVANCE/APPLICATION

Combined isotropic 3D T2-DRIVE and 3D TOFMRA has advantage over isotropic 3D T2-DRIVE in detecting micorvascular compression for facial-acoustic nerves, and over isotropic 3D TOFMRA as well. The approach could be widely utilized in the radiologically diagnostic scenario of potential microvascular compression for cranial nerves.

SST08-03 Static and Dynamic Evaluation with MRI of Larynx and Oro-Pharingeal Cavity in Professional Opera Singers

Friday, Dec. 1 10:50AM - 11:00AM Room: E353A

Participants
Marco Di Girolamo, MD, Rome, Italy (*Presenter*) Nothing to Disclose
Paolo Bonome, Rome, Italy (*Abstract Co-Author*) Nothing to Disclose

digirolamomarco@hotmail.com

PURPOSE

To assess the anatomical configuration of phonetic organs by MRI in professional opera singers with different vocal range.

METHOD AND MATERIALS

26 professional opera singers (12 men (7 tenors and 5 basses) and 14 women (8 sopranos and 6 mezzosopranos) were evaluated with MRI. We performed both static and dynamic study with MRI. The static study was performed with TSE T2-weighted axial scans at the level of larynx (TR:2000 ms; TE:120ms; slice thick:3mm) in order to evaluate the area of superior surface of vocal cord. In the dynamic study, the singers were asked to perform a prolonged vocalization at a confortable tonality of the fundamental vowel a. We performed a midsagittal Turbo Field Echo scan (TR:12ms; TE:6ms; fa:30°; acq.time:6s) at the level of the oro-pharyngeal cavity measuring the area of the mouth and pharyngeal lumen. These data underwent statistical evaluation using the Mann-Whitney U-test (non-parametric test) considering: 1) vocal tessitura; 2) size of the vocal cord; 3) area of the mouth and pharyngeal lumen during the utterance of the vowel a.

RESULTS

The average size of the vocal cord was: 0.71 cm2 for sopranos; 1.20 cm2 for mezzosopranos; 1.58 cm2 for tenors; 2.88 cm2 for basses. The average area of mouth and pharyngeal lumen on midsagittal scan during the utterance of the vowel a was: 15.8 cm2 for sopranos; 14.6 cm2 for mezzosopranos; 23.6 cm2 for tenors; 32.2 cm2 for basses. We found that the differences in vocal cord size between sopranos and mezzosopranos (P: 0.0641) and between tenors and basses (P: 0.0833) are tendentially statistically significant. The variation in vocal tract size during the utterance of the vowel a between tenors and basses is considered tendentially statistically significant (P: 0.0833) while the difference between sopranos and mezzosopranos is not considered statistically significant (P: 0.6434). The difference in the vocal register between soprano and mezzosoprano is less considerable in comparison with tenor and bass or with soprano and contralto.

CONCLUSION

Our results demonstrate a correlation between the surface of the vocal cord and the configuration of vocal tract and the vocal tessitura of a singer.

CLINICAL RELEVANCE/APPLICATION

Long vocal cord and wide vocal tract are characteristic of singers with low-pitched voice types (bass, baritone, contralto) while short vocal cord and narrow vocal tract are characteristic of singers with high-pitched voice types (tenor, soprano).

SST08-04 Basic Consideration for Facial Aging: Anatomic and Radiological Analysis of the Superficial Musculoaponeurotic System (SMAS)

Friday, Dec. 1 11:00AM - 11:10AM Room: E353A

Participants
Itsuko Okuda, MD, Minato-Ku, Japan (*Presenter*) Nothing to Disclose
Masahiro Irimoto, MD, Kunitachi, Japan (*Abstract Co-Author*) Nothing to Disclose
Yasuo Nakajima, MD, Kawasaki, Japan (*Abstract Co-Author*) Nothing to Disclose
Katsuhiro Abe, Minato-ku, Japan (*Abstract Co-Author*) Nothing to Disclose
Keiichi Akita, MD, PhD, Tokyo, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Facial aging is caused not only by skin aging, but also by aging changes of the subcutaneous structures. The SMAS is situated in the superficial fascia. SMAS weakness was reported as one factor of cheek sagging related with facial aging. The purpose of this study is to analyze the anatomic radiological correlation of the SMAS, and establish CT findings of the SMAS.

METHOD AND MATERIALS

This retrospective study was approved by the institutional review board. Step 1: five cadaver faces were used to confirm the morphology and distribution of the SMAS. Right halves of those were dissected, and examined the structures of SMAS. The left were used for cross-sectional anatomic and histological examinations. Step 2: To select the interpretation sites of the SMAS, the SMAS's findings of the cadaveric studies were compared to the CT findings. Step 3: To confirm CT findings of SMAS, CT images of 18 females (age range, 21-82 years) without lesions that would influence the superficial structures of their faces were enrolled. Two observers assessed CT findings of the SMAS independently, and the criteria was used for the following three-grade scales: G-2 (entire visualization as a thick layer); G-1 (entire visualization as a thin layer); or G-0 (obscured or partial visualization as a thin layer). The interobserver differences were assessed by kappa coefficient.

RESULTS

The SMAS was observed as a subcutaneous fibro-membranous structure extending from the superficial temporal fascia to the parotid fascia, and contained the major and minor zygomatic muscles and platysma. CT showed the subcutaneous linear opacities corresponding to the fibro-membranous structures of the cadaveric studies. Among the 18 cases, observer 1 judged G-2:11, G-1:7, G-0:0. Observer 2 judged G-2:13, G-1:5, G-0:0. There was good agreement between 2 observers about CT findings of SMAS (kappa=0.75, p **CONCLUSION**

The SMAS is a definite anatomic structure that can be demonstrated as an anatomic membranous layer in subcutaneous adipose tissue from the superficial temporal fascia to the parotid fascia on CT. This analysis is applicable to evaluating age-related changes of the face, and can contribute to the elucidation of the mechanism of facial aging.

CLINICAL RELEVANCE/APPLICATION

CT is the useful tool to evaluate the SMAS that is important structures to maintain a young appearance, and clinical applications can contribute to the elucidation of the mechanism for facial aging.

SST08-05 CT Texture Analysis of Lymphoid Tissues on FDG-PET/CT in HIV-positive Patient

Friday, Dec. 1 11:10AM - 11:20AM Room: E353A

PURPOSE

Differentiating lymphoid malignancy from reactive lymphoid tissue in HIV-infected patients with 18F-FDG PET/CT can be challenging as increased FDG uptake secondary to inflammation and infection may cause false-positive results for assessment of lymphoid tissue, such as palatine tonsils. The purpose of this study was to assess the utility of CT texture analysis characteristics of lymphoid tissues in HIV-positive patients on 18F-FDG-PET/CT in making the distinction between malignancy and non-neoplastic process with increased FDG uptake.

METHOD AND MATERIALS

Fifty-eight HIV-positive patients (age 9-80 years; median age, 48 years; median absolute CD4 count, 237 cells/mm3 [range; 17-1900]) who underwent contrast-enhanced CT with 18F-FDG-PET for various reasons were retrospectively reviewed. The whole normal right palatine tonsil was segmented on CT and texture analysis was performed using an in-house MATLAB-based texture analysis program. Forty-two texture features were extracted, including histogram-based, gray-level co-occurrence matrix-based (GLCM), gray-level run-length-based features (GLRL), gray level gradient matrix (GLGM), and Laws' features from the segmented volume. SUVmax values of the right palatine tonsil were obtained by manual selection of the lymphoid tissue at a PET/CT workstation. Multiple regression analyses were performed to assess the association between 42 texture features and the SUVmax value in palatine tonsil with adjustments for age and absolute CD4 cell counts.

RESULTS

The median SUVmax in normal tonsil of HIV positive patients was 4.4 (range, 1.2-10.4). Significant correlation were seen in 2 GLCM features [entropy (*P*=.039) and homogeneity (*P*=.008)], 7 GLRL features [RP (*P*=.018), LGRE (*P*=.019), HGRE (*P*=.018), SRLGE (*P*=.019), SRHGE (*P*=.001), LRLGE (*P*=.001), LRHGE (*P*=.003), 7 Law's features [L1 (*P*=.040), L2 (*P*=.002), L3 (*P*=.033), L4 (*P*=.003), L5 (*P*=.043), L7 (*P*=.042) L9 (*P*=.037)] and 4 GLGM features [MGR (*P*<.001), VGR (*P*<.001), skewness (*P*<.001) and kurtosis (*P*<.001)] with tonsil SUVmax value. There was no significant correlation between texture features and absolute CD4 cell counts in this model.

CONCLUSION

Lymphoid tissue CT texture analysis parameters are associated with abnormal FDG uptake in patients with HIV.

CLINICAL RELEVANCE/APPLICATION

CT texture analysis may be used as a type of noninvasive imaging biomarker capable of detecting obscure lymphoid inflammation in HIV positive patient.

SST08-06 Ultrasound and Clinicopathological Features of Papillary Thyroid Carcinomas with BRAF and TERT Promoter Mutations

Friday, Dec. 1 11:20AM - 11:30AM Room: E353A

Participants
Soo Yeon Hahn, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Jung Hee Shin, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Hankyul Kim, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Jooyeon Cho, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Seung Mi Ha, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Solbee Han, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To investigate if any relationship exists between the telomerase reverse transcriptase (TERT) promoter or BRAF mutation and ultrasound (US) and clinicopathological features of papillary thyroid carcinomas (PTCs).

METHOD AND MATERIALS

The Institutional Review Board approved the study protocol and the use of human thyroid tissue. The study included 150 patients with surgically confirmed PTC from October 1994 to December 2004. The mean clinical and imaging follow up periods were 149.6 ± 24.6 and 143.1 ± 34.5 months, respectively. According to the existence of TERT promoter or BRAF mutations, we categorized patients into three groups (no mutation, BRAF mutation alone, or TERT+BRAF mutations) and analyzed the relationships between TERT promoter or BRAF mutation and US and clinicopathological features using uni- and multinomial logistic regression analysis and Cochran-Armitage trend test. The rate of recurrence or death according to mutation analysis was estimated by the Kaplan-Meier method.

RESULTS

There were 35 (23.3%) cases with no mutation, 104 (69.3%) with BRAF mutation alone, and 11 (7.3%) with TERT+BRAF mutations. According to the results of the Cochran-Armitage trend test, as the number of genetic mutations increased from no mutation to BRAF mutation alone to both BRAF and TERT mutations, the proportions of hypoechogenicity (31.4% vs. 66.4% vs. 54.5%, P = .0066), non-parallel orientation (25.7% vs. 49.0% vs. 72.7%, P = .0023), spiculated/microlobulated margin (45.7% vs. 51.9% vs. 90.9%, P = .0364), microcalcifications (62.9% vs. 72.1% vs. 90.9%, P = .0822), and K-TIRADS category 5 (48.6% vs. 71.1% vs. 63.6%, P = .0670) increased. PTCs with TERT+BRAF mutations recurred more frequently than other groups (odd ratio [OR] = 17.921 and 31.468). The intervals to recurrence and overall survival were significantly shorter in the TERT+BRAF mutation group than in the other groups (P < .0001 and P < .0001).

CONCLUSION

PTCs with no mutation, with BRAF mutation alone, and with both TERT and BRAF mutations linearly increase in the probability of displaying malignant US features. In PTCs, the coexistence of BRAF with TERT mutations is more strongly correlated with recurrence and mortality than BRAF mutation alone.

CLINICAL RELEVANCE/APPLICATION

US imaging characteristics of PTCs based on molecular biomarkers including BRAF and TERT promoter mutations can serve as predictors of patient prognosis.

SST08-07 Oral Carcinoma: Clinical Evaluation using Diffusion Kurtosis Imaging and its Correlation with Histopathologic Findings

PURPOSE

To determine the clinical usefulness of diffusion kurtosis imaging (DKI) for patients with oral carcinoma as a noninvasive method of evaluating the histologic grades of oral carcinomas and lymph node metastasis by oral carcinomas.

METHOD AND MATERIALS

Twenty patients with oral carcinoma were examined with a 3-T MR system equipped with a 16-channel head and neck coil. DKI data were obtained by using a spin echo-based single-shot echo-planar imaging sequence: repetition time, 10000 ms; echo time, 94 ms; field of view, 250 mm x 204.25 mm; matrix, 120 x 98; section thickness, 4 mm without intersection gaps; four b values of 0, 500, 1000, and 2000 s/mm2; and motion-probing gradients set along three orthogonal directions. Diffusivity (D) and kurtosis (K) were calculated by using the equation: $S = S0 \bullet \exp(-b \bullet D + b2 \bullet D2 \bullet K/6)$, and standard apparent diffusion coefficient (ADC) was also calculated by using the conventional monoexponential fit. The MR images were then compared with the histopathologic findings as the reference standard.

RESULTS

In all 20 oral carcinomas, the diffusivity was calculated as 1.777 ± 0.377 x 10-3 mm2/s, kurtosis 0.839 ± 0.130 (arbitrary unit [a.u.]), and ADC 0.790 ± 0.089 x 10-3 mm2/s. With the histologic grades (Grades 1, 2, and 3) of the oral carcinomas, the diffusivity showed a statistically significant inverse correlation ($r = -0.893$; $P < 0.001$) and the kurtosis showed a statistically significant positive correlation ($r = 0.851$; $P < 0.001$), while the ADC showed no significant correlation ($r = -0.341$; $P = 0.196$). Furthermore, between metastatic lymph nodes and nonmetastatic lymph nodes, the diffusivity (1.365 ± 0.395 vs. 1.985 ± 0.540 x 10-3 mm2/s; $P < 0.05$) and kurtosis (1.110 ± 0.242 vs. 0.746 ± 0.078; $P < 0.01$) showed statistically significant differences, while the ADC (0.726 ± 0.071 vs. 0.787 ± 0.056 x 10-3 mm2/s; $P = 0.127$) showed no significant differences.

CONCLUSION

In patients with oral carcinoma, DKI seems to be clinically useful for evaluating the histologic grades of oral carcinomas and lymph node metastasis by oral carcinomas.

CLINICAL RELEVANCE/APPLICATION

By using DKI for patients with oral carcinoma, we may have an effective tool to noninvasively diagnose the histologic grades of oral carcinomas and lymph node metastasis by oral carcinomas.

SST08-08 Computed Diffusion Weighted Imaging with Noise Reduction: Utility in Diagnosing Middle Ear Cholesteatoma

Friday, Dec. 1 11:40AM - 11:50AM Room: E353A

Participants
Koji Yamashita, MD, PhD, Fukuoka, Japan (*Presenter*) Nothing to Disclose
Akio Hiwatashi, MD, Fukuoka, Japan (*Abstract Co-Author*) Nothing to Disclose

Taro Takahara, MD, PhD, Isehara, Japan (*Abstract Co-Author*) Nothing to Disclose
Hiroshi Honda, MD, Fukuoka, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate whether computed DWI (cDWI) with noise reduction increases the contrast-to-noise ratio (CNR) compare to that without noise reduction algorithm in middle ear cholesteatoma.

METHOD AND MATERIALS

This retrospective study was approved by the institutional review board, and the requirement for informed consent was waived. Consecutive patients diagnosed with suspected cholesteatoma who underwent preoperative MR imaging between October 2014 and August 2016 were eligible for inclusion. cDWI (b = 800 sec/mm2) was generated from two b-values of 0 and 400 sec/mm2 by voxel wise fitting on a 3D workstation (Ziostation2). Noise reduction was performed by the cutoff values of ADC < 0 (ADC0) and 0.4 × 10-3mm2/sec (ADC0.4). Region-of-interests were manually placed on the cholesteatoma and background, respectively. Subsequently, the CNR was compared between ADC0, ADC0.4, and the control (without noise reduction algorithm) using one-way ANOVA followed by the Bonferroni correction for multiple comparison.

RESULTS

The study group consisted of 25 patients (M:F = 14:11, median age = 51 years). The CNR of ADC0 (mean ± SD = 6.72 ± 1.77) and ADC0.4 (mean ± SD = 7.00 ± 2.21) were significantly higher than those of the control (mean ± SD = 5.17 ± 1.43; $p < 0.01$ and $p < 0.001$, respectively).

CONCLUSION

The cholesteatoma-background CNR was increased using a noise reduction algorithm for cDWI.

CLINICAL RELEVANCE/APPLICATION

The computed DWI (cDWI) with noise reduction algorithm may be useful to distinguish cholesteatoma from adjacent soft tissues such as granulation or fibrous tissue. The increase of CNR could improve in the diagnostic accuracy of cholesteeatoma.

SST08-09 Intravoxel Incoherent Motion Magnetic Resonance Imaging of the Normal-Appearing Parotid Glands in Patients with Differentiated Thyroid Cancer After Radioiodine Therapy

Friday, Dec. 1 11:50AM - 12:00PM Room: E353A

Participants
Xiao_quan Xu, Nanjing, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

xiaoquanxu_1987@163.com

PURPOSE

Radiation damage to the salivary gland is a common complication of radioiodine therapy (RIT) in the patients with differentiated thyroid cancer (DTC). To investigate the feasibility of using intravoxel incoherent motion (IVIM) magnetic resonance (MR) imaging to detect radiation-induced changes of normal-appearing parotid glands in the patients after RIT for DTC.

METHOD AND MATERIALS

We prospectively enrolled 20 patients with RIT-induced sialoadenitis and 20 healthy control (HC) participants. The patients were divided into intermediate and late groups, and questionnaire was used to assess the related symptoms. IVIM MR imaging was scanned using 9 b values (0, 50, 100, 150, 200, 400, 600, 800 and 1000 sec/mm2). Quantitative parameters (pseudodiffusion coefficient, D*; perfusion fraction, f; tissue diffusivity, D) were obtained using a biexponential model, and compared among different groups using one-way analysis of variance (ANOVA) test. Correlations between significant parameters and symptom score were assessed using Spearman's correlation analysis.

RESULTS

The f and D value differed significantly (f, P=0.016; D, P=0.006) among different groups. Post hoc analysis showed that f and D value of intermediate group were significantly higher than those of HC group (f, P=0.012; D, P=0.004), while no significant differences between late group and HC group (f, P=0.852; D, P=0.707). Significant positive correlation was found between f value and the total symptom score of the patients in intermediate group (P=0.028, r=0.762).

CONCLUSION

The IVIM MR imaging might be feasible to detect the radiation-induced changes of parotid glands in the patients after RIT for DTC.

CLINICAL RELEVANCE/APPLICATION

Our study showed that both the perfusion fraction f and tissue diffusivity D of intermediate group were higher than the HC group. Perfusion fraction f had a significant correlation with symptom score. Our study results demonstrated that IVIM MR imaging was feasible to detect the radiation-induced changes of parotid glands of the patients after radioiodine therapy for DTC.

wanghong730326@163.com

PURPOSE

To investigate the influence of cerebral blood flow in preterm with perinatal asphyxia using multiple inversion time arterial spin labeling(mTI-ASL) technique.

METHOD AND MATERIALS

A total of 40 preterm infants at term-equivalent age underwent MRI examination in the study. A MRI examination including mTI-ASL prototype sequence and other conventional plain sequences was performed on MAGNETOM Skyra (Siemens Healthcare, Erlangen, Germany). According to clinical history and MR diagnosis, 40 preterm infants were divided into three groups: group1 (n=14, no brain injury without perinatal asphyxia), group 2 (n=12, no brain injury with perinatal asphyxia) and group 3 (n=14, brain injury with prenatal asphyxia). Mean cerebral blood flow(CBF) values from ROIs drawn in the basal ganglia and thalami (BGT), gray matter (GM) including frontal lobe, temporal lobe and occipital lobe, and white matter (WM)were calculated and analyzed by SPSS 21.0 statistical software. CBF values for each ROIs were analyzed by one-way ANOVA across groups. And then if $P < 0.05$, q test for multiple comparison with SNK would be conducted.

RESULTS

The difference of CBFBGT and CBFGM was statistically significant between Group 1 and Group 2 ($P < 0.05$). The differences of CBFBGT, CBFGM and CBFWM were statistically significant between Group 2 and Group 3 (CBFBGT: $P < 0.01$; CBFGM, CBFWM: $P < 0.05$). However, the difference of CBFWM between Group 1 and Group 2 was not statistically significant. And CBFBGT, CBFGM, CBFWM between Group 1 and Group 3 were not statistically significant. In group1, the difference of CBF was statistically significant between frontal lobe and occipital lobe, between temporal lobe and occipital lobe, whereas the difference of CBF was not statistically significant between frontal lobe and temporal lobe.

CONCLUSION

mTI-ASL is a noninvasive MR method for accurately measuring CBF in neonates. Autoregulation of the cerebral blood flow has association with the outcome of preterm infants with perinatal asphyxia. Perinatal asphyxia may affect the regional regulation of CBF in gray matter.

CLINICAL RELEVANCE/APPLICATION

mTI-ASL is a feasible approach to measuring brain perfusion and it offers the possibility to investigate the impact of cerebral hemodynamics in high-risk preterm infants.

SST09-02 Acute Ischemic Stroke in Patients Younger than 18: Why Not Wide the Therapeutic Window for Mechanical Thrombectomy?

carmenparrafarinas@gmail.com

PURPOSE

This study aimed to analyze the safeness and effectiveness of endovascular approach in pediatric intracranial recanalization and to propose a diagnostic and therapeutic algorithm for patients younger than 18 with acute ischemic stroke based on our experience.

METHOD AND MATERIALS

We studied patients prospectively included in SONIIA registry (2011-2015), a mandatory, externally audited registry that monitors the quality of reperfusion therapies in Catalonia. Clinical evaluation: neurological severity, functional independence. Radiological examination: multimodal CT/MRI. Treatment criteria: clinical-radiological mismatch. Analysis and outcome parameters: successful recanalization (TICI >=2b), dramatic neurological improvement (>=10 points decrease in NIHSS score at 24 hours), independent functional outcome (mRS <=2) at three months.

RESULTS

Among the 1640 patients included, mechanical thrombectomy occurred in five. Mean age was 14.6±1.6, four female. Median NIHSS score: 13 (7-19) on arrival, 4 (1-5) at 24 hours. Underlying diseases: Osler-Weber-Rendu (n=1), congenital heart defect (n=1), none (n=3). Etiology: iatrogenic (n=1), non-compliance of anticoagulation (n=1), idiopathic (n=3). Clinical presentation: hemiparesis (n=4), aphasia (n=1). We used the neuroimaging standard protocol during acute ischemic stroke: multimodal CT (n=3), multimodal MRI (n=2). Occlusion site: internal carotid artery (n=2), middle cerebral artery (n=2), basilar artery (n=1). We combined stent-retriever technology plus distal aspiration in four patients (median number of passes: 2), direct aspiration first pass technique in one (duration of aspiration: 30 s). Procedural time: 68.4±26.4 min. All patients achieved successful recanalization. All procedures resulted in functional independence. No complications were reported.

CONCLUSION

The presence of a clinical-radiological mismatch in acute ischemic stroke patients younger than 18 should let us consider an "aggressive treatment", such as mechanical thrombectomy, as it allows safe, effective, and prompt recanalization. The MRI should be the diagnostic technique in all types of stroke, diagnosing underlying conditions while reducing radiation exposure.

CLINICAL RELEVANCE/APPLICATION

Acute ischemic stroke in children is difficult to diagnose and manage due to atypical presentation and imaging challenge. There is a lack of evidence-based data concerning mechanical thrombectomy for patients younger than 18 years old.

SST09-03 Multi-Delay Arterial Spin Labeling MRI in Neonates: Regional Differences and Changes in Brain Perfusion during Brain Maturation

catharina315@aumc.ac.kr

PURPOSE

The purpose of this study was to evaluate cerebral blood flow (CBF) in neonates using multi-delay arterial spin labeling (ASL).

METHOD AND MATERIALS

A 7 post-labeling delay pseudo-continuous ASL was applied on 20 neonates (6 preterm vs. 14 term-equivalent age [TEA]) and 4 infants (mean age, 3 months). We adjusted longitudinal relaxation rate of blood in each patient with hematocrit values. CBF in the thalamus, frontal gray matter (F_GM), occipital gray matter (O_GM), frontal white matter (F_WM), and occipital white matter (O_WM) were measured in ml/100g min and relative CBF (rCBF) to that of the whole brain CBF (wbCBF) were calculated.

RESULTS

In all neonates, CBF of O_WM was significantly higher than F_WM (16.5ml/100g min vs. 12.2ml/100g min, p = .001), but CBF of O_GM and F_GM showed no significant difference (26.2ml/100g min vs. 27.5ml/100g min, p = .253). Mean wbCBF significantly increased from 13.4ml/100g min at preterm to 18.0ml/100g min at TEA (p = .009) and it further increased to 32.8ml/100g min at 3 months (p = .001). From preterm to TEA, there was significant decrease of rCBF of thalamus (252% to 197%, p = 0.02) and F_GM (160% to 122%, p = .026) and significant increase of rCBF of O_GM (163% to 125%, p = .015). From TEA to 3 months, rCBF were significantly decreased in thalamus (197% to 140%, p = .046), F_WM (108% to 57%, p = .001), and O_WM (139% to 79%, p = .003).

CONCLUSION

Multi-delay ASL showed differences and changes in regional CBF in neonates and infants, which may reflect metabolic and developmental stages of brain.

CLINICAL RELEVANCE/APPLICATION

Multi-delay ASL can be a non-invasive tool to study brain maturation in neonates.Cerebral perfusion changes by hypoxic ischemic injury in neonates can further investigated with multi-delay ASL.

SST09-04 Expression Changes in Lactate and Glucose Metabolism and Associated Transporters in Basal Ganglia Following Hypoxic-Ischemic Reperfusion Injury in Piglets

Friday, Dec. 1 11:00AM - 11:10AM Room: E350

Participants
Yang Zheng, Shenyang, China (*Presenter*) Nothing to Disclose
Xiaoming Wang, MD, Shenyang, China (*Abstract Co-Author*) Nothing to Disclose

zhengyang19871114@163.com

PURPOSE

To investigate the regulatory mechanisms of energy metabolism in neurons and astrocytes in the basal ganglia of a neonatal hypoxic-ischemic brain injury piglet model.

METHOD AND MATERIALS

A total of 35 healthy piglets (3-5 days old, 1.0-1.5 kg) were selected. They were divided into control (n=5) and hypoxic-ischemic (HI) model groups. The HI model group was further divided into six groups according to 1H- MRS and PET/CT scan times after HI (0-2 h, 2-6 h, 6-12 h, 12-24 h, 24-48 h and 48-72 h; n = 5/group). The HI model was established by bilateral common carotid artery occlusion and simultaneous hypoxia treatment for 40 min. Piglets in the control group received the same surgical procedure without the hypoxia-ischemia process. 1H-MRS and 18F- FDG PET/CT imaging were performed at various time points after HI. The right basal ganglia were the ROI in 1H-MRS imaging for which data was processed by LCModel software. The bilateral basal ganglia (BG) and occipital cortex (OC) on the same slide were selected as the ROI for PET/CT imaging. Maximum standard uptake values (SUVmax) of basal ganglia to occipital cortex (BG/OC) ratios were determined. The right hemisphere was used for the pathological examination and immunohistochemical staining of glucose transporters (GLUTs) and monocarboxylate transporters (MCTs). The left hemisphere was immediately frozen at -80ºC for western blotting.

RESULTS

The lactate level became reduced after an initial increase, with the maximal level occurring around 2-6 h following HI. After HI, the BG/OC in the basal ganglia initially increased then decreased; the maximum value occurred at approximately 6-12 h. The content of lactate and the BG/OC showed a positive correlation ($r = 0.74$, $P=0.003$). The expression of GLUT-1 and GLUT-3 correlated positively with BG/OC ($r = 0.64$, $P=0.014$, and $r = 0.75$, $P=0.036$, respectively).

CONCLUSION

These results indicate that lactate and glucose transporters have a synergistic effect on the energy metabolism of neurons and astrocytes following hypoxic-ischemic reperfusion brain injury.

CLINICAL RELEVANCE/APPLICATION

The HI model monitor the regulatory mechanisms of energy metabolism after HI.

SST09-05 3D Ultrasound Provides Accurate Tonsillar Volumes to Assess Hypertrophy

Friday, Dec. 1 11:10AM - 11:20AM Room: E350

Participants
Daniel I. Chung, MD, Washington, DC (*Presenter*) Nothing to Disclose
Anjum Bandarkar, MD, Washington, DC (*Abstract Co-Author*) Nothing to Disclose
Pooneh Tabrizi, Washington, DC (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Each year, there are millions of hospital visits in the United States for obstructive sleep apnea (OSA), a disease that is primarily caused by adenotonsillar hypertrophy. Adenotonsillectomy (T&A) is an effective solution for OSA and the second most common surgical intervention in the country. We investigated the ability of 3D ultrasound (3DUS) imaging with quantitative imaging analysis to safely, accurately and objectively assess tonsillar hypertrophy for the potential identification of candidates for adenotonsillectomy.

METHOD AND MATERIALS

A prospective study was performed evaluating patients (N=17) undergoing T&A for OSA symptoms ranging from 4-14 years with a mean of 7.8. Tonsillar imaging was performed by an attending radiologist using the Philips iU22 3DUS system with xMatrix probe. The volume and two principal axes (width and height) of the left and right tonsils were determined from 3DUS using ITKSnap software. The tonsils were then removed the same day in the operating room and immediately assessed by measuring the two principal axes of each tonsil using a Neiko 0417A Electronic Digital Caliper. The physical volume was then obtained by water submergence in a graduated cylinder. The findings from 3DUS and physical examination of the tonsils were compared using Bland-Altman analysis to determine their agreement (mean) and bias (mean+/-1.96 SD). Significance was assessed using the Wilcoxon signed-rank test.

RESULTS

The average tonsillar physical measurements of width and height were 20+/-3.2 mm and 27.23+/-41.4 mm, and 16.11+/-2.14 mm and 29.76+/-27.75 mm from 3DUS estimations, respectively ($p < 0.001$ for both). The average tonsillar volume was 3.84+/-1.23 ml and 4.29+/-1.14 ml from physical and 3DUS measurements, respectively ($p=0.09$). The Bland-Altman agreement +/- bias of the measured width, height, and volume results from the two measurements were -3.92+/-6.33 mm, 2.5+/-7.71 mm, and 0.45+/-2.32 ml, respectively.

CONCLUSION

We demonstrated the potential of 3DUS with quantitative imaging analysis to safely, accurately and objectively estimate tonsillar volume for assessing hypertrophy. 3DUS tonsil volumes were similar to physical measurements and more reliable than 2D measures of width and height.

CLINICAL RELEVANCE/APPLICATION

3DUS with quantitative imaging is an effective tool to objectively evaluate the tonsillar dimensions. This will allow for a more accurate selection for candidates for adenotonsillectomy.

SST09-06 What is the Optimal Needle Gauge and Injection Rate for Contrast Enhanced Ultrasound in the Evaluation of Therapeutically Cooled Neonatal Brains after Hypoxic Ischemic Injury?: Preliminary Data from an Experimental in Vitro Study

Friday, Dec. 1 11:20AM - 11:30AM Room: E350

Participants
Matthew Thimm, Baltimore, MD (*Presenter*) Nothing to Disclose
Misun Hwang, MD, Pittsburgh, PA (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

mhwang11@jhmi.edu

PURPOSE

Therapeutic hypothermia for hypoxic-ischemic encephalopathy (HIE) in neonates is used to reduce morbidity and mortality. However, optimum ultrasound (US) contrast delivery under therapeutic hypothermia is not well known. We aimed to quantify microbubble contrast intensity under these temperature conditions to determine optimal microbubble delivery.

METHOD AND MATERIALS

We injected Lumason® contrast agent into saline bags using 22 and 25-G needles under different injection rates: 0.1 mL/sec, 0.3 mL/sec, and 0.5 mL/sec. We performed injections at both 37ºC and 33.5ºC to reproduce normothermia and hypothermia conditions, respectively. We qualitatively evaluated for homogenous mixing and quantitatively assessed microbubble intensity with QLab US contrast quantification software installed on a Philips EPIQ scanner.

RESULTS

We found that 22-G needles yielded significantly higher peak intensities than 25-G needles ($p=0.0495$). Using 22-G needles, an injection rate of 0.3 mL/sec was optimal at 37ºC, and a rate of 0.5 mL/sec was optimal at 33.5ºC. There was no significant difference in the distribution of peak intensities between the two temperature groups using 22-G needles ($p=0.2752$). Using 25-G needles, an injection rate of 0.5 mL/sec was optimal at 37ºC, but at 33.5ºC no injection rate appeared most optimal. Additionally, using 25-G needles, the peak intensities at 37ºC were significantly higher than at 33.5ºC ($p=0.0495$).

CONCLUSION

The temperature reduction significantly impacted microbubble behavior, reducing the ability of the microbubbles to homogenously mix unless injected at a rate of 0.5 mL/sec. Additionally, 25-G needles increase microbubble destruction. Further study is needed to optimize contrast delivery under hypothermia conditions.

CLINICAL RELEVANCE/APPLICATION

Contrast enhanced ultrasound is valuable imaging modality in assessing brain injury in hypoxic-ischemic encephalopathy. Contrast delivery must be optimized under therapeutic cooling conditions.

SST09-07 Multispectral Data Analysis of Reduced FOV Diffusion Tensor Images of Pediatric Spinal Cord Injury

PURPOSE

A key challenge in the imaging of spinal cord injury (SCI) patients is the ability to accurately determine structural or functional

A key challenge in the imaging of spinal cord injury (SCI) patients is the ability to accurately determine structural or functional abnormality as well as level and severity of injury. Diffusion tensor imaging (DTI) allows the characterization of physical and functional properties of tissues. The purpose of this study is to assess quantitative multispectral texture (MST) features of diffusion tensor images and its potential clinical relevance in discriminating typically developing (TD) pediatric spinal cords and those with cervical spinal cord injury (SCI).

METHOD AND MATERIALS

A total of 15 subjects (10 TD and 5 cervical SCI patients) ranging in age from 6-16 yrs were recruited and scanned for DTI along cervical spinal cord using 3.0T Siemens Verio MR scanner. Initially, DTI images were corrected for motion induced artifacts and then robust estimation of tensor was used to generate DTI indices including fractional anisotropy (FA) and mean diffusivity (MD). Finally, 33 texture features were generated from both FA and MD maps. These features included 5 first order features (mean, variance, skewness, kurtosis and entropy), 16 second order feature vector elements calculated from grey level co-occurrence matrices (GLCM) in directions of 0°, 45°, 90° and 135° and 12 high order texture features generated from three different coefficients matrices in directions of horizontal (0°), vertical (45°), and diagonal (90°) of wavelet decomposition. These features then were compared between TD and cervical SCI subjects based on standard least squared linear regression model and restricted maximum likelihood method.

RESULTS

The experimental findings show that there are significant differences in texture values of FA and MD maps between TD and cervical SCI population. A total of 7 texture features from the FA map and 8 MST features from MD map showed statistically significant discrimination between TD and cervical SCI (tables1-3).

CONCLUSION

We have demonstrated experimentally that MST features have the potential for better discrimination of patients with SCI compared to the TD. MST features quantify macroscopic and also the microscopic abnormalities that may be undetectable using conventional DTI analysis.

CLINICAL RELEVANCE/APPLICATION

Texture descriptors could be used as quantitative imaging markers in addition to conventional MR imaging for the facilitation of diagnosis and characterization of the tissues in the pediatric spinal cord.

SST09-08 Radiologic Features of Posterior Reversible Encephalopathy Syndrome (PRES) After Hematopoietic Stem Cell Transplantation in Pediatric Patients

PURPOSE

To assess the incidence and imaging features of posterior reversible encephalopathy syndrome (PRES) in pediatric patients after hematopoietic stem cell transplantation (HSCT)

METHOD AND MATERIALS

This prospective study was conducted on all pediatric patients who underwent HSCT between March 2014 and June 2016. Brain CT scan was carried out in all patients who developed neurologic symptoms/signs followed by brain MRI. In those with diagnosis of PRES, follow-up MRI was conducted within two months. MRI was performed using a 1.5 Tesla magnet (Avanto, Siemens) including DWI and SWI sequences.

RESULTS

A total of 254 patients (160 males, mean age:7.6±4 years) underwent HSCT including 65 individuals with thalassemia, 41 with fanconi anemia, 59 with lymphoma/leukemia and 89 with other miscellaneous disorders. Brain MRI revealed PRES in 23 (9.1%). Seizure was the most common presenting symptom followed by headache. Patients with fanconi anemia were at greater risk of developing PRES compared to other diseases as PRES was seen in 9 out of 41 of patients with fanconi anemia (p value: 0.004). MRI showed asymmetric lesions in 10 patients of which, unilateral hemispheric involvement was noted in two patients . Superior frontal sulcus distribution was the most frequent imaging pattern (8/23, 34.8%) followed by holo-hemispheric (6/23, 26.1%), dominant posterior (6/23, 26.1%) and partial (3/23, 13%) distributions. Transient restricted diffusion was noted in one patient with unremarkable follow-up MRI. Microhemorrhagic foci were depicted In 4 patients. Of them, one patient died shortly after PRES. Follow-up MRI showed persistent microhemorhagic foci in the other three patients. Another patient with hemorrhagic PRES died later due to a second episode of PRES.

CONCLUSION

This study showed high incidence of PRES in children after HSCT especially in those with fanconi anemia. Various patterns of edema distribution is seen in brain MRI of pediatric population with PRES. Hemorrhagic PRES occurs in a minority of patients, which is possibly associated with worse prognosis.

CLINICAL RELEVANCE/APPLICATION

PRES shows various imaging patterns in pediatric patients following Hematopoietic stem cell transplantation; with microhemorrhagic

PRES shows various imaging patterns in pediatric patients following Hematopoietic stem cell transplantation, with microhemorragic PRES being probably associated with worse prognosis.

PURPOSE

The pulmonary airway display can reflect the image quality of the chest CT.this retrospective study comparative evaluation of model-based iterative reconstruction (MBIR),adaptive statistical iterative reconstruction (ASIR) with lung kernel on the performance of computer-aided detection (CAD) for quantitative analysis of airway in routine dose chest CT.

METHOD AND MATERIALS

30 patients were included who were scanned for pulmonary disease using a clinical routine dose MDCT system (Discovery CT750 HD,GE Healthcare).Data were reconstructed with MBIR,ASIR(40% ASIR and 60% FBP mix).Airway dimensions were measured from the two reconstructions using an automated, quantitative software that was designed to segment and quantify the bronchial tree, and a skeletonization algorithm to extract the center-line of airway trees automatically (Figure 1).For each patients and reconstruction algorithm chose the right middle lobe bronchus with the least tortuous and bifurcation as a representative to measure the bronchial length of the matched airways. Two radiologists used a semi-quantitative 5-point scale (from -2 for inferior to +2, for superior; -1 for slightly inferior to +1 slightly superior ; and 0, equal with ASIR) to rate subjective image quality of airway trees on the MBIR images.Using paired t and Wilcoxon signed-rank tests for comparison.

RESULTS

Algorithm impacted the measurement variability of the length of bronchus in routine dose chest CT,and MBIR was better,which produced longer bronchus than ASIR($P<0.05$) (Table 1, Figure 2). ($P<0.05$) (Table1,Figure 2).MBIR reconstructions also had higher subjective scores for the airway trees than ASIR($P<0.05$) (Table 2, Figure 3).

CONCLUSION

The quantification accuracy of airway is strongly influenced by reconstruction algorithm.The MBIR algorithm potentially allows the desired airway quantification accuracy to be achieved. which may enable a wider clinical use of low-dose Chest MDCT.

CLINICAL RELEVANCE/APPLICATION

Compare ASIR,MBIR algorithm potentially allows the desired airway quantification accuracy to be achieved on the performance of CAD in routine dose chest CT.which may be used to reduce radiation dose.

SST10-02 Optimization of Multi-Energy Non-Local-Means Denoising for Ultra High Resolution Photon Counting Detector CT Images

ferrero.andrea@mayo.edu

PURPOSE

Ultra-high-resolution (UHR) photon-counting-detector (PCD) CT has been shown to produce clinical images of unsurpassed spatial resolution, with slices as thin as 0.25 mm. However, the substantially increased noise of UHR images at these thin slices could potentially degrade diagnostic value. In this work, we investigated how to optimize noise reduction with an image based multi-energy, non-local-means (MENLM) method without loss of anatomical details.

METHOD AND MATERIALS

After IRB approval, UHR-PCD CT images of patients were obtained for different diagnostic tasks, including high resolution chest and musculoskeletal exams. MENLM was applied to the 0.25-mm thick filtered-back-projection (FBP) images for each case with variable filter strengths. Each denoised image was then combined with the original FBP image with variable blending ratios. 2D noise power spectra (NPS) were generated from a clinically relevant anatomic region within the patient anatomy. The optimal combination of FBP weighting and MENLM filtration was determined as the one producing the largest amount of image noise reduction without significantly shifting the NPS towards lower spatial frequencies. A board-certified radiologist reviewed all combinations of denoised images and ranked them for image noise, sharpness, presence of artifacts and overall diagnostic quality.

RESULTS

Approximately equal weighting between FBP and aggressively filtered MENLM-denoised images was shown to be the best compromise for the evaluated clinical tasks. For both exams, the radiologist assessment of image quality confirmed the selection based on NPS profiles. The images that were ranked with the highest overall diagnostic quality showed 40% noise reduction for the knee exam and upwards of 50% noise reduction for the chest exam, compared to the original FBP images. In both cases, denoised images received much higher scores in every aspect of image quality that was assessed.

CONCLUSION

NPS profiles computed directly from a relevant anatomic region provide a useful reference to guide a clinical task-specific optimization of denoising algorithms for UHR PCD CT images, allowing noise to be reduced by 40-50% without alteration of fine details or noise texture.

CLINICAL RELEVANCE/APPLICATION

Noise reduction algorithms can be limited by degradation of fine structures. Blending aggressively denoised images with the FBP data resulted in improved performance with preserved anatomical details.

SST10-03 Achieving Higher Image Quality at 75% Lower Dose with Model-Based Iterative Reconstruction in Abdominal CT

PURPOSE

To assess image quality of a model-based iterative reconstruction (MBIR) in lower-dose abdominal CT, in comparison with the filtered back projection (FBP) reconstruction with standard dose.

METHOD AND MATERIALS

This study was approved by ethics committee and written consent was provided by all patients. Twenty patients underwent (75%) lower dose contrast-enhanced abdominal CT and reconstructed with MBIR after routine-dose contrast-enhanced CT which was reconstructed with conventional FBP algorithm. Two radiologists assessed the images blindly per the sharpness, image noise, diagnostic acceptability and artifacts with 5-point scoring (1-5 points, Grade 1: cannot be used for diagnosis; Grade 2: poor; Grade 3: acceptable; Grade 4: good; Grade 5: very good). Image noise and signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of abdominal organs relative to abdominal fat were assessed. The volume CT dose index (CTDIvol), dose length product (DLP) and dose reduction rate were also obtained.

RESULTS

CTDIvol and DLP were 3.04±1.48mGy and 95.56±47.17mGy*cm for the lower-dose CT, 12.16±5.18mGy and 376.39±160.40mGy*cm for the routine-dose CT, respectively with 75% reduction (Table 1). Lower-dose MBIR images had significantly lower objective image noise (6.12±1.03HU), higher SNR (11.56±3.30) and CNR (26.96±5.88) than both the lower-dose (39.61±4.55HU, 2.03±0.41 and 4.75±0.98, respectively) and routine-dose (21.45±3.92HU, 3.79±0.68 and 9.01±1.90, respectively) FBP images (all $P<0.001$) (Table 2). In addition, MBIR had better subjective scores (4.20±0.77) than FBP (2.70±0.66 in routine-dose and 1.55±0.51 in lower-

dose) in noise, sharpness and artifacts (Fig. A-D).

CONCLUSION

The MBIR significantly improves the objective and subjective image quality in (75%) lower-dose abdominal CT scans, compared with the routine-dose FBP reconstructions.

CLINICAL RELEVANCE/APPLICATION

The MBIR significantly improves the objective and subjective image quality in (75%) lower-dose abdominal CT scans, compared with the routine-dose FBP reconstructions.

SST10-04 Combination of Dual Phase Acquisition and Snapshot Freeze Technique to Improve the Image Quality in Patients with Intermediate Heart-Rate

xiaoxiao_8236@sina.com

PURPOSE

To investigate the value of dual phase (45% and 75% of R-R interval) acquisition and snapshot freeze technique on the image quality of coronary computed tomographic angiography (CCTA) on patients with intermediate heart rate (70 to 80bpm), in comparison with single phase.

METHOD AND MATERIALS

Forty-six patients [28 men and 18 women; age (M±SD), 55.3 ± 8.0 years; body mass index (BMI) (M±SD), 25.20±2.8kg/m2] with intermediate heart rate (70 to 80bpm) were scanned on a 256-row detector CT scanner (Revolution CT, GE healthcare). The volume and flow rate of the contrast medium were adapted to the patient's body weight. The scanning range was 140mm or 160mm from the level of the tracheal bifurcation to the diaphragm. Dual phase (45% and 75% of R-R interval) acquisition was performed for all the patients. For both phases, snapshot freeze (SSF) and standard (STD) reconstructions were applied for each patient. Two experienced radiologists, who were blinded to reconstruction information, independently graded the CT images in terms of visibility and artifacts with likert 4-point score(1 = insufficient, 4 = excellent) on a per-patient- and a per-artery-base analysis.Image interpretability of 45%+75% of R-R interval was compared with single 45% and 75% of R-R interval with paired Chi-square test. Image score of 45%+75% of R-R interval was compared with 45% and 75% of R-R interval with signed rank sum test.

RESULTS

For STD reconstruction, dual phase showed higher interpretability than single 45% and 75% of R-R interval on per-artery level [84.8%(117/138) vs 62%(85/138) vs 67%(93/138),P<0.001], and on per-patient level [63%(29/46) vs 39%(18/46) vs 37%(17/46),P=0.021]. When combined with SSF reconstruction, image interpretability on per-artery level and per-patient level was further improved from [84.8%(117/138) and 63%(29/46)] to [96.4%(133/138) and 89.1%(41/46)]. The image quality score for dual phase was higher than single 45% and 75% of R-R interval on both per-artery level and per-patient level (both P<0.001).

CONCLUSION

Combination of dual phase (45% and 75% of R-R interval) acquisition and snapshot freeze technique could improve the image quality and interpretability of CCTA of patients with intermediate heart rate.

CLINICAL RELEVANCE/APPLICATION

Adequate selection of the cardiac phase with this SSF can provide acceptable diagnostic image in patients with an average 70<=HR<=80.

SST10-05 An Image Quality Assessment of the Noise Problem in Edge Preserving Regularization of Low-dose Statistical Iterative CT Image Reconstruction

Friday, Dec. 1 11:10AM - 11:20AM Room: E264

Participants
Zhicong Yu, Mayfield Village, OH (*Abstract Co-Author*) Employee of UIH America Inc
Chunfeng Qian, MD, Shanghai, China (*Abstract Co-Author*) Employee of United Imaging Healthcare
Wenjing Cao, Shanghai, China (*Abstract Co-Author*) Employee of United Imaging Healthcare

Patrick Kling, Mayfield Village, OH (*Abstract Co-Author*) Employee , UIH America, Inc
Stanislav Zabic, PhD, Mayfield Village, OH (*Presenter*) Employee, UIH America, Inc

PURPOSE

This report assesses a new regularization within the framework of statistical iterative image reconstruction in CT, which results in a more uniform noise distribution than other edge preserving regularizations.

METHOD AND MATERIALS

Iterative image reconstruction with edge preserving penalties in CT is known for noise reduction while recovering high spatial resolution and low contrast details. However, a preserved edge is also known to keep the surface around anatomic features noisier

than the surrounding flat areas, which may degrade diagnostic performance of an observer. The new coherent L1 norm reduces the dimensionality of the noise reduction close to the surface between the two tissues and performs noise reduction more uniformly across the entire volume, while keeping the advantage of high spatial resolution.

RESULTS

A medical doctor was asked to review 24 low dose CT abdomen cases, with each containing 4 images reconstructed using the new coherent L1 norm, total variation, Huber penalty and quadratic penalty regularizations. Special attention was paid to critical anatomy with known diseases, including stomach cancer, hemangioma, small cyst, cirrhosis, liver abscess, carcinoma, liver and pancreatic cancer. Total variation and Huber penalties produced images with rough edges, quadratic penalty produced images with low spatial resolution and coherent L1 norm images had both high spatial resolution and uniform noise performance, receiving the highest rating from the observer in all cases. A noise study was conducted on an analytic phantom with inserts of various contrast and image pixel noise variance was calculated for every voxel in the image. We compared the noise variation on the edge voxels and noise variation on the flat regions; the coherent L1 norm showed the least amount of difference on those regions of interest.

CONCLUSION

Coherent L1 norm substantially improves the edge appearance in the reconstructed image with preserved low-contrast details and high-contrast spatial resolution.

CLINICAL RELEVANCE/APPLICATION

Low-dose CT may result in images that have rough edges and leave a doubt with the physician about the condition of the patient. The main cause is the edge preserving regularization in CT reconstruction reduces the noise, but makes organ edges appear rough. Coherent L1 norm with its edge preserving and uniform noise reduction across the image volume has a potential to increase physicians diagnostic confidence.

SST10-06 The Application of Deep Learning Algorithm Pixel Shine in Arterial Phase Pelvic CT for Image Quality Improvement

Friday, Dec. 1 11:20AM - 11:30AM Room: E264

Participants
Shifeng Tian, Dalian, China (*Abstract Co-Author*) Nothing to Disclose
Ailian Liu, MD, Dalian, China (*Abstract Co-Author*) Nothing to Disclose
Jinghong Liu, MD, PhD, Dalian, China (*Abstract Co-Author*) Nothing to Disclose
Yijun Liu, Dalian, China (*Abstract Co-Author*) Nothing to Disclose
Judong Pan, MD, San Jose, CA (*Abstract Co-Author*) Medical Advisor, AlgoMedica Inc
Miao Niu, Dalian, China (*Presenter*) Nothing to Disclose

PURPOSE

To assess the effect of a deep learning denoising algorithm, Pixel Shine (AlgoMedica, Inc, Sunnyvale, CA) on the quality of pelvic arterial phase CT images.

METHOD AND MATERIALS

A retrospective analysis was performed on arterial phase pelvic CT images from 33 patients (BMI<=20) obtained with a GE Revolution CT (70 kVp tube voltage, and ASIR-V-FBP 50% blending) and designated group A. Group B images were then obtained by applying Pixel Shine algorithm to group A image datasets. Subjective image quality was evaluated using a 5-point scoring system by two radiologists, and the scores of the groups were compared. Image signal was assessed using CT values of the urinary bladder. The CT and standard deviation (SD) values of the gluteus maximus were measured, and the SD values of the gluteus maximus were used to represent image noise. The signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of the bladder were then calculated. The image noise, SNR and CNR of two groups were compared using paired t-test.

RESULTS

The subjective visual image quality score of groups A and B, respectively, were 3.03±0.17 vs. 3.85±0.57, the image noise was 15.79±2.05 HU vs. 11.06±2.22 HU, the SNRs of bladder were 0.50±0.23 vs. 0.79±0.39, the CNRs of bladder were 3.72±0.85 vs. 5.14±1.27. Group B showed better subjective image quality, lower image noise, and improved SNR and CNR compared to group A; these differences were statistically significant ($p<0.05$).

CONCLUSION

Processing of arterial phase pelvic CT images reconstructed using ASIR-V technique by deep learning algorithm Pixel Shine significantly improved subjective image quality, reduced image noise, and increased SNR and CNR.

CLINICAL RELEVANCE/APPLICATION

Superior image quality and reduced image noise may be achieved by processing of low-dose ASIR-V reconstructed pelvic CT images using deep learning algorithm such as Pixel Shine.

SST10-07 Human Observer Performance for Localization of Liver Lesions: Correlation between Anatomical and Uniform Background

Friday, Dec. 1 11:30AM - 11:40AM Room: E264

Yu.Lifeng@mayo.edu

PURPOSE

To determine the correlation of human performance for localization of small low contrast lesions within uniform water background and within anatomical liver background under the conditions of varying dose, lesion size, and reconstruction algorithm.

METHOD AND MATERIALS

Liver lesions of 5, 7, and 9mm diameter (contrast -21HU) were digitally inserted into projection data of disease-free liver CT scans in regions free of major vessels. Noise was inserted into the full-dose projection data to create three image sets: full dose, simulated half dose, and simulated quarter dose. The images were reconstructed with a standard filtered back projection (FBP) and an iterative reconstruction (IR) algorithm. Lesion and noise insertion procedures were repeated for water phantom data at the same three dose levels. For each background, 2D regions of interest were selected, randomized, and independently reviewed by three medical physicists. Each region of interest had either one lesion present or no lesions present (66 lesion-present, 34 lesion-absent). The readers identified the most likely location of the lesion and provided a confidence score. The locations and confidence scores were assessed using the area under the localization receiver operating curve (AzLROC). We examined the correlation of human performance for the cases of uniform and liver backgrounds as dose level, lesion size, and reconstruction type varied.

RESULTS

As lesion size or dose increased, the readers' ability to locate the lesion improved. At full dose, the AzLROC for the 5, 7, and 9mm lesions in the liver background IR images were 0.53, 0.91, and 0.97, respectively. Similarly, the AzLROC in the uniform background IR images were 0.51, 0.96, and 0.99 for the 5, 7, and 9mm lesions. Similar trends were seen for the other dose levels. The performances between liver and uniform water backgrounds were highly correlated for both FBP and IR. For liver vs. uniform background, the average difference in AzLROC was 0.03±0.03 and had a Spearman correlation of ρ=0.97.

CONCLUSION

For the task of localizing low contrast liver lesions, human observer performance was highly correlated between anatomical and uniform backgrounds.

CLINICAL RELEVANCE/APPLICATION

Liver lesion localization studies may use uniform or anatomic backgrounds, as similar and highly correlated human performances were seen between uniform and liver backgrounds.

SST10-08 Quantifying Quality: Correlating Phantom and Clinical Scan CT Noise Levels to Construct a Quality Reference Level

CONCLUSION

This study represents a proof of concept method to develop and refine a Noise Reference Level for a given protocol and scanner. This represents a first step in establishing an automated Performance Reference Level for a given scan protocol that incorporates both radiation dose and image quality.

Background

The use of ionizing radiation in computerized tomography mandates risk-benefit understanding. However, this consideration may weight the presumed risk of the ionizing radiation at the expense of the benefits of the examination, with protocol optimization often focusing on dose reduction to the potential detriment of image quality, hence diagnostic value. In fact, the standardized Diagnostic Reference Levels (DRL) are based solely on dose metrics. The purpose of this study is to begin to systematically evaluate an efficient tool for image quality, an automated noise metric in CT to eventually develop a performance metric consisting of both radiation dose and image quality.

Evaluation

Using an IRB-exempt protocol, automated noise values were determined for 1904 contrast enhanced abdominopelvic (AP) and unenhanced chest CT scans on two different scanner models. These data were used to calculate a Noise Reference Level (NRL) by calculating a noise median across a 25-35 cm patient size range, defining the NRL as this median ±20%. A variable diameter phantom was also scanned utilizing both protocols on both scanners, and the resultant noise-size curves for the phantom were compared to those utilizing clinical scan data.

Discussion

Utilizing our novel noise evaluation tool, noise-patient size curves demonstrate agreement between clinical scan and phantom data. Noise measurements were varied based on the region scanned, with the NRL interval between 25 and 37 HU for AP CT, and between 10 and 15 HU for chest CT. This demonstrates the utility of noise monitoring across large numbers of scans to generate a target noise range based on region scanned and scanner equipment, and to identify and evaluate image quality outliers. This automated tool can thus be used to compare performance in a single scanner and between scanners for similar sized patients independent of interpreting radiologist subjective biases.

SST10-09 Quantification of Ellipticity Ratios for Head, Shoulders, Chest, and Abdomen and Their Impact on AEC in CT

Friday, Dec. 1 11:50AM - 12:00PM Room: E264

Participants

tszczykutowicz@uwhealth.org

PURPOSE

It has been reported that CT scanner automatic exposure control (AEC) systems consider patient ellipticity ratio when setting the dose level. In other words, two patients of identical water equivalent diameter (WED) would receive different doses if their ellipticity ratio differed. Because of this effect, understanding large aggregate dose datasets where one plots WED against dose requires incorporation of patient ellipticity ratio to fully predict and model a scanner AEC response.

METHOD AND MATERIALS

We analyzed 884 patient CT scans under IRB approval. The average effective mAs, WED, and ellipticity ratio were calculated for each patient's scan. Data from routine head, chest, ad abdomen/pelvis scans was included for both adults and pediatrics. These datasets were further broken into specific body regions corresponding to: head, chest, shoulders, thorax, abdomen, and abdomen/pelvis. We measured the ellipticity ratio by taking the ratio of the lateral to anterior-posterior patient dimension for each body region. We developed a theoretical model for the CT scanner's AEC function that includes parameters for angular tube current modulation, WED based dose compensation, and ellipticity based dose compensation. We applied the model to fit a dataset containing 294 adult abdomen/pelvis exams under IRB approval.

RESULTS

As expected, the ellipticity ratio of the shoulder region was the highest at 2.28+/- 0.22. The abdomen/pelvis, chest, thorax, and abdomen regions all had ellipticity values near 1.5. The adult head had an ellipticity value of 0.85 +/- 0.08. Our AEC model predicted changes in effective mAs for a given WED as a function of ellipticity as desired. We noted that issues due to patient truncation and the presence of metal implants caused our model to fail. The former is understandable as a truncated image produces a WED smaller than what the AEC systems assumed. Interestingly, the presence of metal orthopedics caused an increase in WED but not a corresponding increase in effective mAs.

CONCLUSION

We measured and showed why patient ellipticity is important in understanding the function of a CT scanner's AEC system.

CLINICAL RELEVANCE/APPLICATION

AEC systems are complex and take into consideration more than just the patient size in terms of WED. We report on and model how ellipticity of a patient influences the output of a CT scanner.

PURPOSE

The administration of Gadolinium based contrast agents is associated with the risk of allergic reactions and the development of a systemic nephrogenic fibrosis (NSF). Current research showed remnants of some types of Gadolinium based MR contrast agents in the brain - with unknown long-term effects. Purpose of our work is to examine dynamic nuclear polarization (DNP) as an alternative method for MR angiography.

METHOD AND MATERIALS

The used liquid-state Overhauser DNP is a technique to achieve hyperpolarization by microwave irradiation of electron spins in TEMPOL radicals, which are coupled with the nuclear spins of water molecules. Our setup comprises a 42 GHz microwave source and a 1.5 T in-bore DNP MRI polarizer, equipped with a multimode resonator. The continuously hyperpolarized water was administered with a flow of 1.2 ml/min into the aorta of five C57BL/6 mice via catheterization (0.15 mm ID) through iliac vessels. The aorta and its branches were visualized with GRE-sequences (TR 110s, TE 3.8s, FoV 78x58x2 mm, Matrix 256x192 px) and intravascular DNP signal intensities, SNR and CNR values were measured and compared to its native values.

RESULTS

Maximum intravascular signal intensities were increased 4.3-fold from 231±47 to 994±194 by infusion of hyperpolarized water. Thus better SNR and CNR values were measured for hyperpolarized vessels with an SNR increased 5.3-fold from 24±2 to 126±62 and CNR increased 26.3-fold from 3±2 to 79±49.

CONCLUSION

The used in-bore DNP setup continuously creates hyperpolarized water, which features high T1 signal enhancements in MR imaging and a short relaxation time. In our mice experiments the strong enhancement and its high CNR made a visualization of the aorta and its branches possible - even using a standard clinical 1.5 T scanner.

CLINICAL RELEVANCE/APPLICATION

Hyperpolarized water might be a promising future alternative to Gadolinium based contrast agents in MR angiographies without risking the potential adverse effects or intracorporal remnants of Gadolinium based contrast agents.

SST11-02 Type 2 Diabetes is Related to Increased Carotid Plaque Inflammation: A Novel Finding of Dynamic Contrast-Enhanced MR Imaging

Friday, Dec. 1 10:40AM - 10:50AM Room: E352

Participants
Beibei Sun, Shanghai, China (*Presenter*) Nothing to Disclose

Huilin Zhao, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

alisabeibei@163.com

PURPOSE

Although many pathological study have demonstrated that more microvessels and macrophages which associated with increased inflammation was exhibit in diabetic plaques, in vivo study of carotid plaque inflammtion in type 2 diabetes mellitus(T2DM) with dynamic contrast-enhanced (DCE) magnetic resonance (MR) imaging is rare. Thus our study aim to evaluate carotid plaque inflammation in stroke patients with and those without type 2 diabetes(T2DM) and to determine which risk factors might be associated with plaque inflammation in T2DM subjects.

METHOD AND MATERIALS

A total of 55 patients(25 T2DM and 30 non-T2DM) with carotid plaque ipsilateral to ischemic event were underwent bilateral carotid artery MRI examination. Multicontrast sequences for characterizing plaque morphologic and DCE MR images for assessing atherosclerotic plaque inflammation were obtained in T2DM and non-T2DM patients.

RESULTS

Compared with non-T2DM patients, patients with T2DM had more severe inflammtion, as evidenced by higher Ktrans(transfer constant) (0.099 vs 0.061, P=0.005). Compared with well controlled diabetes(Hemoglobin A1c[HbA1c] <7%), poorly controlled diabetes(HbA1c >=7%) also have increased inflammation, as evidenced by higher Ktrans (0.126 vs 0.074±; P=0.009) and ve (extracellular extravascular volume fraction) (2.301% vs 6.187%; P=0.026). HbA1c level was independently associated with Ktrans in overall patients and T2DM patients after adjusting for plaque characterization and comprehensive confounding factors.

CONCLUSION

This study demonstrated an increased plaque inflammation in T2DM patients and poorly controlled T2DM patients. There have an independent pathophysiological link between the HbA1c level and Ktrans. Thus, DCE-MRI may be useful in monitoring the efficacy of some anti-hyperglycemic agents on atherosclerotic plaque inflammation in T2DM patients.

CLINICAL RELEVANCE/APPLICATION

Thus, this in vivo plaque inflammation imaging may potentially useful in providing a clinical tool to better understand the role of inflammation and angiogenesis in plaque progression/regression, and to monitor and predict therapeutic response to inflammation-targeted pharmacotherapy.

SST11-03 Comparison of [18F] FDG-PET/CT and 3D-Black-Blood 3T-MRI for the Diagnosis of Large Vessel Vasculitis

Friday, Dec. 1 10:50AM - 11:00AM Room: E352

PURPOSE

To investigate the concordance of a high-resolution three-dimensional (3D) black-blood turbo spin echo (TSE) MRI sequence with variable flip angles and [18F]FDG-PET/CT for the diagnosis of large vessel vasculitis (LVV).

METHOD AND MATERIALS

24 consecutive patients with suspected LVV who underwent 3D-black-blood 3T-MRI and [18F]FDG-PET/CT imaging between 2013 and 2016 in our center were retrospectively reviewed. For image analysis 11 different vessel segments were evaluated in both modalities. The MRI-slides were analyzed for signs of vessel wall inflammation, which are concentric contrast enhancement (CCE) and concentric wall thickening (CWT) as well as image quality (IQ) and flow artifact intensity (FAI), using 4-point Likert scales. [18F]FDG-PET/CT analysis comprised qualitative, quantitative and semiquantitative methods. [18F]FDG uptake was analyzed in patients with and without immunosuppressive medication. Imaging findings were correlated with the final clinical diagnosis for each diagnostic method.

RESULTS

In 19 of 24 patients (79%), active or inactive LVV was confirmed by clinical follow-up. 3T-MRI was positive in 17 patients, while [18F]FDG-PET/CT identified vasculitis in 14 patients. On MRI, 72% of vessel segments showed no or only minor flow artifacts and 82% disposed an excellent or good IQ (82.2%). Among the patients with LVV, the frequency of CWT and CCE was comparable (62.5% vs. 63.1%) and both parameters showed high correlation (Spearman`s R = 0.933; P<0.001). The subgroup analysis of patients with anti-inflammatory medication revealed no statistical difference regarding the results of the [18F]FDG-PET/CT examination.

CONCLUSION

Free breathing navigated black-blood MRI and [18F]FDG-PET/CT are promising imaging tools in diagnosing patients with LVV.

CLINICAL RELEVANCE/APPLICATION

3D-black-blood 3T-MRI could be a future radiation-free alternative to PET-CT for the diagnosis and follow-up of patients with LVV,

especially in young patients.

SST11-04 Correlation of the Potential Biomarker for Ascending Aortic Aneurysms, MMP-9 with Quantitative Flow Parameters Measured by 4D Flow MRI

Friday, Dec. 1 11:00AM - 11:10AM Room: E352

Participants
Nadja M. Kocher, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose
Maximilian Russe, MD, Freiburg, Germany (*Abstract Co-Author*) Nothing to Disclose
Fabian A. Kari, Freiburg, Germany (*Abstract Co-Author*) Nothing to Disclose
Mathias F. Langer, MD, PhD, Freiburg, Germany (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

nadja.kocher@uniklinik-freiburg.de

PURPOSE

This translational study intends to evaluate if MMP-9, a matrix metallopeptidase involved in the degradation of extracellular matrix, in the serum of patients with thoracic aortic aneurysms (TAAs) could be used as potential biomarker for TAAs in the future. Therefore MMP-9 serum levels were correlated with quantitative hemodynamic flow parameters measured by 4D flow MRI.

METHOD AND MATERIALS

16 patients (age 56±13years) with aortic root/ascending aortic aneurysms >45mm underwent 4D flow MRI. Flow quantification was performed using ECG gated three-directional velocity encoding with full 3D coverage of the thoracic aorta. 4D flow MRIs were acquired in a sagittal oblique 3D volume using a flip angle of 8°, VENC: 150 cm/s, spatial resolution = (2.0-2,4)³mm³, and temporal resolution: 20-40 ms. Data analysis included 3D blood flow visualization (EnSight, CEI, USA) based on 3D particle traces and 3D streamlines. Time-resolved 2D data was extracted on a plane. The diameter, mean wall shear stress magnitude (meanWSSmag), 3D oscillatory shear index (OSI 3D) and percentage of retrograde flow were derived. MMP-9 levels in blood samples of these 16 patients were identified by ELISA tests. Patients were divided into two groups; Group A with bicuspid aortic valves (5 patients), Group B with tricuspid aortic valves (11 patients).

RESULTS

The following differences and correlations were shown in Groups A and B: MMP-9 levels were significantly higher in patients with BAV (Group A: 645.4(±203.9)ng/ml; Group B: 393.7(±129.1)ng/ml; +64%; p-value <0.05). Furthermore, within each group exist high correlations between MMP-9 levels and both meanWSSmag (Group A: r=0.74; Group B: r=0.5) and percentage of retrograde flow (Group A: r=0.69; Group B: r=0.5). There was also found to be a high negative correlation between MMP-9 and OSI 3D in Group B (r=0.54). The biggest diameters correlate in Group B to MMP-9 levels (r=0.54). No correlation was found for both of these parameters in Group A.

CONCLUSION

These results revealed a high correlation between quantifiable blood flow within TAAs and MMP-9. Further studies are warranted to investigate the influence of specific aneurysmatic blood circulation on the aortic wall and if MMP-9 can be used as potential biomarker for TAAs.

CLINICAL RELEVANCE/APPLICATION

MMP-9 could be used as an easy to gain biomarker for TAAs in the future. This would simplify the diagnosis.

SST11-05 Diagnostic Efficacy of Free-Breathing Contrast-Enhanced T1 Gradient Echo Sequences Compared to Standard Breath-Hold T1 Gradient Echo Sequences in the Assessment of Thoraco-Abdominal Aorta Having CT Angiography as Standard of Reference

Friday, Dec. 1 11:10AM - 11:20AM Room: E352

ctfdoc@hotmail.com

PURPOSE

To evaluate the diagnostic accuracy of contrast-enhanced T1 free-breathing gradient echo sequences in the evaluation of aortic disease, in comparison with standard MR-angiographic sequences and CT-angiography studies.

METHOD AND MATERIALS

Fifty-three patients, with known aortic disease at CT-angiography evaluation, were prospectively evaluated with a 1.5T magnet (Achieva,Philips), with a phased array multi-coil, after the intravenous injection of 0.1 mL*Kg of gadobutrol. A standard MR angiography examination was performed with 3D-angiographic sequences and T1 breath-hold sequences (THRIVE). Multiplanar T1 free-breathing gradient-echo fat-suppressed (THRIVE-FB) sequences were additionally performed in all the examinations. Two radiologists independently compared the diagnostic quality of MR-angiographic sequences and CT-angiography studies, in terms of visualization of aortic wall and lumen and main arterial branches. Vascular calipers measured at different aortic levels were compared between the MR-sequences and CT evaluations and statistically analyzed. The interobserver agreement was investigated using the Intraclass Correlation Coefficient (ICC).

RESULTS

Free breathing sequences showed good diagnostic accuracy in the assessment of vascular calipers, with no significant differences compared to standard breath-hold MR-sequences and CT-studies. THRIVE-FB also demonstrated high sensitivity and specificity in the evaluation of vascular wall, plaques, thrombus and adjacent structures. Not significant differences were obtained in terms of diagnostic quality, between THRIVE-FB sequences, standard angiographic sequences and CT-angiography, with a good interobserver agreement (ICC of 0.85).

CONCLUSION

Free-breathing contrast-enhanced T1 gradient-echo fat-suppressed sequences, combined with high relaxivity contrast agent, demonstrated high diagnostic efficacy, permitting to correctly evaluate the aorta and its major branches, with no significant differences in comparison with standard breath-hold MR-sequences and CT studies.

CLINICAL RELEVANCE/APPLICATION

Angiographic free-breathing sequences may represent a useful tool in not-compliant patients, allowing to correctly evaluate main thoraco-abdominal arteries, with good diagnostic quality images.

SST11-06 Computed Tomography Guided Lumbar Sympathectomy (CTLS) as a Palliative Treatment in Patients with Critical Limb Ischemia Not Amenable to Therapeutic Revascularization

Friday, Dec. 1 11:20AM - 11:30AM Room: E352

For information about this presentation, contact:

anuragchahal18@gmail.com

PURPOSE

To evaluate the safety and efficacy of CTLS in the management of patients of critical limb ischemia without revascularization optionsTo assess the effects of technical parameters of CTLS on the clinical success of the procedure

METHOD AND MATERIALS

Patients with critical limb ischemia with angiographic anatomy not amenable for revascularization were included in the study. Exclusion criteria were patients not giving consent, unable to lay prone and deranged coagulation parameters. CTLS was performed with patient in prone position using 22 G chiba needle at L1-L3 vertebral level with a mixture of neurolytic solution (99% alcohol) and non-ionic contrast in the ratio of 10:1 after confirming the spread with a check solution of diluted contrast. Patients were observed for 4 hours before discharge. Periprocedural complications were noted; Numerical pain score (NPS) and limb changes were assessed before and after the procedure at 3 weeks and 3 months. Spread of neurolytic mixture was categorised as medial or lateral with respect to lateral edge of vertebral body. Treatment results were categorized into improved, unchanged or worsened.

RESULTS

22 patients (19 males, 3 females) with mean age 45.3 years (range: 25-78 years) were included. Bilateral procedure was done in 19 patients and unilateral in 3 patients. The mean volume of absolute alcohol injected per side was 7.5 mL. No procedure related complications were noted. 18 (81.8%) patients improved and 4 patients (18.2%) were unchanged. The mean NPS pre-procedure, 3 weeks and 3 months post procedure were 6.82, 3.32 and 3.05 respectively.($p<0.0001$). Pain relief was significantly better in patients with medial spread of the neurolytic agent compared to those without medial spread ($p=0.027$). Interestingly, 7/16(43.75%) patients reported ulcer healing in 3 months follow up.

CONCLUSION

CTLS is a simple, safe and effective procedure in patients with critical limb ischemia due to infragenicular diffuse arterial disease. Medial spread of the neurolytic agent provides significantly better results.

CLINICAL RELEVANCE/APPLICATION

CT guidance is optimal for exact needle positioning to achieve medial spread of neurolytic mixture which gives better results as seen in this study. CTLS helps in ulcer healing especially in patients with buergers disease who quit smoking since it provides pain relief and helps in opening collateral vessels via chemical sympatheticolysis.

SST11-07 String-Like Lumen in Below-the-Knee Chronic Total Occlusions on Contrast-Enhanced Magnetic Resonance Angiography Predicts Intraluminal Recanalization and Better Blood Flow Restoration

Friday, Dec. 1 11:30AM - 11:40AM Room: E352

Participants
Yingsheng Cheng, MD, Shanghai, China (*Presenter*) Nothing to Disclose

CONCLUSION

In patients with BTK CTOs, SL predicted intraluminal angioplasty and good blood-flow restoration for BTK CTOs.

Background

To determine whether string-like lumina (SLs) on contrast-enhanced magnetic resonance angiography (CE-MRA) predict better outcomes in diabetic patients with below-the-knee (BTK) chronic total occlusions (CTOs)

Evaluation

This study involved 317 long-segment (>5cm) BTK CTOs of 245 patients that were examined using CE-MRA and treated using endovascular angioplasty. A SL with a CTO was slowly filled with blood on conventional CE-MRA. SL-positive CTOs (n=60) achieved a higher technique success rate, preferred intraluminal angioplasty and better blood flow restoration than SL-negative CTOs (n=257 P<0.05). Multivariate analyses revealed that lesion length was the independent predictor of procedural success (P=0.028). SL was a predictor of intraluminal angioplasty (P<0.001) and good blood-flow restoration (P=0.004). Kaplan-Meier analyses at 12 months revealed a higher target lesion patency rate (P=0.04) and limb-salvage rate (P=0.35) in SL-positive CTOs.

Discussion

Our main findings are as follows: (1) intraluminal recanalization was more frequently used for BTK CTOs with SLs than without SLs; (2) CTO length was the only independent predictor of successful CTO recanalization; (3) SL was the only predictor of intraluminal angioplasty in the BTK CTOs; (4) SL and CTO length were predictors of good blood-flow restoration after recanalization; and (5) restenosis-free and limb-salvage rates were better for SL-positive CTOs than SL-negative CTOs.

SST11-08 Ultrasound-Guided Percutaneous Thrombin Injection for the Treatment of Iatrogenic Femoral Pseudoaneurysms

Friday, Dec. 1 11:40AM - 11:50AM Room: E352

PURPOSE

To evaluate clinical and imaging factors that may affect successful ultrasound-guided percutaneous thrombin injection of iatrogenic femoral artery pseudoaneurysms.

METHOD AND MATERIALS

This was an IRB approved, HIPAA compliant retrospective study. The study population consisted of 326 consecutive subjects (138 males, 188 females; mean age 68 years, range 18 - 95 years) who underwent ultrasound guided percutaneous thrombin injection for the treatment of an iatrogenic femoral artery pseudoaneurysm. The number of pseudoaneurysm lobes, longest dimension, and volume of thrombin injected was recorded along with pre-procedure laboratory values of international normalized ratio (INR), activated partial thromboplastin time (aPTT) and platelet count. A follow up ultrasound was available in 146 subjects.

RESULTS

Technical success was achieved in 99.4% (324/326) of subjects. Technique efficacy, as measured by complete thrombosis on a follow up ultrasound, was achieved in 87.0% (127/146) of subjects. In 68% (13/19) of subjects who had not achieved complete thrombosis on follow up ultrasound, repeat thrombin injection was performed and deemed successful; 3 subjects required operative intervention and 3 subjects underwent no subsequent intervention. No imaging or procedure factor was associated with technique failure, including volume of thrombin injected (mean 476 units for complete thrombosis (CT) vs. 671 units for incomplete thrombosis (IT); p=0.105), number of pseudoaneurysm lobes (mean 1.33 for CT vs. 1.37 for IT; p=0.826) or largest size of pseudoaneurysm (mean 3.0 cm for CT vs. 3.6 cm for IT; p=0.133). No statistically significant difference in pre-procedure INR, aPTT or platelet count was found between subjects with CT and those with IT (p>0.125).

CONCLUSION

Imaging guided percutaneous thrombin injection has a high technical success rate for the treatment of iatrogenic femoral artery pseudoaneurysm. No imaging, procedure or laboratory factors are predictive of technique failure.

CLINICAL RELEVANCE/APPLICATION

Abnormal coagulation parameters do not affect technique efficacy for imaging guided percutaneous thrombin injection of iatrogenic femoral artery pseudoaneurysms.

SST11-09 Nephroprotective Imaging for Evaluation of Peripheral Arterial Occlusive Disease (PAOD): A Multi-Observer Comparison Study between Quiescent-Interval Single-Shot MR Angiography (QISS-MRA) and Invasive Angiography with Carbon Dioxide (CO2-DSA)

Friday, Dec. 1 11:50AM - 12:00PM Room: E352

PURPOSE

Non-contrast QISS-MRA and CO2-DSA remain promising nephroprotective methods for accurate staging of PAOD in patients with chronic renal failure (CRF). The aim of our study was to assess the diagnostic value and subjective image quality of QISS-MRA in comparison with CO2-DSA.

METHOD AND MATERIALS

Sixteen consecutive patients (77.5±12.6 years, 64% male) with impaired renal function (eGFR 23.9±7.9 ml/min/1.73 m²) who underwent QISS-MRA at 3 Tesla and CO2-DSA within two weeks were retrospectively included. Identification of significant (>=50%) stenoses of the lower extremity arteries (21-segment-model) was evaluated by 4 independent readers with different level of experience per-segment in random order. Subjective image quality was determined using a 5-point Likert scale (1, non-diagnostic quality; 5, excellent quality or non-perceivable artifacts). CO2-DSA of an experienced interventional radiologist was considered the standard reference method.

RESULTS

115 segments were available for direct MRA-DSA comparison with a prevalence of >=50% stenoses of 27.8% (32/115). Diagnostic parameters of QISS-MRA yielded as follows: sensitivity 90.6% [95%CI: 84.2-95.1%], specificity 94.0% [95%CI: 90.9-96.3%], PPV 85.3% [95%CI: 79.1-89.9%], NPV 96.3% [95%CI: 93.8-97.8%], with an ICC of 0.89. Median values of qualitative imaging parameters for QISS-MRA were as follows: arterial signal intensity: 4 (pelvis), 4 (thigh), 5 (calf); venous overlay: 4, 4, 5; susceptibility artifacts: 5, 5, 5; motion artifacts: 4, 5, 5; ECG-related artifacts: 5, 5, 5. Values for ICC were 0.72, 0.73, 0.93, 0.69 and 0.79, respectively. Opacification of arteries at CO2-DSA was rated 3, 4, 3, with an ICC of 0.65.

CONCLUSION

Non-invasive QISS-MRA offers high diagnostic performance for the detection and ruling out of PAOD in comparison with invasive CO2-DSA. In a direct comparison, image quality of QISS-MRA was prefered by observers over CO2-DSA.

CLINICAL RELEVANCE/APPLICATION

Patients with symptomatic PAOD and CRF could undergo a non-invasive diagnostic evaluation of the lower extremities using QISS-MRA with subsequent guidance to vessels of interest for percutaneous intervention in DSA-technique.
