Program subject to change until 12/16/2019.
**LEARNING OBJECTIVES**

1) Discuss application of optimized non-vascular thoracic MR protocols for troubleshooting problematic mediastinal masses. 2) Use case based discussion to highlight which indeterminate mediastinal masses could benefit from further tissue characterization provided by MR. 3) Describe MR imaging appearances of select indeterminate and complex cystic mediastinal masses. 4) Harness the tissue characterization properties of MRI to add diagnostic specificity to assessment of pleural lesions beyond that of CT. 5) Understand how higher soft tissue contrast of MR can make CT-occult lesions visible. 6) Recognize how the higher soft tissue contrast of MR than CT can: a) add precision to lesion compartment localization, narrowing the differential diagnosis b) better show integrity of tissue planes and invasion across them. 7) To give an overview over the diagnostic scope of lung MRI for pathologies of lung parenchyma and airway disease. 8) To review the diagnostic yield of MRI for the detection and characterisation of lung nodules. 9) To introduce MRI as potential first choice modality for imaging pulmonary disease in young or pregnant patients. 10) To discuss the potential role of lung MRI as an alternative or adjunct modality, e.g. in COPD or interstitial lung diseases. 11) List most common benign and malignant cardiac masses. 12) Assemble key magnetic resonance imaging sequences into a protocol to assess cardiac masses. 13) Recognize magnetic resonance imaging features of select benign and malignant cardiac masses.

**Sub-Events**

**RC801A  Troubleshooting Problematic Mediastinal Masses with MR Imaging**

Participants
Rachna Madan, MD, Boston, MA (Presenter) Nothing to Disclose

For information about this presentation, contact:
rmadan@bwh.harvard.edu

**LEARNING OBJECTIVES**

1) Discuss application of optimized non-vascular thoracic MR protocols for troubleshooting problematic mediastinal masses. 2) Use case based discussion to highlight which indeterminate mediastinal masses could benefit from further tissue characterization provided by MR. 3) Describe MR imaging appearances of select indeterminate and complex cystic mediastinal masses.

**RC801B  The Value of MRI for Diagnosis of Pleural Disease**

Participants
Jeanne B. Ackman, MD, Weston, MA (Presenter) Spouse, Stockholder, Everest Digital Medicine; Spouse, Consultant, Everest Digital Medicine; Spouse, Stockholder, Cynvenio Biosystems, Inc; Spouse, Scientific Advisory Board, Cynvenio Biosystems, Inc; Spouse, Consultant, PAREXEL International Corporation

**LEARNING OBJECTIVES**

1) Harness the tissue characterization properties of MRI to add diagnostic specificity to assessment of pleural lesions beyond that of CT. 2) Understand how higher soft tissue contrast of MR can make CT-occult lesions visible. 3) Recognize how the higher soft tissue contrast of MR than CT can: a) add precision to lesion compartment localization, narrowing the differential diagnosis b) better show integrity of tissue planes and invasion across them.

**RC801C  MR Imaging of the Lung: Added Value for Your Thoracic Imaging Practice**

Participants
Juergen Biederer, MD, Heidelberg, Germany (Presenter) Nothing to Disclose

For information about this presentation, contact:
juergen.biederer@uni-heidelberg.de

**LEARNING OBJECTIVES**

1) To give an overview over the diagnostic scope of lung MRI for pathologies of lung parenchyma and airway disease. 2) To review the diagnostic yield of MRI for the detection and characterisation of lung nodules. 3) To introduce MRI as potential first choice modality for imaging pulmonary disease in young or pregnant patients. 4) To discuss the potential role of lung MRI as an alternative or adjunct modality, e.g. in COPD or interstitial lung diseases.

**ABSTRACT**

MRI of the lung can play an interesting role and be added value to your thoracic imaging practice besides X-ray and CT. The sensitivity of MRI for infiltrates is at least similar to X-ray and CT, lung nodule detection is superior to X-ray and slightly inferior to CT and favorable options for tissue characterization (exclusion of malignancy) and functional imaging capacities (perfusion, ventilation, respiratory motion) are available with standardized protocols. Given this, MRI may serve as a radiation-free alternative in patients who should not be exposed to ionizing radiation (children and young subjects, pregnant patients), e.g. as your first
choice modality in patients with cystic fibrosis. It may well serve as an adjunct to other modalities for comprehensive lung imaging in COPD and some cases of interstitial lung diseases, e.g. sarcoidosis (dark lymph node sign). In young patients, MRI may well be used for the long term follow-up of malignancy (e.g. seminoma) or inflammatory disease (e.g. GPA/Wegener's disease). As an adjunct or alternative to other modalities, MRI can be helpful in lung cancer staging and follow-up (differentiation of atelectasis and lung cancer) or the characterization of lung nodules ('actionable nodules' with contrast uptake, high NPV in nodules with no or low contrast uptake, fatty content in hamartoma). MRI might even be suitable for the early detection of lung cancer, either as the primary screening tool or for the ad-hoc diagnostic work-up of detected lesions on site.

**RC801D  Magnetic Resonance Imaging of Cardiac Masses**

Participants
Nila J. Akhtar, MD, Rochester, MN *(Presenter)* Nothing to Disclose

**LEARNING OBJECTIVES**

1) List most common benign and malignant cardiac masses.
2) Assemble key magnetic resonance imaging sequences into a protocol to assess cardiac masses.
3) Recognize magnetic resonance imaging features of select benign and malignant cardiac masses.

**RC801E  MR Imaging of Aortopathies**

Participants
Cristina Fuss, MD, Portland, OR *(Presenter)* Spouse, Officer, ViewRay, Inc

**LEARNING OBJECTIVES**

1) To familiarize the learner with the most common familiar aortopathies, their clinical background, imaging appearance on MRI and specific considerations for MR acquisition planning.

**ABSTRACT**

Familial aortopathies comprise a group of inherited disorders of aortic aneurysms and/or dissection including. These include Thoracic Aortic Aneurysms and Aortic Dissections (TAAD), Marfan syndrome, Loeys-Dietz syndrome, and Ehlers-Danlos syndrome, only to name the most common ones.

Printed on: 10/20/19
Avulsion Injuries of the Upper and Lower Extremities

Friday, Dec. 6 8:30AM - 10:00AM Room: E451B

Participants
Zehava S. Rosenberg, MD, Hoboken, NJ (Director) Nothing to Disclose

Sub-Events

RC804A Upper Extremity

Participants
Lee F. Rogers, MD, Tucson, AZ (Presenter) Nothing to Disclose

For information about this presentation, contact:
lfrogers@comcast.net

LEARNING OBJECTIVES

1) Obtain appropriate radiographs, AP, lateral and obliques; oblique views are essential as certain fractures may be visible only on this projection. 2) Certain fractures and dislocations are notorious for being overlooked; know these injuries and be certain to identify or exclude them. 3) Certain ligamentous avulsion of the digits are associated with characteristic deformities allowing a definitive diagnosis of the underlying abnormality. 4) Be aware of the potential for satisfaction of search and the potential of diagnostic oversights in certain injuries; once such an injury is noted look closely for the commonly associated injury. 5) When the clinical diagnosis is not apparent or uncertain on the initial radiographs, do not hesitate to obtain CT or MRI to confirm or exclude an injury.

RC804B Avulsion Injuries of the Pelvis and Hip

Participants
Omer A. Awan, MD, Baltimore, MD (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Outline the spectrum of avulsive injuries in the pelvis and hip. 2) Delineate imaging characteristics of pelvic and hip avulsive injuries, with emphasis on radiography and MRI. 3) Elucidate practical and clinical applications to pelvic and hip avulsive injuries.

ABSTRACT
n/a

RC804C Knee

Participants
Thomas L. Pope, MD, Denver, CO (Presenter) Nothing to Disclose

For information about this presentation, contact:
thomaspopemd@gmail.com

LEARNING OBJECTIVES

1) Delineate the most common avulsion injuries in the knee. 2) Outline the most common imaging features of avulsion injuries in the knee. 3) Describe the complimentary role of radiography, CT and MR imaging in the diagnosis of avulsion injuries of the knee. 4) Provide some hints on keys to avoid missing these lesions in your clinical practice.

RC804D Foot and Ankle

Participants
Zehava S. Rosenberg, MD, Hoboken, NJ (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Familiarize the radiologist with radiographic findings of common avulsion injuries of the ankle and foot with emphasis on frequently missed entities. 2) Provide cross sectional imaging correlation for all the described entities. 3) Provide the radiologist with tools for distinguishing radiographic evidence of pathology from mimickers of disease.
Call in the Troops, or Walk on By? Management of Unexpected Findings in Neuro/Head & Neck (Interactive Session)

Friday, Dec. 6 8:30AM - 10:00AM Room: E450B

AMA PRA Category 1 Credits ™: 1.50
ARRT Category A+ Credit: 1.75

Participants
Deborah R. Shatzkes, MD, New York, NY (Moderator) Nothing to Disclose
Pejman Jabehdar Maralani, MD, FRCPC, Toronto, ON (Moderator) Nothing to Disclose

For information about this presentation, contact:
pejman.maralani@utoronto.ca

Sub-Events

RC805A Unexpected Intracranial Findings
Participants
Alireza Radmanesh, MD, New York, NY (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Identify and describe the most frequently encountered unexpected/incidental intracranial findings. 2) Characterize some potentially significant consequences of incidental intracranial findings. 3) Identify and implement the best available recommendations to handle incidental intracranial findings.

RC805B Unexpected Skull Base Findings
Participants
Tabassum A. Kennedy, MD, Saint Louis, MO (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Recognize common anatomic variants of the skull base. 2) Recommend the appropriate next step in evaluating a patient with an unexpected skull base lesion. 3) Generate a short differential for common skull base lesions based on anatomic location.

RC805C Unexpected Spine Findings
Participants
Jason F. Talbott, MD, PhD, Novato, CA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Gain familiarity with 4 basic craniospinal metrics that will enable the radiologist to readily identify unexpected congenital anomalies of the spine and craniovertebral junction. 2) Identify and the top blindspots in spine CT and MRI for frequently missed and clinically significant incidental findings. 3) Review clinical recommendations for the most frequent incidental findings on spine imaging.

ABSTRACT
With the progressive increase in spine imaging, unexpected findings not related to the initial clinical indication for imaging are increasingly recognized. While many of these findings are incidental and require no further management recommendations, some incidental findings are of clinical significance. Thus, it is paramount that the radiologist is familiar with the imaging appearance of clinically significant incidental findings of the spine. It is equally important that the radiologist's diagnostic search pattern of the spine includes areas where incidental, but clinically significant spine findings are frequently observed. This presentation will prepare the radiologist to identify the most frequent and clinically significant incidental findings on cross-sectional spine studies including unexpected congenital, infectious, and traumatic pathologies. Appropriate clinical recommendations will also be discussed.

RC805D Unexpected Neck Findings
Participants
Phillip R. Chapman, MD, Birmingham, AL (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Identify and describe the most frequently encountered unexpected/incidental findings in neck, 2) Characterize some potentially significant findings of clinical significance.
1) Identify and describe the most frequently encountered unexpected/incidental findings in neck. 2) Characterize some potentially significant consequences of incidental neck findings. 3) Identify and implement the best available recommendations to handle incidental intracranial findings. 4) Improve awareness of learn search strategies for identifying incidental or unexpected findings in the neck.

Printed on: 10/20/19
Body CT Angiography: 2019 Update
Friday, Dec. 6 8:30AM - 10:00AM Room: E351

CT  VA

AMA PRA Category 1 Credits ™: 1.50
ARRT Category A+ Credit: 1.75

Participants
Alan H. Stolpen, MD, PhD, Iowa City, IA (Moderator) Nothing to Disclose
Gregory Kicska, MD, PhD, Seattle, WA (Moderator) Nothing to Disclose

For information about this presentation, contact:
alan-stolpen@uiowa.edu

Sub-Events

RC812A  Thoracic CTA

Participants
Gregory Kicska, MD, PhD, Seattle, WA (Presenter) Nothing to Disclose

For information about this presentation, contact:
kicskag@uw.edu

RC812B  Abdominal CTA

Participants
Eric E. Williamson, MD, Rochester, MN (Presenter) Nothing to Disclose

For information about this presentation, contact:
Williamson.eric@mayo.edu

LEARNING OBJECTIVES
1) Identify common clinical indications for abdominal CT angiography, 2) Describe techniques for performing abdominal CTA, 3) Discuss how recent developments in CT have influenced these techniques and the resulting imaging findings.

RC812C  Peripheral CTA

Participants
Alan H. Stolpen, MD, PhD, Iowa City, IA (Presenter) Nothing to Disclose

For information about this presentation, contact:
alan-stolpen@uiowa.edu

LEARNING OBJECTIVES
1) Identify common clinical indications for peripheral CTA. 2) Describe protocols for performing and strategies for reviewing peripheral CTA. 3) Recognize a variety of vascular pathologies. 4) Understand the strengths, weaknesses and pitfalls of peripheral CTA.

Printed on: 10/20/19
LEARNING OBJECTIVES

1) Review causes of atraumatic pediatric brain emergencies. 2) Illustrate "teaching points" and things not to miss. 3) Discuss optimal imaging techniques for lesion detection.

ABSTRACT

The topic of 'Nontraumatic Brain Emergencies' include several causes of significant morbidity and mortality in children. Vascular causes, such as stroke and sinus thrombosis will be discussed, with illustrative cases to demonstrate tips for interpreting neuroimaging in children of all ages. Infectious and subtle neoplastic cases will also be reviewed to highlight 'what not to miss' in this 20 minute review.

LEARNING OBJECTIVES

1) Identify the pediatric head and neck pathologies that can present in the emergency setting. 2) Describe the complications and routes of spread of pediatric head and neck infections. 3) Recommend the best imaging technique and next step in management for common head and neck emergencies.

LEARNING OBJECTIVES

1) To identify and understand the significance of critical imaging findings in pediatric spine emergencies in both traumatic and atraumatic settings.
The Neoadjuvant Patient

Friday, Dec. 6 8:30AM - 10:00AM Room: E352

AMA PRA Category 1 Credits ™: 1.50
ARRT Category A+ Credit: 1.75

Participants
Eric L. Rosen, MD, Seattle, WA (Moderator) Nothing to Disclose

For information about this presentation, contact:
zuleyml@upmc.edu

LEARNING OBJECTIVES
1) To discuss three clinically significant areas involving care of the breast cancer patient undergoing neoadjuvant therapy. 2) To apply in everyday clinical practice the principles and conclusions learned.

Sub-Events

RC815A State-of-the-Art: An Evidence-based Approach

Participants
Eric L. Rosen, MD, Seattle, WA (Presenter) Nothing to Disclose

RC815B Ongoing Trials and Future Directions

Participants
Jessica W. Leung, MD, Houston, TX (Presenter) Scientific Advisory Board, Subtle Medical

LEARNING OBJECTIVES
1) To learn the design of some of the ongoing clinical trials involving care of the breast cancer patient receiving neoadjuvant therapy. 2) To describe the imaging components of these trials. 3) To understand the role that imaging plays in these trials.

RC815C Ultrasound Evaluation of the Axilla in the Neoadjuvant Patient

Participants
Steven P. Poplack, MD, Saint Louis, MO (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Identify the key US criteria that are predictive of axillary lymph node metastases. 2) Appraise the accuracy of axillary US in the setting of Invasive Breast Cancer. 3) Describe the role of axillary US in the surgical management of the axilla after neoadjuvant treatment.

Printed on: 10/20/19
Taking Action to Promote Gender Inclusion in Radiology: A Roadmap for Progress (Sponsored by the RSNA Professionalism Committee)

Friday, Dec. 6 8:30AM - 10:00AM Room: E253CD

Participants
Anastasia L. Hryhorczuk, MD, Ann Arbor, MI (Moderator) Nothing to Disclose
Kate Hanneman, MD, FRCPC, Toronto, ON (Moderator) Nothing to Disclose

For information about this presentation, contact:
laurabancoftmd@gmail.com

LEARNING OBJECTIVES
1) Implement strategies to address unconscious bias and improve gender disparity in radiology. 2) Discuss strategies that can be used to promote engagement and retention of radiologist with young families. 3) Describe professional development programs that can be utilized to support women in radiology. 4) Demonstrate the ability to identify and address sexual misconduct and discrimination.

ABSTRACT
In 2017, the number of women enrolling in American medical schools surpassed men for the first time. However, women continue to comprise a minority of the radiology workforce, with women representing only 27% of the radiology residents and 23% of attending physicians in the United States. How can radiologists construct an inclusive workplace that actively recruits and retains an increasingly diverse population of physicians? This refresher course, sponsored by the RSNA Professionalism Committee, will suggest concrete, practical, and actionable ways to build a culture that recognizes and values equitable gender diversity in radiology, both with respect to recruiting and hiring women and to developing and sustaining professional careers.

Sub-Events

RC816A Unconscious Bias in Recruiting Female Radiologists

Participants
Katarzyna J. Macura, MD,PhD, Catonsville, MD (Presenter) Author with royalties, Reed Elsevier; Research Grant, Profound Medical Inc; Research Grant, GlaxoSmithKline plc; Research Grant, Siemens AG

For information about this presentation, contact:
kmacura@jhmi.edu

LEARNING OBJECTIVES
1) Discuss unconscious bias as a natural phenomenon that needs to be managed. 2) Mitigate bias in recruitment, promotion, and attitudes to others in the workplace.

ABSTRACT
Addressing the gender disparity in radiology requires an understanding of and willingness to tackle unconscious biases—the pervasive tendencies to make assumptions about people based on gender, race and other characteristics rooted in unconscious feelings.

RC816B Sexual Misconduct in Radiology

Participants
Anastasia L. Hryhorczuk, MD, Ann Arbor, MI (Presenter) Nothing to Disclose

For information about this presentation, contact:
ahryhorc@med.umich.edu

LEARNING OBJECTIVES
1) To discuss the pervasiveness of sexual harassment and misconduct in radiology. 2) To describe education and management skills that have been deployed in other work environments to address harassment and discrimination.

ABSTRACT
As discussions of sexual misconduct and gender discrimination continue to merit significant attention in society at large, radiologists, too, are being forced to grapple with harassment and bias in the workplace.

RC816C Work-Life Balance for Radiologists with Young Families

Participants

...
LEARNING OBJECTIVES
1) To discuss the challenges that face young and dual-career families in radiology and strategies to promote work life balance, engagement and retention of radiologists during and after parental leave.

ABSTRACT
For young women and men in radiology, the beginning of a career often coincides with starting a family. As young physicians are trying to gain their footing at work, external and family pressures may begin to encroach on career advancement. Are radiology workplaces enthusiastically supporting individuals who are facing new challenges once they have already entered the career pipeline?

RC816D  Informal Programs for Mentoring Women in Radiology

Participants
Ella A. Kazerooni, MD, Ann Arbor, MI (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) To discuss the importance of professional development and the role of informal programs for mentoring women in radiology. 2) Explore strategies for developing these initiatives as new programs in academic institutions.

ABSTRACT
Women remain underrepresented in leadership positions in radiology and academic medicine. Once women gain faculty positions in radiology, professional development and sponsorship are essential to providing them with the tools needed to progress through their career.

RC816E  Formal Programs for Mentoring Women in Radiology

Participants
Lucy B. Spalluto, MD, Nashville, TN (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) To discuss the implementation and evaluation of a formal leadership program designed to improve access to opportunities for women's faculty development and advancement in radiology.

ABSTRACT
Formal faculty development and mentorship programs are also important, fostering career development opportunities and the executive skills necessary for women to achieve academic career success and assume leadership positions.

ARRT Category A+ Credit: 1.75
FDA
Discussions may include off-label uses.

Participants
Rathan M. Subramaniam, MD, PhD, Dallas, TX (Moderator) Nothing to Disclose

For information about this presentation, contact:
rathan.subramaniam@utsouthwestern.edu

LEARNING OBJECTIVES
1) To review the established and emerging molecularly targeted radionuclide therapies for human solid tumors.

Sub-Events

RC817A  Thyroid Cancer: 131-I Na Therapy

Participants
Neeta Pandit-Taskar, MD, New York, NY (Presenter) Consultant, Actinium Pharmaceuticals, Inc; Consultant, Progenics Pharmaceuticals, Inc; Consultant, inviCRO, LLC; Consultant, AstraZeneca PLC; Advisory Board, Actinium Pharmaceuticals, Inc; Advisory Board, Progenics Pharmaceuticals, Inc; Advisory Board, InviCRO, LLC; Advisory Board, AstraZeneca PLC; Speaker, Actinium Pharmaceuticals, Inc; Speaker, Progenics Pharmaceuticals, Inc; Speaker, AstraZeneca PLC

RC817B  Phaeochromocytomas and Paragangliomas: 131-I MIBG Therapy

Participants
Lilja B. Solnes, MD, Baltimore, MD (Presenter) Advisory Board, Progenics Pharmaceuticals, Inc

RC817C  Neuroendocrine Tumors: 177Lu-DOTATATE Therapy

Participants
Rathan M. Subramaniam, MD, PhD, Dallas, TX (Presenter) Nothing to Disclose

For information about this presentation, contact:
rathan.subramaniam@utsouthwestern.edu

LEARNING OBJECTIVES
1) To learn the indications and patient selections for 177Lu DOTATATE therapy. 2) To review the 177Lu DOTATATE therapy procedures, toxicity monitoring and patient care follow-up. 3) To review therapy response methods for 177Lu DOTATATE treatments.

RC817D  Prostate Cancer: 177Lu-PSMA Therapy

Participants
Ayse Tuba Karagulle Kendi, MD, Rochester, MN (Presenter) Investigator, Endocyte, Inc

For information about this presentation, contact:
kendi.ayse@mayo.edu

LEARNING OBJECTIVES
1) Brief review of clinical background. 2) Discuss basic principles of Lu-PSMA therapy. 3) Describe therapy methods. 4) Explain side effects. 5) Review clinical impact/outcomes of Lu-PSMA therapy.

Printed on: 10/20/19
Participants

Sandy Napel, PhD, Stanford, CA (Coordinator) Medical Advisory Board, Fovia, Inc; Scientific Advisor, EchoPixel, Inc; Scientific Advisor, RADLogics, Inc

LEARNING OBJECTIVES

1) Learn about the role of image annotations in radiology and their relevance to enabling interoperability and for communicating results and value for machine learning and decision support. 2) Become acquainted with important standards and tools that support the creation, management, and use of image annotations. 3) See case examples of image annotations in practice to enable developing applications that help the practice of radiology. 4) Understand the categories of, and the specific radiomic image features that can be computed from images. 5) Understand the effect and implications of image acquisition and reconstruction on radiomic image features. 6) Learn about workflows that drive the creation of predictive models from radiomic image features. 7) Understand the methods for and the potential value of correlating radiological images with genomic data for research and clinical care. 8) Learn how to access genomic and imaging data from databases such as The Cancer Genome Atlas (TCGA) and The Cancer Imaging Archive (TCIA) databases, respectively. 9) Learn about methods and tools for annotating regions within images and link them with semantic and computational features. 10) Learn about methods and tools for analyzing molecular data, generating molecular features and associating them with imaging features. 11) Learn how deep learning can revolutionize interpretation of medical images.

Sub-Events

RCB2SA  Image Annotation and Semantic Labeling

Participants

Daniel L. Rubin, MD, Stanford, CA (Presenter) Consultant, F. Hoffmann-La Roche Ltd

For information about this presentation, contact:
daniel.l.rubin@stanford.edu

LEARNING OBJECTIVES

1) To learn about the role of image annotations in radiology and their relevance to enabling interoperability and for communicating results and value for machine learning and decision support. 2) To become acquainted with important standards and tools that support the creation, management, and use of image annotations. 3) To see case examples of image annotations in practice to enable developing applications that help the practice of radiology.

RCB2SB  Image feature Computation and Considerations

Participants

Sandy Napel, PhD, Stanford, CA (Presenter) Medical Advisory Board, Fovia, Inc; Scientific Advisor, EchoPixel, Inc; Scientific Advisor, RADLogics, Inc

For information about this presentation, contact:
snapel@stanford.edu

LEARNING OBJECTIVES

1) To understand the categories of, and the specific radiomic image features that can be computed from images. 2) To understand the effect and implications of image acquisition and reconstruction on radiomic image features. 3) To learn about workflows that drive the creation of predictive models from radiomic image features.

RCB2SC  Correlating Image features with Multi-Omics Data

Participants

Olivier Gevaert, PhD, Stanford, CA (Presenter) Nothing to Disclose

For information about this presentation, contact:
ogevaert@stanford.edu

LEARNING OBJECTIVES

1) Understand the methods for and the potential value of correlating radiological images with genomic data for research and clinical care. 2) Learn how to access genomic and imaging data from databases such as The Cancer Genome Atlas (TCGA) and The Cancer Imaging Archive (TCIA) databases, respectively. 3) Learn about methods and tools for annotating regions within images and link them with semantic and computational features. 4) Learn about methods and tools for analyzing molecular data, generating
molecular features and associating them with imaging features. 5) Introduction into how deep learning can revolutionize interpretation of medical images: challenges and opportunities.

ABSTRACT

Radiogenomics is an emerging field that integrates medical images and genomic data for the purposes of improved clinical decision making and advancing discovery of critical disease processes. In cancer, both imaging and genomic data are becoming publicly available through The Cancer Imaging Archive (TCIA) and The Cancer Genome Atlas (TCGA) databases, respectively. The TCIA/TCGA provide examples of matched molecular and image data for five cancer types, namely breast, lung, brain, prostate and kidney. The data in TCGA includes various omics data such as gene expression, microRNA expression, DNA methylation and mutation data. Quantitative image analysis from MRI, CT and/or PET images in TCIA has now become widespread and these image features represent concepts such as tumor volume, shape, edge sharpness, voxel-value histogram statistics, image textures, and specialized features developed for particular acquisition modes. Similarly, images are being annotated with semantic descriptors by radiologists using controlled terminologies to record the visual characteristics of the diseases. The availability of these linked imaging-genomic data provides exciting new opportunities to recognize imaging phenotypes that emerge from molecular characteristics of disease and that can potentially serve as biomarkers of disease and its response to treatment. They also provide an opportunity to discover key molecular processes associated with distinct image features, within one cancer type and across different cancer types. More recently, deep learning approaches have become very popular to analyze medical images. Deep learning has the advantage that no features have to be engineered beforehand, and everything is learned from the image. This workshop will describe datasets and tools that enable research at the intersection of imaging and genomics, and focus on the opportunities and challenges to develop future applications that leverage this knowledge for diagnostic decision support and treatment planning.

Engaging Patients: Opportunities and Challenges for Radiology

Friday, Dec. 6 8:30AM - 10:00AM Room: E261

Participants
Ramin Khorasani, MD, Roxbury Crossing, MA (Moderator) Nothing to Disclose

Sub-Events
RC827A Price Transparency

Participants
Gelareh Sadigh, MD, Atlanta, GA (Presenter) Nothing to Disclose

For information about this presentation, contact:
gsadigh@emory.edu

LEARNING OBJECTIVES
1) Define health-related financial toxicity and healthcare price transparency. 2) Differentiate cost vs charges vs paid price. 3) Assess impact of financial burden from cost of treatment on patient-reported outcomes. 4) Assess impact of healthcare price transparency tools on patients' spending. 5) Apply knowledge gained from this session in their encounter with patients.

RC827B Patient Reported Data and Its Impact on Quality and Safety

Participants
Keith D. Hentel, MD, MS, New York, NY (Presenter) Nothing to Disclose

RC827C Patient Portals to Access Results: Opportunities and Challenges

Participants
Teresa Martin-Carreras, MD, Philadelphia, PA (Presenter) Nothing to Disclose

For information about this presentation, contact:
Teresa.Martin-Carreras@pennmedicine.upenn.edu

RC827D Eliminating Ordered but Not Performed Imaging in Your Practice: What Are the Safety Risks and Solutions?

Participants
Ronilda Lacson, MD, PhD, Brookline, MA (Presenter) Nothing to Disclose

For information about this presentation, contact:
rlacson@rics.bwh.harvard.edu

LEARNING OBJECTIVES
1) To quantify the incidence of diagnostic imaging that are ordered but not performed in clinical practice. 2) To identify factors that affect failure in scheduling and performance of diagnostic imaging orders. 3) To learn potential solutions for eliminating unperformed diagnostic imaging orders in practice.

Printed on: 10/20/19
LEARNING OBJECTIVES

1) Understand the advantages and disadvantages of MRI in the acute setting for the diagnosis of acute genitourinary disorders. 2) Identify the diagnostic criteria for ovarian torsion and also predict ovarian viability with MRI. 3) Contrast the strengths of different MRI sequences for the diagnosis of pyelonephritis. 4) Apply a rapid, noncontrast MRI protocol for the imaging of acute abdominopelvic pain that is accurate for the diagnosis of acute genitourinary disorders. 5) Discuss clinical and imaging features of a spectrum of entities that present with acute female pelvic pain including complications of fibroids, pelvic inflammatory disease and complicated cysts. 6) Highlight the pathogenesis and pertinent MR imaging features of adnexal (ovarian and tubal) torsion. 7) Assess the relative advantages and disadvantages for MR vs. other imaging modalities for suspected appendicitis in adults. 8) Assess the ability of MR for making alternative diagnoses to acute appendicitis in the setting of non-traumatic abdominal pain. 9) Consider the implications for the potential increased use of MR in the ED for non-traumatic abdominal pain. 10) Identify patients who will benefit from MR enterography in the emergency setting. 11) Protocol and perform MR enterography in the acute setting. 12) Identify and report acute findings of Crohn's disease in MR enterography. 13) Discuss the most common indications for abdominal or pelvic MRI in pediatric patients in the emergent setting. 14) Demonstrate and discuss the most frequently encountered MRI imaging manifestations of these conditions. 15) Review the most appropriate MRI protocols for evaluation of pediatric patients presenting to the Emergency Department with acute abdominal or pelvic pain. 16) Discuss available techniques for achieving patient cooperation and limiting exam time in pediatric patients. 17) Understand MRI safety concerns in the setting of pregnancy. 18) Understand indications for emergency MRI during pregnancy. 19) Implement an imaging protocol for emergency MRI during pregnancy. 20) Understand MRI appearance of common acute disease processes during pregnancy.

Sub-Events

RC829A MRI for Acute Genitourinary Disorders

Participants
Bobby T. Kalb, MD, Tucson, AZ (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Discuss clinical and imaging features of a spectrum of entities that present with acute female pelvic pain including complications of fibroids, pelvic inflammatory disease and complicated cysts. 2) Highlight the pathogenesis and pertinent MR imaging features of adnexal (ovarian and tubal) torsion.

RC829B MRI for Acute Pelvic Pain in Women

Participants
Christine O. Menias, MD, Chicago, IL (Presenter) Nothing to Disclose

For information about this presentation, contact:
menias.christine@mayo.edu

LEARNING OBJECTIVES

1) Assess the relative advantages and disadvantages for MR vs. other imaging modalities for suspected appendicitis in adults. 2) Assess the ability of MR for making alternative diagnoses to acute appendicitis in the setting of non-traumatic abdominal pain. 3) Consider the implications for the potential increased use of MR in the ED for non-traumatic abdominal pain.

RC829C MRI for Acute Appendicitis and Differential Diagnosis

Participants
Perry J. Pickhardt, MD, Madison, WI (Presenter) Stockholder, SHINE Medical Technologies, Inc; Stockholder, Elucent Medical; Advisor, Bracco Group;

LEARNING OBJECTIVES

1) Understand the advantages and disadvantages of MRI in the acute setting for the diagnosis of acute genitourinary disorders. 2) Identify the diagnostic criteria for ovarian torsion and also predict ovarian viability with MRI. 3) Contrast the strengths of different MRI sequences for the diagnosis of pyelonephritis. 4) Apply a rapid, noncontrast MRI protocol for the imaging of acute abdominopelvic pain that is accurate for the diagnosis of acute genitourinary disorders.

RC829D MRI for Crohn's Disease in the Acute Setting

Participants
For information about this presentation, contact:
dgrand@lifespan.org

LEARNING OBJECTIVES
1) Identify patients who will benefit from MR enterography in the acute setting. 2) Protocol and perform MR enterography in the acute setting. 3) Identify and report acute findings of Crohn's disease on MR enterography.

RCB29E  MRI for Acute Pediatric Disorders

Participants
Sarah D. Bixby, MD, Boston, MA (Presenter) Nothing to Disclose

For information about this presentation, contact:
sarah.bixby@childrens.harvard.edu

LEARNING OBJECTIVES
1) Discuss the most common indications for abdominal or pelvic MRI in pediatric patients in the emergent setting. 2) Demonstrate and discuss the most frequently encountered MRI imaging manifestations of these conditions. 3) Review the most appropriate MRI protocols for evaluation of pediatric patients presenting to the Emergency Department with acute abdominal or pelvic pain. 4) Discuss available techniques for achieving patient cooperation and limiting exam time in pediatric patients.

RCB29F  Emergency MRI During Pregnancy

Participants
Gaurav Khatri, MD, Irving, TX (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Understand MRI safety concerns in the setting of pregnancy. 2) Understand indications for emergency MRI during pregnancy. 3) Implement an imaging protocol for emergency MRI during pregnancy. 4) Understand MRI appearance of common acute disease processes during pregnancy.

Sub-Events

RC832A  Measuring Radiology Productivity

Participants
Sanjay Saini, MD, Boston, MA (Presenter) Nothing to Disclose

RC832B  Measuring Radiology Quality

Participants
Lauren P. Golding, MD, Summerfield, NC (Presenter) Nothing to Disclose

For information about this presentation, contact: laurengoldingmd@gmail.com

LEARNING OBJECTIVES
1) Understand the role of Quality in the Merit Based Incentive Payment System. 2) Become familiar with the collection types available for reporting quality measures into MIPS. 3) Understand the history of Qualified Clinical Data Registries. 4) Learn how to implement radiology specific QCDR into your practice.

RC832C  Radiology Compensation Benchmarks

Participants
Vincent P. Mathews, MD, Hartland, WI (Presenter) Nothing to Disclose

For information about this presentation, contact: vmathews@mcw.edu

LEARNING OBJECTIVES
1) To learn about the implementation of fair market value compensation plans. 2) To understand the importance of utilizing appropriate benchmarks for clinical productivity measures.

RC832D  The Financial Impact of Payment Reform on Radiology

Participants
Suresh K. Mukherji, MD, Northville, MI (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Review the different financial reforms that have affected radiology. 2) Explain the effects these reforms have had on radiology. 3) Discuss future strategies that can help mitigate the downward trends on radiology reimbursement.

LEARNING OBJECTIVES

1) Describe the technique and optimally perform carotid Doppler ultrasound. 2) Describe the technique and optimally perform renal Doppler ultrasound. 3) Review qualitative and quantitative criteria for diagnosing abnormalities in carotid and renal ultrasound Doppler examinations.

ABSTRACT

This hands-on course will provide participants with a combination of didactic lectures and an extended 'live' scanning opportunity on normal human volunteers, as follows: Didactic lectures (30 minutes): Carotid Doppler ultrasound: scanning technique, diagnostic criteria and interesting teaching cases. Renal Doppler ultrasound: scanning technique, diagnostic criteria and interesting teaching cases. Mentored scanning (60 minutes): Following the didactic lectures, the participants will proceed to a scanning area with normal human volunteers and ultrasound machines from different manufacturers. Participants will be able to perform live scanning with direct assistance, as needed, by faculty. Faculty will be able to offer feedback, help participants improve their scanning technique as well as answer any questions. Time permitting, faculty will also be available to answer general questions relating to all aspects of vascular ultrasound, not just limited to carotid and renal Doppler studies.

whsu@mednet.ucla.edu

**LEARNING OBJECTIVES**

1) Identify the year's most important advances in imaging informatics. 2) Describe the ways in which Artificial Intelligence (AI) and machine learning are impacting radiology. 3) Define how radiomics, radiogenomics, and 'big data' have added to our knowledge of radiology.

**ABSTRACT**

The field of imaging informatics continues to advance rapidly. Machine learning, a form of artificial intelligence (AI), has improved the ability to detect image features, make diagnoses, and assess prognosis from image data. Radiomics - which generates high-dimensionality datasets from radiology images - provides insights to support precision medicine. Novel approaches have improved sharing of images and image-derived findings with patients and clinicians. Current research efforts go beyond pixel data to integrate imaging with other biomedical data, standardize imaging workflows, and improve the quality and utility of image-derived information in clinical practice. This session reviews key advances in imaging informatics research published this past year.
International Symposium on Cardiothoracic Imaging

Friday, Dec. 6 8:30AM - 12:00PM Room: E353C

**SPIS61A**  
**Diffuse Lung Disease**  
Friday, Dec. 6 8:30AM - 9:20AM Room: E353C

Participants  
Jeremy J. Erasmus, MD, Houston, TX (Director)  
Carol C. Wu, MD, Houston, TX (Director)  
Nothing to Disclose

For information about this presentation, contact:  
carolcwu@gmail.com

**LEARNING OBJECTIVES**

1) Define the role of imaging in the diagnosis and characterization of cardiothoracic diseases.  
2) Describe available advanced imaging techniques in the evaluation of cardiothoracic diseases.

**Sub-Events**

**SPIS61B**  
**Introduction to Idiopathic Pulmonary Fibrosis: What Radiologists Need to Know**  
Friday, Dec. 6 8:30AM - 9:20AM Room: E353C

Participants

**LEARNING OBJECTIVES**

1) To introduce most common imaging features of ILD.  
2) To introduce ATS / ERS / JRS /ALAT guidelines.

**SPIS61C**  
**Imaging Diagnosis of Idiopathic Pulmonary Fibrosis: Status and Challenges**  
Friday, Dec. 6 8:30AM - 9:20AM Room: E353C

Participants  
Qihang Chen, MD, Beijing, China (Presenter)  
Nothing to Disclose

**LEARNING OBJECTIVES**

1) To compare the white paper of the Fleischner society with ATS/ERS/JRS/LATA guidelines.  
2) To differentiate the honeycomb and mimic honeycomb.  
3) To introduce the status of diagnosis of IPF in China.

**SPIS61D**  
**Staging and Prognostication of Idiopathic Pulmonary Fibrosis**  
Friday, Dec. 6 8:30AM - 9:20AM Room: E353C

Participants  
Nicola Sverzellati, MD, Parma, Italy (Presenter)  
Consultant, PAREXEL International Corporation; Consultant, Biomedic System;  
Consultant, F. Hoffmann-La Roche Ltd; Consultant, Boehringer Ingelheim GmbH; Consultant, Galapagos; Advisory Board, F. Hoffmann-La Roche Ltd; Advisory Board, Boehringer Ingelheim GmbH; Speaker, F. Hoffmann-La Roche Ltd; Speaker, Boehringer Ingelheim GmbH;

**LEARNING OBJECTIVES**

1) To understand the most accurate visual and computer-based CT indexes for IPF staging and prognostication.  
2) To describe some of the current technologies and cutting edge perspective for objective quantification of IPF on CT.

**SPIS61E**  
**Quantitative Assessment of Interstitial Lung Disease on CT**
Participants
Joon Beom Seo, MD, PhD, Seoul, Korea, Republic Of (Presenter) Stockholder, Coreline Soft Co;

For information about this presentation, contact: 
joonbeom.seo@gmail.com

LEARNING OBJECTIVES
1) To understand why quantitative assessment of interstitial lung disease on CT is necessary. 2) To know the basic technical concept of various software methods for quantification of interstitial lung disease. 3) To acknowledge the potential clinical values of using quantitative imaging biomarkers in practice.

SPIS61F  Lung Nodules and Cancer
Friday, Dec. 6 9:25AM - 10:15AM Room: E353C

Participants
Claudio Silva Fuente-Alba, MD, MsC, Santiago, Chile (Moderator) Nothing to Disclose
Carol C. Wu, MD, Houston, TX (Moderator) Author, Reed Elsevier

For information about this presentation, contact:
carolcwu@gmail.com

LEARNING OBJECTIVES
1) Compare and contrast lung cancer screening strategies in the United States and Asia. 2) Describe the role of computer softwares, CT and MRI in the detection and characterization of lung nodules.

SPIS61G  Lung Cancer Screening in the US
Friday, Dec. 6 9:25AM - 10:15AM Room: E353C

Participants
Carol C. Wu, MD, Houston, TX (Presenter) Author, Reed Elsevier

LEARNING OBJECTIVES

SPIS61H  Lung Cancer Screening in Asia
Friday, Dec. 6 9:25AM - 10:15AM Room: E353C

Participants
Yeun-Chung Chang, MD, Taipei, Taiwan (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) To understand the incidence and some screening programs of lung cancer in Asia. 2) To know the characteristic CT findings of screen detected lung cancer in Asian and how it is managed.

ABSTRACT
Lung cancer is the leading cause of cancer death worldwide so dose it in Asia. There is a much higher prevalence of epidermal growth factor receptor (EGFR) mutation, predominantly among patients with adenocarcinoma and never-smokers. Some reports of lung cancer screening in Asia show a cancer detection rate about 1.0-2.5% in Asia. CT characteristic of lung cancer with EGFR mutation and clinical management of the screen detected lung cancer in Taiwan will be described.

SPIS61I  Pulmonary Nodules: Impact of Computer Support
Friday, Dec. 6 9:25AM - 10:15AM Room: E353C

Participants
Cornelia M. Schaefer-Prokop, MD, Amersfoort, Netherlands (Presenter) Researcher, Thirona; Researcher, Varian Medical Systems, Inc; Spouse, Speaker, Bracco Group; Spouse, Speaker, Bayer AG; Spouse, Speaker, Canon Medical Systyerm Corporation; Spouse, Speaker, Siemens AG; Spouse, Research support, Siemens AG; Spouse, Research support, Canon Medical Systems Corporation; Spouse, Researcher, Thirona; Spouse, Researcher, Varian Medical Systems, Inc

LEARNING OBJECTIVES
1) To learn about available computer tools for detection and characterization of pulmonary nodules. 2) To understand the potential but also shortcomings of current computer tools for nodules. 3) To learn about various models for malignancy risk assessment and how they are implemented in computer tools.
LEARNING OBJECTIVES

1) To deliver the updates of PET, PET/CT and MRI for lung nodule characterization and management of pulmonary nodule.

ABSTRACT

In this lecture, I will talk about 1) lung nodule detection capability, 2) morphological evaluation of lung nodule characterization and 3) quantitative potential for lung nodule characterization on PET, PET/CT and MRI. I hope this lecture will contribute your daily clinical practice.

LEARNING OBJECTIVES

1) To become familiar with the variable imaging findings related to CAP. 2) To discuss the role of HRCT in the diagnosis of CAP. 3) To discuss a general approach to CAP diagnosis using the predominant imaging pattern.

ABSTRACT

Community-acquired pneumonia refers to an acute infection of the lung in patients who did not meet any of the criteria for HCAP and associated with at least some symptoms of acute infection, accompanied by the presence of an acute infiltrate on a chest radiograph. Chest radiography remains an important component of the evaluation of patient with a suspicion of pneumonia, and usually is the first examination to be obtained. The diagnosis of CAP is based on the presence of select clinical features and is supported by imaging of the lung, usually by chest radiography. Infection of the lower respiratory tract typically presents radiologically as one of three patterns: a) focal nonsegmental or lobar pneumonia, b) multifocal bronchopneumonia or lobular pneumonia, and c) focal or diffuse 'interstitial' pneumonia. Bacterial and viral micro-organisms are the most common etiologic agents responsible for CAP. Identification of causative micro-organisms in CAP remains challenging and in 30% to 65% of cases.

LEARNING OBJECTIVES

1) To understand the imaging characteristics of HIV infection related thoracic manifestations. 2) To emphasize the importance and urgency in medication of HIV related thoracic manifestations. 3) To introduce the research development of HIV infection pulmonary disease.

ABSTRACT

Pulmonary lesions in HIV/AIDS patients are most common with opportunistic infections and tumors. Pulmonary infection is a common complication and cause of death in HIV/AIDS patients. The pathogens mainly include Pneumocystis jirovecii, Cryptococcus, Mycobacterium tuberculosis and so on. Imaging findings are varied and nonspecific. HIV/AIDS complicated with Pneumocystis pneumoniae pneumonia is typically characterized by a frosted glass-like shadow symmetrically distributed around the hilum; pulmonary cryptococcosis is characterized by a single, multiple nodule or mass near the pleura with wide base. The nodule cavity is a characteristic CT manifestation of pulmonary cryptococcosis. The imaging patterns of tuberculosis in HIV-infected patients are upper lung consolidation and multiple nodules, which may cavitate. Centrilobular nodules are presented in endobronchial spread of
turberculosis. Kaposi sarcoma (KS) is the most common AIDS-defining malignancy. A characteristic CT finding in AIDS-related KS is the presence of bilateral and symmetric ill-defined nodules in a peribronchovascular distribution (flame-shaped lesions) and ground-glass opacities may be seen surrounding the nodules. AIDS-related lymphoma is another common malignancy in HIV infected patients. Compared to KS, it is peripheral and air-bronchograms can be seen with unusual cavitation. Imaging examination is a powerful and effective tool of examination for AIDS-related lung lesions. The diagnosis combined with clinical and laboratory tests is helpful to medical treatment.

**SPIS61N  Pulmonary Tuberculosis and Nontuberculous Mycobacterial (NTM) Infection: An Overview**

Friday, Dec. 6 10:25AM - 11:10AM Room: E353C

**Participants**
Kyung S. Lee, MD, PhD, Seoul, Korea, Republic Of (Presenter) Nothing to Disclose

**For information about this presentation, contact:**
kyungs.lee@samsung.com

**LEARNING OBJECTIVES**
1) To deliver the updates in pulmonary tuberculosis and nontuberculous mycobacterial (NTM) pulmonary infection in terms of pathogenesis and imaging findings.

**ABSTRACT**
In this overview of pulmonary tuberculosis and nontuberculous mycobacterial (NTM) infection, this speaker will talk about 1. Mode of tuberculous pulmonary infection, 2. Identification of latent tuberculous infection, 3. Serial CT features in primary multidrug-resistant pulmonary tuberculosis, 4. Prevalence of nontuberculous mycobacterial (NTM) infection in US and Canada, 5. Clinical and radiological findings of Mycobacterium avium-intracellulare (MAC) infection, 6. Natural course of MAC pulmonary infection, 7. Chronic pulmonary aspergillosis in NTM infection.

**SPIS61O  Cardiovascular Imaging**

**LEARNING OBJECTIVES**
1) To learn the CT features of aortic intramural hematoma. 2) The learn the types of focal contrast enhancement in the hematoma and their differential prognosis impacts. 3) The learn the CT predictors of poor prognosis of aortic intramural hematoma.

**ABSTRACT**
Aortic intramural hematoma (AIMH) is one major component of acute aortic syndrome, esp. in Asia. We will review the CT characteristic of AIMH, including the inframural focal contrast enhancement. Two types of the intramural lesions will be introduced. One is ulcer-like projection, one is intramural blood pool. Their prognosis is different. We will also review the prognosis predictor of AIMH, and the nature course of the AIMH on the follow-up CT.

**SPIS61P  Aortic Intramural Hematoma: The Prognostic Impact of CT Features**

Friday, Dec. 6 11:15AM - 12:00PM Room: E353C

**Participants**
Ming-Ting Wu, MD, Kaohsiung, Taiwan (Presenter) Nothing to Disclose

**For information about this presentation, contact:**
wu.mingting@gmail.com

**LEARNING OBJECTIVES**
1) Detect CT signs of pulmonary hypertension. 2) Identify CT features suggesting a thromboembolic origin. 3) Differentiate the various causes of pulmonary hypertension on CT.

**ABSTRACT**
CT allows depicting pulmonary hypertension (PH), helps identifying its cause and therefore plays a crucial role in the diagnostic work-up of PH. CT features of pulmonary hypertension include dilatation of the main pulmonary artery, with a diameter greater than or equal to 29 mm, a ratio to the aortic diameter greater than 1:1 and a segmental artery-to-bronchus ratio greater than 1:1 in at least three lobes. On ECT-gated CT, loss of pulmonary artery distensibility with a cut-off value of 16.5% has 86% sensitivity and
96% specificity. CT is especially useful for detecting signs of chronic thromboembolic pulmonary hypertension, that must be recognized and distinguished from idiopathic pulmonary artery hypertension. These signs include wall adherent thrombi, bands webs or chronic arteriolar occlusion, mosaic perfusion and systemic collateral supply. Signs of pulmonary edema, such as thickening of the interlobular septa, centrilobular ground glass, mediastinal lymph node enlargement and plural effusion are seen on CT in PH due to venoocclusive disease, left heart diseases or fibrosing mediastinitis. Signs of lung parenchyma diseases can be identified on CT. PH is a late complication in patients with lung fibrosis, sarcoidosis or COPD but may affect systemic sclerosis patients with limited lung parenchyma involvement. Congenital cardiac abnormalities with untreated right-to-left shunting resulting in Eisenmenger syndrome can also be identified, especially ventricular septal defect. Conversely, signs of peripheral arteriovenous shunting in hepatopulmonary syndrome are more difficult to assess.

**LEARNING OBJECTIVES**

1) The global cardiac function depends on four cardiac chambers' function and their interactions. 2) Left and right ventricular function evaluation by cardiac CT has been validated favorably. 3) Three or four chamber function evaluation techniques are developed and equipped in available image-processing workstations. 4) In cardiac CT with retrospective ECG-gating, multi-chamber function evaluation supports comprehensive cardiac evaluation.

**ABSTRACT**

By evaluating the adjacent cardiac chambers, more reliable information about single chamber function and inter-related compensatory functional mechanism may be acquired. Based on cardiac CT data with multi-phase reconstruction, morphological image markers are useful for evaluating the levels of the preload, inotropy, and afterload in each cardiac chamber as well as the global multi-chamber cardiac function. In the clinical practice, the inotropic function and the afterload of left ventricle are major concerns. The left ventricular ejection fraction and the cardiac output are good markers for the inotropy. The left ventricular end-systolic volume, the peripheral vascular resistance, and the aortic distensibility are useful markers for the afterload of left ventricle. The second major concern may be the afterload of right ventricle, which can be evaluated by the right ventricular end-systolic volume, the pulmonary vascular resistance, and the structural deformations. As we have been aware through multinational cohort studies, the left ventricular function and volume with cardiac CT improves risk stratification and identification of patients at risk for incident morality. The left ventricular function has been recognized a representative cardiac function in academic and practical fields. However, the global cardiac function should depend on four cardiac chambers' function and their interactions. For example, in a case with systemic hypertension, left ventricular concentric remodeling with accentuated left atrial late contraction and normal right ventricular function can be depicted in cardiac CT function study. This case suggests an early-stage hypertensive heart disease with compensated global cardiac function during resting state by left atrial inotropy. If the information about the cardiac function and the chamber volume could be acquired additionally on the CT coronary angiography in cases with retrospective ECG-gating, it may be useful for clinical management of diverse cardiac diseases including ischemic heart disease, essential or secondary cardiomyopathies, and heart failure. In this lecture, we will discuss about background concept of multi-chamber cardiac functions, image-based parameters for the comprehensive cardiac function, and clinical application of this methodology.
Breast Imaging (Interventional and Pathological Correlation)

Friday, Dec. 6 10:30AM - 12:00PM Room: E450A

**Purpose**

Neoadjuvant chemotherapy (NAC) has changed the management of breast cancer. The best outcome post-NAC is a pathologic complete response (pCR). There remains no minimally-invasive approach with sufficient accuracy to diagnose a pCR so surgery remains the standard of care. The purpose of this proof-of-concept clinical trial is to evaluate the accuracy of MRI-biopsy in diagnosing a pCR post NAC compared to reference-standard breast surgery specimen.

**Method and Materials**

Between 2017-2019, our IRB approved this pilot study that accrued 15 women with biopsy-proven operable invasive breast cancer who met the following inclusion criteria: (a) standard-of-care NAC, (b) pre- and post-NAC MRI, (c) imaging complete response defined as no residual enhancement on post-NAC MRI and (d) planned definitive surgery at our institution. A post-NAC standard of care MRI-guided biopsy was performed of the 15 treated tumor beds without intravenous contrast. The primary endpoint is to estimate the negative predictive value (NPV) of MRI biopsy to reference-standard breast surgery specimen. In this context, NPV is defined as the number of true pCR (biopsy negative, i.e. no disease found on the percutaneous biopsy and pCR at surgery) divided by the number of all biopsy negatives. The positive predictive value (PPV), sensitivity, and specificity of the biopsy were also calculated.

**Results**

15 patients with an MR imaging complete response post-NAC underwent MRI biopsy. Reference standard surgical pathology demonstrated a pCR in 10/15 (67%) and no-pCR in 5/15 (33%). The accuracy of MRI biopsy was 14/15 (93%). MRI biopsy was false in 1/15 (7%). In this false negative case surgical pathology identified 0.2mm of invasive disease, a true positive (no-pCR). All no-pCR tumor beds demonstrated very small volume residual disease with the largest invasive cancer measuring 3mm. The statistical measurements of MRI-guided biopsy in diagnosing a pCR compared with the reference standard surgical pathology are: NPV 91%, PPV 100%, Sensitivity 80% and Specificity 100%.

**Conclusion**

The accuracy of MRI-guided biopsy in diagnosing a pCR post-NAC in this pilot study is very high when compared to reference standard surgical pathology, which supports the need for a larger study.

**Clinical Relevance/Application**

MRI-guided biopsy is a promising minimally-invasive approach with accuracy in diagnosing a pCR post-NAC to potentially obviate surgery in this subset of patients.
PURPOSE
To evaluate the utility and compliance of 6 month follow up MRI following benign concordant MRI guided breast biopsy and investigate potential causes for noncompliance.

METHOD AND MATERIALS
IRB approved retrospective review of all benign concordant MRI biopsies from 1/1/2013 to 1/1/2018. Biopsy results with high risk lesions or malignancy were excluded. For each benign concordant MRI biopsy, the following was collected from the electronic medical record: patient age, pathology from MRI biopsy, any recommendation for 6 month follow up MRI, any documented communication to referring physician, available follow up imaging, repeat biopsies, subsequent malignancies, insurance type, and referring physician's institution and specialty.

RESULTS
There were 139 benign concordant MRI biopsies in 127 patients during the study period. Mean patient age was 47.6 years (range 25 to 73). Follow-up MRI was performed at 6 months in 31.5% (40/127) and at 12 months in 18.1% (23/127) (Table 1). A 6 month follow up MRI was recommended in 63/127 (49.6%). Of these, 33/63 (52.4%) had a 6 month follow up MRI. Communication of the 6 month follow up recommendation was documented in only 6/63 (9.5%). Most patients without subsequent MRI in our system (n=50) had follow-up benign mammography at a mean of 0.9 years following MRI biopsy (range 0.2 to 2.2 years). There were no repeat biopsies or subsequent malignancies at the site of benign MRI biopsy. No correlation was observed between likelihood of 6 month follow up MRI and patient insurance type, ordering provider specialty or institution.

CONCLUSION
When 6 month follow-up MRI was recommended following a benign concordant biopsy, compliance was 52.4%. Lack of communication of the recommendation between the radiologist and referring physician may at least partially explain the low compliance. There were no false negative biopsies identified in this study, raising questions about the utility and cost-effectiveness of routine 6 month follow-up MRI following benign concordant MRI biopsy.

CLINICAL RELEVANCE/APPLICATION
Careful assessment of each benign concordant MRI biopsy may be more appropriate than routine 6 month follow-up MRI recommendation.

SST01-03 The Feasibility of Breast Conservation Therapy in Multifocal/Multicentric Breast Cancer Using Multiple Radioactive Seeds: A Paradigm Shift

PURPOSE
Our study aims to validate breast conservation therapy in multifocal/multicentric (MF/MC) breast cancer (BC) using multiple radioactive seeds for localization.

METHOD AND MATERIALS
We retrospectively reviewed all radioactive-seed-localized segmentectomies at our institution between January 1, 2014 and April 26, 2017, where two or more radioactive seeds were used in the same breast. Patients with benign breast disease, unifocal BC and noncontiguous multicentric BC were excluded. Patient's age, demographics, pathology, and imaging were reviewed. Pre-operative diagrams were provided denoting the number and location of radioactive seeds, which were then examined intraoperatively using handheld gamma probes prior to segmentectomy. Intraoperative margin assessment was performed for all cases, including whole specimen radiography and gross-sectioning. Positive or close margins were re-excised intraoperatively and examined by permanent pathology.

RESULTS
Ninety-two patients underwent breast conservation therapy for MF/MC BC, using two or more radioactive seeds for preoperative localization without technical problems. Mean patient age was 56.8 years (range 33-80), and 55% of patients received neoadjuvant chemotherapy. Forty-six percent of patients had invasive ductal carcinoma and ductal carcinoma in situ (DCIS), 30% invasive ductal carcinoma, 10% invasive lobular carcinoma, 9% DCIS, and 5% invasive mammmary carcinoma. Forty-nine percent of patients had two seeds, 45% had three seeds, and 6% had 4 or more seeds. The mean distance between seeds was...
4.8 cm (range 1-10). Seventy-five percent (69/92) had negative final margins, 15% (14/92) close or 2 mm margins, and 10% (9/92) positive margins. Of those with positive margins, 3 underwent margin re-excision, and 6 completion mastectomy. One patient with close margins underwent re-excision, while the remaining patients with close margins did not require repeat surgery and were treated with adjuvant radiation therapy.

CONCLUSION
Preoperative localization of MF/MC BC with multiple radioactive seeds can successfully achieve clear surgical margins in 75% of cases.

CLINICAL RELEVANCE/APPLICATION
Patients with MF/MC BC can achieve breast conserving surgery, instead of mastectomy, if meticulous preoperative localization is performed using multiple radioactive seeds.

PURPOSE
To evaluate our institution's experience of preoperative Savi Scout reflector localization for breast lesions and potential variables that could influence surgical margins for breast cancer patients.

METHOD AND MATERIALS
This single institution, retrospective, IRB-approved, HIPAA-compliant study consisted of 111 Savi Scout reflectors placed for 109 breast lesions in 103 women from September 1, 2016 to December 31, 2017. Reflectors were placed percutaneously under image-guidance by breast imaging radiologists. Dedicated breast surgeons performed the surgery. Breast density, lesion type and size, number of reflectors, placement modality, distance of the reflector from the lesion, specimen radiograph findings, excision of lesion, excision of reflector(s), volume of tissue excised, margin status and re-excision rates for malignant cases, and final pathology were recorded and statistical analysis performed.

RESULTS
111 reflectors were deployed in the breasts of 103 women with 109 breast lesions using image-guidance. 90(81.1%) reflectors were placed under mammographic guidance and 21(18.9%) under ultrasound guidance. The lesion type consisted of 68(62.4%) masses, 17(15.6%) calcifications, 22(20.2%) marker clips and 2(1.8%) architectural distortions. Mean lesion size was 15.1 mm. Mean distance of a reflector to the lesion center, lesion margin, and closest skin surface were 7.9 mm, 0.3 mm, and 35.5 mm, respectively. Mean pathologic specimen volume was 37.6 cm³. In 2(1.8%) cases, the reflector localized target was not initially excised: 1 was due to intraoperative deactivation of the reflector with electrocautery and the second was reflector placement (>2 cm from the targeted lesion). On final pathology, there were 72(66.0%) malignant, 22(20.2%) high-risk, and 15(13.8%) benign cases. For the malignant cases, the positive margin rate was 20.8%(15 cases). Univariate and multivariate logistic regression analysis revealed no statistically significant parameters associated with a positive surgical margin.

CONCLUSION
Savi Scout reflector localization is an alternative to wire localization in the surgical excision of breast lesions. There was no lesion-specific or technical parameter affecting positive surgical margins in malignant cases.

CLINICAL RELEVANCE/APPLICATION
Wireless localization with a reflector device is a promising alternative to conventional wire and seed localization as a guide to the excision of non-palpable breast lesions.

alourenco@lifespan.org

PURPOSE
To compare biopsy outcomes from two years preceding and following implementation of digital breast tomosynthesis (DBT)-guided biopsy.

METHOD AND MATERIALS
IRB-approved, HIPAA compliant retrospective review of all vacuum-assisted core breast biopsy procedures using 2D stereotactic guidance from 2013-2015 and DBT-guided biopsy from 2015-2017. All screening and diagnostic mammography was performed with DBT during the study period. Patient demographics, biopsy target type, pathology from 9G vacuum assisted core biopsy, surgical excision pathology when available, breast density, and imaging follow-up results were recorded. Biopsy targets and radiology-pathology discordance rate were compared between the two groups. Generalized mixed modeling was used to examine pre/post DBT biopsy results using SAS 9.4.

RESULTS
There were 1405 breast biopsy procedures in 1313 patients; 643 using 2D stereotactic guidance (2013-2015) (median age 56) and 762 using 3D DBT guidance (2015-2017) (median age 58). Of the 2D group, 55.6% had dense breast tissue as compared with 57.5% in the DBT group. Calcifications were the most common biopsy target for both groups constituting 89.9% (578/643) of 2D biopsies and 71.1% (542/762) of DBT biopsies (p<0.0001). For 2D biopsies, architectural distortion (AD) was the least common biopsy target at 2.0% (13/643) but increased to 17.7% (135/762) for the DBT group (p<0.0001). Overall radial scars identified increased from 1.7% [1.0, 3.1] to 8.3% [6.5, 10.5] (p<0.0001). The discordance rate increased from 1.4% [1.0, 2.7] to 4.5% [3.2, 6.2] following the implementation of DBT-guided biopsy (p=0.0021). Of the 34 discordant DBT-guided biopsies, 30 of the biopsy targets were architectural distortions.

CONCLUSION
With the transition from 2D stereotactic biopsy to DBT biopsy, there was a significant increase in the number of architectural distortions targeted for biopsy, the number of radial scars identified, and the radiology-pathology discordance rate.

CLINICAL RELEVANCE/APPLICATION
While DBT biopsy has enabled the targeting of very subtle lesions such as architectural distortion, radiologists should be cognizant of the potential for radiology-pathology discordance.

SST01-06 Radial Scars in the Era of Digital Breast Tomosynthesis: What is the Rate of Upgrade to Malignancy?
Friday, Dec. 6 11:20AM - 11:30AM Room: E450A

Participants
Pamela Yan, Providence, RI (Presenter) Nothing to Disclose
Linda DeMello, MD, Warwick, RI (Abstract Co-Author) Nothing to Disclose

alourenco@lifespan.org

PURPOSE
To determine the rate of upgrade for radial scars (RS) diagnosed at core needle biopsy and to assess how the radiologist’s recommendation for excision based on imaging features compares with excisional biopsy results.

METHOD AND MATERIALS
IRB approved, HIPAA compliant retrospective review of radiology and pathology databases at a tertiary breast center to identify all “radial scar” and “complex sclerosing lesions” between March 2012 and December 2017. During the study period, all mammography was performed with digital breast tomosynthesis. Patient demographics, initial imaging, needle and excisional biopsies, and follow-up imaging data were collected. Upgrade to malignancy was defined as discovery of DCIS or invasive carcinoma at the same site as the RS upon surgical excision. Initial imaging leading to the discovery of the radial scar was reviewed by a fellowship trained breast radiologist. Based on the imaging findings, this radiologist recommended excisional biopsy or imaging follow-up for each case.

RESULTS
There were 146 biopsy-proven radial scars in 142 patients. Median patient age was 57 (range 26-87). Presenting imaging findings on mammography were mass 49 (34%), architectural distortion 40 (27%), calcifications 37 (25%), asymmetry 4 (3%), and 5 (3%) mass on ultrasound; on MRI 7 (5%) mass and 4 (3%) non-mass enhancement. 117 (80%) demonstrated radial scar as the most ominous histological finding at that biopsy site (no atypia or cancer). The remaining 29 cases had associated atypia (n=15) or cancer (n=14) and were excluded. Of the 117 RS without associated atypia, 1 (0.8%) was upgraded to invasive ductal carcinoma at excision. Of these 117 RS without atypia, 72 were excised, 19 underwent benign imaging follow-up for a median of 3 years (range 1 to 5.5 years) and 16 were lost to follow-up. Based on initial imaging review, the radiologist recommended excision in 87%. No malignancy would have been missed if the remaining cases had not been excised.

CONCLUSION
Radial scars without atypia had an upgrade rate of 0.8% in this study. Radiologist assessment of imaging findings and recommendation for excision vs imaging follow-up would not have missed the one malignancy in this study.

CLINICAL RELEVANCE/APPLICATION
The very low upgrade rate of RS without atypia supports imaging follow-up rather than excision, which could reduce the number of benign surgeries patients undergo.

SST01-07 Evaluation of Pathological Results of Tomosynthesis Guided Vacuum Assisted Breast Biopsy
Friday, Dec. 6 11:30AM - 11:40AM Room: E450A

Participants
Xiaoqin J. Wang, MD, Lexington, KY (Presenter) Nothing to Disclose
Arzu Canon, MD, Dallas, TX (Abstract Co-Author) Nothing to Disclose
Li Chen, PhD, Lexington, KY (Abstract Co-Author) Nothing to Disclose
Digital breast tomosynthesis (DBT) guided vacuum assisted breast biopsy (TVAB) can target not only the calcified lesions detected on 2D mammogram but also non-calcified lesions only visualized on DBT. It is unknown if TVAB will result in more malignant or invasive cancer. In this study, we aimed to evaluate the pathological results of tomosynthesis guided vacuum assisted breast biopsy (TVAB) and compare to those of conventional stereotactic vacuum assisted biopsy (SVAB).

METHOD AND MATERIALS
All women who underwent TVAB (from May 2013 to April 2015) or SVAB (from June 2015 to May 2017) procedure were included in this retrospective study. Patients' demographics, lesion mammographic appearance, and biopsy pathologic results were compared between these two groups. The significance level was accepted as p<0.05.

RESULTS
389 patients with 410 lesions underwent SVAB and 340 patients with 579 lesions underwent TVAB. The mean ages in SVAB and TVAB groups are 55.9±10.3 and 57.9±10.5, respectively. TVAB is found to have a higher biopsy rate of non-calcified lesions than SVAB (26% vs 16%, P < 0.05). No statistically significant differences were found between the two groups with respect to histological results of lesions such as breast tissue, benign changes, high risk lesions, or malignant lesions (p=0.161). Similar high-risk lesion upgraded rate was also observed. Among the malignant lesions, the rate of ductal carcinoma in situ (DCIS) is high in both SVAB group (88.6%) and TVAB group (77.9%), but no difference in the rate between these two groups is identified either (p=0.26).

CONCLUSION
TVAB group can biopsy more non-calcified lesions compared to conventional SVAB because it can target not only the calcified lesions detected on 2D mammogram but also non-calcified lesions only visualized on DBT. However, no significant histological differences (malignant vs benign or DCIS vs invasive cancer) in the biopsied lesions were found in these two groups.

CLINICAL RELEVANCE/APPLICATION
With increasing utilization of digital breast tomosynthesis and DBT guided vacuum-assisted biopsy (TVAB) in clinical practice, understanding this new technology and predicting biopsy results are important for the radiologist.

SST01-08 Digital Breast Tomosynthesis (DBT)-Guided Vacuum-Assisted Biopsy (VAB) with Integrated Real-Time Radiography System (IRRS): Initial Single-Center Experience
Friday, Dec. 6 11:40AM - 11:50AM Room: E450A

without calcifications (13%), a strategy for reducing the number of samples based the IRRS result (presence or absence of calcifications) is not feasible due to the too overall high probability of non-cancer specimens (727/888, 82%, 95% CI 79%, 84%).

**CLINICAL RELEVANCE/APPLICATION**

The IRRS makes the operator more confident that the sample is adequate and may allow for sparing subsequent control mammogram after the procedure, with a better patient compliance. Nevertheless, an earlier completion of the procedure, reducing the number of samples, does not seem to be feasible.

**SST01-09  Results of a Phase I, Prospective, Non-Randomized Study Evaluating a Magnetic Occult Lesion Localization Instrument (MOLLI) for Excision of Non-Palpable Breast Lesions**

Friday, Dec. 6 11:50AM - 12:00PM Room: E450A

Participants

Nicole Look Hong, MD,MSc, Toronto, ON (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

The purpose of this first-in-human study was to evaluate the clinical feasibility of using a Magnetic Occult Lesion Localization Instrument (MOLLI) for localizing non-palpable breast lesions.

**METHOD AND MATERIALS**

A pilot study of 20 women with non-palpable lesions visualized under ultrasound received a lumpectomy using the MOLLI guidance system at a single institution. Patients were co-localized with magnetic and radioactive markers up to 3 days before excision under ultrasound guidance by a dedicated breast radiologist. Both markers were localized intraoperatively using dedicated hand-held probes. The primary outcome was successful excision of the magnetic marker, confirmed both radiographically and pathologically. Demographic data, margin positivity, and re-excision rates are reported. Surgical oncologists, radiologists and pathology staff were surveyed for user satisfaction using 5-point Likert scale questionnaires.

**RESULTS**

Demographic data can be found in Table 1. *Post-Radiological Analysis*: Post-implant mammograms verified that 17/20 markers were placed directly in the lesion center and 20/20 had minimal to no migration. Radiologists reported that all marker implantations procedures were 'easy' or 'very easy' following a single training session. *Post-Surgical Analysis*: All MOLLI markers were removed with the specimen during surgical excision; no cases required final verification using the radioactive marker. Measurement of the distance of the MOLLI marker from anterior, posterior, superior, inferior, medial and lateral aspects of the excised tissue specimen agreed with radiological imaging estimates to within 2 mm. In all cases, surgeons ranked the MOLLI guidance system as 'very easy' for lesion localization. *Pathologic Analysis*: All patients had negative margins and did not require re-excision. All Anatomic Pathology staff ranked the MOLLI system as 'very easy' to use and localize markers.

**CONCLUSION**

The MOLLI guidance system is a reliable, accurate, and non-radioactive method for localization and excision of non-palpable breast lesions. Further clinical evaluation of the MOLLI system in comparative studies against current standards of care are required to demonstrate efficacy and patient-reported outcomes.

**CLINICAL RELEVANCE/APPLICATION**

MOLLI guided lumpectomy results in similar re-excision and margin positivity rates are radioactive-seed localization.

Printed on: 10/20/19
**Purpose**

This study investigates the effect of combining two different advanced image processing (AIP) techniques, initially developed for chest X-ray reading by radiologists, on the disease classification accuracy of a Convolutional Neural Network (CNN): Bone Suppression (BS) and Lung Field Cropping (LFC).

**Method and Materials**

Following early work in this domain, BS and LFC have a positive effect on chest disease classification by CNNs. In this study, we propose ensembling to combine the effects of multiple CNNs optimized for different image inputs - i.e. normal, BS, LFC and the combination of BS and LFC. Like a radiologist, the information of multiple input sources is combined in this way. We pretrain our CNN, optimized for X-ray analysis, on a large publicly available X-ray dataset (ChestX-ray14) and fine-tuned it afterwards on a new dataset. For evaluation and testing, two radiologists annotated the Indiana dataset (3125 DICOM images) with eight different classes: pleural effusion, infiltrate, congestion, atelectasis, pneumothorax, cardiomegaly, mass and foreign object.

**Results**

In a five-fold cross-validation, we use ROC statistics to evaluate the effect of ensembling. To have a fair comparison, we compare our AIP ensemble against an ensemble build with four CNNs trained on normal images. Overall the AIP ensemble increased the average AUC significantly by 1.56 % (from 0.898±0.013 to 0.912±0.011). Furthermore, for selected classes - i.e. mass - a total of 0.068 (8.84 %) AUC increase was achieved.

**Conclusion**

We have presented a novel ensemble of advanced image processings to train a CNN. It outperforms a standard ensemble in 6 out of 8 classes and increased the average AUC. Leveraging the information of different advanced processed images help to increase the AUC significantly.

**Clinical Relevance/Application**

Automatic disease classification on chest X-rays can be improved by applying different methods of advanced image preprocessing and not focusing on a single input source.

PURPOSE
To compare the performance of disease detection on chest radiographs with that of unsupervised anomaly detection with generative adversarial networks (AnoGAN) model and that of preexisting supervised anomaly detection with convolutional neural net (CNN) model.

METHOD AND MATERIALS
Total of 100 chest radiographs were obtained from one hospital to validate the model. The 100 examinations were composed of 12 classes as follows: nodule (n=8), calcification (n=9), consolidation (n=6), interstitial opacity (n=9), atelectasis (n=9), mediastinal widening (n=6), pleural effusion (n=8), pneumothorax (n=9), rib fracture (n=10), pneumomediastinum (n=10), subcutaneous emphysema (n=6), and pneumoperitoneum (n=10). AnoGAN model and 6-class CNN system (6-class: normal, nodule, consolidation, interstitial opacity, pleural effusion, and pneumothorax) were used for disease detection of the images. For these 100 query images, AnoGAN model generated normal fake image most similar to that image and then detected disease by subtraction of two images. After the test set, one board certified cardiothoracic radiologist reviewed the images to evaluate the model performance.

RESULTS
Of 100 chest radiographs, 90 diseases were detected using AnoGAN model as follows: Nodule 100.0% (8/8), calcification 100.0% (9/9), consolidation 100.0% (6/6), interstitial opacity 100% (9/9), atelectasis 88.9% (8/9), mediastinal widening 83.3% (5/6), pleural effusion 87.5% (7/8), pneumothorax 100.0% (8/9), rib fracture 80.0% (8/10), pneumomediastinum 60.0% (6/10), subcutaneous emphysema 83.3% (5/6), and pneumoperitoneum 100.0% (10/10). The 6-class CAD system detected 37 of 40 diseases for trained classes (92.5%) whereas that detected only 14 of 60 disease for untrained classes (23.3%). Overall detection rate was higher in AnoGAN model than that of 6-class CAD system (90.0% vs. 51.0%, p < 0.001).

CONCLUSION
AnoGAN model can detect diseases on chest radiograph without training for each disease. We propose that AnoGAN model can overcome the limitation of current CAD system.

CLINICAL RELEVANCE/APPLICATION
Using AnoGAN model, disease detection of chest radiographs can be helpful for evaluation of chest radiograph.

SST02-03 Deep Learning-Based Automatic Classification of the Normal, Active Tuberculosis and Other Abnormal Patterns on Chest Radiographs

PURPOSE
To develop a deep learning-based automatic algorithm for classifying active pulmonary tuberculosis (TB) from other pulmonary abnormalities and normal looking lung with chest radiographs (CR).
accuracies were 78.5% for per-CR and 82.7% for per-ROI. The overall accuracy of the algorithm was 95.61% for per-CR and 93.29% for per-ROI. Sensitivity and specificity of the algorithm for active TB were 79.73% and 96.96% for per-CR and 77.83% and 95.38 for per-ROI.

CONCLUSION
Deep learning with CNN demonstrated high diagnostic performance in the classifying normal, active TB and other abnormal patterns CRs.

CLINICAL RELEVANCE/APPLICATION
Deep learning with CNN can be useful in the screening of the active TB with CR, thereby improving diagnostic-flow efficacy.

SST02-04 Deep Neural Network to Determine the Activity of Pulmonary Tuberculosis on Chest Radiograph

PURPOSE
Determining the activity of pulmonary tuberculosis on chest radiograph is difficult even for tuberculosis experts. We aimed to develop a deep neural network for determining the activity of pulmonary tuberculosis on chest radiographs.

METHOD AND MATERIALS
From January 2011 through December 2017, we retrospectively collected a total of 6,647 baseline and post-treatment chest radiographs in 2,052 adult patients with sputum smear- or culture-proven tuberculosis who were successfully treated from five tertiary or secondary hospitals. Baseline and post-treatment chest radiographs were labeled as active and inactive tuberculosis, respectively. A deep neural network was trained with those radiographs to output the percentage score regarding the activity of tuberculosis. The validation dataset consisted of a series of 619 monthly radiographs during the treatment from 46 patients with the same inclusion criteria in 2018. Baseline and post-treatment radiographs in the validation dataset were read by the network and by a pulmonologist and thoracic radiologist with 20 and 10 years of dedicated experience to tuberculosis regarding the activity of tuberculosis in a five-point scale. Receiver operating characteristic curves and areas under the curve (AUROC) were used to evaluate the performance. One-sample t-test and linear regression analysis were used to analyze a tendency of tuberculosis activity score during anti-tuberculosis treatment.

RESULTS
The preliminary results showed that the AUROC of deep neural network was 0.80 (95% confidence interval [CI]: 0.71 ~ 0.89), which was comparable with thoracic radiologist (0.71 (95% CI: 0.60 ~ 0.82)) and pulmonologist (0.74 (95% CI: 0.64 ~ 0.84)). During the period of anti-tuberculosis treatment, Log odds of Tb activity score gradually decreased with mean decrease of 2.82 (95% CI: 1.55 - 4.09) at 2 months (P<.001) and 5.10 (95% CI: 2.28 - 7.91) at 6 months (P=.001).

CONCLUSION
The deep neural network could accurately determine the activity of tuberculosis on chest radiograph, and the network was comparable to tuberculosis experts.

CLINICAL RELEVANCE/APPLICATION
The deep neural network can be used to determine the activity of tuberculosis in settings with limited tuberculosis experts and to monitor the response of anti-tuberculosis treatment, potentially in patients with drug-resistant tuberculosis.

SST02-05 Development of a Deep Learning-Based Algorithm for Independent Detection of Chest Abnormalities on Chest Radiographs

Developed algorithms are based on large public datasets, which contain inaccurate labels. This study indicates that developing algorithms for Computer-Aided Detection (CAD) of chest X-ray (CXR) diseases is a challenging problem. Many newly labeled labels are needed as accurate as we can achieve. Clean labels are considered as a vital condition in deep learning based classification. However, since labels of many large public datasets are preprocessed by natural language processing, they contain inaccurate, noisy labels to some extent.

### METHOD AND MATERIALS

We collected a total of 151228 CXRs comprised of 79113 cases with abnormal findings (M:F=0.51:0.49; mean age=56.19±16.55). The dataset was made up of 12173 atelectasis, 1617 calcification, 4059 cardiomegaly, 7915 consolidation, 2473 fibrosis, 14422 nodule, 264 mediastinal widening, 11412 pleural effusion, 5304 pneumoperitoneum, 8286 pneumothorax, and 72115 normal cases. The dataset was randomly split into training (70353 normal, 73753 abnormal), validation (881 normal, 2680 abnormal) and test (881 normal, 2680 abnormal) sets. We developed a deep convolutional neural network with 34 layers and 16 residual connections, and it generates 10 separate 2D maps which indicate the location of each abnormality. The dataset was labeled by 18 radiologists and 16194 cases were further annotated to specify the locations of the findings. Each case in the test set has been annotated by 5 radiologists. The annotations used for the test set were taken by a majority vote. We verified the network's performance by measuring the area under the Receiver Operating Characteristic (ROC) curve and jackknife alternative free-response receiver operating characteristics (JAFROC).

### RESULTS

Our network's performance for combined abnormalities was calculated to be AUC: 0.958, JAFROC: 0.911. For the settings comparing each abnormality to the normal cases, the AUC and JAFROC were 0.983, 0.965 for atelectasis, 0.981, 0.966 for consolidation, 0.985, 0.954 for calcification, 0.984, 0.984 for cardiomegaly, 0.995, 0.988 for fibrosis, 0.971, 0.918 for nodule, 0.981, 0.978 for mediastinal widening, 0.997, 0.994 for pleural effusion, 0.999, 0.998 for pneumoperitoneum, and 0.997, 0.994 for pneumothorax.

### CONCLUSION

DLAD can accurately detect and localize 10 abnormal findings in the CXRs.

### CLINICAL RELEVANCE/APPLICATION

Since DLAD can detect abnormal findings commonly found in CXRs, it can help radiologists accurately interpret various abnormalities and may also be used to distinguish between normal and abnormal CXRs.

### SST02-06  Too-Sensitive Error Caused by Label Noises for Training Classification Network with Deep Convolutional Neural Net in Chest PA X-ray

Friday, Dec. 6 11:20AM - 11:30AM Room: E451A

Participants

Ryoungwoo Jang, Seoul, Korea, Republic Of (Presenter) Nothing to Disclose
Yongwon Cho, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
Namkg Kim, PhD, Seoul, Korea, Republic Of (Abstract Co-Author) Stockholder, Coreline Soft, Co Ltd; Stockholder, Anymedi, Inc
Joon Beom Seo, MD, PhD, Seoul, Korea, Republic Of (Abstract Co-Author) Stockholder, Coreline Soft Co;
Sang Min Lee, MD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose

### PURPOSE

Clean labels are considered as a vital condition in deep learning based classification. However, since labels of many large public dataset are preprocessed by natural language processing, they contain inaccurate, noisy labels to some extent. To evaluate robustness of classification network with deep-learning based chest X-ray (CXR) we measured deep convolutional neural network model by making labels inaccurate intentionally.

### METHOD AND MATERIALS

CXR collected from two hospitals, which consisted of 10137 healthy subjects and 3244 patients and 1035 healthy subjects and 4404 patients with various kinds of diseases including nodule (ND), consolidation (CS), interstitial opacity (IO), pleural effusion (PE), and pneumothorax (PT), respectively. Every abnormal lesion was confirmed with its corresponding computed tomography (CT) image by expert thoracic radiologists with more than 10 years experiences. We split this dataset into two groups including normal and abnormal. Fine-tuned resnet-50 architecture for this classification with labels changed randomly at 0%, 1%, 2%, 4%, 8%, 16%, 32% rates were evaluated. Every training was done by 20 epochs and test set performances for every epoch were recorded. To assess the accuracies, we compared it with Receiver Operating Characteristic (ROC) curve and Area Under the Curve (AUC).

### RESULTS

CXR classification model with noisy labels was not robust to any noise levels. Accuracies fall continuously when noises were given. ROCs were 0.94, 0.91, 0.90, 0.88, 0.86, 0.81, 0.78 at 0%, 1%, 2%, 4%, 8%, 16%, 32% rate, respectively which dropped linearly when semi-log scale plot was drawn.

### CONCLUSION

As every CXR was confirmed with CT image by expert radiologists, our dataset was regarded as nearly absolute clean labels. In this study, the classification network was very sensitive to any degree of label noise rate. This implies that labels are needed as accurate as we can achieve.

### CLINICAL RELEVANCE/APPLICATION

Developing algorithms for Computer-Aided Detection (CAD) of CXR diseases is challenging problem. Many newly developed algorithms are based on large public datasets, which contain inaccurate labels. This study indicates...
algorithms based on noisy dataset cannot be valid models regardless of noise levels. Therefore CAD developers should contemplate using clean label datasets for lung nodule detection as well as other various diseases.

**SST02-07** Deep Learning for Pulmonary Nodule Diagnosis on Computed Tomography: Comparison with 126 Physicians

For information about this presentation, contact:

lwh1993@163.com

**PURPOSE**

To compare the diagnostic performance of a deep learning algorithm with a large panel of physicians for pulmonary nodules diagnosis at unenhanced CT.

**METHOD AND MATERIALS**

The deep learning algorithm was developed using 1186 pathologically confirmed pulmonary nodules found in local hospital between 2009 and 2018 and 620 nodules from National Lung Cancer Screening Trial (NLST). Internal (local set, n = 100, NLST set, n = 200) and external validation (multi-center set, n = 242) of the algorithm were performed. The performance of the algorithm was evaluated by using the area under the receiver operating characteristic curve (AUC), sensitivity and specificity. An observer performance test involving 126 board-certified physicians was conducted using local set. All physicians individually reviewed the nodules and scored them from 1-4. Spearman's correlation coefficient was used to calculate the consistency between the scores ranked by physicians and the algorithm. The nodules in the local set were further divided into easy-to-diagnose and hard-to-diagnose group according to the proportion of physicians who diagnosed it correctly. The performance of algorithm in the two groups was compared with that of the physicians.

**RESULTS**

The AUC of the algorithm was 0.968 and 0.855 on internal and external validation set, respectively. The mean AUC of results from 126 physicians (0.759 ± 0.080, p < 0.001) was outperformed by the algorithm (0.927) on local set. The scores rated by physicians were highly related with the algorithm (r = 0.663, p < 0.001). Taken an arbitrary of 80% as the threshold, the AUC of the algorithm were higher than that of the physicians both in the easy-to-diagnose group (0.9921 vs. 0.9108 ± 0.0854, p < 0.001) and hard-to-diagnose group (0.8541 vs. 0.6203 ± 0.0860, p < 0.001), respectively.

**CONCLUSION**

This deep learning-based diagnostic algorithm exhibited strong performance on internal and external validation and outperformed a large panel of physicians in pulmonary nodule classification.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning exhibits great cognitive consistency with physicians in pulmonary nodule diagnosis and may have the potential for clinical applications.

**SST02-08** Evaluation of Deep Learning-Based Automatic Classification of Pneumothorax on Frontal Chest X-Ray Images

For information about this presentation, contact:

Karl.Yaeger@sluhn.org
To evaluate the performance of AI algorithms to automatically detect the presence of pneumothorax (PTX) on frontal chest x-ray images.

A dataset of 808 adult frontal chest x-ray images was formed from an American (51%) and a Canadian hospital (49%) comprising of AP view/portable system (62%) and PA view / fixed system (38%). Images were generated systems manufactured by GE (67%), Philips (32%), and Agfa (1%). Initially, ground truth for the presence, laterality, and size of a PTX was determined by two blinded radiologists, with a subsequent blinded arbitrator in cases of disagreement. Inferencing was then performed by two deep learning-based AI algorithms that were developed from independent datasets of over 44,000 images; a frontal chest x-ray classifier and a PTX classification algorithm - detecting the presence or absence of a PTX.

Radiologist’s deemed PTX present as ground truth in 47% of the data set, with laterality of right for 53%, left for 44%, and bilateral for 3%. PTX size was determined to be small for 56%, large for 43%, and small + large for 1% in bilateral cases. The frontal chest x-ray classifier correctly identified 99.5% of the images as frontal chest, only the 804 images correctly identified as frontal chest were then subsequently inferenced by the PTX classifier. The PTX classifier had an AUC of 0.96 (0.95, 0.97) with AUC of 0.96 (0.95, 0.98) for AP and 0.96 (0.94, 0.98) for PA images. Balanced accuracy was achieved with overall sensitivity and specificity of 89% (82% sensitivity for small and 97% for large). Alternative ROC operating points offer high overall sensitivity performance of 94%, specificity of 80% (sensitivity of small and large PTX of 90% and 99% respectively), or high specificity with overall sensitivity of 84%, specificity of 93% (sensitivity of small and large PTX of 75% and 96% respectively).

Deep learning-based algorithms can effectively detect PTX in frontal x-ray images with high accuracy.

A deep learning-based PTX algorithm could be an effective triaging tool for identifying exams that need a prioritized review, contributing towards improved workflow efficiency and patient outcomes.

The purpose of this study was to determine the learning and training time curves of a DCNN trained to classify frontal chest radiographs (CXRs) into AP or PA views based on increasing dataset sizes.

We obtained 112,120 CXRs from the NIH ChestX-ray14 database which contained 44,810 (40%) AP and 67,420 PA (60%) CXRs. We created datasets based on random selection, each balanced to have 50% AP and 50% PA CXRs which would gradually increase by a factor of 2; accordingly, the largest dataset we used was 89,620 CXRs with 11 other smaller datasets (Table 1). Each dataset was randomly split into training (70%), validation (10%), and test (20%) sets, which were used to train, validate, and test the ResNet-50 DCNN pretrained on ImageNet. During each training epoch, each image was augmented by a random rotation between -5 and 5 degrees, random cropping, and horizontal flipping. All DCNN development and testing was performed using PyTorch on a 2.5 GHz Intel Haswell dual socket (12-core processors) with 128 GB of RAM and 2 NVIDIA K80 GPUs. Receiver operating characteristic (ROC) curves with area under the curve (AUC) and total training time was plotted to dataset size with regression analysis performed.

DCNNs trained to classify AP vs. PA CXRs achieved high AUC of 0.88 with the smallest utilized sample size of 44 and reached a consistent plateau of AUC of 1 with 350 CXRs, with no improvement in performance thereafter (Table 1). Interestingly, there was a linear increase in training time required as dataset size increased; in fact, there was a linear relationship defined by the equation, y = 1.1x - 286 (R2=0.999).

Semantic labeling of radiographs only require small datasets on the scale of hundreds to train a diagnostically-perfect DCNN. Accordingly, curating large datasets for these purposes is not worthwhile, especially given the increased training time required for larger datasets. For the development of CXR-classification DCNNs, we propose that 350 CXRs is a
reasonable starting point.

**CLINICAL RELEVANCE/APPLICATION**

Semantic labeling of radiographs only require small datasets on the scale of hundreds to train a diagnostically-perfect DCNN. Accordingly, curating large datasets for these purposes is not worthwhile, especially given the increased training time required for larger datasets.

Non-Enhanced Magnetic Resonance Imaging versus Ultrasonography for Surveillance of Hepatocellular Carcinoma: Intraindividual Comparison in a Prospective Cohort

**PURPOSE**

We aimed to compare the performance of non-enhanced MRI and US as a surveillance tool for hepatocellular carcinoma (HCC) by making intraindividual comparisons in a prospective cohort at high risk of HCC.

**METHOD AND MATERIALS**

This prospective cohort included 382 patients with an estimated annual HCC risk > 5% who underwent paired gadoxetic acid-enhanced MRI and US between 2011 and 2013. Non-enhanced MRI consisted of diffusion-weighted images (DWI) ($b = 0, 50, \text{and} \ 500 \text{ s/mm}^2$) and T2-weighted images (T2WI), and was considered positive when a lesion $\geq 1 \text{ cm}$ showed diffusion restriction or mild-moderate T2 hyperintensity on a retrospective analysis. On US, a discrete mass $\geq 1 \text{ cm}$ or a suspicious tumor thrombus was regarded as positive. HCC was diagnosed pathologically and/or radiologically. Sensitivity and positive predictive value (PPV) obtained on a per-lesion and per-patient basis, and specificity and negative predictive value (NPV) obtained on a per-patient basis, were compared between modalities using generalized estimating equations, McNemar tests, and Fisher's exact tests, as appropriate.

**RESULTS**

Thirty-two HCCs were diagnosed in 28 patients. The per-lesion and per-patient sensitivities of non-enhanced MRI were 84.5% (27/32) and 85.7% (24/28), respectively, and were higher than those of US (34.6% [11/32] and 39.3% [11/28], respectively, $P \leq 0.001$). PPVs were higher on non-enhanced MRI (65.9% [27/41] per-lesion and 64.9% [24/37] per-patient) than on US (32.4% [11/34] and 35.5% [11/31], $P \leq 0.028$), while the specificity of non-enhanced MRI was not significantly different from that of US (96.3% [341/354] vs. 94.4% [334/354] for US, $P = 0.377$). The NPV of non-enhanced MRI (98.8% [341/345]) was higher than that of US (95.2% [334/351], $P = 0.006$).

**CONCLUSION**

Non-enhanced MRI consisting of DWI and T2WI showed better sensitivity, PPV, and NPV than US. Non-enhanced MRI is a promising option for HCC surveillance.

**CLINICAL RELEVANCE/APPLICATION**

In patients at high risk of HCC, non-enhanced MRI consisting of DWI and T2WI can be considered an alternative surveillance tool to US.
**Purpose**

Chronic Liver Disease (CLD) is currently one of the major causes of death and the major cause of Hepatocellular Carcinoma (HCC) development. Therefore, accurate diagnosis regarding CLD progression is very important. Although Liver Biopsy (LB) is considered as the 'Gold Standard' for diagnosis, several non-invasive methods exist to avoid LB complications. Sound Touch Elastography (STE) that is available in Resona 7 Ultrasound (US) device and is similar to Shear Wave Elastography (SWE), seems promising but needs to be validated. The aim of this study is to compare the diagnostic performance between the STE and SWE for CLD assessment, using LB as "Gold Standard".

**Method and Materials**

290 subjects, 68 normal (F0) and 222 with CLD (F1-F4), were included in the study. A B-Mode and Elastographic examination was performed on each patient with Resona 7 and Aixplorer US devices. The STE (Resona 7) and SWE (Aixplorer) measurements were performed on the right lobe (RL) of each patient and were compared to LB results according to the Metavir Classification System (F0-F4). Receiver Operating Characteristic (ROC) analysis was then performed for each of the two methods to obtain best cut-off stiffness values.

**Results**

ROC analysis showed AUCSTE=0.9741 and AUCSWE=0.9854 for F=F4 Cirrhosis, AUCSTE=0.9723 and AUCSWE=0.9755 for F>=F3 Fibrosis Stage, AUCSTE=0.9675 and AUCSWE=0.9662 for F>=F2 Fibrosis Stage, AUCSTE=0.8889 and AUCSWE=0.9288 for F>=F1 Fibrosis Stage. Best cut-off stiffness values were calculated for each method (STE/SWE) compared to Metavir fibrosis stages:

- F=F4: 12.2/13.5 kPa, F>=F3: 9.5/8.7 kPa, F>=F2: 9.15/8.55 kPa, F>=F1: 6.5/6.05 kPa respectively.

**Conclusion**

Both STE and SWE can differentiate between the 5 Metavir fibrosis stages. SWE seems more reliable in differentiating normal subjects from subjects with CLD (F>=F1) and cirrhotic patients (F=F4) but less accurate in diagnosing intermediate stages (F>=F2, F>=F3).

**Clinical Relevance/Application**

Many Elastography technologies emerged with liver in focus. Comparison between them is useful in order to make Elastography reliably applicable to patients regardless of the underlying technology.

**SST03-03 ACR US LI-RADS: Outcomes of Category US-2 Observations**

**Purpose**

To evaluate the outcomes of ACR US LI-RADS Category 2 (US-2) observations detected at ultrasound performed for hepatocellular carcinoma (HCC) screening and surveillance.

**Method and Materials**

In this retrospective, single center study, 138 patients at high risk for HCC (77 men and 61 women; mean age 58.7 years) underwent screening liver ultrasound between January 2017 and December 2018 and were assigned US-2 observations on a prospective clinical basis. Results of follow-up imaging studies and/or histopathology were recorded. Statistical analysis was performed.

**Results**

The most common indications for HCC screening were cirrhosis (111/138, 80%), chronic hepatitis B virus without cirrhosis (15/138, 11%), and chronic hepatitis C virus without cirrhosis (7/138, 5%). Reasons for US-2 observations were a measureable mass (116/138, 84%; mean size 0.7 ± 0.2 cm; range 0.3-0.9 cm) and a subcentimeter area of parenchymal heterogeneity (22/138,
16%). 72% (99/138) of patients had imaging follow-up and management was discordant with US LI-RADS recommendations in 56% (55/99) of these patients. Confirmatory tests including multiphase contrast-enhanced CT or MRI (61/80), histopathology (6/80), or negative ultrasound follow-up for at least 1 year (13/80) were available for 59% (80/138) of patients. Etiologies of US-2 observations in the subset of 67 patients with CT, MRI, or histopathology included no mass/benign tissue (48/67, 72%), hemangioma (5/67, 7.5%), regenerative nodule (5/67, 7.5%), cyst (3/67, 4%), HCC (2/67, 3%), granuloma (2/67, 3%), LR-3 observation (1/67, 1.5%), and focal steatosis (1/67, 1.5%). Positive predictive value of a US-2 observation for HCC was 2.5%.

CONCLUSION
The positive predictive value of a US-2 (subcentimeter) observation for the detection of HCC is very low. As per US LI-RADS guidelines, US-2 observations can be safely followed with ultrasound rather than escalating workup to contrast-enhanced imaging.

CLINICAL RELEVANCE/APPLICATION
The vast majority of US LI-RADS Category 2 (US-2) observations are benign and can be safely followed with ultrasound.

SST03-04 Subharmonic Aided Pressure Estimation (SHAPE) for Long-Term Follow up of Patients with Portal Hypertension

Friday, Dec. 6 11:00AM - 11:10AM Room: E352

PURPOSE
To verify if noninvasive contrast-enhanced ultrasound (US) in the form of subharmonic aided pressure estimation (SHAPE) can accurately monitor disease progression or treatment response in patients identified with portal hypertension.

METHOD AND MATERIALS
SHAPE is based on the inverse relationship between the subharmonic amplitude of US contrast microbubbles and ambient pressure. A modified Logiq 9 scanner with a 4C curvi-linear probe (GE, Waukesha, WI) was used to acquire SHAPE data (transmitting/receiving at 2.5/1.25MHz) using Sonazoid (GE Healthcare, Oslo, Norway; IND 124,465). This IRB approved study has enrolled 177 subjects undergoing a transjugular liver biopsy, 22 patients have been identified with clinically significant portal hypertension (median age 59 yrs; 13 Males) based on their HVPG results. These subjects had follow-up clinic visits or CT/MRI scans every 6 months and at those times a repeat SHAPE examination was performed collecting data from the portal and hepatic vein in triplicate. The SHAPE gradient was calculated as the difference between subharmonic signals in the two vessels. Liver function tests (albumin, bilirubin and coagulation panel), MELD scores and presence of ascites and varices were used to establish clinical treatment response.

RESULTS
Of the 22 portal hypertensive cases, 1 patient has had four follow up scans, 1 has had three follow up scans, 3 have had two follow up scans, 7 have had one follow up, 7 have not had any follow up yet and 3 were lost due to death or refusal to follow up. There was a significantly higher signal reduction in the group who were classified as responders according to the SHAPE study compared to the SHAPE non-responders (p < 0.001). The mean change in the SHAPE gradient for the responders (n = 9) was -4.70 ±3.27 dB vs 1.77±0.55 dB in the SHAPE non-responders (p < 0.001). Results matched the corresponding clinical outcomes of improved MELD scores, improvement in underlying cause of portal hypertension, decreased bilirubin and reduced ascites indicating a reduction in portal hypertension amongst responders.

CONCLUSION
SHAPE can noninvasively monitor disease progression in portal hypertensive patients and hence, may help clinicians in patient management.

CLINICAL RELEVANCE/APPLICATION
Serial SHAPE can be a cost-effective and noninvasive technique to differentiate between portal hypertension treatment responders and non-responders and reduce the need for repeat catheterizations.

SST03-05 Inter-System Agreement and Repeatability of Two-Dimensional Shear Wave Elastography Measurements in Elastic Phantoms and In Vivo Human Livers Across Six Commercially-Available Ultrasound Systems

Friday, Dec. 6 11:10AM - 11:20AM Room: E352

Participants
Leah Gilligan, MD, Cincinnati, OH (Presenter) Nothing to Disclose
but no further features to suggest rejection, 4 were followed with endoscopy with no features of rejection. The remainder were normal findings consistent with concurrent CT or endoscopy findings. 11 studies in 6 patients demonstrated minimal mural thickening related to rejection confirmed at histology. 3 demonstrated recovery. 5 patients underwent US immediately post-surgery with the US performed for ACR, concurrent endoscopy (within 1 week) occurred in 11 US studies. 8 endoscopies demonstrated features patients with a history of ACR had normal US appearances at follow up, which correlated with endoscopic findings of recovery. Of (23 studies in 9 patients) were undertaken in those with biopsy-proven acute cellular rejection (ACR). Imaging findings of mural thickness in 97 patients received an IT between 2007 and 2019. There were 45 US studies undertaken in 27 patients. The majority of studies (23 studies in 9 patients) were undertaken in those with biopsy-proven acute cellular rejection (ACR). Imaging findings of mural thickening, loss of mural stratification, reduced peristalsis and mesenteric hypervascularity were observed in 7 patients with ACR. 2 patients with a history of ACR had normal US appearances at follow up, which correlated with endoscopic findings of recovery. Of the US performed for ACR, concurrent endoscopy (within 1 week) occurred in 11 US studies. 8 endoscopies demonstrated features related to rejection confirmed at histology. 3 demonstrated recovery. 5 patients underwent US immediately post-surgery with normal findings consistent with concurrent CT or endoscopy findings. 11 studies in 6 patients demonstrated minimal mural thickening but no further features to suggest rejection, 4 were followed with endoscopy with no features of rejection. The remainder were
followed clinically and radiologically.

CONCLUSION

Small bowel US is a useful technique in establishing normal appearances of the bowel. When interpreted in conjunction with clinical and endoscopic findings in patients with ACR it could have a role in surveillance.

CLINICAL RELEVANCE/APPLICATION

Ultrasound (US) is established in imaging of Crohn's disease. Rejection in intestinal transplantation is evaluated with endoscopic surveillance. We hypothesize that US may be used as an adjunct.

SST03-07 Spleen Elastography as a Predictor of Esophageal Varices

Friday, Dec. 6 11:30AM - 11:40AM Room: E352

Participants
Monica P. Cueva, MD, Quito, Ecuador (Presenter) Nothing to Disclose
Jorge R. Aldean, MD, Quito, Ecuador (Abstract Co-Author) Nothing to Disclose
Xavier S. Herdoiza, MD, Quito, Ecuador (Abstract Co-Author) Nothing to Disclose
Maria J. Andrade, Quito, Ecuador (Abstract Co-Author) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance of splenic elastography and other non-invasive methods to detect high-risk esophageal varices in patients with cirrhosis. The verification of the existence of varices was performed with upper digestive endoscopy, which is the gold standard.

METHOD AND MATERIALS

A prospective study was performed with 100 patients with a recent diagnosis of cirrhosis who were evaluated with upper abdomen ultrasound, hepatic Doppler, liver elastography, upper digestive endoscopy and that complied with the following criteria: no history of digestive bleeding, no treatment with beta-blockers, no thrombosis of the holder. Splenic elastography was performed by a radiologist with training in elastography using shear wave point elastography with a 5-7MHz convex probe. After the imaging studies, upper digestive endoscopy was performed by two hepatologists who were blinded to the information and the diagnosis of esophageal varices was obtained as well as the classification of patients into three groups: those who had no varices, low-risk varices and high-risk varices. A cross-sectional, unicentric study was carried out from April 2017 until December 2018. The data was organized in frequency tables. The comparison with the gold standard included the use of Chi square and ROC curves were obtained to present sensitivity and specificity data.

RESULTS

Spleen elastography proved to be a good predictive study of the presence of esophageal varices (AUC 0.84, CI 95%: 0.71-0.97), followed by the diameter of the spleen (AUC 0.81, 95% CI: 0.66-0.96), while the congestivity index (AUC 0.46, 95% CI: 0.27 - 0.64) and liver elastography (AUC 0.39, 95% CI: 0.21 - 0.58) proved to be the parameters with less precision. The cut-off point of 3.8m/s in the splenic elastography was able to identify high risk varices with a sensitivity of 90.9%.

CONCLUSION

Splenic elastography demonstrated sensitivity and specificity values similar to the ones published in international studies with adequate correlation with endoscopy for diagnosing high-risk esophageal varices.

CLINICAL RELEVANCE/APPLICATION

Bleeding is the most common and dangerous complication of esophageal varices. With early detection of high-risk varices using a non-invasive technique such as spleen elastography, patients can start prophylaxis with beta-blockers.

SST03-08 A Diagnostic Role of US-Guided Percutaneous Biopsy in Patients at Risk for Hepatocellular Carcinoma: Comparison with Noninvasive Diagnostic Approaches

Friday, Dec. 6 11:40AM - 11:50AM Room: E352

Seung Soo Lee, MD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
Jae Ho Byun, MD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose

PURPOSE

To explore a diagnostic role of US-guided percutaneous biopsy for suspicious focal hepatic lesions in patients at risk for hepatocellular carcinoma (HCC) and to compare the results with noninvasive diagnostic approaches using the Liver Imaging Reporting and Data System (LI-RADS) classification

METHOD AND MATERIALS

We retrospectively included 169 lesions in 160 patients at risk for HCC who underwent US-guided percutaneous biopsy for newly developed suspicious hepatic malignancy in 2016. Each target lesion on biopsy was evaluated on CT and/or MRI and was assigned to the LI-RADS v2018 categories. We compared the biopsy results with the LI-RADS categories and evaluated the agreement by using percent agreement and Cohen's kappa statistic after recategorization of the LI-RADS into three groups: (a) favoring HCC (including LR-4, 5, and TIV without targetoid mass) (b) favoring non-HCC malignancy (including LR-M and TIV with targetoid mass)
RESULTS

US-guided biopsy achieved successful diagnostic results in 81.7% (138/169) without difference across the LI-RADS categories (CT, p = 0.35; MRI, p = 0.86). Among these 138 lesions, 73 lesions were evaluated both on CT and MRI, whereas 65 were solely assessed by using either CT or MRI. Biopsy showed fair-to-good agreement with noninvasive categorization by CT and MRI (κ=0.61 for each) with substantial percent disagreement (CT, 24%; MRI, 23%). Three of LR-3 lesions each on CT (20%) and MRI (27%) were diagnosed with malignancy on biopsy; 3 (7%) on CT and 3 (7%) on MRI favoring HCC were benign on biopsy; 4 (11%) on CT and 3 (7%) on MRI favoring HCC were non-HCC malignancy on biopsy. Biopsy showed higher percent agreement (90%) with surgical pathology than the diagnostic categories on CT (75%) and MRI (70%).

CONCLUSION

Despite its substantial non-diagnostic results, US-guided percutaneous biopsy showed superior diagnostic performance for focal hepatic lesions than noninvasive imaging diagnosis using the LI-RADS classification.

CLINICAL RELEVANCE/APPLICATION

If diagnostically adequate samples are obtained, US-guided percutaneous biopsy poses an important role for classifying hepatic nodules which even show the typical HCC hallmarks on imaging in patients at risk for HCC.

SST03-09 Diagnostic Benefit of Oral Contrast Administration (Small Intestine Contrast-Enhanced Ultrasonography [SICUS]) over Conventional Enteric US in Crohn’s Disease

Purposes

Enteric ultrasound (US) following an oral contrast agent (SICUS) may facilitate better visualisation of the bowel wall compared to unprepared US. The purpose of this study was to compare the diagnostic accuracy of unprepared US and SICUS for detecting small bowel Crohn’s disease (CD).

METHOD AND MATERIALS

The study utilised patients recruited to a prospective trial comparing the diagnostic accuracy of MRE and US for CD (either newly diagnosed or with relapsing disease) recruited across 8 hospitals. A construct reference standard (multidisciplinary panel diagnosis) was used in the trial, incorporating 6 months of patient follow up. 64 patients underwent standard US followed by SICUS (using 1L of hyperosmolar luminal contrast), performed by the same practitioner, blinded to all clinical data. Practitioners recorded findings on the presence of small bowel/colonic CD after each US examination. Sensitivity and specificity for small bowel disease extent (i.e. presence and correct segmental location) was compared to the trial construct reference standard using bivariate multilevel patient specific random effects models, from paired data using meqrlogit in STATA 14.2.

RESULTS

Sensitivity and specificity for small bowel disease extent was identical between SICUS and unprepared US (71% [58-81] and 86% [49-97] respectively). SICUS specificity for colonic disease was 92%[80-97] and 82%[68-91] for unprepared US, a non-significant difference of 10% (95% CI -2 to 22), p=0.125. Both US and SICUS detected 9/14 (64%) of segments deemed to be stenosed and causing obstruction by the consensus reference standard. There were numerically fewer false positive diagnoses of obstructing stenosis on SICUS compared to US (7 vs. 11 respectively).

CONCLUSION

We found no evidence that SICUS increases diagnosed accuracy for small bowel disease extent compared to conventional US. Stenosis detection was not improved by SICUS but false positive diagnoses may be reduced.

CLINICAL RELEVANCE/APPLICATION

SICUS offers no significant advantage over standard US for detecting small bowel CD. Given the patient symptom burden induced by ingesting hyperosmolar fluid, first line SICUS cannot be recommended.
PURPOSE

Asymptomatic microscopic hematuria (AMH) can be a sign of upper tract (UT) malignancy and requires evaluation. However, the preferred imaging modality of the UT is controversial. Our healthcare system is an integrated medical center with 30 regional clinics serving 21 counties over a tri-state region has routinely used renal ultrasound (RUS) for the initial evaluation of the UT in patients with AMH because of cost and performance. The purpose of this study was to evaluate the sensitivity of RUS for detecting UT malignancy in patients with AMH.

METHOD AND MATERIALS

An IRB approved, retrospective study was performed of all patients who received a renal ultrasound in our health system from January 1, 1997 to July 1, 2015. Patients were excluded if they had <3 years of follow-up, <18 years old, history of prior UT genitourinary cancer, catheter, inpatient status, pregnant status, gross hematuria (GH) or spotting, or if the health record did not contain sufficient detail to rule out GH. The initial RUS was considered positive if findings led to a diagnosis of UT malignancy. Regardless of the RUS results, health records were then reviewed to determine whether any UT cancer was subsequently diagnosed to assess for false negatives.

RESULTS

Of the 4871 patients who underwent a RUS during the study period, 2124 met eligibility criteria. The average follow-up was 11.6 years (range: 3-21.6, stdev: 4.9). Twelve (0.6%) patients were diagnosed with UT malignancy (9 renal cell carcinoma and 3 urothelial carcinomas) during their initial evaluation, all of whom had an initial RUS positive for malignancy for an overall sensitivity of 100% and negative predictive value of 100%. Four patients were diagnosed with UT malignancy >3 years after an initially negative RUS.

CONCLUSION

We have demonstrated that the sensitivity of RUS is adequate for detection of UT malignancy in patients with AMH, a low-risk population. This study represents a general population from a community outpatient setting with reliable long-term follow-up. Patients whose RUS and cystoscopy findings are negative for signs of malignancy can safely be advised to return for further evaluation if they develop GH, flank pain, or irritative voiding symptoms.

CLINICAL RELEVANCE/APPLICATION

Renal ultrasound is highly sensitive for detection of upper tract malignancies and can be used for initial screening in low-risk patients with asymptomatic microhematuria.
PURPOSE

Current American Urological Association (AUA) guidelines recommend risk-stratified cystoscopy in the workup of hematuria. However, due to insufficient evidence for risk-stratified upper urinary tract imaging, the AUA recommends multiphasic computed tomography urography (CTU) for all patients. The aims of this study are to determine the diagnostic yield of CTU in patients evaluated for hematuria with negative cystoscopy, and to identify those at highest risk of urinary tract malignancy, who would benefit most from upper urinary tract imaging.

METHOD AND MATERIALS

A retrospective study was conducted of patients who underwent CTU within 12 months of negative cystoscopy for workup of hematuria at our institution between January 2017-December 2017. Patients were grouped according to etiology of hematuria. Clinical diagnoses were correlated with patient characteristics, including age, sex, smoking history, and type of hematuria, as well as renal ultrasound (US) and CTU results. Diagnostic concordance of renal US and CTU was compared.

RESULTS

258 patients met the inclusion criteria. Of these, only 1 patient was diagnosed with an upper urinary tract malignancy. 6 other malignancies were diagnosed including 3 renal cell carcinomas (RCC), 2 prostate adenocarcinomas, and 1 metastatic gynecologic malignancy. All malignancies were diagnosed in patients over 50 years of age. 60 patients were diagnosed with urolithiasis, and 56 were diagnosed with benign prostatic hyperplasia (BPH). There was no etiology identified in 109 patients, including 21 of 30 patients age 50 years and under. Renal US was performed in 93 patients. Renal US was diagnostic and concordant with CTU in 56 patients. Renal US failed to detect the diagnosis identified on CTU in 18 cases, including 1 RCC, 7 urolithiasis, 7 BPH, and 3 other benign findings. Both renal US and CTU were non-diagnostic in 11 patients in whom the etiology of hematuria was identified on cystoscopy.

CONCLUSION

Renal US with or without computed tomography of the kidneys, ureters, and bladder (CT KUB) should be considered as an alternative to multiphasic CTU in the workup of hematuria in patients with negative cystoscopy.

CLINICAL RELEVANCE/APPLICATION

Risk-stratified upper tract imaging in the workup of hematuria may reduce radiation exposure with no significant effect on detection of upper urinary tract malignancy or other significant findings.

PURPOSE

The aim of this in-vitro study was to compare the performance of six dual-energy CT (DECT) scanners in determination of stone composition.

METHOD AND MATERIALS

A total of 71 urinary stones (size: 2 mm - 16 mm) of known chemical composition (51 calcium, 4 struvite, 4 cystine and 12 urate) were placed in a custom-made cylindrical phantom. Consecutive scans with manufacturer-recommended protocols were performed on second-generation dsDECT (S1: SOMATOM Definition Flash, Siemens;100/Sn140kVp), third-generation dsDECT (S2: Force,Siemens;100/Sn150kVp), sfDECT (S3: Edge, Siemens;AuSn120kVp), first-generation rsDECT (S4: Discovery750HD, GE; 80/140kVp), second-generation rsDECT (S5: Revolution, GE; 80/140kVp) and dlDECT (S6: IQon, Philips; 120kVp). Data sets were analysed using effective atomic number (Zeff) and dual-energy ratio indices (DEI) of maximally available spectra (40/190 keV for dsDECT and 40/200 keV for dlDECT) and comparable spectra (40 keV/140 keV) all S1-S6 were computed. Agreement of Zeff and DEI among the scanners was assessed with inter-class coefficient test.

RESULTS

Both Zeff and DEI could differentiate between non-urate and urate stones. For all stone compositions, Zeff showed excellent agreement between scanners (ICC:0.90, 95% CI : 0.86- 0.93). DEI showed lower agreement compared to Zeff. Both, DEI computed by maximally separated spectra (40/190 keV for dsDECT and 40/200 keV for dlDECT) and comparable spectra (40 keV/140 keV) all S1-S6 were computed. Agreement of Zeff and DEI among the scanners was assessed with inter-class coefficient test.
CONCLUSION
Overall cross-vendor measurements for determination of stone composition were comparable with all DECT techniques. Zeff is a better quantitative measure than DEI for stone characterization.

CLINICAL RELEVANCE/APPLICATION
In a busy practice with multivendor setup it is important to cross validate the performance for stone composition to provide consistent results since patients can be scanned at different scanners.

SST04-04  Automated Radiomic Analysis of Ureteral Stones Using ER Renal Stone CT Images Predicts Likelihood of Spontaneous Passage
Friday, Dec. 6 11:00AM - 11:10AM Room: E350

fletcher.joel@mayo.edu

PURPOSE
To quantify the ability of automated radiomic analysis of CT images to predict the likelihood of spontaneous passage of symptomatic renal stones, and to compare the results with the performance of manual measurements.

METHOD AND MATERIALS
This IRB-approved, HIPAA-compliant, retrospective study included symptomatic patients undergoing emergency renal stone CT who had one stone in the kidney or ureters; patients with bladder stones were excluded. Spontaneous passage (or not) was documented based on review of clinical records, patient report, follow-up CT scans, or the need for stone extraction during 6 months of follow-up. Radiologists-in-training manually measured axial and coronal stone dimensions. Automated quantitative stone analysis software computed stone length, width, height, maximum dimension, volume, and CT number, as well as morphologic parameters related to stone heterogeneity and roughness. Univariate logistic regression was used to define odds ratios (OR) of spontaneous passage and ROC analysis was used to assess the ability to predict stone passage. Independent variables identified using multivariable logistic regression were used to create models that incorporated parameters such as patient age and sex, stone volume and dimensions, and morphological features.

RESULTS
Of 195 patients, spontaneous passage was documented in 58% (114/195). Univariate analysis demonstrated numerous significant stone parameters (from the CT data) associated with stone passage (p<0.001), including OR (95% CI) of 10.1 (5.11, 19.9) for axial dimension < 4.6 mm and 9.40 (4.84, 18.2) for coronal dimension < 4.9 mm (manual measurements), and 11.14 (5.21, 23.8) for volume < 81 mm³ and 10.58 (5.37, 20.8) for mean curvature < -0.14 (automated measurements). Area under the ROC curve was 0.83 for manual measurements and increased to 0.88 when patient and morphological stone features were included.

CONCLUSION
Automated radiomic analysis quickly and reproducibly predicted stone passage better than manual radiologist measurements. Prospective clinical validation of the developed model is needed.

CLINICAL RELEVANCE/APPLICATION
Automated radiomic analysis of CT data can quickly provide reproducible objective data for guiding management of patients with acute ureterolithiasis.

SST04-05  Dose Independent Characterization of Renal Stones by Means of Spectral Detector Computed Tomography and Machine Learning
Friday, Dec. 6 11:10AM - 11:20AM Room: E350

PURPOSE
To predict the main component of both, pure and compound kidney stones using dual energy computed tomography and machine...
METHOD AND MATERIALS

200 kidney stones with a known composition as determined by infrared spectroscopy were examined using a non-anthropomorphic phantom on a spectral detector computed tomography scanner. Stones were of either pure (monocrystalline, n=116) or compound (dicrystalline, n=84) composition. Image acquisition was repeated twice using both, normal and low-dose protocols, respectively (ND/LD). Conventional images and low and high keV virtual monoenergetic images were reconstructed. Stones were semi-automatically segmented. Further analysis was conducted on a per-voxel basis, using a shallow neural network (SNN). ND data was imported in the SNN and split in training (70%), testing (15%) and validation-datasets (15%). LD data then was analyzed by the same network. Accuracy on a per-voxel and a per-stone basis was calculated.

RESULTS

Main components were: Whewellite (n=80), weddellite (n=21), Ca-phosphate (n=39), cysteine (n=20), struvite (n=13), uric acid (n=18) and xanthine stones (n=9). Stone size ranged from 3 - 18 mm. Overall diagnostic accuracy attained with test/training dataset for determining stone composition was 91.1%. On independently tested LD-acquisitions accuracy was 87.1-90.4%.

CONCLUSION

Even in compound stones, the main component can be reliably determined using dual energy CT and machine learning, irrespective of dose protocol.

CLINICAL RELEVANCE/APPLICATION

After transfer to patients, spectral detector CT and machine learning may enable a detailed analysis of renal stone composition and therefore a targeted therapy of different types.

SST04-06  Estimating Differential Renal Function in Patients with Upper Urinary Tract Stones Using Non-Enhanced Computed Tomography

Friday, Dec. 6 11:20AM - 11:30AM Room: E350

Participants
Jiali Li, Wuhan, China (Presenter) Nothing to Disclose
Daoyu Hu, Wuhan, China (Abstract Co-Author) Nothing to Disclose
Zhen Li, MD, PhD, Wuhan, China (Abstract Co-Author) Nothing to Disclose

PURPOSE

For chronic urinary tract stones patients, differential renal function (DRF) is a key indicator for assisting urologists in selecting treatment options (lithotripsy versus nephrectomy). The wide popularity and short acquisition time of unenhanced computed tomography (CT) make it a first-line examination method for imaging patients with ureteral stones. Therefore, this study aimed to determine whether unenhanced CT imaging can estimate DRF in patients with chronic unilateral obstructive upper urinary tract stones.

METHOD AND MATERIALS

This was a retrospective study of 76 patients, and all patients underwent nonenhanced CT and nuclear renography (RG) at an interval of 4 to 6 weeks due to chronic unilateral obstructive urinary stones. Renal CT measurements (RCMs), consisting of residual parenchymal volume (RPV) and volumetric CT texture analysis parameters, were obtained using a semiautomated method. The percent RCM were calculated using the general format ‘100*[(Left RCM/[(Left RCM+Right RCM])]’. Then percent RCMs were evaluated for their correlation power to DRF derived from RG.

RESULTS

The strongest Pearson coefficient between percent RCM and DRF was reflected by RPV (r=0.957, P<0.001). Combinations of RPV and other parameters did not significantly improve the correlation compared with RPV alone (Pearson’s r=0.957 versus r=0.957, 0.957, 0.887, 0.815, and 0.956, for combinations of Hounsfield unit, parenchymal voxel, skewness, kurtosis, and entropy, respectively; all P<0.001). Percent RPV was subsequently introduced into linear regression, and the equation y = -2.66+1.07*x (P < 0.001) was derived to calculate predicted DRF. No statistically difference was found between predicted DRF using the equation and observed DRF according to RG (P=0.959).

CONCLUSION

Unenhanced CT imaging can estimate DRF and may reduce unnecessary use of RG for most patients with chronic unilateral obstructive upper urinary tract stones.

CLINICAL RELEVANCE/APPLICATION

Unenhanced CT can be used as a convenient tool to predict DRF and RPV should be considered as part of routine CT reporting in patients with chronic unilateral obstructive upper urinary tract stones.

SST04-07  Computed Tomography Findings of Upper-Urinary-Tract Lesions in Immunoglobulin G4-Related Disease: Comparison with Urothelial Carcinoma

Friday, Dec. 6 11:30AM - 11:40AM Room: E350

Participants
Minobu Kamo, MD,PhD, Hamburg, Germany (Presenter) Nothing to Disclose
Taiki Nozaki, MD, Tokyo, Japan (Abstract Co-Author) Nothing to Disclose
Natsuka Muraishi, MD, Tokyo, Japan (Abstract Co-Author) Nothing to Disclose
Jin Yamamura, MD, Hamburg, Germany (Abstract Co-Author) Nothing to Disclose

PURPOSE

Immunoglobulin G4-related disease (IgG4-RD) can sometimes involve the upper urinary tract and mimic urothelial carcinoma.
clinically. There have been indeed quite a few reports mentioning that unnecessary radical nephroureterectomy was performed to those patients. The purpose of this study was to investigate computed tomography (CT) findings of IgG4-RD lesions involving the upper urinary tract and to compare them with those of urothelial carcinomas.

METHOD AND MATERIALS

Pretreatment CT images of 13 consecutive patients of IgG4-RD with urinary tract lesions and 80 consecutive patients with urothelial carcinoma were retrospectively evaluated by two board-certified radiologists. Clinical information of each group was obtained by chart review.

RESULTS

Upper-urinary-tract findings between two groups is summarized in the table. Bilaterality (P < 0.0001), symmetry (P < 0.0001), extramural growth pattern (P < 0.0001), longer lesions (P < 0.04) and gradual dynamic enhancement pattern (P < 0.001) were statistically more frequent in IgG4-RD patients compared to urothelial carcinoma patients. Concerning extra-urinary-tract findings, following findings were significantly common among IgG4-RD patients; paraaortic fat stranding (P = 0.03), presacral fat stranding (P < 0.001), and fat stranding of pelvic walls (P < 0.001). Aortic lesions were significantly more frequent in IgG4-RD patients (P < 0.001), on the other hand kidney lesions was seen in only one patient of IgG4-RD and patients with urothelial carcinoma tended to present with direct tumoral invasion to renal parenchyma, although there was no significant difference. There was no significant difference on frequency of hydronephrosis and coexisting pancreatic lesions between each group.

CONCLUSION

Compared to urothelial carcinoma, bilateral, symmetric, and longer involvement, extramural growth pattern, ill-defined margin, gradual enhancement pattern in dynamic CT are suggestive findings of IgG4-RD urinary tract lesions. IgG4-RD can also manifest as ipsilateral asymmetric lesion, which could overlap with those of urothelial carcinoma. Extra-urinary-tract findings such as fat stranding in paraaorta, presacral or pelvic wall area are also useful findings in differentiating IgG4-RD lesions from urothelial carcinoma.

CLINICAL RELEVANCE/APPLICATION

CT is useful in differentiating urinary tract lesions of IgG4-RD from urothelial carcinoma and can prevent unnecessary ureteronephrectomy.

SST04-08 The Feasibility of Compressed Sensing With and Without Breath-Holding on Magnetic Resonance Urography: A Comparison with Conventional 3D Magnetic Resonance Urography Looking at Acquisition Time, Image Quality, and Diagnostic Performance

Friday, Dec. 6 11:40AM - 11:50AM Room: E350

wumingjubo@hotmail.com

PURPOSE

To investigate the feasibility of prototypical 3D magnetic resonance urography (MRU) with a compressed sensing (CS) technique for patients with or without breath-holding (BH) capabilities.

METHOD AND MATERIALS

MRU was performed in 66 patients on a 3T system, including BH with CS, navigator-triggered (NT) CS, and conventional NT (cNT) protocols. The patients were divided into two groups, Group I (the BH group, n = 56) and Group II (the compromised BH group, n = 10), according to the image quality of a BH-T1-weighted protocol. The quality of urinary tract sharpness and background suppression were scored with a scale of 1 to 5 (poor to good). Urinary tract lesions were detected on reconstructed maximum intensity projections, multiplanar reconstructions, and source images, and graded with the same scale. Comparative analyses of acquisition time and image quality were performed. Receiver operating characteristic (ROC) curve analysis was performed, and sensitivity, specificity, and the area under the ROC curve (AUC) were calculated to determine diagnostic performances.

RESULTS

BH-CS MRU showed reductions of 88.1% and 96.7% in acquisition times compared with NT-CS MRU and cNT MRU in Group I. The acquisition time was reduced by 71.2% for NT-CS MRU compared with cNT MRU in Group II. BH-CS MRU had the best urinary tract sharpness in Group I, and NT-CS MRU had the least background signal in both groups (both P < 0.05). BH-CS MRU presented superior urinary tract sharpness and background suppression in Group I than Group II (both P < 0.05). Group I had better urinary tract sharpness with NT-CS MRU and less background suppression with cNT MRU than Group I (both P < 0.05). Diagnostic efficiencies of all protocols were comparable in Group I (all P > 0.05), while the diagnostic efficiency of BH-CS MRU was significantly lower than the other two protocols in Group II (both P < 0.05).

CONCLUSION

BH-CS MRU showed great potential for urinary tract imaging with the shortest acquisition times and excellent image qualities in patients that can hold their breath. For patients that cannot hold their breath, NT-CS MRU would be helpful.

CLINICAL RELEVANCE/APPLICATION

Compressed sensing magnetic resonance urography (MRU) can shorten MR acquisition time with better image quality compared with
Validation of Vesical-Imaging Reporting and Data System (VI-RADS): A Single-Centre Retrospective Evaluation of Interobserver Agreement and Diagnostic Accuracy of Multiparametric MRI (mpMRI) in the Setting of Bladder Cancer

Friday, Dec. 6 11:50AM - 12:00PM Room: E350

pecoraro.martina1@gmail.com

PURPOSE
Vesical Imaging-Reporting and Data System (VI-RADS) has been developed to standardize multiparametric MRI (mpMRI) approach to bladder cancer (BC). The aim of this study was to evaluate interobserver agreement and diagnostic accuracy of mpMRI with the use of VI-RADS to discriminate between non-muscle invasive bladder cancer (NMIBC) and muscle-invasive bladder cancer (MIBC).

METHOD AND MATERIALS
Between September 2017 and March 2019, 138 patients referred for suspected bladder cancer underwent multiparametric MRI of the bladder (mpMRI) prior to transurethral resection of bladder tumor (TURBT). All mpMRI were reviewed by two radiologists, who scored each lesion according to VI-RADS. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated for each VI-RADS cutoff. Receiver operating characteristics curves were used to evaluate the performance of mpMRI. The k statistics was used to estimate inter-reader agreement.

RESULTS
One hundred twenty-six patients were included in the final analysis, 88 with NMIBC and 38 with MIBC. Sensitivity and specificity were 93% and 91% for reader 1 and 86% and 85% for reader 2 respectively when the cutoff VI-RADS > 2 was used to define MIBC. At the same cutoff, PPV and NPV were 81% and 97% for reader 1 and 75% and 94% for reader 2. When the cutoff VI-RADS > 3 was used, sensitivity and specificity were 84% and 95% for reader 1 and 79% and 91% for reader 2. Corresponding PPV and NPV were 85% and 92% for reader 1 and 79% and 92% for reader 2. Area under curve was 0.918 and 0.886 for reader 1 and 2 respectively. Inter-reader agreement was good for the overall score (k =0.748).

CONCLUSION
VI-RADS is accurate in differentiating MIBC from NMIBC. The optimal cutoff is VI-RADS >2 to maximize sensitivity and NPV. Inter-reader agreement is overall good.

CLINICAL RELEVANCE/APPLICATION
Magnetic resonance imaging (MRI) scans for bladder cancer with the use of a standardized and validated score as the VI-RADS may help improve patient care.

ARRT Category A+ Credit: 1.75

PURPOSE
To determine if TNM sub-stage (IA1-IB) and PET tumor measurements are predictive of survival in surgical patients with both clinical and pathological stage I non-small cell lung cancer (NSCLC).

METHOD AND MATERIALS
This study reviewed surgical patients with clinical and pathological stage I NSCLC and a baseline FDG PET/CT between Feb 2004 and Dec 2014. The pathological staging was based on the prevailing staging system at the time of the surgery. The clinical stage (8th edition) was determined retrospectively by radiologists based on FDG PET/CT and contrast CT. The metabolic tumor volume (MTV), total lesion glycolysis (TLG), and SUVmax from PET/CT were measured. The primary endpoint was overall survival (OS). Kaplan-Meier and Cox survival analyses were performed.

RESULTS
172 surgical patients with pathological stage I also had clinical stage I (9 with IA1, 63 with IA2, 63 with IA3 and 37 with IB) (111 females and 61 males), with 44.8% who expired during follow-up, median OS was 69.1 months; and the 1-year, 2-year, and 5-year OS rates were 96.0%, 88.3% and 71.7 %, respectively. The median follow-up among survivors was 79.2 months. Univariate analysis showed that age (hazard ratio (HR) of age for every year= 1.04, p=0.001) and ECOG performance status (p=0.027) were associated with OS. Clinical TNM sub-stage (p=0.702), gender (p=0.405), smoking status (0.171), histology (p=0.111), ln(MTV) (p=0.120), ln(TLG) (p=0.147) and ln(SUVmax) (p=0.316) were not significantly associated with OS. The statistically significant association of age (HR= 1.04, p=0.002) and ECOG performance status (p=0.027) with OS persisted in multivariate Cox regression analyses after adjusting for clinical TNM sub-stage and ln(MTV). However, there was no significant association of clinical TNM sub-stage (p=0.451) and ln(MTV) (p=0.08) with OS. Kaplan-Meier survival analysis showed statistically significant association of MTV (>=3.5 ml vs <3.5ml, p=0.049), age (p=0.001) and ECOG performance status (p=0.02) with OS.

CONCLUSION
Clinical TNM sub-stage is not associated with OS in the surgical patients with both clinical and pathological stage I NSCLC. Age, MTV (>=3.5 ml vs <3.5ml) and ECOG performance status are significantly associated with OS in such patients.

CLINICAL RELEVANCE/APPLICATION
Patients with clinical stage 1 as determined with CT and PET, and pathologic stage 1 do well after surgery. Clinical TNM sub-stages add little prognostic information in this group.

Mediastinal Lymph Nodal Staging by 18 F FDG PET CT in Patients with Co-Existent Carcinoma Lung and Tuberculosis: A Tertiary Care Centre Experience

Friday, Dec. 6 10:40AM - 10:50AM Room: E353B

The aim of this study was to determine a predictive model that could improve the accuracy for identifying mediastinal (N2) nodal metastases based on both PET and CT findings seen on baseline 18F-FDG PET/CT. The overall diagnostic accuracy of 18F-FDG PET CT in mediastinal lymph nodal staging in patients with co-existent Carcinoma lung and Tuberculosis is 67.4%, if SUV Max of 2.5 is taken as the cut off criteria, however if SUV Max-Ratio is taken into consideration, the overall diagnostic accuracy increases to 74.8%, thus helping in the accurate staging of patients.

**RESULTS**

A total of 118 lymph node stations with a mean of 4.6 lymph node station per patient and total of 540 lymph nodes with a mean of 21.6 lymph nodes per patient were resected and biopsied. 79 nodes were reported positive for metastasis and 27 nodes were reported as granulomatous. On pre-treatment 18F-FDG PET/CT scan, the mean SUV Max-Tumour of squamous cell carcinoma was significantly higher than that of adenocarcinoma (9.9±3.97 vs. 5.76±3.48, P<0.001). The mean SUVmax of malignant lymph nodes was significantly higher than that of tubercular lymph nodes (6.7±0.94 vs. 2.7±0.84 P<0.001). The mean SUV Max -Ratio in patients with malignant lymph nodes was significantly higher than in those with tubercular lymph nodes (0.91±0.36 vs. 0.41±0.28, P<0.001).

**CONCLUSION**

The overall diagnostic accuracy of 18 F FDG PET CT in mediastinal lymph nodal staging in patients with co-existent Tuberculosis and Carcinoma lung carcinoma is 67.4 %, if SUV Max of 2.5 is taken as the cut off criteria, however if SUV Max-Ratio is taken into consideration, the overall diagnostic accuracy increases to 74.8%, thus helping in the accurate staging of patients.

**CLINICAL RELEVANCE/APPLICATION**

Carcinoma lung with co-existing Tuberculosis results in false positive mediastinal lymph nodes and fallacies in pre-operative staging.
CONCLUSION

Predictive model (PM3) which combined visual PET positivity, N/A ratio >= 2 and HU < 75 showed much improved accuracy in the preoperative diagnosis of mediastinal nodal metastases.

CLINICAL RELEVANCE/APPLICATION

Predictive model combining PET and CT parameters can identify N2 nodal involvement with high accuracy than either alone. The specificity and NPV appears excellent. However the sensitivity and PPV is only modest, demanding invasive nodal sampling especially in infectious endemic areas.

**SST06-04 Multimodal Radiomics Analysis Based on 18F-FDG and 18F-FLT PET/CT to Identify Benign and Malignant Lung Nodules**

PURPOSE

This study aims to distinguish benign and malignant pulmonary nodules using multimodal image radiomic analysis based on 18F-FDG and 18F-FLT PET/CT.

METHOD AND MATERIALS

We retrospectively analyzed 114 patients newly diagnosed with NSCLC who underwent PET/CT with 18F-FDG and 18F-FLT and were pathologically confirmed by biopsy afterwards. A semi-automatic threshold method, using SUVmax 40% as the threshold, was used to segment lesions. Radiomic features were automatically extracted. The dataset was divided into training set and test set at a ratio of 8:2. The radiomic features extracted from FDG images were used to construct the machine learning model with the features selected by analysis of variance (ANOVA) and the least absolute shrinkage and selection operator (LASSO) methods. Meanwhile, whether lesions were showed in FLT images were treated as a trait, combined with the selected radiomic features from FDG/CT image, a new model was established. Two radiomic-based models were established using Logistic Regression (LR) to distinguish benign from malignant, and the test set was used for verification respectively. The performance of the two model were evaluated using the area under the receiver operating characteristic (ROC) curve (AUC), sensitivity and specificity.

RESULTS

A total of 123 lesions were acquired from 113 patients included 63 benign lesions and 60 malignant lesions. 678 radiomic features were extracted from the lesions. ANOVA selected 192 features with p value less than 0.05. Based on these features, Lasso selected 6 features through 5-fold cross-validation. FDG-model with radiomic features and combined-model with FLT as an additional trait were constructed. Combined-model allowed non-invasive diagnosis prediction of benign and malignant (AUC = 0.819, sensitivity = 0.835, specificity = 0.742) which significantly outperformed FDG-model (AUC = 0.806, sensitivity = 0.827, specificity = 0.775). The LASSO processing, ROCs, sensitivity and specificity of two models are shown in Figure.

CONCLUSION

The radiomic model based on 18F-FDG and 18F-FLT PET/CT images demonstrate that the feasibility of non-invasive method to differentiate benign lesions from malignant.

CLINICAL RELEVANCE/APPLICATION

The multimodal image radiomics based on FDG and FLT PET tracers has been identified and validated and it can help to distinguish benign from malignant lung nodules.

**SST06-05 FDG-PET/MRI versus Whole-Body MRI versus FDG-PET/CT versus Conventional Radiological Examination: Diagnostic and Prediction Capabilities for Postoperative Recurrence in Non-Small Cell Lung Cancer Patients**

PURPOSE
To investigate whether the radiomics features of 18F-FDG PET-CT in lung adenocarcinoma combining with relevant clinical characteristics can predict the EGFR mutation status, and to explore the association with the prognosis of patients with different mutation status.

METHOD AND MATERIALS
A total of 174 patients with lung adenocarcinoma who received PET/CT scan and EGFR gene test were retrospectively analyzed. 1672 Radiomics features were extracted from PET/CT images using a Radiomics prototype (Frontier, VB10, Siemens Healthineers). The clinical and pathological data were retrospectively analyzed and a combination of radiomics signature with clinical factors model was constructed using the Randon Forest (RF) method to identify EGFR mutants from wild types. The mutant/wild model was trained on a set of 149 patients and validated on an independent test group (n=35) using the AUC. A subset of 99 patients with EGFR mutation were further analyzed. The second model was built with RF classifier to predict 19/21 mutation site. The performance of training group (n=79) and test group (n=20) were evaluated by AUC. And then, and the COX proportional hazard model of multivariate analysis was established.

RESULTS
Area under the curves (Azs) of PET/MRI (Az=0.99) was significantly larger than that of MRI (Az=0.97, p<0.05), PET/CT (Az=0.97, p<0.05) and conventional radiological examination (Az=0.94, p<0.05). When applied feasible threshold values, accuracy of PET/MRI (97.7%) was significantly higher than that of others (MRI: 96.3%, p=0.004; PET/CT: 94.8%, p=0.0001; conventional radiological method: 90.0%, p=0.0001). Accuracy of MRI was also significantly higher than that of PET/CT (p=0.02) and conventional radiological method (p<0.0001). Moreover, accuracy of PET/CT was significantly higher than that of conventional radiological method (p=0.0001). As the results of multivariate analysis for prediction of postoperative recurrence, histological subtype (p=0.005), tumor marker (p=0.001), PET/MRI result (p=0.001) and conventional radiological method result (p=0.002) were determined as significant predictors.

CONCLUSION
FDG-PET/MRI has better potential for diagnosis of postoperative recurrence than others and considered as one of the predictors in postoperative NSCLC patients.

CLINICAL RELEVANCE/APPLICATION
FDG-PET/MRI has better potential for diagnosis of postoperative recurrence than others and considered as one of the predictors in postoperative NSCLC patients.
PURPOSE

To investigate if 18F-FDG PET-CT has the potential to predict the major pathologic response to the neoadjuvant PD-1 blockade in resectable NSCLC patients.

METHOD AND MATERIALS

From March 2018 to March 2019, 35 patients with resectable NSCLC (the largest diameter of the pulmonary mass was 2.0 cm or larger) who were eligible to the open-label, single-center, single-arm phase Ib clinical trial with PD-1 blockade (IBI308) as neoadjuvant therapy treatment were enrolled. All patients received two doses of intravenous PD-1 blockade (at a dose of 200mg) every 2 weeks. PET-CT scan was performed before neoadjuvant therapy (baseline) and 4 weeks after the first dose (before surgery). PET responses were classified using PET response criteria in solid tumors (PERCIST). Peak standardized uptake values normalized by lean body mass (SULpeak) were measured, and post-treatment percentage changes in SULpeak (ΔSULpeak%) were calculated. The above metabolic information on FDG-PET was correlated with the surgical pathology.

RESULTS

After 4 weeks of neoadjuvant PD-1 blockade treatment, all 35 patients were under surgery, and the major pathological response (MPR, defined as 10% or less residual viable tumor) occurred in 13 of 35 resected tumors (37%). 13 patients (37%) showed partial metabolic response (PMR), 21 (60%) had stable metabolic disease (SMD), and 1 (3%) had progressive metabolic disease (PMD). There was a significant correlation between the pathological response and the PET responses which were classified using PET response criteria in solid tumors (PERCIST). All (100%) the partial metabolic response (PMR, ΔSULpeak% < -30%) tumors showed the major pathological response (MPR, defined as 10% or less residual viable tumor). The patient who had progressive metabolic disease (PMD, ΔSULpeak% > 30%) was progressive confirmed by the biopsy of the pleural metastasis.

CONCLUSION

18F-FDG PET-CT can predict the major pathologic response to the neoadjuvant PD-1 blockade in resectable non-small cell lung cancer.

CLINICAL RELEVANCE/APPLICATION

Metabolic responses by 18F-FDG uptake which were classified using PET response criteria in solid tumors (PERCIST) are significant associated with therapeutic response at 4 weeks after PD-1 blockade treatment. Even if morphological changes on CT scans are investigated to evaluate the response to PD-1 blockade at an early phase, it is difficult to distinguish between responders and non-responders. Thus, the uptake of 18F-FDG PET-CT appears to be a promising biomarker for sift patients who probably benefit form immunotherapy.

SST06-08 Relationship between the Expression of PD-L1 and F-FDG Uptake in Advanced Non-Small Cell Lung Cancer (NSCLC)

PURPOSE

Programmed cell death-ligand 1 (PD-L1) have been identified as novel targets of immunotherapy of lung cancer. To our knowledge, all published studies of the relationship between the 18F-FDG uptake of lung cancer and PD-L1 expression were performed in patients undergoing surgical resection. However, majority of reports have demonstrated the superiority of PD-L1 inhibitors as a therapy for patients with advanced lung cancer. The purpose of this study is to investigate the predictive value of 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) in evaluating PD-L1 expression in advanced non-small cell lung cancer (NSCLC).

METHOD AND MATERIALS

From January 2017 to December 2018, advanced NSCLCs were retrospectively identified in 154 consecutive patients who underwent 18F-FDG PET/CT scan and PD-L1 expression test. The histopathological results were confirmed by aspirated or biopsied samples. The maximum standardized uptake value (SUV(max) of 18F-FDG uptake were calculated for the primary lesion. Associations between quantitative continuous variables and PD-L1 expression were investigated by using the Mann-Whitney U test. This study was approved by the institutional review board of our hospital.

RESULTS

PD-L1 expression were identified in 77 patients (50%). PD-L1 expression of NSCLC occurred more frequently in larger lesions (p =
0.039), higher SUVmax value (p = 0.019), KRAS mutation-positive (p = 0.048). PD-L1 expression of adenocarcinoma (ADC) occurred more frequently in larger lesions (p = 0.022), higher SUVmax value (p = 0.043). The receiver operating characteristic (ROC) curve yielded area under the curve (AUC) values of 0.596 (95%CI, 0.506-0.686, p = 0.039) and 0.633 (95%CI, 0.509-0.756, p = 0.043) for NSCLC and ADC, respectively.

CONCLUSION
We demonstrated that higher 18F-FDG uptake may be helpful in predicting PD-L1 expression of advanced NSCLC, especially advanced ADC.

CLINICAL RELEVANCE/APPLICATION
For the first time, we demonstrated that PD-L1 expression were more frequent in advanced NSCLC with higher 18F-FDG uptake.

SST06-09  The Role of 18F-FDG SPECT/CT in Predicting Expression of PD-1/PD-L1 in Surgically Resected Non-Small Cell Lung Cancer (NSCLC)

Friday, Dec. 6 11:50AM - 12:00PM Room: E353B

Participants
Wang Huoqiang, MD, Shanghai, China (Abstract Co-Author) Nothing to Disclose
Zhao Long, MD, Shanghai, China (Presenter) Nothing to Disclose

For information about this presentation, contact:
whq2216@sina.cn

PURPOSE
Although 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) has been widely used, there are still many hospitals performing 18F-FDG single photon emission computed tomography/computed tomography (18F-FDG SPECT/CT) scan. In previous studies, 18F-FDG SPECT/CT was a reliable tool in evaluation of malignant tumours, which were concordant with 18F-FDG PET/CT. At present, some studies have demonstrated a correlation between PD-1/PD-L1 expression and SUVmax in NSCLC, but the relationship between PD-1/PD-L1 expression and T/NT value are not clear. The purpose of this study is to investigate the value of 18F-FDG SPECT/CT predicting expression of PD-1/PD-L1 in NSCLC.

METHOD AND MATERIALS
From July 2014 to May 2016, NSCLCs were retrospectively identified in 229 consecutive patients who underwent 18F-FDG SPECT/CT scan and PD-1/PD-L1 expression test. The histopathological results were confirmed by resected samples. Tumor-to-normal tissue (T/NT) uptake ratios of 18F-FDG were calculated for the primary lesion.

RESULTS
PD-1 and PD-L1 expression were identified in 120 patients (52.4%) and 81 patients (35.4%), respectively. PD-L1 expression occurred more frequently in males (p = 0.013), larger lesions (p < 0.001), higher T/NT value (p < 0.001), T3/4 stage (p = 0.002), III stage (p = 0.002). In multivariate analysis, T/NT was significantly associated with PD-L1 expression. PD-1 expression occurred more frequently only in patients with higher T/NT value (p = 0.028). The receiver operating characteristic (ROC) curve yielded area under the curve (AUC) values of 0.685 (95%CI, 0.615-0.756, p < 0.001) and 0.568 (95%CI, 0.512-0.659, p = 0.025) for PD-L1 and PD-1 expression, respectively.

CONCLUSION
We demonstrated that T/NT value of FDG uptake may be helpful in predicting PD-1/PD-L1 expression, which is consistent with results of 18F-FDG PET/CT. In some countries, 18F-FDG SPECT/CT scan is covered by medical insurance, while 18F-FDG PET/CT is not, which enhances the clinical value of 18F-FDG SPECT/CT scan for cost reasons.

CLINICAL RELEVANCE/APPLICATION
For the first time, we demonstrated that PD-1/PD-L1 expression were more frequent in NSCLC with higher T/NT value.

Printed on: 10/20/19
Neuroradiology (Vascular and Interventions)
Friday, Dec. 6 10:30AM - 12:00PM Room: E353A

PURPOSE
The Society for Vascular Surgery currently recommends carotid artery duplex ultrasonography (DUS) as the first-line imaging modality for the diagnosis of carotid artery stenosis, and this is in keeping with Appropriateness criteria of the American College of Radiology. We sought to investigate compliance with these guidelines on a national level for the initial work-up of suspected carotid artery stenosis in the outpatient setting.

METHOD AND MATERIALS
Using a national commercial claims database, we identified patients between 18-65 years old who had an outpatient visit with an associated initial diagnosis of carotid stenosis (ICD-9 433.10; ICD-10 165.2) from 2011-2016. Use of imaging was identified by Current Procedural Terminology (codes for DUS, CTA, and MRA associated with the initial outpatient visit. Trends were assessed using logistic regression analyses. Patients with any of the relevant ICD codes or CPT codes for one year prior to the encounter were excluded.

RESULTS
Overall, 229,464 patients with a new diagnosis of carotid artery stenosis were included in the analysis (mean age 55 years, 51.2% male). The majority (95.8%) of patients received DUS as the initial imaging modality, 2.4% received CTA, 1.3% received MRA, and 0.5% had more than one study associated with the encounter. The proportion of patients receiving DUS as the only initial imaging modality decreased from 97% in 2011 to 94% in 2016 (p<0.001). The rate of patients receiving CTA as the initial imaging modality increased from 1.6% in 2011 to 4.7% in 2016 (p<0.001). Use of MRA relatively stable (1.2%-1.5%) over the course of the study period. Use of initial advanced imaging (MRA/CTA) was highest in the West region of the USA (5.5%) and lowest in the Northeast (2.0%), p<0.001.

CONCLUSION
Our findings demonstrate that while the majority of initial imaging studies for suspected carotid artery stenosis are compliant with current recommendations from the Society of Vascular Surgery, the use of CTA is significantly increasing with time (p<0.001). Compared to DUS, CTA is associated with radiation exposure to the patient and a significantly higher imaging cost.

CLINICAL RELEVANCE/APPLICATION
Further education of the outpatient provider is needed to shift the current trend of initial CTA use for carotid stenosis; in particular in the setting of increasing availability of CT technology.
**PURPOSE**

This study aims to develop a natural language processing (NLP) model to retrospectively retrieve patients with presence, history and severity of carotid stenosis (CS) using their ultrasound reports.

**METHOD AND MATERIALS**

Ultrasound reports from our institution between January 2016 and December 2017. To process the texts, we developed a parser to divide the raw text into fields. For baseline method, we use bag of n-grams and term frequency inverse document frequency as the features and use linear classifiers. Logistic regression is performed as the baseline model. Convolution and recurrent neural networks (CNN; RNN) with attention mechanism are applied to the data set to improve the classification accuracy.

**RESULTS**

We had 1,220 ultrasound reports for training, and 307 for testing, totaling to 1,527 reports. For predicting history of CS, both CNN and RNN-Attention models have a significantly higher specificity than logistic regression. In addition, RNN-Attention also has a significantly higher F1 score and overall accuracy. For predicting presence, all models achieved above 93% accuracy. RNN-attention achieved a 95.4% overall accuracy, although the difference with logistic regression is not statistically significant with. RNN-Attention has a statistically significant higher specificity than logistic regression.

**CONCLUSION**

We have developed a parser to automatically segment the report text into different sections and predict history, presence and severity of CS. We have demonstrated NLP to be an efficient approach for large-scale retrospective patient identification, with wide applications in long-term follow-up of patients and further clinical research studies.

**CLINICAL RELEVANCE/APPLICATION**

NLP is shown to be an efficient approach for large-scale retrospective patient identification, with wide applications in long-term follow-up of patients and further clinical research studies.

SST07-03  **One-Step Dual-Source CT Angiography for Coronary, Carotid, and Cerebral Arteries at Low kV Using ECG-Triggered High-Pitch Spiral Mode with Low-Concentrated Contrast Media**

**Friday, Dec. 6 10:50AM - 11:00AM Room: E353A**

**Participants**

Aishi Liu, MD, Hohhot, China (Presenter) Nothing to Disclose
Lei Zhao, Hohhot, China (Abstract Co-Author) Nothing to Disclose
Yang Lin, Shanghai, China (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

To evaluate the image quality and radiation dose of high-pitch coronary, carotid and cerebral arteries CT angiography with low kV and low-concentrated contrast media on dual-source CT.

**METHOD AND MATERIALS**

A total of 78 consecutive patients were prospectively enrolled and divided into two groups randomly (group A, n=38; group B, n=40). All patients underwent high-pitch ECG-triggered CT angiography for coronary, carotid and cerebral arteries on a second-generation 128-slice dual-source CT (Somatom Definition Flash; Siemens Medical Solutions, Forchheim, Germany). Protocol for group A was: tube voltage, 70 kVp/80 kVp; 40 mL of low-concentrated contrast agent (270 mgI/mL). Protocol for group B was: tube voltage, 100 kVp; 60 mL of contrast medium (370 mgI/mL). A bolus tracking technique was used with a ROI put in the left atrium (group A) or aortic root (group B) for each patient, the scan was automatically triggered when the tracking ROI reached a threshold of 50 HU (group A) or 100 HU (group B) above baseline attenuation. A 40 mL of saline chaser was injected at a rate of 5.0 mL/s for both groups (Table 1). Image acquisition was prospectively triggered at 55% of the R-R interval in each patient. The image quality and radiation dose were evaluated and compared between the two groups.

**RESULTS**

Patients of group A and B showed no significant differences in age, sex, heart rates, and BMI (Table 2). The assessment of coronary artery image quality showed comparable results between the two groups on a per patient-based analysis (92.11% Vs 95.00%, P=0.602). In group A, image quality was found to be sufficient for diagnosis of 99.58% of arterial segments of carotid and cerebral arteries. The mean dose-length product (DLP) of group A (62.95±21.54 mGy*cm) was significantly lower in comparison with group B (160.15±15.13 mGy*cm; P<0.001). The average iodine intake was decreased by 51% in group A (10.8±4.0 mg) compared with group B (22.2±0.0 mg, P<0.001). Figure 1, 2 showed two cases of excellent image quality of coronary, carotid and cerebral arteries with high-pitch spiral CTA scan.

**CONCLUSION**

Low-kV CT angiography with low-concentrated contrast media using ECG-triggered high-pitch spiral scan provides an excellent image quality of coronary, carotid and cerebral arteries with low radiation dose.

**CLINICAL RELEVANCE/APPLICATION**

Dual-source CT is valuable for one-step evaluation of coronary, head and neck arteries with ECG-triggered high-pitch spiral scan.

PURPOSE
To evaluate the accuracy of ultrasonographic 3D-Arterial Analysis and CEUS in assessing severity and vulnerability of carotid plaques.

METHOD AND MATERIALS
134 patients were enrolled with the following criteria: (1) asymptomatic stenosis of carotid artery >70% but <100%; or (2) recent transient ischemic attack or ischemic stroke, and ipsilateral carotid stenosis >50%. All the patients underwent endarterectomy and gross and histology evaluation was performed to grade the plaque. 3D-Arterial Analysis provided a colour map to evaluate plaque vulnerability and a 3D volumetric stenosis evaluation. Its diagnostic performance has been compared to histological examination for plaque's vulnerability and to CEUS and CTA for stenosis' grading.

RESULTS
94 vulnerable plaques at histological examination were identified with at least one of the following criteria: fibrous cap < 200 μm, preexistent lipid core, intraplaque haemorrhage, leukocyte recruitment. CTA were able to detect 84, 82 and 82 of these 94 vulnerable plaques respectively, with 89%, 87% and 87% sensitivity and 100% specificity. CEUS has identified 84 severe stenosis of which 83 were correctly evaluated by 3D-Arterial Analysis software and CEUS, with a sensitivity of 88% and specificity of 100%.

CONCLUSION
3D-Arterial Analysis software and CEUS seem effective tools to assess plaque's vulnerability and stenosis severity, providing useful information for surgery planning. Multicenter prospective evaluation is warranted to clarify the role of US multiparametric evaluation.

CLINICAL RELEVANCE/APPLICATION
Pre-operative evaluation of carotid plaque is crucial for prompt follow-up or treatment. New Ultrasound diagnostic tool may open new further prospects. Multicenter prospective evaluation is warranted to clarify the role of US multiparametric evaluation.

SST07-05 Current Challenges and Accuracy of Carotid Plaque Neovascularization Grading with Contrast-Enhanced Ultrasound Method

Participants
Andrejs Lioznovs, Riga, Latvia (Presenter) Nothing to Disclose
Maija Radzina, MD,PhD, Riga, Latvia (Abstract Co-Author) Speaker, Canon Medical Systems Corporation

mradzina@gmail.com

PURPOSE
One of the stroke risk factors is unstable carotid atherosclerotic plaque with ulceration, soft plaque with surface irregularity as well as presence of neovascularisation. Contrast ultrasound (CEUS) is a new noninvasive method, that can detect vasa vasorum within plaque. The purpose of the study was to analyze CEUS technique ability to confirm plaque instability in correlation with CT angiography (CTA) and histological findings and to determine methods accuracy and limitations.

METHOD AND MATERIALS
Within period of 2 years a prospective study enrolled 54 patients with unstable plaque signs on ultrasound (US), all patients received baseline Duplex scanning, microvascular imaging (SMI) and contrast enhanced US with sulfur hexafluoride 1 ml followed by saline flush. CTA and histology results were used as reference standart. 32 patients underwent endarterectomy surgery. Based on CEUS results 2 groups were identified: poor (Grade 1) neovascularization and well visible (Grade2) vasa vasorum. For determination of CEUS sensitivity and specificity and limitations - two groups were compared - extensive calcified vs. soft plaques.

RESULTS
The neovascularization was diagnosed in 27 (50%) patients by CEUS - in 12 cases (44.4%) plaques showed neovascularization grade 1 and in 15 cases (55.6%) grade 2 plaques were detected. Comparing CEUS method and results of histology statistically significant correlation was found (rs = 0.624; p = 0.002). Comparing 2 groups: soft plaques neovascularization by CEUS was diagnosed in 13 cases (48.1%) with sensitivity - 77.78%, specificity 60%, positive predictive value 77.78%, negative predictive value 60%, accuracy 76.3%; In a group with extensive calcified plaques - neovascularization was detected in 14 patients (51.9%), methods sensitivity 53.33%, specificity 37.5%, positive predictive value 61.54%, negative predictive value 30%, accuracy 47.83% regardless stenosis grade.

CONCLUSION
CEUS is accurate method for confirmation of unstable plaque neovascularization regardless of stenosis grade well corresponding to histological results, but it cannot be recommended in cases of extensive calcinosi
**Clinical Relevance/Application**

CEUS is a new noninvasive method, that may facilitate early detection of unstable carotid plaque (neovascularization) and may change patient management regardless stenosis grade concept in high stroke risk. Prerequisite is informative, but inconclusive baseline Duplex US and/or CTA findings.

**SST07-06 Carotid Plaque Ulceration on Contrast-Enhanced Ultrasound: Diagnostic Accuracy Compared to Angiography**

Friday, Dec. 6 11:20AM - 11:30AM Room: E353A

Participants
Ji Eun Park, Seongnam, Korea, Republic Of (Presenter) Nothing to Disclose
Yeo Koon Kim, Seongnam-si, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose

**Purpose**
The plaque ulceration is one of the features of plaque vulnerability and related to the risk for embolic stroke. The purpose of this study was to define the diagnostic accuracy of contrast-enhanced ultrasound (CEUS) for the carotid plaque ulceration.

**Method and Materials**
This study is a retrospective case series study. Institutional review board approved the study and waived informed consent. Patients who had CEUS and carotid angiography for evaluation of carotid plaque from September 2015 to June 2018 in our institution were consecutively included in this study (184 patients, 142 males, 280 carotid arteries, age 72±8.5 years, age range 32-91 years). The time interval between angiography and CEUS was limited to within six months. Carotid arteries with prior intervention (endarterectomy and stent) were excluded. CEUS was performed in order of 1) Doppler ultrasound, 2) injection of ultrasound contrast agent (SonoVue, Bracco, Italy), and 3) CEUS. A radiologist who was blinded to clinical information reviewed the CEUS images for plaque ulceration and the degree of stenosis. A neuro-intervention radiologist reviewed the angiography images. The plaque ulceration was defined to plaque surface indentation deeper than 2mm on both CEUS and angiography. Sensitivity, specificity and diagnostic accuracy were calculated for the detection of plaque ulceration and the significant (>50%) stenosis.

**Results**
The prevalence of plaque ulceration was 25% on angiography. The sensitivity of CEUS for detection of plaque ulceration was 85.7% (95% confidence interval [CI]: 75.3% to 93.9%), specificity was 96.2% (95% CI: 92.6% to 98.3%), positive predictive value was 88.2% (95% CI: 79% to 93.7%), negative predictive value was 95.2% (95% CI: 91.9% to 97.2%), and the diagnostic accuracy was 93.6% (95% CI: 90% to 96.1%). The reason of false-negative cases was mainly calcification shadow on CEUS, and the false-positive cases were due to plaque surface irregularity.

**Conclusion**
CEUS can accurately visualize carotid plaque ulceration.

**Clinical Relevance/Application**
The CEUS showed excellent diagnostic accuracy for carotid plaque surface evaluation.

**SST07-07 Elevated Hemoglobin A1c is Associated with Intracranial Plaque Enhancement: Novel Findings from Magnetic Resonance Imaging Study in Stroke Patients**

Friday, Dec. 6 11:30AM - 11:40AM Room: E353A

Participants
Xiao Li, Shanghai, China (Presenter) Nothing to Disclose
Beibei Sun, Shanghai, China (Abstract Co-Author) Nothing to Disclose
Xiaosheng Liu, Shanghai, China (Abstract Co-Author) Nothing to Disclose

**Purpose**
Few study reported the association between Hemoglobin A1c (HbA1c) level and intracranial plaque vulnerability by magnetic resonance imaging (MRI). The present study of MRI-identified intracranial atherosclerotic lesions in patients with ischemic symptom therefore sought to determine the association between HbA1c level and intracranial plaque morphological and compositional characteristics and cerebral infarction severity.

**Method and Materials**
108 patients with intracranial ischemia were recruited. All patients were stratified into high (>6.5%) and low (<6.5%) HbA1c groups and underwent both intracranial vessel wall MRI and brain MRI scans. Intracranial plaque features and intracranial ischemic lesions were assessed.

**Results**
More intracranial plaques (2.38±1.50 vs. 0.96±0.75, P=0.001), higher incidence rate of intracranial symptomatic plaque enhancement (88.24% vs. 45.95%, P=0.001), more acute cerebral infarct (50.00% vs. 25.67%, P=0.013) and more recurrent infarct (67.65% vs. 45.95%, P=0.036) were in the high as compared to the low HbA1c group. High HbA1c was the independent risk factor for the presence of intracranial symptomatic plaque enhancement [odds ratio (OR)=7.05].

**Conclusion**
Our study suggested that an elevated HbA1c might have an adverse effect on intracranial plaque enhancement, which might induce acute cerebral infarct.

**Clinical Relevance/Application**
Our findings indicate that determination of HbA1c levels and characterization of intracranial atherosclerotic plaque by MR vessel wall imaging might be useful to better select proper treatment options of stroke subjects.
Readmission after Treatment of Symptomatic Carotid Stenosis: A Nationwide Readmission Database Analysis

Friday, Dec. 6 11:50AM - 12:00PM Room: E353A

PURPOSE

Carotid endarterectomy (CEA) and stenting (CAS) are two well-described methods for treating symptomatic carotid artery stenosis. However, literature on readmission after CEA and CAS is limited. We therefore utilized the Nationwide Readmission Database (NRD) to characterize the rate and causes of 30 and 90-day unplanned readmissions after CEA and CAS for symptomatic stenosis.

METHOD AND MATERIALS

Data was extracted from the NRD spanning 2010 to 2015. The population consisted of adult patients who underwent CEA or CAS with a primary diagnosis of occlusion and/or stenosis of carotid artery with cerebral infarction or TIA. Non-elective readmission rates within 30 and 90 days for CEA vs CAS were compared. To calculate 30 and 90-day readmission rates, we included patients within the first 11 and 9 months of each year respectively. Poisson regression was performed using generalized estimating equations and adjusted risk ratio (aRRs) were obtained for factors associated with 30 and 90-day readmission. The adjusted model included terms for patient- and hospital-specific factors, comorbidity scores and disease severity.
RESULTS

Of 54,704 patients treated and discharged alive, 8.0% patients were readmitted within 30 days, and 13.6% patients were readmitted within 90 days. The 30 and 90-day non-elective readmission rate for CEA vs CAS was 7.7% vs 9.1% (p<0.0001) and 12.8% vs 17.0% (p=0.0001), respectively (figure). Patients undergoing CAS had a higher adjusted risk of non-elective 30 and 90-day readmission than patients having CEA (aRR=1.16; 95%CI, 1.09-1.23; p<0.001 and aRR=1.04; 95%CI, 1.01-1.05; p=0.024, respectively). The most common primary diagnoses for non-elective readmission within 30 and 90 days, respectively, were cerebral artery occlusion with infarct, septicemia, TIA, myocardial infarction, pneumonia, carotid artery stenosis/occlusion without infarction, and acute kidney failure.

CONCLUSION

Common reasons for 30 and 90-day non-elective readmission after CEA or CAS for symptomatic stenosis were cerebral artery occlusion with infarct, septicemia and TIA. Adjusted risk and rates of non-elective readmission after 30 and 90 days were higher after CAS than CEA.

CLINICAL RELEVANCE/APPLICATION

Patients undergoing CAS had higher risk of readmission than those undergoing CEA at 30 and 90-day post-procedure.

SPECIAL NOTE

This paper has received the Kuo York Chynn Neuroradiology Research Award. This award is funded in perpetuity by the Chynn Family Foundation. Through the Chynn Family Foundation, Emil William Chynn, MD, FACS, MBA will guide future distributions to support research in radiology.

PURPOSE

Fracture dating (acute vs healing) of various pediatric long bone fracture subtypes is routinely performed by human radiologists by identifying presence of periosteal reaction or callus. We evaluate if fracture acuity or evidence of healing can be accurately categorized in a heterogeneous group of pediatric long bone fractures using a properly designed and trained Convolutional Neural Network (CNN).

METHOD AND MATERIALS

Our IRB approved this retrospective study. Radiographs collected in a large pediatric hospital during 2018 were selected using a search of radiology reports containing keywords: humerus, tibia, fibula, radius, or femur. The radiographs were reviewed and manually labeled by a box overlaying the fracture location to facilitate CNN training. These fractures included Salter-Harris, oblique, transverse, and buckle fractures with or without varying degrees of displacement and angulation. These individual fractures were subclassified as healing or acute by two faculty pediatric radiologists and two radiology physician assistants with reference to the final signed radiology report. Healing was defined as any radiologically visible callus or early periosteal reaction. The resulting 3801 radiographs consisted of 1910 acute and 1891 healing fractures (mean age 7.2 years, male 55.6%). They were patched into 512x512 pixels subdomains, thus building training, validation and test sets with 3001/400/400 patches respectively, and an almost perfect 50/50 class balance in each set. Transfer learning CNN was utilized with an additional four fully connected top layers of the network. A 10-fold cross-validation approach was used by shifting each set (training/validation/test) sequentially. Trained networks classified single views from each study till all available views were classified, and a decision calculated based on the algebraic mean of results from all views.

RESULTS

The 3 best CNN’s exhibit stable high accuracy of 92.02%, AUC-ROC of 0.96, with the best performing CNN achieving 94.35% accuracy and 0.97 AUC-ROC. The CNNs performance are summarized in table 1, confirming stable results.

CONCLUSION

CNN based pediatric long bone fracture acuity classification using a multi-view approach is highly accurate. The 10-fold cross-validation approach limits possible bias due to relatively low size of the dataset.

CLINICAL RELEVANCE/APPLICATION

This is the first study showing CNNs are capable of fracture subtype categorization.
The purpose of this study was to assess the feasibility and diagnostic performance of using a dual-input convolutional neural network (CNN)-based deep learning algorithm which utilizes both anteroposterior (AP) and lateral elbow radiographs for automated detection of pediatric supracondylar fracture on conventional radiography.

METHOD AND MATERIALS

For the development of deep learning model, 1,266 pairs of AP and lateral elbow radiographs examined between January 2013 and December 2017 at a single institution were split into a training set (1,012 pairs, 79.9%) and a validation set (254 pairs, 20.1%). We used 258 pairs of radiographs examined in 2018 at the same institution as a temporal test set and 95 examined between January 2016 and December 2018 at another hospital as a geographic test set. Images underwent preprocessing including cropping and histogram equalization and were passed into a dual-input neural network constructed by merging two ResNet models. Observer study by radiologists was performed on the geographic test set. The area under the receiver operating characteristic curve (AUC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the model and human readers were calculated.

RESULTS

Our trained model showed an AUC of 0.976 (95% CI, 0.949-0.991) in the validation set, 0.985 (95% CI, 0.962-0.996) in the temporal test set, and 0.992 (95% CI, 0.947-1.000) in the geographic test set; The AUCs of human readers in the geographic test set showed a range of 0.977 to 0.997. Using the optimal operating point derived from the validation set, the model showed a sensitivity of 93.9%, a specificity of 92.2%, a PPV of 80.5%, and a NPV of 97.8% in the temporal test set and a sensitivity of 100%, a specificity of 86.1%, a PPV of 69.7%, and a NPV of 100% in the geographical test set.

CONCLUSION

A dual-input deep learning model which interprets both AP and lateral elbow radiographs provided an accurate diagnosis of pediatric supracondylar fracture comparable to radiologists. Our study suggests a potential role of deep learning as triage in the management of pediatric elbow trauma, as our model showed high sensitivity and high negative predictive value in automated detection of a supracondylar fracture on elbow radiography.

CLINICAL RELEVANCE/APPLICATION

This is the first study showing CNNs are capable of fracture subtype categorization.
RESULTS
X-ray imaging scans of 103 subjects (48 male/55 females, mean age 12.99, SD 2.84) were identified in this study. We randomly selected 70 subjects as training data and 33 images as testing data. After the data augmentation by shape based image registration, the training data had 19600 samples. Results demonstrated that the cascaded coarse-fine deep learning method performed accurate segmentation on pediatric legs. On the testing data, the segmentation accuracy was 0.90, the correlation value between truth measurement from radiology reports and calculated measurements was 0.9772 (p<0.001), and the mean squared error was 1.4 mm. The automated measurements took less 1 second for each subject.

CONCLUSION
The deep learning algorithm can quickly perform the task of measuring leg lengths as accurately as subspecialty trained pediatric radiologists.

CLINICAL RELEVANCE/APPLICATION
The rapid and automated measurement of leg length as accurately as subspecialty trained pediatric radiologists will help make more efficient use of the radiologist's time and expertise. The automation of the labor intensive and cognitively undemanding task of measurement can enable radiologists to focus on seeking subtle additional findings such as bone tumors or metabolic disease.

SST08-05  Rethinking Greulich & Pyle: Deep Learning Models for Pediatric Bone Age Assessment
Friday, Dec. 6 11:10AM - 11:20AM Room: E261

Participants

ianpan358@gmail.com

PURPOSE
The Greulich & Pyle (G&P) atlas is the most common standard by which bone age assessment (BAA) is performed. This study compares G&P-based BAA (GP-BAA) with deep learning-based BAA (DL-BAA).

METHOD AND MATERIALS
DL-BAA uses a 3-model MobileNetV2 convolutional neural network (CNN) ensemble trained on 13,769 pediatric trauma hand radiographs (male: 6,889, female: 6,880, age range: 0-18 years, mean age: 11.1 years) from a large academic medical center using the patient's chronological age as ground truth. Separate models were trained for male and female patients. The test set comprised 214 pediatric trauma hand radiographs (male: 100, female: 114, age range: 1-18 years, mean age: 11.7 years) from a geographically distinct large academic children's hospital with chronological age as ground truth. Using mean absolute error (MAE), we compared performance of DL-BAA on the test set with that of 3 GP-BAA ratings, including two board-certified pediatric radiologists who each used G&P, and a CNN ensemble trained on G&P-labeled pediatric hand radiographs from the RSNA Pediatric Bone Age Machine Learning Challenge (RSNA-AI). The RSNA-AI had achieved a MAE of 4.35 months in the challenge. Statistical analysis was performed using the bootstrap method.

RESULTS
The MAE between radiologists 1 and 2 for the test set was 6.3 months; the MAEs between RSNA-AI and radiologists 1 and 2 were 8.6 months and 10.1 months, respectively. The MAEs in months of DL-BAA, radiologist 1, radiologist 2, and RSNA-AI were 11.8, 14.6, 14.2, respectively. For female (male) patients, the MAEs of DL-BAA and GP-BAA were 11.6 (12.0) months and 14.6-16.8 (13.5-15.0) months, respectively. All MAE differences between DL-BAA and GP-BAA were statistically significant with p < 1e-6. On average, all ratings overestimated chronological age by 5.2 to 8.3 months. DL-BAA and GP-BAA estimated bone ages within 12, 18, and 24 months of chronological age for 68% vs. 61-68%, 85% vs. 65-78%, and 94% vs. 85-87% of test cases.

CONCLUSION
DL-BAA performed with lower mean absolute error for a normal pediatric population than either pediatric radiologist or automated GP-BAA. Future work will validate this method on other patient populations with more test data.

CLINICAL RELEVANCE/APPLICATION
DL-BAA should be an integral part of the future of BAA, as it can achieve equal-to-superior performance versus conventional methods and easily be adapted to different patient populations.

SST08-06  Prediction of Neurodevelopmental Outcome in Preterm Neonates with Cerebral MR Spectroscopy and DTI Using Feed-Forward Neural Networks
Friday, Dec. 6 11:20AM - 11:30AM Room: E261

Participants
Tanja Janjic, Innsbruck, Austria (Presenter) Nothing to Disclose
Sergiy Pereverzyev Jr, Innsbruck, Austria (Abstract Co-Author) Nothing to Disclose

Vera Wallner, Innsbruck, Austria (Abstract Co-Author) Nothing to Disclose
Ruth Steiger, Innsbruck, Austria (Abstract Co-Author) Nothing to Disclose
Martina Zimmermann, Innsbruck, Austria (Abstract Co-Author) Nothing to Disclose
PURPOSE
We aimed to evaluate if proton magnetic resonance spectroscopy (1H-MRS) and diffusion tensor images (DTI) performed in very preterm neonates (PNs) at term equivalent age (TEA) can predict their neurodevelopmental outcome (NDO) at the corrected age of 12 months using feed-forward neural-networks (fNNs).

METHOD AND MATERIALS
From 346 PNs born before 32 gestational weeks, 246 were excluded due to missing or poor-quality spectroscopy data and/or missing neurodevelopmental tests at 12 months corrected age. The data sets of 100 PNs were considered for motoric and cognitive development, of whom 8 and 5, respectively were categorized as underdeveloped. We evaluated five potentially relevant metabolite ratios and two DTI characteristics, each in six different areas of the brain. We performed a feature selection algorithm for receiving a subset of those characteristics that we could assume as significant. To reduce bias by unbalanced classes, only PNs that share approximate values of those characteristics with ones that had shown underdevelopment were considered for further calculations. On those smaller sets of PNs, we finally constructed predictors using fNNs, which were able to predict underdevelopment in PNs after considering the characteristics selected previously.

RESULTS
The constructed predictors give a 100% accuracy in the case of the motoric underdevelopment. In the case of cognitive underdevelopment, we obtain a true positive rate of 100% and a positive predictive value of 83.3%.

CONCLUSION
1H-MRS and DTI obtained at TEA in PNs allow prediction of their motoric and cognitive development at the corrected age of 12 months. The proposed approach using fNNs promises its use in clinical practice and could be useful for spotting those PNs, who would mostly benefit from early intervention services.

CLINICAL RELEVANCE/APPLICATION
1H-MRS and DTI obtained at term equivalent age in very preterm neonates allow prediction of their motoric and cognitive development at the corrected age of 12 months, and the proposed approach using fNNs could be useful for spotting those preterm neonates, who would mostly benefit from early intervention services.
CLINICAL RELEVANCE/APPLICATION

Radiomics is an approach which can provide a great deal of quantitative features reflecting intratumoral heterogeneity. Combined with clinical and conventional MR imaging features, radiomics could increase predictive accuracy for children with medulloblastoma.

SST08-08 MRI Based Radiomics Predicts Response to Natural Killer (NK) Cell Infusion Immunotherapy in Pediatric Recurrent/Refractory Posterior Fossa Brain Tumors

PURPOSE
To determine the ability of radiomics to predict response in pediatric patients with recurrent/refractory medulloblastoma (MB) and ependymoma (EP) who received locoregional infusions of NK cell infusions as an immunotherapeutic strategy.

METHOD AND MATERIALS
We developed an MRI based radiomic signature for 5 patients with refractory/recurrent MB (N=2) or Ep (N=3) who received the first-in-human, loco-regional infusion of autologous ex-vivo expanded NK cell. The patients were enrolled on a Phase-1 trial and received 3 cycles of intraventricular NK cell infusions. (N=5, males=3, females=2; mean age 11.1 years). Patients were categorized based on response assessment in neuro-oncology (RANO) into progressive disease (PD, n=3) and stable disease (SD, n=2). Using the pre-infusion MRI scans and 3D slicer software, an experienced radiologist segmented manually 3 radiophenotypes in the axial plane: enhancement, edema/invasion, and necrosis. The extracted volumes of interest were submitted into our in-house radiomic pipeline. A total of 3,660 radiomic features per scan were extracted. Feature selection was performed using minimum redundancy and maximum relevance (mRMR), and binomial logistic regression for model building, and leave-one-out cross-validation for model's performance assessment. The unsupervised hierarchical clustering was used to categorize the patients into PD and SD based on their response.

RESULTS
The least redundant and maximum relevant 2 features obtained from the edema/invasion region were used to build the radiomic signature which showed high discriminatory performance in predicting response to NK cell therapy. Using receiver operating characteristic curve (ROC), area under the curve, sensitivity, and specificity of 100% were attained; Using the previous 2 mRMR features, unsupervised hierarchical clustering successfully classified the patients into PD (n=3) and SD (n=2)

CONCLUSION
To our knowledge, this is the first study developing a radiomic signature able to predict response in NK cell infusion immunotherapy. A larger prospective study is necessary; this might enhance the patient’s stratification for NK cell infusion candidacy.

CLINICAL RELEVANCE/APPLICATION
Radiomics is an emerging tool which might be able to predict treatment response using baseline/pre-NK infusion MRI scans in children with recurrent (MB) and (EP), warranting larger prospective studies.

SST08-09 CT-Based Radiomic Analysis Predicts Prognosis in Pediatric Malignant Peripheral Neuroblastic Tumors: A Single Center Retrospective Study

PURPOSE
The aim of this study was to develop and validate a preoperative radiomics analysis system based on CT images to predict outcome in pediatric malignant PNTs.

METHOD AND MATERIALS
A total of 405 patients (training cohort: n =280; validation cohort: n =121) pathologically diagnosed as malignant PNTs including neuroblastoma (NB) and ganglioneuroblastoma (GBN) were retrospectively studied between January 2010 and June 2018. Every patient underwent post-contrast enhanced CT examination before any treatment. Patients were divided into low-, intermediate-, and high-risk groups according to clinical prognostic factors. All radiomics features were extracted from manually segmented tumors...
in artery phase of CT images in all cases, and they were derived from first-order histogram, tumor shape, gray-level co-occurrence matrix (GLCM), gray-level run length matrix (GLRLM), gray-level size zone matrix (GLSZM), neighboring gray-tone difference matrix (NGTDM), gray-level dependence matrix (GLDM). Spearman's rank order correlation with 0.9 threshold and least absolute shrinkage and selection operator (LASSO) were used for redundancy elimination and feature selection, respectively. To build a classifier for stratifying three groups of risk, two logistics regression models were applied in a cascade way. The first model (model1) was used for classifying high-risk group and the rest, while the rest were classified into intermediate- and low-risk groups by the second model (model2). The performance of the predictive models was evaluated with the respect to the receiver operating characteristics (ROC) curve. Above works were completed by IFoundry (Intelligence Foundry 1.1, GE Healthcare).

RESULTS

18 and 32 features were obtained after the process of redundancy elimination and feature selection for model1 and model2 respectively. The models demonstrated good discrimination in both training cohort and validation cohort, with AUC of 0.826 for model1 and that of 0.811 for model2.

CONCLUSION

Radiomics analysis based on preoperative CT images has the potential to predict clinical prognosis and aid to stratify individualized treatments of pediatric malignant PNTs. Future studies are needed to validate these findings.

CLINICAL RELEVANCE/APPLICATION

Radiomics approach may be used to aid intratumoral heterogeneity detection and outcome prediction in malignant PNTs children.

Printed on: 10/20/19
CONCLUSION

Our proposed deep learning model yields better metal artifact reduction performance than other state-of-the-art methods and can be applied in the real world.

Background

Metallic implants cause severe streak and beam hardening artifacts in CT scans. Traditional methods, like linear interpolation (LI) and NMAR, inpaint affected sinogram to reduce artifact, but induce secondary artifacts or suffer from false tissue segmentation. Recently, deep learning based method, cGan-CT, tries to reduce artifacts in image domain but the effect is limited. Here, we propose a Dual-Domain Network (DuDoNet) and demonstrate its application to clinical data.

Evaluation

DuDoNet consists of a sinogram enhancement network (SE-Net), a differentiable Radon inversion layer (RIL) and an image enhancement network (IE-Net). The SE-Net learns to restore sinogram data via a mask pyramid U-Net. RIL reconstructs images from sinograms and allows joint learning of the two networks. The IE-Net further refines the images by a U-Net with residual learning. The learning of DuDoNet, which takes metal affected sinograms and corresponding metal traces as inputs, is supervised with clean sinograms and images. We synthesize 360,000 training and 2,000 validation samples based on DeepLesion. In synthesized data, DuDoNet restores the most details among all methods, with a PSNR of 32.29dB and a SSIM of 0.959. Our model successfully reduces the streak and shadowing artifacts and alleviates drawbacks of single domain methods. Then, DuDoNet trained on simulated data is applied to a total of 100 clinical images from DeepLesion and SpineWeb. Visual comparison shows that DuDoNet effectively suppresses the secondary artifacts and avoids false structural segmentation problem in prior based methods. Blinded qualitative evaluation by radiologists shows DuDoNet achieves the best performance (rank: 3.13) and significantly outperforms LI, NMAR, cGan-CT (p<0.028).

Discussion

In DuDoNet, SE-Net first recovers inconsistent sinograms and IE-Net further reduces secondary artifacts. Our model effectively reduces metal artifacts in both simulated and clinical scans and achieves better image quality than other single domain approaches.
Moving, high-density objects in the heart, including catheters and pacemaker leads, cause substantial artifacts in cone beam CT (CBCT) images. The purpose of this study was to exploit a deep learning method to efficiently segment and remove these objects from projection rotational angiography (RA) images, thereby reducing artifacts in cardiovascular CBCT images.

METHOD AND MATERIALS

Segmentation of the high-density objects from the RA images was performed using a deep convolutional neural network with an encoder-decoder architecture based on the VGG-16 network. Synthetic training (3,000) and validation (2,000) images were created by adding augmented RA images of a pigtail catheter to RA images of an anthropomorphic phantom acquired with a clinical angiography system. The model trained with the synthetic images was then used as a starting point to learn to label pacemaker leads and different types of catheters in two real patient data sets. The new image set consisted of 450 and 50 RA images in total for training and validation, respectively. Data was augmented by reflection, translation, size scaling, rotation, and noise addition in both image sets. To remove high-density object artifacts, the segmented image pixels were inpainted by solving the Dirichlet boundary value problem. Correlated Poisson noise was then added to the inpainted pixels to match image texture. The original and modified RA images were reconstructed using filtered back-projection to create CBCT images.

RESULTS

Training for the synthetic and patient images took 25 and 2 hours, respectively. A Sørensen-Dice coefficient of 80.8% and 75.6% was obtained for each set, respectively. These values are partly explained by the model output which extended modestly beyond the edges of the ground truth representation of the objects. Visual inspection of the resultant patient CBCT images demonstrated that artifacts associated with moving catheters and pacemaker leads were nearly completely resolved without introduction of other image defects.

CONCLUSION

A deep learning method to segment catheters and pacemaker leads in projection RA images of the heart was implemented and used to mitigate associated artifacts in CBCT images of the heart.

CLINICAL RELEVANCE/APPLICATION

This work demonstrates a deep learning segmentation method to mitigate the artifacts caused by moving high-density objects in the heart, thereby providing substantially improved CBCT images.
higher energy levels and highest CNR and SNR was found at lower energy levels. Furthermore, subjective review indicated that MAR reconstructions provided higher quality images. Finally, GSI MAR was found to improve iodine concentration estimation.

CLINICAL RELEVANCE/APPLICATION
Dental artifact remains a significant challenge on neck computed tomography. This study evaluates the effectiveness of a novel metal artifact reduction algorithm.

SST09-04  CT Image Quality for Five Different Metal Artifact Reduction Algorithms

PURPOSE
To evaluate the effectiveness of five CT Metal Artifact Reduction (MAR) Algorithms from four vendors in improving the image quality using a novel phantom for Metal Artifact Analysis.

METHOD AND MATERIALS
A Catphan 605 phantom with extension ring was scanned with different inserts (Hard Steel, Titanium, and Water) on 5 CT scanners reconstructed with and without MAR algorithms. The MAR algorithms used; GSI MAR (GE Revolution CT), Smart MAR (GE Revolution Frontier), O-MAR (Philips Ingenuity CT), iMAR (Siemens Somatom Drive) and SEMAR (Toshiba Aquilion One Genesis). Phantom was scanned at 120 kVp and at 120 kVp equivalent for GSI MAR and iMAR. Image quality was assessed by obtaining Contrast to Noise Ratio (CNR), Metal Artifact Analysis and Noise Power Spectrum (NPS). The parameters were obtained from ImageOwl Catphan QA software and Matlab.

RESULTS
For Titanium, Smart MAR, IMAR and SEMAR images had more noise than the images without MAR algorithms, while GSI MAR and O-MAR images had less noise than the images without MAR. MAR images had a lower CNR than the corresponding images without MAR, except GSI MAR images which had higher CNR than the images without MAR. For water, there was no difference in CNR for images with and without MAR, except iMAR and SEMAR. Metal Artifact Analysis showed artifact reduction around the insert and at a distance from the insert for all MAR algorithms in like manner. For titanium, GSI MAR showed the largest artifact reduction (87%, 73% respectively) followed by Smart MAR, SEMAR, O-MAR and IMAR. For hard steel, Smart MAR showed the largest artifact reduction (92%, 82%) followed by GSI MAR, SEMAR, IMAR, and O-MAR. There was no difference in NPS with and without MAR.

CONCLUSION
GSI MAR showed the most consistent performance under different conditions. Different MAR algorithms compensate differently for metal artifacts under different conditions. Thus, it is important to know the effects of the algorithms on image quality. Images obtained with MAR algorithms should be compared with those without MAR algorithms.

CLINICAL RELEVANCE/APPLICATION
Different MAR algorithms compensate for metal artifacts differently under different conditions. Thus, it is important to know the effects of the algorithms on image quality.

SST09-05  Image Quality Assessment of Metal Artefact Reduction in CT Using a Novel Abdominal Phantom

PURPOSE
To evaluate a novel anthropomorphic abdominal phantom specially designed for qualitative and quantitative metal artefact assessment in CT for two different metal artefact reduction technologies.

METHOD AND MATERIALS
An anthropomorphic abdominal phantom with different inserts (bone with metal, low contrast, spatial resolution and homogeneity) was used in this study. Titanium, Hard and stainless steel inserts were placed in the center of the bone insert. All scans were performed on a GE Revolution CT at 15 and 20 mGy CTDIvol, 40 mm collimation, 120 kVp (+/- HiRes) and spectral imaging (GSI). Images were reconstructed with standard kernel, 2.5 mm slices, ASIR-V 50% and +/− MAR. Four observers evaluated lesion conspicuity and scored artefacts on a 4-point scale for all reconstructions. HU uniformity, coefficient of variation, reduction in noise streaks (range and standard deviations (SD)), noise power spectrum (NPS) and modulation transfer function (MTF) were evaluated for all reconstructions.

RESULTS
Preliminary quantitative and qualitative results showed that both single energy MAR (SMAR) and GSI MAR (GSIMAR) reduced streaks artefacts surrounding (2123-7019 vs 1267-5993 HU) and at a distance (196-251 vs 78-83 HU). Lesion conspicuity was not affected by MAR. HU uniformity and SD around the metals (223.08-438.76 vs 105.02-260.75 HU) and the bone insert (SD: 71.48 - 143.17 vs 39.59 - 69.97 HU) were improved by the use of both SMAR and GSIMAR. These improvements were independent of dose. The use of only HiRes without MAR did not reduce streaks artefact, noise or HU uniformity. MAR hardly affected the MTF@50%. NPS profile
was not affected by MAR.

**CONCLUSION**

Both SMAR and GSIMAR reduced metal artefact and improved image quality. Anthropomorphic phantom designed for qualitative and quantitative image quality analysis evaluation of metal artefact reduction should be used to assess image quality and lesion detection when MAR is introduced in daily routine to ensure that pathology is not missing after MAR has been applied.

**CLINICAL RELEVANCE/APPLICATION**

New anthropomorphic phantom specially designed for quantitative and qualitative assessment of metal artefact reduction in CT is important to ensure that pathology is not missing when MAR is applied.

**SST09-06 Reduction of Cone-Beam Artifacts in Axial CT Systems with Large Detector Coverage**

Friday, Dec. 6 11:20AM - 11:30AM Room: E351

Participants
Stanislav Zabic, PhD, Lyndhurst, OH (Presenter) Employee, UIH America, Inc
Hao Zhao, Shanghai, China (Abstract Co-Author) Employee, Shanghai United Imaging Healthcare Co, Ltd
Rengcai Yang, Shanghai, China (Abstract Co-Author) Employee, Shanghai United Imaging Healthcare Co, Ltd

**PURPOSE**

We report cone-beam artifact reduction on axial scans with a 16cm coverage CT system using a recursive application of 3D filtered backprojection (FBP).

**METHOD AND MATERIALS**

Axial CT for voxels outside the acquisition plane does not satisfy a fundamental completeness condition, which leads to cone-beam artifacts. This is particularly evident in systems with large detectors. Previously published re-projection based recursive application of FBP was used to improve image quality in large pitch helical scans. We revisit this approach, apply it to the axial 3D FBP reconstruction and explain the effectiveness of the algorithm using a new argument based on the minimization of Bregman distances. The theoretical result is tested with analytic simulations and clinical data sets, reused from the previous clinical trials.

**RESULTS**

Recursive FBP algorithm reduced the low frequency artifacts in simulations effectively, returning images which are approaching the analytic ground-truth with every repeated recursive step. In clinical data, cone beam artifacts were considerably reduced with a more pragmatic combination of image processing and one recursive FBP application.

**CONCLUSION**

Bregman distance minimization algorithm leads to a previously known recursive 3D FBP algorithm, which proves to be effective for axial scans on systems with large detector coverage, offering a strong, new theoretical foundation for this algorithm. A pragmatic combination of recursive FBP with image processing returns high quality results from single-shot axial scans with improved bone clarity and more accurate CT numbers in the soft tissue.

**CLINICAL RELEVANCE/APPLICATION**

Cardiac scans can be performed within a single heartbeat using an axial CT with 0.25s rotation time and 16cm detector coverage. Tilted single shot axial head scanning ensures an efficient protection against excessive x-ray dose delivered to the eye lenses. Efficient reduction of cone-beam artifacts for both of these protocols is necessary.

**SST09-07 Reduction of Artifact Caused by Embolization Coil Implant in Spectral CT Examination by Means of Virtual Monochromatic Imaging (VMI) and Monochromatic Imaging Combined with Metal Artifact Reduction Software (MARs)**

Friday, Dec. 6 11:30AM - 11:40AM Room: E351

Participants
Zhipeng Yao, Beijing, China (Presenter) Nothing to Disclose
Yahui Peng, PhD, Chicago, IL (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

To evaluate the reduction of artifact from embolization coil implant using VMI and VMI combined with MARs in spectral CT.

**METHOD AND MATERIALS**

Embolization coil implant was placed in an intermediate tube of the Quantitative Standard Pulsating Phantom (QSP) that contained an Iodine solution of 7 mgI/ml (CT value = 160HU at 120 kVp, representing the portal vein attenuation in the portal vein phase). Subsequently, 20 ml of sodium chloride solution was contained in eight tubes and inserted into the QSP. Two spectral CT scan protocols were used for image acquisition: conventional CT scan with tube voltage of 120 kVp (Group A); Spectral Imaging scan (Group B). A conventional image (CI) and virtual monochromatic images (70 - 140 keV, of 10 keV interval) with and without MARs were reconstructed, respectively. In each of the images, a measurement region of interest (ROI) was placed around the tube, including all pixels contaminated by the metal artifact but excluding the pixels inside the tube (ROItube). Besides, a background ROI was placed above the tube not influenced by the artifact, from where mean CT number (NCT) and standard deviation (SD) were measured. ΔCT was defined as the absolute value of NCT in hyperdense or hypodense artifact minus NCT in background ROI.

**RESULTS**

VMIMARs showed a significant decrease of hyperdense artifact (p<0.05) and hypodense artifact (p<0.05) in term of lower ΔCT as compared to 120kVp imaging. With increasing of KeV, ΔCT and SD of artifact were decreasing in VMIMARs. In addition, noise image in VMIMARs exhibited a decreasing trend with increasing KeV level. Whereas VMI only showed a significant decrease of hyperdense artifact (p<0.05). VMIMARs at 70 keV - 140keV could show a better effect on the reduction of metal artifact as compared VMI at 140keV (p<0.05).
CONCLUSION

Compared with conventional CT scanning, VMIMARs by using spectral CT could significantly reduce metal artifacts caused by embolization coil implants and provide better image noise.

CLINICAL RELEVANCE/APPLICATION

When using spectral CT for patients underwent Gastric coronary vein embolization(GCVE) procedure, VMIMARs could significantly reduce metal artifacts caused by embolization coil implants in portal vein phase.

SST09-08 Ability of a Single Adaptive Iterative Metal Artifact Reduction Algorithm to Improve CT Image Quality in Patients with Multiple Metal Implants

PURPOSE

To compare performance of a single, adaptive iterative metal artifact reduction (AiMAR) algorithm applied to an entire patient’s CT exam to 7 anatomically specific iMAR presets, in patients with multiple metal implants.

METHOD AND MATERIALS

In 30 patients with 72 types of implants, CT images were reconstructed with different strength settings of a single AiMAR algorithm and 2 – 3 iMAR presets (selected for body part/implant). The AiMAR algorithm enables real-time image-based measurements to adapt the degree and level of artifact reduction. In separate sessions, 2 trained radiologists evaluated artifacts (0 - 5), visualization of critical anatomic structures (1 - 5) and diagnostic confidence (1 - 5) in the region of each implant, also assigning an overall ‘whole body’ image quality score (1 - 5), considering all evaluated regions, with lower values for all scales being better. The optimal AiMAR strength was determined by comparing whole body image quality scores with individual iMAR presets in each body region. Significance was tested by Wilcoxon Signed rank test for paired samples.

RESULTS

Optimized results using AiMAR were achieved using strength settings 4 and 5 for head&neck, thoracic and extremity areas (dental, neuro, cervical spine, shoulder, thoracic spine, cardiac, arms/elbow, legs/knee). For abdomen/pelvis (hip, lumbar spine), preferred AiMAR strengths varied between 2 - 5, with the lower strengths providing higher diagnostic confidence and the higher strengths providing better artifact reduction. AiMAR strength 5 setting was preferred over lower strengths (p<0.05) when evaluating whole body image quality scores. For every body region, AiMAR strength 4 and 5 settings demonstrated widely overlapping (p>0.05) diagnostic confidence, visualization and artifact performance with the dedicated anatomically specific iMAR presets (figure).

CONCLUSION

In patients with multiple metal implants, a strength based adaptive implementation of artifact reduction (AiMAR) permits a single reconstruction of the entire body that provides a diagnostic quality anatomic evaluation and metal artifact reduction of similar quality compared to multiple reconstructions using separate body part specific iMAR presets.

CLINICAL RELEVANCE/APPLICATION

AiMAR can dramatically improve clinical workflow by minimizing the need for body-part specific iMAR reconstructions without compromising image quality, diagnostic confidence or artifact reduction.

SST09-09 Reproducibility and Validity of Approaches for Artifact Quantification in CT Imaging

PURPOSE

To objectify metal artifact reduction, numerous methods and approaches have been suggested. We aimed to compare results of such methods to visual perception of artifacts in order to establish a standard for artifact quantification in CT imaging.
METHOD AND MATERIALS
Two titanium rods (5 and 10mm) were examined with 25 different scanning and image reconstruction parameters to obtain a reference database of different types and extents of artifacts. 4 radiologists separately evaluated every image against each other (2-pair forced choice) using an in-house developed software. Rating was repeated two times (2400 comparisons = 2 times x 4 readers x 300 comparisons). Rankings were combined to obtain a reference ranking reaching from best to worst image. Proposed approaches for artifact quantification have been identified in literature, including manual measurement of artifact attenuation, standard deviation and noise as well as sophisticated algorithm-based approaches within the image- and frequency-domain (ImgD and FreqD, respectively). Two radiologists conducted manual measurements twice while the aforementioned algorithms were developed within the Matlab-Environment allowing for automated image analysis. The reference ranking was compared to all aforementioned methods for artifact quantification to identify suited and less-suited approaches. Besides visual analysis, Kappa-statistics were used to evaluate agreement between quantitative methods and visual perception. Intraclass correlation coefficients (ICC) indicated intra- and interreader agreement.

RESULTS
Intra- and Interreader agreement of visual artifact perception were excellent (ICC 0.85-0.92). No quantitative method was able to represent the exact ranking of visually perceived artifacts; however, ICC for manual measurements were low (ICC 0.25-0.97). The methods that showed best correspondence and reproducibility were ImgD and FreqD-based.

CONCLUSION
Artifact quantification in CT is challenging. Manual measurements show a limited reproducibility. We propose two methods that quantify artifacts in the image- and frequency-domain and that correspond closely to visual artifact perception.

CLINICAL RELEVANCE/APPLICATION
Automated measurements of artifact extent should be preferred over manual measurements as they correspond close to visual perception while the latter show a limited reproducibility.

Printed on: 10/20/19
Purpose

To determine the accuracy and effectiveness of transoral contrast-enhanced ultrasound (CEUS) guided core needle biopsy (CNB) for oral lesions that could not be accurately identified or had a previously non-diagnostic cyto-histological biopsy.

Method and Materials

A consecutive series of 29 patients (age range, 31-81 years; mean 61±12 years; 18 male and 11 female) who underwent transoral CEUS-guided CNB of oral lesions at our hospital were evaluated retrospectively. Among them, 10 (34.5%) lesions were inconspicuous and 19 (65.5%) patients had a previously non-diagnostic cyto-histological exam by endoscopic or surgical incisional biopsy. Transoral CEUS-guided CNB was performed by using an endocavitary transducer and needle guide device attached to the transducer shaft. The CEUS characteristics, successful biopsy rate, diagnostic performance and complications were assessed and recorded.

Results

Of the 29 lesions (median size: 31.5±14.3 mm; range: 9-58mm), 18 lesions were located in oral cavity (oral tongue (n=6), floor of the mouth (n=5), gingiva (n=5), hard palate (n=1) and lip (n=1)) and 11 lesions were located in oropharynx (base of the tongue (n=6), parapharyngeal space (n=4) and tonsil (n=1)). CEUS improved the conspicuity of target lesions and detection rate of internal liquefied necrosis comparing with transoral US (p <0.05). Successful biopsy rate was 100%. Based on the final diagnosis: 19 malignant lesions (15 squamous cell carcinomas, 2 adenoid cystic carcinomas, one mucoepidermoid carcinoma and one melanoma) and 10 benign lesions (5 inflammatory lesions, 3 pleomorphic adenomas, one schwannoma and one hematoma), the diagnostic sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of this technique for the diagnosis of oral lesions were 94.7%, 100%, 100%, 90.9% and 96.6% respectively. No serious complications were observed.

Conclusion

Transoral CEUS-guided CNB can be considered as a complementary technology for pathological diagnosis of oral lesions that could not be accurately identified or had a previously non-diagnostic cyto-histological biopsy.

Clinical Relevance/Application

Transoral CEUS-guided CNB can serve as a safe, feasible and accurate technique for pathological diagnosis and decision making of oral lesions.
METHOD AND MATERIALS

HighNoon - Shadow based needle navigation device is used to perform high precision percutaneous CT guided needle placement. The device is ceiling mounted and can be guided easily to area of action. Device has central camera, four sources of light at right angle to each other and a laser source which project a crosser on the patient. The device can make left to right and head to toe swinging motion. 140 biopsies were performed on mannequins under C-arm guidance following which detailed results were presented to the ethics committee. After approval from ethics committee 55 cases are done using HighNoon prototype.

RESULTS

We are presenting here the results of our initial 55 patients. In these 55 Patients Average target accuracy achieved was 1mm as compared to 5mm without needle guidance device. Average manipulations done was 3%, average no of check scans was 1.24 using High Noon when compared to free hand biopsies where it was 5-10% & 0.4 - 6 respectively. Average wheel in & wheel out time was 26 mins with High noon and between 35 to 50 mins without needle guidance. Patient movement can be identified and corrected and respiratory misregistration can be avoided using visual feedback for radiologist & bagging anesthetist.

CONCLUSION

The 'High noon device' helps to place the needle/device with precise angles of incidence from the point of entry in both axis (X & Z axis), thereby adding to accuracy, reducing the number of insertions, pain, discomfort, radiation, and complications.

CLINICAL RELEVANCE/APPLICATION

WHO states that 9.6 million deaths occurred globally in 2018, 30% increase in cancer cases is expected in 2030. As the cancer mortality is decreased by early detection - the action plan of WHO is to develop tools to help early detection. HighNoon can help in assessing the smaller lesions in easy & difficult locations to be biopsied and reach the final histopathological diagnosis leading to timely, correct treatment saving lives. Also in countries like India where tuberculosis including extra pulmonary tuberculosis mimicking malignancy is very common - deep seated mediastinal lymph nodes & vertebral lesions can be easily accessed by HighNoon alleviating the unnecessary apprehension and initiating the correct medication.

SST10-03 Video Augmented Reality Percutaneous Needle Intervention Decreases Radiation Dose While Maintaining Accuracy Compared to C-Arm Cone Beam CT with Fluoroscopy Overlay: A Prospective Clinical Study with a Matched Control

PURPOSE

To compare navigational accuracy and radiation dose during percutaneous needle intervention for video augmented reality (AR) guidance (study group) versus c-arm cone beam computed tomography (CT) with fluoroscopy overlay (control group)

METHOD AND MATERIALS

This is an IRB approved prospective study with a retrospective matched-control group. Matching was performed for clinical indication. Patients requiring c-arm cone beam CT and integrated fluoroscopy overlay guidance for biopsy, drainage, injection, or ablation were eligible to be prospectively enrolled for the procedure to be performed with video AR. Three interventional radiologists performed 15 video AR procedures in 11 patients. The video AR procedures were compared to an equal number of procedures and patients using c-arm cone beam CT with fluoroscopy overlay. Accuracy of needle guidance was defined as distance between the needle tip and planned anatomic target. Target depth from skin surface, fluoroscopy time, and complications were recorded. Correlation between accuracy and depth of target was assessed using Pearson correlation coefficient. Student's t-test was applied to evaluate statistical difference between groups for each continuous variable.

RESULTS

Age in the study and control groups was 19±6 yrs and 14±4 yrs (p<0.05), respectively. There were 6 biopsies (3 ilium, 1 femur, 1 tibia, 1 sternum) and 9 injections (4 pars interarticularis, 3 sacroiliac, 1 hip, 1 sternum) in each group. Accuracy in the study group was superior to the control group (2.9±2.3 mm vs. 5.6±4.5 mm) although not statistically significant (p=.07). Fluoroscopy time was significantly lower in the study group compared to the control group (0.8±1.0 min vs. 2.1±2.0 min, p<0.05). Target depth in the study group (48±20 mm) and control group (60±27 mm) were not statistically different (p=.18). There was higher negative correlation between the accuracy and the depth of the anatomic target in control group compared to the study group. There were no complications in either group.

CONCLUSION
METHOD AND MATERIALS

Translation of a software system that supports planning and conducting a focused ultrasound treatment in the moving liver. The anatomical location of the malignancy by the rib cage. The EU project TRANS-FUSIMO aimed at the development and clinical translation of a software system that supports planning and conducting a focused ultrasound treatment in the moving liver.

CLINICAL RELEVANCE/APPLICATION

Replacing fluoroscopy with video AR guidance decreases x-ray dose to patients and interventionalists without compromising accuracy or clinical outcome.

SST10-04 Comparison of the Complications of Percutaneous versus Transjugular Liver Biopsies Performed at a Single Institution

Friday, Dec. 6 11:00AM - 11:10AM Room: E451B

Participants
Andrew P. Mai, Houston, TX (Presenter) Nothing to Disclose
Peyton Cramer, BS, Houston, TX (Abstract Co-Author) Nothing to Disclose
Anil K. Pillai, MD, Houston, TX (Abstract Co-Author) Nothing to Disclose

PURPOSE

Transjugular liver biopsy (TJLB) is safer than percutaneous liver biopsy (PLB) in patients with increased risk for hemorrhage. Few clinical studies have directly compared the complication rates between the two procedures. The aim of this study was to retrospectively review patients who underwent liver biopsy and compare the incidence of adverse events and patient factors that were associated with complications.

METHOD AND MATERIALS

Institutional approval was obtained for this study. Data was collected from 158 patients diagnosed with cirrhosis that underwent non-targeted liver biopsies from January 2016 to April 2018. Information included patient demographics, coagulation status, biopsy method, operative findings, and immediate complications (<30 day). Statistical analyses with Fisher's exact test and Wilcoxon rank sum test were then performed to compare the outcomes of the two procedures.

RESULTS

Complications occurred in 7.3%(7/96) who underwent TJLB and included self-limiting post-operative pain (n=4, 4.2%) and major vascular complications (n=3, 3.1%) such as AV fistula and hemoperitoneum. 4.8% (3/62) of patients in the PLBs developed procedural complications including post-operative pain (n=2, 3.2%) and major vascular complications (n=1, 1.6%). The difference in complication rates between the two techniques was not statistically significant (p = 1), nor was there a clinically significant difference in patient demographics, INR, PTT, or PT between the two groups. A larger number of patients who received TJLB were on anticoagulation therapy.

CONCLUSION

Our results show that both TJLB and PLB are safe procedures and there is no significant difference in complication rates between the two biopsy techniques. Although not statistically significant, there was a higher number of major vascular complications with TJLB biopsies. This suggests that the conventional belief of TJLB being the inherently safer approach is not necessarily true in clinical practice.

CLINICAL RELEVANCE/APPLICATION

Transjugular and percutaneous liver biopsies are minimally invasive techniques that allow for hepatic tissue sampling and both are used in the diagnosis and management of cirrhosis.

SST10-05 TRANS-FUSIMO: Conducting FUS Treatments in Moving Abdominal Organs

PURPOSE

In the past years, the application of FUS for various indications was widely introduced in the clinical practice. But for moving abdominal organs like the liver, using FUS still poses a great challenge due to the breathing motion of the target and the occlusion of the anatomical location of the malignancy by the rib cage. The EU project TRANS-FUSIMO aimed at the development and clinical translation of a software system that supports planning and conducting a focused ultrasound treatment in the moving liver.

METHOD AND MATERIALS

Replacing fluoroscopy with video AR guidance decreases x-ray dose to patients and interventionalists without compromising accuracy or clinical outcome.
The TRANS-FUSIMO system contains real-time applicable motion compensation pipelines running during a sonication. Patient specific data is retrieved from the connected MRI in real-time to capture and track the motion of the liver and the target region. With this partially obtained data a set of models for the extrapolation of motion information and tissue response is used to perform the motion compensation. The FUS beam is steered according to this real-time information of the patient and the models.

RESULTS
To validate the TRANS-FUSIMO treatment system, we performed pre-clinical in-vitro studies on phantoms with the system consisting of the complete motion compensation pipeline and the models. These studies have been conducted in static as well as moving scenarios. We showed that the software meets the defined requirements: System's safety requirements as well as functional ones. Furthermore, the successive in-vivo animal study showed in 11.76% of the performed experiments that the software can sonicate safely in a living pig whereas only a good window to the liver could be found in 29% of all cases. In summary, in 40% of the experiments a lesioning was visible after contrast enhanced imaging.

CONCLUSION
In ex-vivo and in-vivo experiments we could show that the TRANS-FUSIMO treatment system is capable of compensating organ motion through real-time motion detection, motion modelling and real-time beam steering. The research leading to these results has received funding from the European Union’s Seventh Framework Program (FP7/2007-2013) under grant agreement no. 611889 (TRANS-FUSIMO).

CLINICAL RELEVANCE/APPLICATION
The results have the potential to finally allow treating both resectable and non-resectable patients while reducing complications and improving the ability to spare non targeted tissues.

SST10-07  Role of Contrast-Enhanced Ultrasound (CEUS) in the Detection of Complications Ensuing US-Guided Interventional Procedures: A Multi-Center Study

Participants
Gianpiero Francica, MD, Castel Volturno, Italy (Presenter) Research Consultant, Shenzhen Mindray Bio-Medical Electronics Co, Ltd

PURPOSE
Vascular roadmaps have limited utility for intravascular procedures in the thorax and abdomen due to severe subtraction artifacts and changes in vessel shape and position caused by respiratory motion. Instead, most interventional radiologists navigate devices (eg. guidewires and catheters) without vascular overlay. This procedure is time consuming and requires experienced interventional radiologists. The purpose of this study was to test the accuracy of a recently developed system that provides real-time motion-compensated vascular overlays for device navigation.

METHOD AND MATERIALS
The proposed system creates a dynamic motion model from contrast enhanced x-ray images acquired under free breathing conditions. During device navigation, a motion-compensated vessel roadmap is created based on respiratory motion estimations from live x-ray images. The device is extracted from the x-ray images and superimposed on the motion compensated roadmap. Alternatively, the system can apply respiratory motion compensation to the device and display a static vascular roadmap. A porcine study was conducted with 3 animals, where a real-time prototype of the system was used to navigate a guidewire within the hepatic arteries. An EM-tracking sensor was placed in different branches of the vasculature to measure motion and compare it to the deformation estimated by the proposed approach.

RESULTS
The average difference between the measured EM-sensor motion and the estimated vessel motion was 1.59 ± 0.64 mm at the detector. The Pearson correlation was 0.94 (p < 0.01). The prototype was able to display the guidewire within the correct vascular branches despite respiratory motion. In some cases, the proximal and less flexible part of the device deforms the surrounding vessels, but the distal part, most relevant for device navigation, is still displayed correctly.

CONCLUSION
Our real-time motion compensated device guidance system provides an intuitive way to accurately navigate devices during intravascular procedures in the abdomen. This could reduce procedure times and therefore decrease risk and radiation exposure to the patient.

CLINICAL RELEVANCE/APPLICATION
Real-time motion compensated roadmaps provide the device position in the vasculature during procedures in the abdomen. This could reduce procedure times and decrease radiation and risk to patients.

The prototype was able to display the guidewire within the correct vascular branches despite respiratory motion. In some cases, the proximal and less flexible part of the device deforms the surrounding vessels, but the distal part, most relevant for device navigation, is still displayed correctly.

CONCLUSION
Our real-time motion compensated device guidance system provides an intuitive way to accurately navigate devices during intravascular procedures in the abdomen. This could reduce procedure times and therefore decrease risk and radiation exposure to the patient.

CLINICAL RELEVANCE/APPLICATION
Real-time motion compensated roadmaps provide the device position in the vasculature during procedures in the abdomen. This could reduce procedure times and decrease radiation and risk to patients.
RESULTS

22 patients (13 M/9F, median age 73 yrs.) experienced complications after 5 liver biopsies with 18g cutting needles (3 for FLL) and 17 ablations of liver tumors (16 HCC) carried out with PEI (2), MW (2), RF (13). Median size of the 20 biopsied/ablated nodules was 22.5 mm (range 15-39 mm). In 10 cases CEUS was performed at the end of ablation (2 PEI, 2 MW, 6 RF) and demonstrated 6 sub-segmental/segmental infarcts, 3 active bleedings (2 capsular tears with hemoperitoneum, 1 hemobilia), and 1 subcapsular hepatic hematoma (SHH). Only 2 patients underwent RF to achieve hemostasis. In 5 symptomatic cases CEUS was performed within 6 hours after biopsy and displayed 1 actively bleeding capsular tear with hemoperitoneum, 1 hemobilia and 3 SHHs, one of which actively bleeding. In the latter case transarterial embolization (TAE) was carried out and another patient needed blood transfusion (BT). Finally, in 7 cases CEUS was performed 24-48 hours after interventional maneuvers. In 5 symptomatic cases CEUS showed 1 actively bleeding capsular tear with hemoperitoneum, 1 hemotherax (due to actively bleeding intercostal artery), 1 pseudoaneurysm of a right arterial branch, 1 segmental infarct, 2 abscessed ablated areas; in the remaining case, routine CEUS check at 24 hours displayed 1 SHH. 5 out of 7 patients in this group were treated with TAE (2 cases), percutaneous abscess drainage (2 cases), and BT plus TAE (1 case).

CONCLUSION

This multicenter survey highlights the potential role of CEUS in the detection of immediate and early (<6 hours) complications ensuing US-guided liver biopsy or ablation. Iatrogenic hemorrhagic complications even with active bleeding and ischemic segmental areas can be successfully demonstrated by CEUS and promptly treated if clinically needed.

CLINICAL RELEVANCE/APPLICATION

CEUS should be considered as an useful tool to detect iatrogenic complications mainly of ischemic and hemorrhagic type occurring after US-guided hepatic interventional procedures.

SST10-08 Detection of Bleeding Complications After Instituting a 1-Hour Post-Procedure Recovery Time Following Renal Transplant Biopsy

Friday, Dec. 6 11:40AM - 11:50AM Room: E451B

Participants

Maitray D. Patel, MD, Paradise Valley, AZ (Abstract Co-Author) Nothing to Disclose

patel.maitray@mayo.edu

PURPOSE

To analyze the timing of major bleeding complications following renal transplant biopsy in the context of a standardized 1-hour post-procedure observation protocol.

METHOD AND MATERIALS

We retrospectively reviewed the electronic medical record for 4519 consecutive US-guided renal transplant biopsies (769 women, 1055 men) from 01/01/2012 to 12/31/2017, after initiating a post-procedural protocol limited to 1 hour of routine observation, additional observation only if symptoms present at 1 hour, and subsequent patient contact within 24 hours after discharge. The development of a major bleeding complication (CTCAE Class 3 or higher) was recorded, along with all available details regarding the time course of patient symptoms and presentation.

RESULTS

There were 11 CTCAE Class 3 complications (11/4519, 0.24%). Seven patients (7/11, 63.6%) were asymptomatic after 1 hour of observation and were discharged. Of these, two (2/11, 18.2%) were admitted after symptoms began 4-8 hours after biopsy; the remaining five (5/11, 45.5%) were admitted after developing symptoms more than 8 hours after biopsy. Four patients (4/11, 36.3%) had symptoms in the 1 hour observation period; of these, two (2/11, 18.2%) had pain combined with hemodynamic alterations, leading to hospital admission. The other 2 patients (2/11, 18.2%) had pain without hemodynamic alterations, leading to an additional hour of observation, and subsequent discharge due to successful pain control with oral analgesics; these 2 patients were later admitted when symptoms returned 4-8 hours after biopsy.

CONCLUSION
Major bleeding complications following US-guided renal transplant biopsy are rare, occurring in 0.24% of patients in this study, and most are not clinically apparent within 4 hours of biopsy. One-third of patients who develop significant hemorrhage have early manifestations, but approximately two-thirds of patients do not have unusual symptomatic manifestations of hemorrhage until more than 4 hours after biopsy. Almost half of all patients do not have unusual symptoms until more than 8 hours after biopsy.

**CLINICAL RELEVANCE/APPLICATION**

A recovery protocol with only 1 hour of routine observation after uneventful renal transplant biopsy can be safely implemented when combined with routine follow-up patient contact. Requiring routine post-procedure observation for 4 hours as used at some facilities uses more resources without improving care.

**SST10-09 High-Intensity Focused Ultrasound (HIFU) Focal Therapy to Primary Treatment of Localized Prostate Cancer Using 68Ga-PSMA PET/MR as Main Guidance: Innovative Experience in 14 Patients**

**PURPOSE**

To identify candidates to High-intensity focused ultrasound (HIFU) focal therapy (FT) for localized prostate cancers (pCa), the following inclusion criteria are commonly used: serum PSA (<15 ng/ml), Gleason score (ISUP 1-3), multiparametric magnetic resonance imaging (mpMRI) with no extracapsular extension, no seminal vesicle invasion or pelvic lymph node disease and negative bone scintigraphy; however, to the best of our knowledge, no prior study has used 68Ga-PSMA PET/MR as the main feature to indicate and guide HIFU procedures.

**METHOD AND MATERIALS**

A single-center prospective analysis of initial 14 patients, candidates for FT (hemi-gland or super-focal ablation) as the primary treatment option, from August 2018 to March 2019. All patients were re-evaluated by mpMRI and transrectal US/MR fusion prostate biopsy and follow-up 68Ga-PSMA PET/MR to better understand the indication of HIFU before the procedure.

**RESULTS**

Mean prostatic volume, age, PSA and region of interest volumes were: 47.9 cc, 68 years, 4.56 ng/dl and 1.1 cm; respectively. Pre-procedure mpMRI showed 7.1% of PIRADS 2, 21.4% of PIRADS 3, 57.3% of PIRADS 4 and 14.2% of PIRADS 5. US-guided fusion + systematic biopsy showed 3 patients with unilateral ISUP 1, 8 patients with unilateral ISUP 2 and 3 patients with ISUP 3. Ten patients (71.4%) had concordant findings between pre-procedure mpMRI, 68Ga-PSMA PET/MR and biopsy. Four patients (28.5%) had discordant findings, altering the treatment planning or contraindicating the procedure, for the following reasons: 2 patients had larger unilateral multifocal disease on 68Ga-PSMA PET/MR than on MRI or US-MR fusion biopsy, with need to extend the treatment area; One patient presented a smaller extent of disease in 68Ga-PSMA PET/MR than in MRI, allowing a reduction of the expected area of treatment; One patient had extensive bilateral disease in 68Ga-PSMA PET/MR that was not suspected in MRI, confirmed by biopsy, contraindicating the procedure.

**CONCLUSION**

In conclusion, 68Ga-PSMA PET/MR may play a fundamental role in the indication and planning of focal ablative prostatic therapy and might be introduced in the inclusion criteria for cases indicated for HIFU.

**CLINICAL RELEVANCE/APPLICATION**

High-intensity focused ultrasound is a promising novel technique but new diagnostic procedures, such as 68Ga-PSMA PET/MR for selection of patients and correct planning of the procedure may alter the oncological outcome and mortality.
LEARNING OBJECTIVES

1) Provide a multidisciplinary perspective on healthy aging, including optimal strategies for imaging, lessons from population health, and insights from research into biologic determinants.

Sub-Events

SPFR61A  Reimagining Imaging and Aging

Participants
Leon Lenchik, MD, Winston-Salem, NC (Moderator) Nothing to Disclose
Stephen B. Kritchevsky, PhD, Winston-Salem, NC (Moderator) Nothing to Disclose

For information about this presentation, contact:
llenchik@wakehealth.edu

LEARNING OBJECTIVES

1) Describe current trends in imaging of aging.

SPFR61B  Keynote: Aging Organs and Aging Systems - A Population Health Perspective

Participants
Stephen B. Kritchevsky, PhD, Winston-Salem, NC (Presenter) Nothing to Disclose

For information about this presentation, contact:
skritche@wakehealth.edu

LEARNING OBJECTIVES

1) Understand the limitations of chronological age in understanding health risks for older adults. 2) Identify several strategies for assigning biologic age to persons of similar chronologic age. 3) Discuss radiological phenotypes that might help predict functional trajectories in older adults.

SPFR61C  Role of Body Composition Imaging in Healthy Aging

Participants
Robert D. Boutin, MD, Davis, CA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Highlight the role of routine imaging techniques to evaluate changes in bone, fat, and muscle that occur with aging.

SPFR61D  Role of Cardiovascular Imaging in Healthy Aging

Participants
John J. Carr, MD, MS, Nashville, TN (Presenter) Nothing to Disclose

For information about this presentation, contact:
j.jeffrey.carr@vanderbilt.edu

LEARNING OBJECTIVES

1) Identify activities that support ideal cardiovascular health from conception, childhood and across adult life.

ABSTRACT
Cardiovascular health across the lifespan is important to maximizing an individuals opportunity for healthy aging.
SPFR61E  Role of Brain Imaging in Healthy Aging

Participants
Christopher T. Whitlow, MD, PhD, Winston-Salem, NC (Presenter) Nothing to Disclose

SPFR61F  Keynote: Biologic Determinants of Aging

Participants
Osvaldo Delbono, Winston Salem, NC (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) To categorize the cellular and molecular determinants of aging. 2) To identify altered intercellular communication as a major driver of loss in tissue composition and function with aging. 3) To discuss the role of cellular imaging in identifying biological processes leading to age-associated diseases.

SPFR61G  Deep Learning and the Imaging of Aging

Participants
Albert Hsiao, MD, PhD, La Jolla, CA (Presenter) Founder, Arterys, Inc; Consultant, Arterys, Inc; Shareholder, Arterys, Inc; Speaker, Bayer AG; Research Grant, Bayer AG; Speaker, General Electric Company; Research Grant, General Electric Company;

LEARNING OBJECTIVES
1) Review the potential for deep learning technology to transform imaging diagnosis. 2) Examine the opportunities for deep learning to perform opportunistic screening and quantification of imaging biomarkers of aging.

SPFR61H  Mind-Body Connection in Aging

Participants
Leon Lenchik, MD, Winston-Salem, NC (Presenter) Nothing to Disclose

For information about this presentation, contact:
llenchik@wakehealth.edu

LEARNING OBJECTIVES
1) Describe the relationship between mind and body in older adults.

SPFR61I  Panel Discussion

Printed on: 10/20/19
