PURPOSE

The 2016 WHO includes molecular markers, such as isocitrate dehydrogenase (IDH) mutation status, to classify diffuse gliomas. This reveals an unmet radiographic need-the ability to identify genetic biomarkers preoperatively, with methods such as MRI. This study aimed to evaluate the power of machine learning based on endogenous mobile protein-based APTw and semi-solid macromolecule-based MT MRI features in classifying IDH1/2 mutation status.

METHOD AND MATERIALS

105 patients with grade-II or -III gliomas with pre-operational routine and APTw MR images, and lab test reports of IDH mutation status were retrospectively recruited. 391 radiomics features were extracted from the tumor ROIs on APTw, MT, and structural MR images. The support vector machine (SVM) method was implemented (A). 70, 25 and 10 cases were randomly assigned to the training set, validation set, and test set. 10-fold cross-validation was used for tuning parameter (γ) selection. The dimensionality of all features is reduced using principal component analysis (PCA). Leave-one-out cross-validation was applied to estimate the classification performance of the models. The alpha level of all tests was set at $P < 0.05$.

RESULTS

43 vs. 62 patients were confirmed as IDH-wildtype or IDH-mutant, respectively. Demographic and clinical characteristics showed no significant difference between the training set and validation set. The IDH-wildtype cohort showed significant higher age and higher WHO grade compared with IDH mutant group. Thus, age and WHO grade were added to SVM classifier. An accuracy of 95.2% in the test set was achieved to predict IDH genotype. The 10 features (age, grade, APTw_mean, APTw_10th percentile, APTw_25th percentile, MT_75th percentile, etc.) that contributed most to the model are presented (B).

CONCLUSION

Our SVM model presented here achieved an accuracy of 95.2% in the test set. The findings support the use of textures extracted from APTw and MT MRI to aid the accurate diagnostic classification of IDH genotype.

CLINICAL RELEVANCE/APPLICATION

The textures extracted from APTw and MT MRI could be used in the accurate diagnostic classification of IDH genotype in patients with WHO grade-II and -III gliomas.

SSG15-02 Identifying Recurrent Tumor in Post-treatment Glioblastomas with Volumetric Amide Proton Transfer-Weighted (APTw) Image Metrics as Biomarkers

Tuesday, Nov. 27 10:40AM - 10:50AM Room: S403B

Participants
Shanshan Jiang, MD, Baltimore, MD (*Presenter*) Nothing to Disclose
Hye-Young Heo, Baltimore, MD (*Abstract Co-Author*) Nothing to Disclose

Jinyuan Zhou, PhD, Baltimore, MD (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Post-treatment glioblastomas are biologically complex and often demonstrate highly variable imaging characteristics. Currently

Post-treatment glioblastomas are biologically complex and often demonstrate highly variable imaging characteristics. Currently, patients with suspected recurrent tumor are often referred for repeat surgery to obtain pathologic confirmation due to the lack of reliable imaging modalities. APTw-MRI is a novel molecular imaging technique that generates contrast primarily based on endogenous cellular proteins. Here, we assessed whether volumetric APTw-MRI metrics could identify recurrent tumor in a heterogeneous background in patients with suspected recurrent glioblastoma.

METHOD AND MATERIALS

31 patients with suspected recurrent glioblastoma were enrolled. MRI sequences included T1w, T2w, FLAIR, Gd-T1w, and volumetric APTw sequences. Diagnosis was made by the RANO criteria and pathological results. Volumes of interest (VOIs) were drawn by a neuroradiologist and a research scientist separately. Three ratios of the volumes of Gd-enhancement, abnormal FLAIR intensity, and APTw hyperintensity were recorded: VGd/VFLAIR, VAPT/VFLAIR, and VAPT/VGd. APTw histogram parameters, including mean, mode, and percentiles, calculated from both VOIs on Gd-T1w and FLAIR images (Fig. 1A, B).

CONCLUSION

Volumetric APTw image metrics are valuable predictors of tumor recurrence in patients with suspected recurrent glioblastoma treated with standard chemoradiation.

CLINICAL RELEVANCE/APPLICATION

APTw-MRI is totally noninvasive and now commercially available, and the results can be readily translated into improved diagnostics for patients with suspected recurrent brain tumors.

SSG15-03 Evaluation of Early Acute Radiation-Induced Brain Injury: Hybrid Multifunctional MR Imaging Based Study

Tuesday, Nov. 27 10:50AM - 11:00AM Room: S403B

imdyang@163.com

PURPOSE

Accidental or deliberate radiation injury is a serious threat to humans that requires prompt accurate diagnosis and assessment. At present, there is no effective imaging method to evaluate the extent of acute radiation brain injury at early stage. We use DCE, IVIM-MRI and 1H-MRS to noninvasively evaluate acute radiation-induced brain injury.

METHOD AND MATERIALS

SD rats were divided into five groups and four groups received a single radiation treatment to the whole brain. The different extent of brain injury was created by exposure different radiation dose, 10, 20, 30, 40Gy respectively. DCE, IVIM-MRI and MRS was performed on day 5 post radiation injury.The correlation between parameters and radiation dose grade was analyzed using Spearman's rank correlation coefficients. ROC analysis of each MRI parameter was carried to differentiate the extent of radiation exposure. Immunohistochemistry, western blot and transmission electron microscopy were used to determine radiation-induced histopathological changes of neurons and glial cells.

RESULTS

For DCE, Ktrans, Ve, Vp and AUC increased significantly with the radiation dose increase. For IVIM, S0, f and D* also increased significantly with the radiation dose increase. For Ktrans, Ve and AUC in DCE and S0, f and D* in IVIM, the value in 30Gy group was significantly higher than other groups ($P<0.05$). The ratio of NAA/Cr in the 30Gy group was significantly lower than other groups and the ratio of NAA/Cho was increase from 10Gy to 20Gy group, but decreased significantly in the 30Gy group ($P<0.05$). VEGF and caspase-3 expression in the cortex was increased with the irradiation dose increasing from10 Gy to 30 Gy ($P<0.05$). Astrocyte population elevated with radiation dose increase ($P<0.05$).MBP staining did not show differences among the sham-radiation and every radiation groups ($P>0.05$). ROC analysis demonstrated that DCE and IVIM parameters are more effective for diagnosing the 30Gy group, but lower for the 10Gy and 20Gy groups.

CONCLUSION

Hybrid multifunctional MRI parameters can non-invasively evaluate acute radiation-induced brain injury at early stage, especially high dose radiation exposure.

CLINICAL RELEVANCE/APPLICATION

In the event of acute radiation exposure accidents, radiation damage can be detected non-invasively by MR imaging markers and used to determine the extent of brain injury without the need for invasive histopathological analysis.

SSG15-04 Glioma Survival Prediction with the Combined Analysis of Multi-Modal MRI, Histopathology, and Patient Characteristics by Supervised Machine Learning

PURPOSE

To establish a survival prediction model for gliomas based on multi-modal MRI, ex vivo histopathology and patient characteristics.

METHOD AND MATERIALS

102 patients with pathologically confirmed WHO I-IV gliomas and complete survival information were retrospectively included. All patients received fluid attenuated inversion recovery, contrast enhanced T1-weighted image, three dimensional pseudo-continuous arterial spin labeling, intravoxel incoherent motion diffusion-weighted images (IVIM-DWI) and dynamic contrast enhanced MRI (DCE-MRI) before surgery. After surgery, histopathology-derived ex vivo features according to WHO 2016, such as tumor grade, histology, isocitrate dehydrogenase mutation status and the methylation of oxygen 6-methylguanine-DNA methyltransferase promoter have been acquired. The histogram and textural features were extracted from tumor volume of interests in each parametric map derived from multi-modal MRI. As for feature selection, pearson correlation and single factor cox regression were utilized to identify relevant features for predicting 2-year overall survival. The multi-factor cox model based on the histopathology and patient characteristics (partial-feature) or their combinations with multi-modal MRI features (full-feature) were established, respectively. Three approaches such as likelihood ratio, Wald and Score (log-rank) test were used to verify the two predictive models.

RESULTS

The predictive model based on the full-feature performed better than that based on partial-feature. The most contributing features to predict overall survival were tumor location, patient age, textural features from DCE-MRI and IVIM-DWI. The likelihood ratio of the full-feature model was 98.23 ($p<0.0001$),while that of the partial-feature one was 62.48 ($p<0.0001$). The hazard ratio of selected image features derived from DCE-MRI and IVIM-DWI were 0.51 ($p = 0.0003$) and -2.37 ($p = 0.0002$) respectively.

CONCLUSION

Survival prediction of glioma patients based on full features containing multi-modal MRI, histopathology and patient characteristics is more accurate than that without multi-modal MRI.

CLINICAL RELEVANCE/APPLICATION

While survival is associated with molecular biomarkers, diagnostic work-up of patients with suspected glioma mainly done by using multi-modal MRI holds great potentials in glioma characterization.

SSG15-05 Clinical Impact of Time Interval Between Gross Total and Subtotal Resection of Glioblastoma and Radiotherapy Using a Large National Database

PURPOSE

Glioblastoma (GBM) is the most common primary malignant brain tumor in adults and standard of care treatment includes maximal safe surgical resection followed by adjuvant radiotherapy (RT) and chemotherapy. The optimal time interval between surgery and the initiation of adjuvant therapy remains unclear.

METHOD AND MATERIALS

The NCDB was queried for adult patients with diagnostic codes for GBM diagnosed from 2004 to 2015 who were treated with RT following surgical resection. Time interval between surgery and the start of RT were grouped into a. <= 4 weeks, b. 4.1-6 weeks, c. 6.1-8 weeks, and d. >8 weeks. Overall survival (OS) was estimated using Kaplan-Meier and log-rank test methods. Univariate (UVA) and multivariable (MVA) modeling with Cox regression analysis was used to determine predictors of OS.

RESULTS

A total of 46,012 patients, with a median age of 61 years (range 18-90 years) met inclusion criteria. Median time interval from resection to RT was 29 days (range 1-620 days). A total of 11,480 patients underwent a gross total resection (GTR) and 13,608

underwent a subtotal resection or biopsy (STR). Median survival was significantly different between time interval groups: 13.9, 15.2, 14.4, and 14.7 months, groups a-d respectively (p<0.0001). Using all variables significant on UVA, the following variables were associated with better OS on MVA: higher KPS, lower age, female gender, black ethnicity, methylated status, unifocal disease, and treatment initiation of RT >4 weeks. When separated by resection status, these variables remained significant; however patients with GTR initiated on RT >8 weeks had worse survival (HR 1.23, p=0.007) whereas patient's with STR did not.

CONCLUSION

Consistent with prior smaller series, this large retrospective analysis of the NCDB suggests that patients with newly diagnosed GBM who start RT within four weeks of surgical resection have worse outcomes. In terms of prolonged delay from surgery to RT, patients with GTR had worse OS if they initiated RT after 8 weeks whereas patients with STR did not. This finding should be considered in the future designs of clinical trials.

CLINICAL RELEVANCE/APPLICATION

This study aims to use the National Cancer Database (NCDB) to identify predictors for and clinical impact of time from surgical resection to initiation of RT in patients with newly diagnosed GBM.

SSG15-06 Assessment of the Alpha/Beta Ratio of the Optic Pathway

PURPOSE

Hypofractionation has been recently considered an alternative to improve stereotactic radiosurgery of lesions in close proximity of the optic pathways. To estimate the intrinsic benefit from fractionation versus single dose radiosurgery for peri-optic lesions, the value of the alpha/beta ratio of the optic pathways has to be taken into account. Most studies expect and use an alpha/beta ratio of 2 Gy, or even 3 Gy, for the visual system. So far, to our knowledge, only 3 alpha/beta ratios have been published: In 1992 Goldsmith and Larson published an alpha/beta ratio of 3.06 Gy, which means that there would be no benefit of hypofractionation for most benign lesions. In 1994 Jiang estimated a ratio of 1.6 Gy based on relatively few data from a single center study. In 2010 Vernimmen derived a negative value of -0.6 Gy, and remarked that a negative value is not permitted by the LQ model.

METHOD AND MATERIALS

The alpha/beta ratio of the optic pathways was estimated from a meta analysis of 388 studies published since 2000. We included 27 studies with fraction numbers between 1 and 31, considering the following inclusion criteria: frequency of radiation induced optical neuropathy RION between > 0 %, and < 10 %, follow up of at least 12 months, no tumor progression, no prior radiation, detailed dosimetric analysis for the visual system. Clinical data provided from our center were added, including 54 hypofractionated Gamma Knife Radiosurgery regimens (4 treatments with 5 sessions, 45 treatments with 4 sessions, and 5 treatments with 3 sessions) and 106 single session treatments of different lesions close to the optic pathways.

RESULTS

The FE plot method revealed an alpha/beta ratio of the optic system of 1.11 Gy, confidence interval [0.39 - 3.59]. There is still not enough data in order to distinguish between alpha/beta ratios of the optic chiasm, the nerves and the tracts.

CONCLUSION

A significant intrinsic benefit from hypofractionation can be expected not only for malignant tumors located in the sellar region but for benign lesions as well, because of the very low alpha/beta ratio of the optic system of 1.11 Gy.

CLINICAL RELEVANCE/APPLICATION

The knowledge of the alpha/beta ratio of the optic system helps to optimize fractionation regimens for peri-optical tumors, facilitating dose restraints, BED and single fraction equivalent doses.

SSG15-07 Repeat Whole Brain Radiation Therapy Using a Pulsed Reduced Dose Rate Technique

PURPOSE

Limited salvage options exist for patients with multiple recurrent brain metastases previously treated with whole brain radiation therapy (WBRT). Pulsed reduced dose rate radiation therapy (PRDR) is a unique irradiation strategy that lowers the effective dose rate, potentially decreasing toxicity to normal tissue by allowing for sublethal damage repair. PRDR is safe and effective in patients with gliomas receiving partial brain re-irradiation. To our knowledge, this technique has not been reported before in patients with brain metastases who have received repeat WBRT with PRDR. We report our early outcomes.

METHOD AND MATERIALS

We conducted a retrospective review of patients with brain metastases who received repeat WBRT with PRDR at the time of clinical and/or radiographic progression. PRDR treatments were delivered with a series of 0.20 Gy pulses given over a 3-minute period. Patients were treated with parallel-opposed whole brain lateral fields with dose prescribed to isocenter.

RESULTS

We identified 26 patients who received WBRT with PRDR since 2012. We excluded 4 patients as 2 patients had no prior WBRT and 2 expired during treatment due to extracranial disease. Primary histology included breast cancer, melanoma, NSCLC, non-seminomatous testicular cancer, SCLC and sarcoma. Initial WBRT dose regimens included 30 Gy in 10 fractions, 37.5 Gy in 15 fractions, and 39.6 Gy in 18 fractions. KPS was 70-100 for all patients at time of first WBRT. Median time to progression after first WBRT was 7.7 months at which time patients underwent repeat WBRT with PRDR. Patients received daily fractions of 2 - 3 Gy to a total dose of 20 Gy - 30 Gy. KPS at repeat irradiation was 70-100. With a mean follow-up of 7.1 months, mean time to intracranial progression after repeat WBRT with PRDR was 4.7 months. Four patients had intracranial disease control after repeat WBRT with PRDR for > 6 months and 1 patient is still alive at the time of this review. No acute grade 3 toxicities were seen as a result of reirradiation based on CTCAE v4.03. Grade 1/2 toxicities included fatigue, anorexia, and alopecia.

CONCLUSION

To our knowledge, this is the first report of repeat WBRT with PRDR. This technique appears to be a safe and feasible option for patients with multiple brain metastases who previously received WBRT.

CLINICAL RELEVANCE/APPLICATION

Future prospective studies using this technique are being considered to determine use as salvage therapy.

SSG15-08 Whole Ventricular Irradiation and Neoadjuvant Chemotherapy for Pure Intracranial Germinoma: A Comparison of Three Dose-Sparing Techniques

Tuesday, Nov. 27 11:40AM - 11:50AM Room: S403B

Awards
Trainee Research Prize - Medical Student

Participants
Jason D. Nosrati, BA, Grand Rapids, MI (*Presenter*) Nothing to Disclose

Jnosrati@live.com

PURPOSE

Radiation therapy (RT) plays a major role in the management of pure CNS germinoma, a disease most commonly seen in children 10-19 years of age. Awareness of late effects of RT has led to a shift in the focus of research to maintaining high cure rates with treatments such as chemotherapy with whole ventricular irradiation (WVI). In the present study, we evaluate three brain-sparing treatment techniques for pure intracranial germinomas with dose-volume analysis of normal brain structures.

METHOD AND MATERIALS

Four patients with intracranial germinomas were treated with chemotherapy followed by 22.5 Gy WVI with simultaneous integrated boost (SIB) to the primary site to 30 Gy. Tumor locations include suprasellar, pineal, or both locations. The SIB plans were replanned with the Japanese (24 Gy WVI only) and current Children's Oncology Group (COG) treatment paradigms (18 Gy WVI with primary site boost to 30 Gy). Target volumes were contoured from registered diagnostic MRIs and included the whole ventricular volume (WVV) and boost volume. Organs at risk (OAR) included hippocampi, temporal lobes, whole brain, and brain-WVPTV. V12, V18, and V20 were recorded for each of these structures, and dose-volume metrics were recorded for all 12 plans. PTV dose-volume coverage and OAR sparing were compared.

RESULTS

For the SIB protocol, the mean total brain V12, V18, and V20 were 59%, 34%, and 28%, respectively; the COG protocol values were 48%, 27%, and 20%; and the WVI values were 57%, 33%, and 28%. Analyzed across 4 patients with varying WVV and boost volumes, the WVI plan giving 24 Gy to the WVV without boost did not result in lower OAR dose-volume metrics yet underdosed the primary by 6 Gy compared to the other two treatment methods. The COG paradigm further reduced the dose to normal brain by reducing the WVPTV dose to 18 Gy while maintaining the 30 Gy boost PTV dose.

CONCLUSION

The WVI treatment plan may not reduce neurocognitive deficits yet potentially risks failure to control the primary site. The COG plan may result in even better neurocognitive outcomes than the SIB treatment, but whether there is an increase in ventricular failures remains to be seen.

CLINICAL RELEVANCE/APPLICATION

Minimization of cognitive late effects during treatment planning for CNS Germinoma is not enhanced by omission of a boost dose to

30 Gy to the primary tumor.

SSG15-09 Biomechanical Model-Based Deformable Image Registration for Glioma Patients

mmmcculloch@mdanderson.org

PURPOSE

Assessment of treatment response for gliomas requires alignment of pre- and post-radiotherapy (RT) images. Large deformations in gross tumor volume (GTV) and surrounding brain can occur due to edema and tumor or surgical cavity growth or shrinkage. These large shifts can propose challenges in aligning serial images. The purpose of this study is to evaluate the accuracy of biomechanical model-based deformable image registration (DIR) driven by modeling the GTV volumetric response.

METHOD AND MATERIALS

Serial MR images of 10 glioma patients from post-surgery/pre-RT and post-RT were imported into an RT treatment planning system for analysis. GTV, ventricles, right and left hippocampi, brainstem and optic chiasm were delineated on each image. Automated rigid registration (RR) was performed between the pre- and post-RT MR images, followed by a biomechanical model-based DIR with boundary conditions on the GTV. Normal tissue contours were propagated from the pre-RT MR to the post-RT MR. The accuracy of the DIR method was evaluated using dice similarity coefficient (DSC) for each propagated contour.

RESULTS

The DSC was calculated between each propagated and original contour on the post-RT MR for both RR and DIR. Rigid registration was sufficient for 9 out of 10 patients in this limited cohort, as they did not have significant GTV or brain changes. In one patient with a large tumor (55 cm3), we qualitatively noted normal tissue shifts and tumor response due to treatment. In this patient, the use of DIR improved DSC for the ventricles from 0.56 to 0.74, left hippocampus from 0.36 to 0.48, and right hippocampus from 0.68 to 0.71.

CONCLUSION

In cases demonstrating therapeutic response of the tumor, biomechanical model-based DIR improves alignment compared to RR alone. This method was particularly beneficial for one patient in this limited cohort. Additional patients are needed to further evaluate impact and accuracy. These models will also aid in tracking the delivered dose and incorporating delivered dose into an adaptive protocol for glioma patients.

CLINICAL RELEVANCE/APPLICATION

For patients with therapeutic response to glioma, biomechanical model-based DIR is beneficial in alignment of normal tissues during RT, potentially aiding in tracking delivered dose.

PURPOSE

To compare imaging response assessment criteria in hepatocellular carcinoma (HCC) treated with stereotactic body radiotherapy (SBRT), and to determine which of these criteria better predicts patient survival.

METHOD AND MATERIALS

In this multicenter retrospective IRB-approved, HIPAA-compliant study, we included 56 HCC lesions (mean size 3.1 cm±1.4) treated with SBRT in 45 patients (age 66.73±7.61; 32 M; 13 F) between 2009 -2017. All patients underwent diagnostic CT/MR imaging within 6 weeks pre-SBRT and at least once 1-6 months post-SBRT. Tumor response on pre- and post-SBRT CT/MR over all assessments was determined using RECIST (response Evaluation Criteria in Solid Tumors) version 1.1, iRECIST (immune-RECIST), WHO (World Health Organization), mRECIST (modified RECIST) and EASL (European Association for the Study of Liver) criteria. Each response criteria was used to classify lesions as responders (i.e. local control: stable disease, partial or complete response) or nonresponders (progressive disease). McNemar's test was used to compare proportions of responders by each method vs RECIST 1.1 assuming independence of lesions. The Kaplan-Meier method was used to estimate 1-year overal survival (OS) from SBRT by each method.

RESULTS

Median follow-up was 19 months (3-29 months). Lesion response rates were 80.4% (n=45) by RECIST 1.1, 94.6% (n=53) by iRECIST, 67.9% (n=36) by WHO, 76.8% (n=43) by mRECIST, 71.4% (n=40) by EASL. Compared to RECIST 1.1, lesion response rate was significanly higher with iRECIST (p=0.005) and lower with WHO (p=0.02). Pseudoprogression occurred in 3 lesions (5%) with RECIST 1.1, 0 (0%) with iRECIST, 5 (9%) with WHO, 4 (7%) with mRECIST, and 7 (12.5%) with EASL. The largest difference in 1-year OS was observed for RECIST 1.1 with longer survival in responders (85%, 90% CI:72-93%) vs non-responders (67%, 90% CI: 35-86%). No differences were found for mRECIST, WHO or EASL. Too few events occurred to assess OS for iRECIST.

CONCLUSION

SBRT is an effective local treatment for HCC. RECIST 1.1 identifies patients with better outcomes; yet iRECIST appears to be promising in overcoming pseudoprogression. Further analysis of association between RECIST 1.1, iRECIST and outcomes are needed.

CLINICAL RELEVANCE/APPLICATION

Response assessment of HCC after SBRT by RECIST 1.1 may be superior to other imaging criteria; however, pseudoprogression

occurs with all of these criteria, except with iRECIST.

MSRO33-03 Stereotactic Body Radiotherapy (SBRT) Utilized as a Bridge to Orthotopic Liver Transplant (OLT) in Patients with Hepatocellular Carcinoma (HCC) and Severe Hepatic Cirrhosis

Tuesday, Nov. 27 1:50PM - 2:00PM Room: S103AB

PURPOSE

To report outcomes on SBRT as a bridging treatment to OLT for patients with HCC and Child-Pugh (CP) score >=8 hepatic cirrhosis.

METHOD AND MATERIALS

Twelve patients, 17 HCC lesions, within Milan criteria for liver transplant who completed liver SBRT prior to OLT from 2010-2017 were retrospectively analyzed. 4D-CT and SPECT imaging were used to facilitate functional treatment planning.

RESULTS

The median age was 60 years (range 48-69 yrs), with a median CP 9 (range 8-11) and MELD-Na 14 (range 9-24). Main cause of cirrhosis was hepatitis C. Three patients required downsizing to be listed within Milan criteria for transplant. The median SBRT dose was 40 Gy in 5 fractions (range 30-50 Gy in 4-6 fractions). The median tumor max dimension was 2.3 cm (range 1.3-5.2 cm). The median PTV size was 37.5 cc (range 9-164 cc). Two patients had a prior TACE. The median time from SBRT to OLT was 5 mos (range 2-10 mos). All patients in the study received planned SBRT prior to OLT. One patient succumbed to progression of hepatic cirrhosis before OLT. The median follow-up and survival was 40 mos (range 3-70 mos) and 46 mos (range 3-70 mos), respectively. Local control was 100%. One patient progressed distantly at 38 mos, with no patients recurring in the liver. The median decrease in size of the HCC lesion was 60%, with five lesions having complete radiographic response by mRECIST criteria. Out of 5 patients who had elevated pretreatment AFP, 4 normalized by 6 mos. Five patients out of the 11 transplanted (45%) had a pathologic complete response on explanted liver. Acute toxicities (CTCAE v4.03) were two Grade 1 gastrointestinal and six Grade <=2 fatigue. No patients were diagnosed with RILD, however 4 patients had grade <=2 elevation of their liver enzymes. The median time to progression of CP > 2 was 9.7 mos (range 7 days-10 mos) while MELD-Na progression leading to an increased 3-month mortality was not met before OLT.

CONCLUSION

Based on our retrospective study we suggest, that SBRT with functional treatment planning can be used safely as a bridging treatment to OLT in select patients with severe cirrhosis meeting Milan criteria for liver transplant

CLINICAL RELEVANCE/APPLICATION

This paper demonstrates promising efficacy and toxicity results in one of the largest series of select patients with severe (Child Pugh $\geq$ 8) cirrhosis treated with SBRT with functional treatment planning for tumor downsizing prior to OLT.

MSRO33-04 Liver Radiomics Using Sulfur Colloid SPECT/CT for Survival Prediction in Primary Liver Cancer Patients Treated with Radiation Therapy

PURPOSE

A critical need in radiotherapy (RT) for primary liver cancer patients is to accurately predict those at risk for toxicity and mortality. We hypothesize that radiomic signatures of the uninvolved liver extracted from pre-treatment functional liver imaging with [99mTc]sulfur colloid (SC) SPECT/CT can improve overall survival (OS) prediction compared with clinical factors alone.

METHOD AND MATERIALS

We retrospectively reviewed 48 primary liver cancer patients with underlying cirrhosis treated with RT for clinical data, including Child-Pugh (CP) score and gross tumor volume (GTV). 30 radiomic features were extracted from pretreatment SC SPECT/CT of the uninvolved liver (histogram, Haralick, neighborhood difference, and zone size features). Cox models were used for univariate and multivariate analysis of OS. Univariate p-values were not adjusted for multiple comparisons. The LASSO was used to construct multivariate models (<=4 variables). Initial model performance was estimated by the apparent c-index (Capp) and models were internally validated with the .632 bootstrap (C.632).

RESULTS

Twelve patients (25%) had CP-B8+ cirrhosis, and median GTV was 10 cc3 [1.2-1573]. 18 died over median follow-up of 13 months. The strongest univariate predictors of OS were GTV (hazard ratio (HR) 2.6, p<0.001) and CP score (HR 1.7, p=0.027), and 9 radiomic features had p<0.05 after adjusting for the strongest predictor (GTV). Multivariate LASSO-Cox performance was Capp=0.75 for GTV, 0.64 for CP score, 0.65 for radiomics, and 0.83 for GTV+CP+radiomics. After internal validation, GTV (C.632 =0.76) and CP models (C.632 =0.64) retained predictive accuracy. However, the radiomics model was not predictive (C.632=0.55, p=0.34) and the GTV+CP+radiomics model was not superior to GTV alone (C.632=0.76, p=0.82).

CONCLUSION

Tumor volume, and to a lesser extent CP score, appear to predict overall survival in primary liver cancer patients. Univariate analysis suggested radiomic features of SC SPECT/CT may provide complementary information beyond GTV and CP score; however, their inclusion did not improve model performance. Prospective validation in a clinical trial is underway.

CLINICAL RELEVANCE/APPLICATION

SC SPECT/CT functional liver radiomics may complement clinical factors to predict survival in primary liver cancer patients for precision radiotherapy that improves outcomes and reduces toxicity.

MSRO33-05 Robotic Stereotactic Radiotherapy for Liver-only Oligometastastic Colorectal Cancer: Single Center Experience

PURPOSE

To report on the safety and clinical benefit of robotic stereotactic body radiotherapy for liver-only oligometastatic colorectal cancer.

METHOD AND MATERIALS

Robotic stereotactic radiotherapy (SBRT) with Cyberknife was applied to oligometastatic colorectal cancer patients defined as having 1-4 liver metastases and absent or controlled extrahepatic disease. The intended prescription dose was 37,5 Gy in 3 fractions, prescribed to the 70% isodose line to cover 95% of the PTV, and adapted if risk-related. Liver - implanted fiducials allowed for tumor tracking during delivery. Treatment efficacy was estimated by clinical benefit rate (CBR), progression free survival (PFS) and overall survival (OS). Toxicity was graded according to CTCAE v. 4.03. Regression analysis was performed to establish whether any correlation could be found between treatment efficacy and biologically effective dose (BED), number of metastatic lesions, number of treated lesions, site of primary tumor, presence of extrahepatic disease and number of lines of systemic treatment.

RESULTS

Between 2012 and 2017, 38 patients (66 lesions) were irradiated. The median delivered biological effective maximum dose (maxBED10) was 142 Gy. At a median follow-up of 11.8 months (range 3.2-58.8), the 1 and 2-year OS were 67.3% and 44.1%, respectively.Local relapse or distant progression occurred in 28 (77,8%) patients, with a 1 and 2-year PFS of 19.3% and 12.2%, respectively. The CBR was 71,4%, with no significant association with max BED10. Age at SBRT > 76 ys and presence of extrahepatic disease had a significant impact on PFS, the latter confirmed at univariate and multivariate analyses. In addition, extrahepatic disease and number of metastatic lesions > 3 had a significant impact on OS, both of which significant at univariate analysis. Mean time of local or distant progression was 4,7 months (SD 3.7). No acute grade 3 gastrointestinal (GI) toxicity was observed.

CONCLUSION

Our results underline the importance of patients' selection to identify the oligo-metastatic scenario most likely to benefit from SBRT. Prospective studies are needed to further assess the role of SBRT among loco-regional treatment options for liver metastases from colorectal cancer.

CLINICAL RELEVANCE/APPLICATION

Our retrospective single center experience adds to the limited available evidence on the promising efficacy and tolerability of SBRT for liver metastases from oligometastatic colorectal cancer

MSRO33-06 Preliminary Clinical Study of Biliary Tract Irradiation Stent for Hilar Cholangiocarcinoma with Malignant Obstructive Jaundice

Tuesday, Nov. 27 2:20PM - 2:30PM Room: S103AB

Participants

Ju Gong, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the efficacy and safety of biliary stent loaded with 125I seeds in treatment of hilar cholangiocarcinoma with malignant obstructive jaundice.

METHOD AND MATERIALS

Totally 43 patients with malignant obstructive jaundice caused by cholangiocarcinoma were included. All the paitents were underwent percutaneous transhepatic puncture ,of, the left and right side branch of the bile duct. In the hilar stenosis, the biliary stent with 125I seeds were implanted, and the biliary drainage tube had been kept in 3 to 5 days after procedures. The drainage tube was removed and the puncture road was closed after the patency of stents were confirmed by cholangiography. The changes of liver function before and after procedures were recorded, and the survival time was observed.

RESULTS

Five biliary stents loaded with 125I seeds were implanted in typeI (n=5), 36 in type II (n=18), 8 in typeIII (n=4) and 25 in typeIV (n=16). The Serum total bilirubin and direct bilirubin of paitents before procedures were (145.5 ±65.3) μmol/L and (124.7±35.0) μmol/L respectively, and (65.9±29.4) μmol/L and (35.5±15.1) μmol/L respectively after procedures. Compared with preoperative, the alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, C-reactive protein and gamma glutamic transaminase decreased significantly (all $P<0.05$); and the lactate dehydrogenase increased significantly ($P=1.05$). The median survival time was 13 months (3.0 to 22.5 months). The serious complications such as biliary puncture, pancreatitis, severe biliary tract infection or biliary bleeding were not occurred.

CONCLUSION

Biliary stent loaded with 125I seeds is an effective therapy to alleviate symptoms of jaundice and prolong the survival time of patients with malignant obstructive jaundice caused by hilar cholangiocarcinoma.

CLINICAL RELEVANCE/APPLICATION

To evaluate the efficacy and safety of biliary stent loaded with 125I seeds in treatment of hilar cholangiocarcinoma with malignant obstructive jaundice.

PURPOSE

To directly compare the capability for therapeutic outcome prediction among dynamics contrast-enhanced (CE-) perfusion area-detector CT (ADCT) and CE-perfusion MR imaging (MRI) assessed by same mathematical method and FDG-PET/CT in small cell lung cancer (SCLC) patients assessed as limited disease (LD).

METHOD AND MATERIALS

Forty-three consecutive pathologically diagnosed SCLC patients assessed as LD (25 male, 18 female; mean age 67 year old) underwent FDG-PET/CT, dynamic CE-perfusion ADCT and MRI, chemoradiotherapy, and follow-up examination. In each patient, therapeutic outcomes were assessed as therapeutic effect based on RECIST guideline, disease free interval and overall survival. Then, all patients were divided into two groups as follows: 1) responder (CR+PR: n=33) and 2) non-responder (SD+PD: n=10) groups. In each patient, total perfusion (TP) and tumor perfusions from pulmonary (TPP) and systemic (TPS) circulations calculated by dual-input maximum slope method from dynamic CE-perfusion ADCT and MRI data and SUVmax on PET/CT were assessed at targeted lesions. Then, final values were determined as average values from all targeted lesion, and compared between two groups by Student's t-test. To compare the capability for distinguishing two groups, all indexes as having significant difference were assessed by ROC analysis. Finally, disease free and overall survivals between responders and non-responders assessed by each index were compared by Kaplan-Meier method followed by log-rank test.

RESULTS

There were significant difference of all indexes except TPP determined by each method ($p<0.05$). Area under the curves (Azs) of TPS (ADCT: Az=0.92, MRI: Az=0.92) were significantly larger than that of SUVmax (Az=0.73, $p<0.05$). Disease free survivals of responder were significantly longer than that of non-responder by TP (ADCT: p=0.006, MRI: p=0.02) and TPS (ADCT: p=0.001, MRI: p=0.02). Overall survivals of responder were also significantly longer than that of non-responder by TP (ADCT: $p<0.0001$, MRI: p=0.0003,) and TPS (ADCT: p=0.001, MRI: p=0.001).

CONCLUSION

Dynamic CE-perfusion ADCT and MRI have better potential for predicting therapeutic outcome than FDG-PET/CT in small cell lung cancer patients with limited disease.

CLINICAL RELEVANCE/APPLICATION

Dynamic CE-perfusion ADCT and MRI have better potential to predict therapeutic outcome than FDG-PET/CT in small cell lung cancer patients with limited disease.

MSRO37-02 Modern Treatment Patterns and Overall Survival of Non-Small Cell Lung Cancer Patients Receiving Palliative Radiation Therapy for Brain Metastases at Diagnosis

PURPOSE

Non-small cell lung cancer (NSCLC) is one of the most common malignancies associated with brain metastases (BM) at diagnosis. Recent randomized trials have shown equivalent survival outcomes and improved neurocognitive outcomes with stereotactic radiosurgery (SRS) compared to whole brain radiation therapy (WBRT). We reviewed the NCDB to identify trends of RT for NSCLC patients with BM.

METHOD AND MATERIALS

11,299 NSCLC patients with BM at diagnosis and treated with palliative brain RT between 2010 and 2014 were identified in the NCDB. Patients receiving "stereotactic radiosurgery, NOS," "LINAC radiosurgery," or "gamma knife radiosurgery," or received external-beam RT with fraction size >=6 Gy were included in the SRS cohort. The WBRT cohort included all patients receiving RT to the brain in >=5 fractions. Patient characteristics were correlated with treatment received using multivariable logistic regression. Kaplan-Meier was used to compare overall survival (OS) between these two groups and Cox Proportional Hazards modeling (CPHM) to identify variables associated with OS.

RESULTS

9,680 (85.7%) patients were included in the WBRT group and 1,619 (14.3%) patients in the SRS group. Median dose in the WBRT was 3000 cGy and 2200 cGy in the SRS group. The frequency of SRS increased from 9.9% in 2010 to 19.6% in 2014. On MVA, variables associated with increased likelihood of receiving SRS included: increasing age (OR 1.01, 95% CI 1.01-1.02; P<0.0001), most recent year (2014) of diagnosis (OR 2.14, 1.78-2.56; P<0.0001), treatment at an academic facility (OR 3.21, 2.51-4.10; P<0.0001), private insurance (OR 2.25, 1.62-3.11), income in zip code >$63,000 (OR 1.33, 1.13-1.56; P=0.001), living >20 miles from treatment facility (OR 1.19, 1.03-1.37; P=0.016), and receipt of chemotherapy (OR: 2.48, 2.12-2.88; P<0.0001). WBRT patients had median OS of 4.1 months (95% CI, 4.0-4.3) vs. 8.9 months (8.2-9.7) for SRS patients (P<0.0001). On CPHM, factors independently associated with improved OS included receipt of SRS, chemotherapy, treatment at an academic center, and private insurance (P<0.02 for all).

CONCLUSION

Our analysis reveals that WBRT remains the most common palliative treatment for BM in NSCLC. SRS use is increasing and has nearly doubled between 2010 and 2014. In this study, SRS was associated with increased OS although there are biases in the selection of patients who receive SRS.

CLINICAL RELEVANCE/APPLICATION

SRS use for NSCLC patients with BM at the time of diagnosis is increasing, and is independently associated with improved OS.

MSRO37-03 Quantification of Radiation Pneumonitis in Lung Cancer Patients Receiving Proton or Photon Radiotherapy Using FDG-PET/CT

PURPOSE

This study assessed the feasibility of FDG-PET/CT to quantify radiation-induced pneumonitis in ipsilateral and contralateral lungs of patients with locally advanced non-small cell lung cancer (NSCLC) who received proton, photon, or combined proton-photon radiotherapy (RT).

METHOD AND MATERIALS

39 consecutive patients (53.8% female, median age 67y) with predominantly stage IIIA (62%) or IIIB (31%) NSCLC underwent FDG-PET/CT before and after proton or photon RT. Regions of interest (ROIs) were drawn manually along the margins of the lung parenchyma on PET/CT images. Lung mean standardized uptake value (SUVmean), global lung glycolysis (GLG), and lung volume were measured. Partial volume correction (PVC) of PET-based parameters was then performed. To quantify tumor metabolic response to RT, metabolically active tumor volume (MTV), tumor SUV, and total lesion glycolysis (TLG) were measured. Total lesion glycolysis was then subtracted from GLG to calculate global lung parenchymal glycolysis (GLPG). Parameters of FDG-PET/CT scans before and after RT were compared using two-tailed paired t-tests.

RESULTS

Among the 9 patients who received photon RT, there was a significant increase in PVC-GLPG of ipsilateral ($p < 0.001$) and in GLG of contralateral ($p = 0.036$) lungs. Also, in the subset of 9 patients who received combination of proton-photon RT, there was a statistically significant increase in PVC-GLPG in only the ipsilateral lung ($p < 0.001$). In contrast, among the 21 patients treated exclusively with proton RT, no significant increase in PVC-SUVmean ($p=0.114$) or in PVC-GLPG ($p=0.453$) were observed in ipsilateral lungs. Also, there were no significant increase in SUVmean ($p=0.841$) or in GLG ($p=0.241$) of contralateral lungs of patients who received exclusively proton RT.

CONCLUSION

We identified significant increases in PVC-SUV and PVC-GLPG in patients who received photon RT (either alone or in combination with proton RT) that were not identified in patients who received only proton RT. These observations suggest less induction of inflammatory response in both ipsilateral and contralateral lungs of patients treated with proton compared to photon or combined proton-photon RT, suggesting a mechanism by which proton therapy reduces radiation-induced pneumonitis.

CLINICAL RELEVANCE/APPLICATION

Proton RT induces less inflammatory response in both the ipsilateral and contralateral lungs of patients compared to photon or combined proton-photon RT.

MSRO37-04 Differentiating EGFR Mutation Status in Non-Small Cell Lung Cancer Using Imaging Features From PET/CT

PURPOSE

In this study, we investigated whether epidermal growth factor receptor (EGFR) mutation status in non-small cell lung cancer (NSCLC) can be assessed from quantitative as well as qualitative features extracted from both CT and PET.

METHOD AND MATERIALS

Eighty patients with stage II and III NSCLC and a confirmed EGFR mutation status (30 patients were positive and 50 were negative for EGFR mutation), who underwent PET/CT between January 2017 to December 2017, were included in this study. We extracted 514 quantitative features from PET/CT (257 for PET and 257 for CT) and 12 qualitative features from CT. Principal component analysis (PCA) was applied for feature selection. We selected principal components retaining 95% of the variability from all features. We then rebuilt the original features using the selected principal components and the original features were selected that correlated by at least 99% to the rebuilt features. Finally, 5 qualitative features, 24 quantitative features for CT as well as 10 quantitative features for PET were selected. A predictive model of EGFR mutation in terms of selected features using generalized linear regression with lasso regularization. The regularization parameter was selected through a 10-fold cross validation. All statistical analysis were performed in R software version 3.4.4.

RESULTS

With the total of 39 features selected which were significantly associated with EGFR mutation status, a predictive model for associating image features with EGFR positive/negative was built. We estimated the performance of the model using the area under the receiver operating characteristic curve (AUC). The result revealed an AUC=0.74.

CONCLUSION

By combing the PET-CT images together with first generation gene testing data, we investigate the relationship between image features and EGFR mutation status and built a radiogenomics model which can predict whether the patients have EGFR mutation or not from a certain number of qualitative features as well as quantitative features.

CLINICAL RELEVANCE/APPLICATION

A non-invasive method from image features to predict gene mutation status correlated with NSCLC and further advancing the role of imaging in precision medicine.

MSRO37-05 Stereotactic Body Radiotherapy for Centrally Located Non-Small Cell Lung Cancer: Single Center Experience

PURPOSE

By definition, centrally located lung tumors are identified as a lesion located within 2 cm or touching the zone of the proximal bronchial tree or tumors immediately adjacent to the mediastinal or pericardial pleura. In these cases, the use of stereotactic body radiotherapy (SBRT) is debated due to the potential risk of severe toxicity. Currently, no high-level evidence is available to support its use.

METHOD AND MATERIALS

Between 2010 an 2015, 40 patients were treated with SBRT for 45 centrally located lesions. SBRT was delivered through either a LINAC-based intensity modulated radiotherapy (IMRT) technique or a robotic technique with Cyberknife. The prescribed total dose varied between 26 and 60 Gy delivered in 1 or 8 fractions, respectively, with median BED10 of 69 Gy (range 37,5-105 Gy). Overall Survival (OS) and Progression Free Survival (PFS) were reported using Kaplan-Meier method. Treatment-related toxicity was evaluated according to CTCAE version 4.0

RESULTS

The median age of the cohort was 62 years (48-86). The majority of treated lesions were secondary hilar or mediastinal lymphadenopathies (31/45, 69%), while unresectable primary tumors represented the remaining 14 cases (14/45, 31%). The most commonly used technique was VMAT for 21 lesions (47%), followed by Cyberknife for 14 (31%) and step and shoot IMRT for 10 targets (22%), respectively. The predominant NSCLC histology was adenocarcinoma (32/45, 71%). The median longest tumor diameter was 31 mm (range 10-60 mm). At a median follow-up of 14.5 months, OS and PFS were 86.5%, 55.6%, 49.4% and 48.6%, 24.1% and 12% at 1, 2 and 3 years, respectively. According to RECIST 1.1 criteria, a clinical benefit was achieved for 23 patients (57.5%) with a complete or partial response or stable disease in 4 (10%), 15 (37.5%) and 4 (10%) patients, respectively. Consistent with previous experiences using the same fractionation regimens, SBRT was well tolerated, with no G3/G4 toxicities: the most severe side effect was G2 esophagitis in 5/40 patients (12.5%).

CONCLUSION

In accordance with standardized risk-dose prescriptions, the use of SBRT for centrally located NSCLC was confirmed to be a safe and effective strategy. Prospective studies are warranted to support its use with high level evidence.

CLINICAL RELEVANCE/APPLICATION

Our single-center experience adds to the limited available evidence on the feasibility and clinical benefit of SBRT for centrally located NSCLC

MSRO37-06 Evaluation of the Tumor Response Using FDG-PET/CT Scans in Non-Small Cell Lung Cancer Patients Treated with Proton or Photon Radiotherapy

PURPOSE

Lung cancer is one the leading causes of death worldwide. Radiation therapy (RT) is a major treatment option for lung cancer, including for unresectable locally advanced non-small cell lung cancer (LA-NSCLC). The aim of this study was to evaluate the response of the primary lung tumor to proton versus photon RT using 18F-fluorodeoxyglucose (FDG)-PET/CT in patients with LA-NSCLC.

METHOD AND MATERIALS

Thirty-nine consecutive patients who underwent FDG-PET/CT imaging pre- and post- proton or photon RT were assessed. Patients were predominantly female (53.8%) with a median age of 67 years and with predominantly stage IIIA (62%). An adaptive contrast-oriented thresholding algorithm was applied to measure metabolically active tumor volumes, uncorrected SUV, partial volume corrected SUV and total lesion glycolysis. Parameters of FDG-PET/CT scans before and after RT were compared using two-tailed paired t-tests.

RESULTS

Among the 9 patients who received photon RT and the 9 patients who received a combination of proton-photon RT, there was a significant decrease in PVC-TLG. Interestingly, among the 21 patients treated exclusively with proton RT, all tumor parameters including MTV, SUVmax, uncorrected SUVmean, PVC-SUVmean, uncorrected TLG, and PVC-TLG after treatment decreased significantly (all $p < 0.001$). The decreases in PVC-TLG and tumor PVC-SUVmean were more obvious than non-PVC ones (ΔPVC-TLG -357.26 cc versus ΔTLG -252.92 cc; ΔPVC-SUVmean -16.2 versus ΔSUVmean -10.19).

CONCLUSION

Adaptive contrast-oriented thresholding algorithm is a promising method to quantify whole tumor glycolysis in LA-NSCLC, and our findings demonstrates that proton RT is as effective as photon RT metabolically in inducing tumor response of LA-NSCLC.

CLINICAL RELEVANCE/APPLICATION

Proton RT, which is much safer, is as effective as photon RT in treatment of LA-NSCLC.

PURPOSE

Although MR imaging may show radiologic complete response (rCR) after neoadjuvant chemotherapy (NAC), there may be discordance between the MR imaging and pathology. The purpose of this study was to evaluate the radiologic and clinicopathologic factors of discordance between rCR and pathologic complete response (pCR) after NAC in breast cancer patients, and to determine whether there are differences among molecular subtypes.

METHOD AND MATERIALS

Our institutional review board approved this retrospective study. We evaluated 209 consecutive patients who showed rCR in MR imaging after NAC between January 2013 and December 2015. All patients had mammography, ultrasound and MR imaging before and after completion of NAC prior to definitive surgery. rCR was diagnosed when no enhancement or faint enhancement was shown in the previous lesion site equal to that of the background normal breast tissue. pCR was defined as the complete absence of both invasive cancer and ductal carcinoma in situ in the breast on the surgical histopathological examination. Clinicopathologic and initial radiologic findings were assessed and factors affecting the radiologic-pathologic discordance were analyzed.

RESULTS

One hundred eight patients (51.7%) showed pCR and 101 (48.3%) had residual lesion on surgical histopathology. The false negative findings were significantly more frequent in luminal A and B subtype (67.3%, 68/101), with radiologic findings such as larger tumor size ($p = 0.048$) in mammography, irregular shape ($p = 0.021$), high proportion of persistent component ($p = 0.008$), and low proportion of washout component ($p = 0.001$). On multivariate analysis of radiologic findings in all patients to predict residual lesion, calcification in mammography ($p = 0.037$), multifocal lesion ($p = 0.004$), and nonmass enhancement in MR ($p = 0.023$) were significantly associated with residual lesion.

CONCLUSION

Luminal subtype has a significant high false negative rate who achieved rCR after NAC. Patients with calcification in mammography, multifocal lesion, and nonmass enhancement in initial MR imaging are significantly associated with residual lesion.

CLINICAL RELEVANCE/APPLICATION

Although MR imaging showed rCR after NAC, multifocal breast cancer with calcification and nonmass enhancement, residual lesions should be considered and may impact surgical planning.

SSJ01-02 How Should a Radiologist Diagnose a Complete Imaging Response on Breast MRI after Neoadjuvant Chemotherapy?

PURPOSE

There is no standard definition regarding what constitutes a complete imaging response (CIR) on breast MRI post-neoadjuvant chemotherapy (NAC). The purpose is to evaluate the accuracy of a CIR defined as no residual enhancement in the tumor bed post-NAC in diagnosing a pathologic complete response (pCR).

METHOD AND MATERIALS

The IRB approved this HIPAA-compliant retrospective study and waived informed consent. Women were identified with biopsy proven invasive breast cancer who underwent: a) NAC, b) pre and post-NAC MRI and c) surgery between 2014-2016. CIR was defined as no residual enhancement on any of the three post-contrast phases on post-NAC MRI. Two breast radiologists (R1 and R2) independently reviewed all pre and post-NAC MRI blinded to pathology. pCR was defined as no residual invasive or in situ carcinoma. Measures of accuracy, including sensitivity, specificity, negative predictive value (NPV) and positive predictive value (PPV) were estimated using no enhancement on MRI to diagnose pCR. Kappa statistic was used to assess agreement between readers.

RESULTS

275 women were included with 280 breast cancers (n=5, 1.8% had bilateral cancers). Of the 280 breast cancers, 256 (91.4%) were invasive ductal carcinoma, 11 (3.9%) were invasive lobular carcinoma and 13 (4.7%) were other invasive carcinoma. 74 (26.4%) had a pCR and 186 (66.4%) had no pCR. The two readers had substantial agreement on enhancement (kappa=0.627, 87.5% concordant readings). Sensitivity was 40.5%(R1)/50.0%(R2), specificity was 87.9% (R1)/86.9%(R2), PPV was 54.5% (R1)/57.8% and NPV was 80.4%(R1)/82.9(R2). These measures of accuracy were not significantly different between different subtypes defined as: ERPR+HER2-(n=99), ERPR+HER2+(n=61), ERPR+HER2equiv (n=1), ERPR-HER2+(n=44) and ERPR-HER2- (n=75).

CONCLUSION

CIR defined as no residual enhancement in the tumor bed on post-NAC breast MRI is not sensitive in diagnosing a pCR. Residual enhancement can be seen with a pCR and a better definition of what constitutes a CIR is needed; our results suggest that it should include some degree of low-level tumor bed enhancement.

CLINICAL RELEVANCE/APPLICATION

Complete imaging response defined as no residual enhancement in the tumor bed is not an accurate assessment of pathologic complete response, which radiologists need to be aware of as management decisions based upon post-NAC MRI interpretation can impact the decision to perform breast conservation versus mastectomy.

SSJ01-03 Predicting Axillary Response to Neoadjuvant Chemotherapy Using Breast MRI and US Based Model in Patients with Clinically Node-Positive Breast Cancer

Tuesday, Nov. 27 3:20PM - 3:30PM Room: E450A

PURPOSE

The axillary LN pathologic complete response (pCR) is increasingly common after neoadjuvant chemotherapy (NAC) in breast cancer patients, for whom axillary LN dissection may be spared. The aim of our study was to develop a clinical model including MRI and US to better predict axillary pCR after NAC in clinically node-positive breast cancer patients.

METHOD AND MATERIALS

An IRB-approved retrospective review was performed for 172 consecutive clinically node-positive breast cancer patients who were treated with NAC and following surgery at our institution from 2016 to 2017. All the patients underwent breast MRI and US, before and after completion of NAC to evaluate the primary tumor extent and axillary LN status. The multivariate logistic regression analysis determined independent predictors of axillary pCR. With combination of those variables we developed a predictive model to increase axillary pCR rate.

RESULTS

Among 172 patients the overall axillary pCR rate was 59%, with 75% (46/61) and 42% (30/71) in cN1 and cN2 patients, respectively. Pretreatment characteristics of clinical N stage, axillary lymphadenopathy and tumor subtype were correlated with axillary pCR (all, $p<0.05$). Post-NAC imaging features including mean tumor size, the size change rate on MRI and the axillary LN cortical thickness on US were predictors of axillary pCR (all, $p<0.05$). From the multivariate logistic regression analysis, independent variables were clinical N stage, tumor subtype, tumor size change rate on MRI and axillary lymphadenopathy on post-NAC US, with an AUC of 0.884 (all, $p<0.05$). The axillary pCR rate of cN1 and non-luminal A model was 88% (38/43) and addition of absent axillary lymphadenopathy improved pCR rate to 94% (33/35). In cN2 patients, the axillary pCR rate of non-luminal A and no axillary lymphadenopathy model increased from 70% (24/34) to 91% (10/11) with additional condition of more than 80% size decrease on MRI.

CONCLUSION

Clinical N stage, tumor subtype and MRI/US findings were predictors of axillary LN pCR. Our predictive model including clinico-pathologic features and image findings could achieve high axillary pCR rate, which may guide LN dissection planning after NAC in clinically node-positive breast cancer patients.

CLINICAL RELEVANCE/APPLICATION

Our imaging based predictive model can improve risk stratification which may avoid unnecessary axillary LN dissection in clinically node-positive breast cancer patients after NAC.

SSJ01-04 Texture Analysis of Lymph Node MRI Characteristics Improves Prediction of Progression-Free Survival Following Chemotherapy in Breast Cancer

PURPOSE

Pathological complete response and reduction in lesion volume (LV) after chemotherapy do not guarantee progression-free survival (PFS). About 1/3 of patients with pathological complete response had relapse at 5 years in our cohort. Breast cancer metastasizes through the lymphatic system. Axillary lymph node (LN) is clinically evaluated by palpation and using ultrasound. This study investigated the efficacy the texture analysis of the LN MRI in predicting PFS.

METHOD AND MATERIALS

Data were obtained from I-SPY 1 trial of breast cancer patients undergoing chemotherapy. We extracted 48 textures for pre- (T1), early- (T2), during (T3) and post-chemo (T4) time points for a subset of patients (N=41) in whom LN MRI were usable. Area under the receiver-operating curve (AUC) was calculated, with PFS at 5-year as a reference variable. Multivariable generalized linear modeling was used to estimate model fit and assign a risk score at each time point based on top-ranking features.

RESULTS

For early (T1) in treatment, LV along with LN histogram skewness and grey-level run length matrix long-run emphasis were top predictors of PFS (AUC=0.68). LV became less predictive in later time points. LN features surpassed LV in post-chemo (T4) time point; the top features were neighborhood grey-level matrix coarseness and grey-level zone length matrix zone length non-uniformity. When changes in texture features over time were analyzed, LN features outperformed LV. Top early (T2-T1) predictors were change in compacity, gray-level non-uniformity, and volume of the LN. Top late (T4-T1) predictors were change in zone length non-uniformity and coarseness. The combination of risk scores across all time points resulted in a model with an AUC of 0.89 (sensitivity:91%, specificity:95%, p= 0.004).

CONCLUSION

Texture analysis of lymph node MRI improves prediction of PFS. The multivariable risk prediction model identified key characteristics and could provide strong predictors of relapse.

CLINICAL RELEVANCE/APPLICATION

Texture analysis of axillary lymph node MRI has the potential to accurately predict 5-year progression free survival.

SSJ01-05 Breast 3D Magnetic Resonance Fingerprinting Relaxometry: Utility in Measuring Early Response to Neo-Adjuvant Chemotherapy in Breast Cancer

drananyapanda@gmail.com

PURPOSE

To assess (1) Repeatability of breast 3D MRF-based relaxometry and (2) preliminarily assess utility in measuring early response to neo-adjuvant chemotherapy in breast cancer

METHOD AND MATERIALS

In this IRB approved pilot study,12 healthy pre-menopausal volunteers were scanned with 3D MRF twice within 7-15 days for repeatability analysis.In 5 volunteers,same-day test-retest scans were also performed with repositioning after a 10-minute scan interval.For breast cancer evaluation,13 women with biopsy-proven invasive ductal carcinoma underwent baseline 3D MRF scans before chemotherapy.So far,7 women have undergone repeat 3D MRF 7-10 days after first cycle of chemotherapy.All scans were performed at 3T(Siemens Verio) using 8-channel breast coil.A 3D FISP-based MRF sequence with fat suppression was used.Overall acquisition time was 5.5min.For repeatability analysis,ROIs were drawn on a 3D MRF partition containing the largest area of normal breast tissue by one radiologist(8 years radiology experience) in both breasts.In breast cancer patients,ROIs were drawn on partitions showing tumor and the opposite normal breast.Mean T1 & T2 were estimated for all scans.Treatment response was based on either final pathology staging after surgery or RECIST criteria and T1 & T2 changes were compared in responders & non-responders

RESULTS

Same-visit test-retest within-subject coefficient of variation(wCV) was <5% for T1 and <6.5% for T2.Two-visit wCV was <6% for T1 and <5% for T2,establishing a measurable effect size.In breast cancer,tumor T1 & T2 were longer than normal breast(mean±SD,Tumor T1:1175±203 ms,Normal T1:846±388 ms,Tumor T2:72±13 ms,Normal T2:48±12 ms,p=0.030 for T1,p<0.001 for T2).After one cycle of chemotherapy,responders(n=4) showed greater decrease in T1 & T2(p=0.026 for T1,p=0.033 for T2) while patients with stable/progressive disease(n=3) showed negligible changes in T1 & T2

CONCLUSION

Breast 3D MRF relaxometry was shown to be repeatable.Baseline tumor T1 & T2 were longer than normal breast.Treatment responders showed larger change in T1 & T2 compared to non-responders.These preliminary results suggest that breast 3D MRF may be useful in quantitatively predicting early response to chemotherapy

CLINICAL RELEVANCE/APPLICATION

Breast 3D MRF relaxometry is a repeatable technique for longitudinal studies in patients.Significant decrease in tumor T1 and T2 after one cycle of chemotherapy may predict treatment response

SSJ01-06 Are the Baseline Imaging Characteristics of Breast Cancer Associated With Reponses to Neoadjuvant Chemotherapy?

a.z.evans@dundee.ac.uk

PURPOSE

Predictors of response to neoadjuvant chemotherapy (NACT) within subgroups are poor and not commonly used. We aimed to establish if baseline mammographic (MGM) and ultrasound (US) features of breast cancer and breast cancer subtypes are associated with rates of pathological complete response (pCR) after NACT.

METHOD AND MATERIALS

The baseline imaging of 210 consecutive women who underwent NACT were reviewed by an experienced breast radiologist blinded to outcomes. The MGM features assessed were the presence or absence of spiculation and calcification. The US features documented were echogenicity, distal effect, the presence of a circumscribed border and the US lesion size. The relationships between baseline imaging features and pCR after NACT were documented. The findings according to sub-group (HER2+ve, triple negative and ER+ve HER2-ve) were also assessed. The significance of differences were analysed using the chi-square test and ROC curves.

RESULTS

Of the 210 patients, 46(22%) had a pCR while 164 did not. The cohort consisted of women with 82 triple negative (21 pCR's), 75 HER2+ve (21 pCR's) and 53 ER+ve HER2-ve (4 pCR's) cancers. For the complete cohort the features significantly associated with pCR were the absence of MGM spiculation (4 of 58 (7%) vs. 42 of 151(28%), p=0.001), the absence of distal shadowing on US (8 of 73(11%) vs. 38 of 136(28%), p=0.015) and small US size (AUC 0.62, P=0.02). In HER2+ve patients all the above associations were confirmed and in addition the presence of a circumscribed border on US was associated with high pCR rates (7 of 14(50%) vs. 14 of 60(23%), p=0.04). None of the above associations held true for triple negative cancers. The number of pCR's in the ER+HER2-ve group was to small to allow analysis.

CONCLUSION

The baseline imaging features of HER2+ve breast cancer are strongly associated with the chance of achieving a pCR following NACT. This is not so for triple negative cancers.

CLINICAL RELEVANCE/APPLICATION

This data could be helpful when discussing NACT and associated surgery with patients who have HER+ve breast cancer.

s.savaridas@nhs.net

PURPOSE

To determine if baseline mammographic and ultrasound features in patients receiving neoadjuvant chemotherapy (NACT) are associated with metastasis free survival (MFS).

METHOD AND MATERIALS

Informed consent for the study was obtained from consecutive women receiving NACT. All participants were metastasis free at diagnosis. Baseline images were retrospectively reviewed by a breast radiologist blinded to outcomes. Ultrasound (US) features documented included echo pattern, posterior effect, circumscribed margins, skin changes (invasion or thickening), lesion size and shear wave stiffness (mean). Mammogram (MMG) features documented were the presence or absence of spiculation and microcalcification. Tumour immunophenotype was assessed on core biopsy. Statistical significance was assessed using chi-square and ROC analysis.

RESULTS

134 breast patients were included; 52 had triple negative cancer, 48 were HER2+ve and 34 had ER+ve, HER2-ve disease. During the follow-up period (mean 4.3yrs) 41 women (31%) developed metastases. Across the whole cohort, skin involvement on baseline US was the only feature associated with metastasis development. MFS was 56% (23/41) vs 75% (70/93) for those with and without skin involvement respectively, p=0.03. US lesion size was not associated with MFS.In the HER2 positive subgroup mammographic calcification was associated with poorer MFS (12/24 (50%) vs 20/23 (87%), p=0.006). The presence of posterior shadowing on US was also associated with poorer MFS (11/22 (50%) vs 21/26 (81%), p=0.02) in this subgroup.No baseline imaging features were shown to be associated with MFS for triple negative and ER+ve HER-ve cancers.

CONCLUSION

We have demonstrated that baseline imaging characteristics are associated with MFS in patients treated with NACT particularly in the HER2 +ve subgroup. This prognostic information, which is available prior to treatment could aid patient treatment selection and counselling.

CLINICAL RELEVANCE/APPLICATION

Baseline imaging characteristics are associated with MFS in patients treated with NACT. This prognostic information, available prior to treatment, may aid patient treatment selection and counselling.

SSJ02-02 Combination of Different Types of Elastography in Downgrading Ultrasound Breast Imaging-Reporting and Data System Category 4a Breast Lesions

Tuesday, Nov. 27 3:10PM - 3:20PM Room: E353C

zhengxy1@sysucc.org.cn

PURPOSE

When using single type of elastography to downgrade ultrasound (US) Breast Imaging-Reporting and Data System (BI-RADS) category 4a lesions, some cancers would be missed. This study purposed to determine whether combination of different types of elastography could improve the accuracy of elastography aided downgrading BI-RADS category 4a lesions and reduce unnecessary biopsies.

METHOD AND MATERIALS

For this prospective institutional review board-approved study, verbal informed consent was obtained from all patients. From January 2016 to February 2018, 329 consecutive women with 347 US BI-RADS category 4a breast lesions were enrolled in the study. These lesions, prior to biopsy, were subject to conventional US supplemented by elastography assessments, including strain elastography of elasticity imaging (EI), virtual touch tissue imaging (VTI) and Virtual Touch IQ (VTIQ). The diagnostic performances were calculated for BI-RADS category, EI, VTI and VTIQ, and the combination among EI, VTI and VTIQ (combined EI and VTI [EI+VTI], combined EI and VTIQ [EI+VTIQ] and combined VTI and VTIQ [VTI+VTIQ]).

RESULTS

Pathologically, 313 lesions (90.2%) were benign and 34 (9.8%) were malignant. The cut-off values were EI score>3, VTI score>3 and shear wave speed (SWS) on VTIQ>3.29 m/s, respectively. For EI, VTI and VTIQ alone, the specificity were significantly higher than that of BI-RADS (P <0.001), while the sensitivity were significantly lower than that of BI-RADS (76.5%, 70.6%, 67.6% vs. 100%, respectively, P <0.05). Among the combinations of different types of elastography, EI+VTI yielded the highest AUROC of 0.800 and negative predictive value of 99.5%. The sensitivity of EI+VTI was significantly increased as compared with single type elastography (P <0.05). There was no significant difference in the sensitivity between EI+VTI and BI-RADS (97.1% vs 100%, P =1.000) while the specificity was significantly higher than that of BI-RADS (P <0.001). When using EI+VTI to downgrade the lesions, 57.1% of the lesions would be downgraded and 99.5% of these lesions were benign.

CONCLUSION

Combinations of EI and VTI to downgrade BI-RADS category 4a lesions increased the sensitivity and reduced the misdiagnosis of breast cancers.

CLINICAL RELEVANCE/APPLICATION

Combination of different types of elastography provides a high sensitive way to downgrade BI-RADS category 4a lesions, potentially applied in clinical practice without increasing misdiagnosed cancers.

SSJ02-03 Correlation Between Apparent Diffusion Coefficient Values and Ultrasound Elasticity kPa Values in Breast Cancers

seonhyeong.choi@samsung.com

PURPOSE

DWI reflects tumor cellularity and integrity of cell membranes. Breast ultrasound elastography is a method of imaging tissue stiffness and the shear-wave elastography (SWE) allows measurement of the propagation speed of shear waves within the tissue to locally quantify its stiffness in kilopascals (kPa) or meters per second (m/sec). This study was performed to evaluate the correlation between breast apparent diffusion coefficient (ADC) values and ultrasound Shear wave elastography kPa values in biopsy proven breast cancers.

METHOD AND MATERIALS

From January 2016 to November 2017, 121 patients who have breast cancer confirmed by US-guided biopsy underwent both pre-operative breast diffusion MRI and breast SWE. Among these patients we included only who underwent examination by same operator to reduce inter-operator variability. Finally, this study included 94 breast cancer patients. The investigated factors included the ADC values, mean kPa values (Emean), maximum kPa values (Emax), pathology, size of tumor, associated calcifications, ER/PR/HER2 status, molecular subtypes, Ki-67 index, mammographic density and BI-RADS US assessment category. The results were analyzed using the statistical software SPSS for Windows (version 24). The correlation analysis was used to study correlation between ADC values, Emean/Emax, size and Ki-67. And independent samples of t-test and ANOVA including post hoc test were performed to evaluate for the above variables.

RESULTS

There was no correlation between ADC values and Emean (p=0.791)/Emax (p=0.634)[Fig1]. However, Emean (p=0.001), Emax (p<0.001), and Ki-67 index value (p=0.010) were significantly correlated with the size of tumor. High Ki-67 index group showed statistically significant lower ADC values (p=0.034) and higher Emean (p=0.064)/Emax value (p=0.065) without statistical insignificance. The Emean (p=0.002)/Emax (p=0.001) were correlation with T stage but ADC (p=0.813) was not. Howevre, the

Eman (p=0.000)/Emax (p=0.000) and ADC (p=0.017) were also correlated with US BIRADS categories.

CONCLUSION

The ADC values and Emean/Emax in breast cancers were nor correlated each other. However, the size of tumor, Ki67 index, BI-RADS assessment category affected the ADC and Emean/Emax values independently.

CLINICAL RELEVANCE/APPLICATION

The size of breast cancer, Ki67 index, BI-RADS assessment category affected the ADC and Emean/Emax values independently.

SSJ02-04 Breast Cancer Staging: Combined Digital Breast Tomosynthesis and Automated Breast Ultrasound versus Magnetic Resonance Imaging

Tuesday, Nov. 27 3:30PM - 3:40PM Room: E353C

Participants
Rossano Girometti, MD, Udine, Italy (*Presenter*) Nothing to Disclose
Ludmila Tomkova, MD, Udine, Italy (*Abstract Co-Author*) Nothing to Disclose

rgirometti@sirm.org

PURPOSE

To investigate whether combined Digital breast tomosynthesis and Automated breast volume scanner (DBT-ABVS) are comparable to Magnetic resonance imaging (MRI) in staging breast cancer.

METHOD AND MATERIALS

We retrospectively included seventy-three patients with histologically proven breast cancer who underwent preoperative DBT, ABVS and 1.5T MRI in the period July 2015-July 2016. Two radiologists in consensus recorded the number, site and BI-RADS category of breast findings during two independent reading strategies, i.e. DBT-ABVS vs. MRI. Using histology or 1-year follow up as the standard of reference, we calculated the accuracy for cancer of both imaging strategies. Bland-Altman analysis was used to evaluate the agreement between MRI vs. DBT or ABVS in cancer size assessment.

RESULTS

Patients showed a total of 160 lesions (108 malignant and 52 benign). Malignant lesions were monofocal, multifocal, multicentric and biltateral in 53, 15, 4 and 1 cases, respectively. Diagnostic accuracy of DBT-ABVS vs. MRI was comparable for all cancers (90.0% vs. 93.8%, respectively), though DBT-ABVS showed lower sensitivity and positive predictive values for additional disease (76.5% vs. 91.7%, and 78.8% vs 93.4%, respectively). Compared to MRI, ABVS+DBT missed 6 lesions, including two invasive cancers and one extensive intravascular invasion associated to ductal carcinoma in situ. Bland-Altman analysis showed ABVS to agree with MRI at a higher extent than DBT in assessing cancer size.

CONCLUSION

DBT-ABVS is less accurate than MRI in staging additional disease.

CLINICAL RELEVANCE/APPLICATION

Though less performing than MRI, DBT-ABVS showed acceptable diagnostic accuracy in staging breast cancer. This strategy might be used if MRI is unavailable or unfeasible.

SSJ02-05 Quantitative Elastic Heterogeneity as a Potential Noninvasive Marker of Lymphovascular Invasion in Breast Cancer

Tuesday, Nov. 27 3:40PM - 3:50PM Room: E353C

PURPOSE

To evaluate the association between quantitative elastic heterogeneity (EH) and lymphovascular invasion (LVI) in breast cancers.

METHOD AND MATERIALS

This retrospective study consisted of 97 patients with breast cancers that had undergone shear wave elastography (SWE) with virtual touch tissue imaging quantification (VTIQ) between August 2015 and August 2017. Three region of interests (ROIs) were placed over the highest stiffness and the lowest stiffness areas of each lesion to measure shear wave velocity (SWV) and EH was determined as the difference between the averaged highest SWV and lowest SWV. Classical prognostic factors including lesion size,

histopathological type and grade, subtype [luminal A, luminal B (HER2-), luminal B (HER2+), HER2 enriched and basal-like], and axillary lymph node (LN) status were reviewed and their correlation with EH values were stratified by the presence or absence of LVI. The diagnostic performance of EH in distinguishing LVI or not were analyzed in lesions smaller than 2 cm.

RESULTS

Tumors with LVI showed significantly higher EH values when compared to tumors without LVI (adjusted $P < 0.001$), regardless of the tumor size, histological grade and type, and LN status. Lymphovascular invasion (adjusted $P < 0.001$), large tumor size (adjusted $P = 0.011$) and lymph node involvement (adjusted $P = 0.046$) showed statistically positive association with high EH values. In breast cancers smaller than 2 cm, tumors with LVI (4.31±1.16 m/s) showed significantly higher EH values when compared to tumors without LVI (2.99±1.18 m/s) (adjusted $P < 0.001$). Using EH higher than 3.66 m/s to suggest LVI, the area under the receiver operating characteristic curve was 0.796, and the sensitivity, specificity, positive predictive value and negative predictive value were 78 % (14/18), 75 % (39/52), 52 % (14/27) and 91 % (39/43), respectively.

CONCLUSION

EH could be served as a potential marker to assess LVI status on preoperative imaging, especially for breast cancer less than 2 cm in size.

CLINICAL RELEVANCE/APPLICATION

Quantitative elastic heterogeneity of breast cancer can be used as a non-invasive marker for preoperative evaluation of LVI, thereby guiding clinical regulation and predicting prognosis.

SSJ02-06 Multiparametric Quantitative Ultrasound of the Breast Can Improve the Diagnostic Performance of the Radiologist

PURPOSE

To evaluate quantitative multiparametric ultrasound (mpUS) of the breast using B-mode US, elastography, Doppler and contrast enhanced US (CEUS) in different combinations of 2, 3 or 4 parameters for the differentiation of benign and malignant lesions and investigate a possible variation according to the degree of experience of the examiner.

METHOD AND MATERIALS

124 patients, each with one biopsy-proven, sonographically evident breast lesion were included in this prospective, IRB-approved study. Each lesion was examined with B-mode US, elastography (Virtual Touch IQ-VTIQ), Doppler US and CEUS. Different quantitative parameters were recorded for each modality: Shear Wave Velocity (SWV) for VTIQ, Pulsatility (PI) and Resistive Index (RI) for Doppler US. For CEUS, 11 different parameters were calculated using a dedicated software. 4 readers (2 experienced breast radiologists and 2 radiology residents) independently evaluated B-mode images of each lesion and assigned a BI-RADS score to it. Using ROC curve analysis, the quantitative parameter with the best diagnostic performance for each modality was chosen and cut-off values were calculated. Using these, all quantitative results were dichotomized. The BI-RADS scores of all readers were then combined with the quantitative parameters. Descriptive statistics were used to evaluate the diagnostic performance of mpUS. Histology served as the reference standard.

RESULTS

59 lesions were benign and 65 malignant. SWV, RI and mean transit time showed the highest diagnostic performance. MpUS with three parameters (B-mode, VTIQ and CEUS) showed the highest diagnostic performance irrespective of the experience level of the readers (averaged AUC 0.812 vs. 0.683 for B-mode US, p-value 0.0001), while the combination of B mode, VTIQ and Doppler US the second best (averaged AUC 0.789, p-value 0.0001). All other combinations (with 2, 3 or 4 parameters) showed a lower AUC. MpUS with B-mode, VTIQ and CEUS was able to significantly reduce the number of false positive biopsy recommendations ($p<0.0001$).

CONCLUSION

Quantitative breast mpUS with three parameters (B-mode US, VTIQ elastography and CEUS) significantly improves the diagnostic performance of B-mode US alone, irrespective of the experience level of the examiner.

CLINICAL RELEVANCE/APPLICATION

MpUS of the breast offers quantitative parameters that may be used as imaging biomarkers for the differentiation of benign from malignant breast lesions.

PURPOSE

Diffuse myocardial fibrosis is associated with chronic heart diseases, including aortic stenosis, and may be quantified using cardiac CT or MRI calculation of extracellular volume fraction (ECV). This study compared a dual-energy CT approach using an iodine map from a single phase to calculate ECV to the standard multiphase technique to calculate ECV.

METHOD AND MATERIALS

61 patients with aortic stenosis (35 male, 26 female; average age = 81 years) undergoing preoperative CT for transcatheter aortic valve replacement (TAVR) were scanned on a Force (Siemens Inc.) using dual energy mode prior to (non-contrast phase) and 10 minutes following (delayed phase) administration of 120-150 cc of iodinated contrast. Matched 1cm² regions of interest were selected in the interventricular septum and ventricular blood pool in each phase. The ROI densities obtained from blended virtual 120 kV images in each phase were used to compute the ECV (standard technique), while the dual energy data from the delayed phase only was used to calculate ECV using iodine map technique. Bias between ECV computation methods was visualized using Bland-Altman plot. Linear regression with Pearson technique was also performed.

RESULTS

The mean ECV calculated using standard method was 28%, while mean ECV measured using the iodine map method was 30%; for a mean bias of +2% [95% CI, -5% to +9%]. The Pearson correlation coefficient between the two ECV measurements was $R^2 = 0.48$.

CONCLUSION

There was good correlation between ECV measured by standard multiphase technique and ECV measured by dual energy technique using iodine maps created from the delayed phase alone. The dual energy technique trended towards mild overestimation of fibrosis, possibly attributable to beam hardening, however this difference was not significant.

CLINICAL RELEVANCE/APPLICATION

Prior studies using histopathology and cardiac MRI have shown that the greater degree of myocardial fibrosis can predict worse outcomes after surgery. ECV is an accepted way to measure myocardial fibrosis. This study demonstrates a dual energy method that simplifies ECV measurement and reduces radiation dose without significant difference relative to standard measurement of ECV.

PURPOSE

Purpose of this study was to analyse the occurrence of myocardial oedema in triathletes after sporting events using T2 and T1 mapping.

METHOD AND MATERIALS

29 competitive asymptomatic triathletes (45 ±10 years) underwent a CMR study performed on a 1.5T Achieva (Philips) before (baseline) and after a sporting event (follow-up). CMR protocol included SSFP cine, T2w-GraSE and T1, T2 mapping using MOLLI 5(3)3 sequence. Additionally, LGE Imaging was performed in the CMR baseline study. T1 and T2 quantification was performed using the OsiriX Software.

RESULTS

CMR performed before the sporting event revealed a normal global T1 time (with 989 ±28ms) of the left ventricular (LV) myocardium. There was no significant change in the global T1 time after the sporting event (988 ±21ms; p=0.926). Furthermore, T2 time was in the normal range before the sporting event (54 ±3ms) without relevant change after the sporting event (53 ±3ms, p=0.797). In 10 of the 29 Triathletes (34%) a focal myocardial fibrosis with a non-ischemic pattern was detected (LGE+ triathletes). Likewise, in the subgroups (LGE+ und LGE-) no significant changes in T1, T2 times before and after the sporting event were detected.

CONCLUSION

In contrast to the previously published T2 STIR data our results using T1, T2 mapping have not revealed any myocardial oedema after sporting events. Exercise-induced myocardial oedema previously detected using T2 STIR sequences might be falsely interpreted due to signal inhomogeneities.

CLINICAL RELEVANCE/APPLICATION

No myocardial oedema indicating acute myocardial injury was detected using mapping methods after sporting events, suggesting that competitive endurance events are safe.

SSJ03-03 Focal and Interstitial Fibrosis in Highly Trained Endurance Athletes

PURPOSE

There is evolving evidence that cumulative effects of intensive endurance exercise may induce a broad spectrum of right ventricular (RV) adaptation/remodelling patterns. Thus, our aim was to assess the prevalence of myocardial fibrosis (MF), focal and interstitial, in the myocardium and its relationship with cardiac remodelling/adaptation, among a cohort of highly trained endurance athletes as compared to control subjects.

METHOD AND MATERIALS

93 highly trained endurance athletes (>12 hours training/week at least during the last 5 years; age: 36 ± 6 years; 52.7% male) and 72 age and gender-matched controls underwent a resting cardiac magnetic resonance to assess biatrial and biventricular dimensions and function. The presence of focal MF was assessed by late gadolinium enhancement (LGE). In a subgroup of 28 athletes, T1 mapping sequence was added and extracellular volume (ECV) measurements were performed in remote myocardium to asses interstitial MF.

RESULTS

High endurance training load was associated with larger bi-ventricular and bi-atrial sizes, mildly reduced systolic ventricular function, as compared to controls in both genders ($p < 0,05$). LGE was significantly more prevalent in athletes (n=35, 37.6% vs 2.8%; $p < 0,001$), with a constant pattern in the RV insertion points (Figure 1). Among men population, those athletes with LGE tended to have trained for more hours per week (14.55±3.6 vs 12.21±3.4, $P = 0.07$). In T1 mapping sequences, abnormal ECV values (>28%) were only found in 2 of 28 subjects. Those athletes who had focal fibrosis had higher ECV at remote myocardium than those without LGE (27,3±1,8 vs 25,1±2,2; $P = 0,01$).

CONCLUSION

Highly trained endurance athletes showed ten times higher prevalence of LGE than control subjects; always confined to the hinge point. Although this pattern of LGE may be another feature of the athlete's heart, our results suggest that those with focal fibrosis might have globally higher myocardial ECV values. Its clinical impact is currently uncertain, and it still warrants further investigation.

CLINICAL RELEVANCE/APPLICATION

Myocardial fibrosis, which is a predictive factor for adverse cardiac outcome, has been also described in some endurance athletes and its clinical meaning remains controversial.

SSJ03-04 Evaluation of a Shortened Cardiac MRI Protocol of Left Ventricular Examinations: Diagnostic Performance of T1-Mapping and Myocardial Function Analysis as a Screening Method

PURPOSE

In this study we sought to retrospective evaluate whether a very brief CMR protocol comprising only left ventricular(LV) function analysis and T1 mapping sufficiently distinguishes patients with relevant myocardial changes with need for further examination from healthy patients.

METHOD AND MATERIALS

From October 2015 until October 2017 all patients with clinical indication for CMR for any myocardial characterisation (n = 160) were included. The scanner was a Philips Ingina 3T. The full CMR protocol comprised sBTFE Cine-Imaging, T1 and T2 mapping, T2w Dark-Blood as well as Early- and Late-Gadolinium-Enhancement. Patients were categorized into two groups depending on presence of LV dysfunction. ROC-analysis was done for results of T1-, T2- mapping and extracellular volume(ECV) in patients without LV dysfunction. Reference was depicted pathology in the conventional CMR techniques and report.

RESULTS

In the patient's cohort without LV dysfunction (n = 78 [49%]) ROC for T1 mapping was 81% with $p < 0.001$, 65 % for T2 mapping with $p= 0.4$ and 82% for ECV with $p < 0.001$. T1 mapping was superior to T2 mapping by trend; $p = 0.057$. ECV was significantly superior to T1 mapping, $p = 0.026$. For maximum T1 relaxation times of 1300ms sensitivity was 83 % and specificity was 55%; the negative predictive value was 91%. In patients with no LV dysfunction 31 (40%) patients did not exceed a maximum T1 of 1300ms; out of those none had significant myocardial alterations but 3 patients were diagnosed with chronic myocarditis. In general, out of the daily routine study population 111 (70%) patients had a pathological finding and in 49 cases (30%) CMR did not provide additional information. In that group T1 mapping detected 57% of the patients who would not benefit from additional CMR.

CONCLUSION

A shortened CMR protocol comprising T1 mapping and LV-function analysis seems to rule out clinically relevant myocardial alterations. However, 3 cases of chronic myocarditis with normal LV-function were overlooked; yet therapeutic consequences remain uncertain in this entity. These results need to be prospectively confirmed in a lager study to increase confidence in this shortened protocol in clinical use.

CLINICAL RELEVANCE/APPLICATION

The proposed protocol might allow for an improvement of efficiency of CMR examinations in the future.

SSJ03-05 Ferumoxytol-Enhanced MRI for Intramyocardial Blood Volume Mapping: Early Pre-Clinical Results

PURPOSE

Myocardial perfusion is important for organ vitality. The intramyocardial blood volume (MBV) represents the fractional blood volume of the intravascular space within a unit volume of myocardial tissue. Because ferumoxytol has high r1 relaxivity and a long intravascular half-life, we hypothesize that ferumoxytol-enhanced (FE) MRI may enable mapping of the MBV. We aim to evaluate the vasodilator-induced variation in myocardial T1 signal in normal swine.

METHOD AND MATERIALS

In this ARC-approved study, four healthy Yorkshire swine (33-52 kg) underwent FE-MRI at 3.0T under general anesthesia. We acquired myocardial T1 maps using 5-(3)-3-(3)-3 MOLLI and FLASH-MOLLI pre- and post-ferumoxytol infusion (4mg/kg). We induced coronary vasodilation with 4-minute cycles of adenosine infusion (200-400 mcg/kg/min). Using in-house T1 fitting algorithms, we generated myocardial T1 maps and derived T1 values from regions of interest drawn in the mid interventricular septum of short axis FE T1 maps.

RESULTS

No adverse events occurred and vital signs were stable throughout the adenosine infusion and FE-MRI exam. Myocardial T1 signal differential between pre- and post-ferumoxytol was -48.5%±6.4%. The adenosine-induced native T1 response as reflected by the slope between baseline and peak adenosine was less robust when compared to FE T1 response (3.0±0.6ms/min vs -35.3±16.1ms/min, p=0.03). During the two adenosine-on cycles post-ferumoxytol, the FE T1 values steadily shortened due to adenosine-induced vasodilation and increasing MBV. During adenosine-off cycles, FE T1 values increased towards values at rest. For adenosine 200-300 mcg/kg/min, the FE T1 shortened (decreased) 10.2±5.4% from baseline. For 400 mcg/kg/min dose, the FE T1 shortened >15% (swine #4). Of note, the increase in native T1 from baseline to peak adenosine was 0.7±0.2%.

CONCLUSION

Ferumoxytol, as a potent intravascular contrast agent, sensitizes the T1 signal to changes in the MBV and substantially amplifies the intramyocardial vascular T1 estimate. Additional work in models of varying myocardial perfusion is needed to better characterize the T1 response in normal vs pathologic states.

CLINICAL RELEVANCE/APPLICATION

Vasodilator-induced changes in ferumoxytol-enhanced myocardial T1 reflect dynamic changes in the intravascular myocardial compartment and has implications for a panoply of myocardial disease states.

SSJ03-06 Simultaneous 18F-FDG PET/MR Study for Assessment of Different Stages of Cardiac Impairment in Patients with Anderson-Fabry Disease

PURPOSE

We evaluated the relationship between T1 mapping and 18F-FDG PET by cardiac PET/MR imaging in AFD female patients.

METHOD AND MATERIALS

Seventeen AFD female patients with normal left ventricular (LV) function underwent simultaneous cardiac PET/MR (Biograph mMR; Siemens Healthcare, Erlangen, Germany) imaging after administration of 18F-FDG and gadolinium-DPTA for assessment of late gadolinium enhancement (LGE). In all patients and in 7 female controls T1 mapping was performed using pre-contrast T1 Modified Look-Locker Inversion-recovery prototype sequence. Mean T1 values were measured by drawing 6-pixel regions of interest in the septal and lateral segments of LV apical, mid-ventricular and basal short-axis slices. Cardiac FDG uptake was quantified by

measuring the standardized uptake value in 17 myocardial segments in each subject. The coefficient of variation (COV, i.e. the standard deviation divided by the average) of the uptake of the 17 segments was calculated as an index of heterogeneity in the heart and values >0.17 were considered abnormal.

RESULTS

Five patients showed focal LGE indicating intra-myocardial fibrosis and were excluded from the final analysis. Compared with controls, mean T1 values of AFD female patients were significantly lower (1238±51.1 vs. 1334.32±26.6, $p<0.001$). At PET, 7 out of the remaining 12 patients showed abnormal COV values suggesting inflammation pattern and the other 5 demonstrated normal COV values (0.32±0.1 vs. 0.12±0.03, $p<0.005$) with homogeneous FDG uptake. Patients with abnormal COV showed higher mean T1 values of lateral segments of the mid-LV wall (1219.16±23.4 vs. 1154±62.1, $p<0.05$), suggesting a potential relationship between progressive myocyte sphingolipid accumulation and inflammation.

CONCLUSION

This study highlights the role of 18F-FDG PET/MR imaging for early detection of cardiac involvement in AFD patients allowing to identify different stages of disease progression. In particular, pseudo-normalization of T1 mapping values, associated with abnormal COV values, may represent an intermediate "inflammatory" stage before the development of myocardial fibrosis.

CLINICAL RELEVANCE/APPLICATION

Simultaneous cardiac 18F-FDG PET/MR imaging may allow early detection of cardiac involvement in AFD patients identifying different stages of disease progression.

PURPOSE

To examine the pathologic changes in rat models of cardiotoxicity and to determine correlation with quantitative magnetic resonance imaging (MRI) parameters.

METHOD AND MATERIALS

All experiments were approved by our institutional animal care and use committee. Cardiotoxicity models were induced by injecting adult male Sprague-Dawley rats with doxorubicin (1mg/kg, twice a week). Cardiac MRI was performed with a 9.4-T scanner (Bruker Biospin Co., Billerica, MA, USA) using cine, pre- and post-T1 mapping sequences. T1 mapping sequences were performed by using a saturation recovery Look-Locker sequence. Left ventricular ejection fraction (LVEF) was evaluated using cine imaging. Native T1 and extracellular volume (ECV) were measured at the mid ventricle. All rats were sacrificed after MRI. Pathologic changes were graded according to their degree and then scored (0:absent, 1:minimal, 2:mild, 3:moderate, 4:severe) and correlated with MRI parameters (native T1 (ms), ECV (%)) and LVEF(%))

RESULTS

A total of 10 control and 14 cardiotoxicity models were included. Rats were classified into two groups, the early (n=9) and late (n=5) group, by 6 weeks after modeling. In cardiotoxicity models, LVEF decreased (control vs. cardiotoxicity subjects: 74%, 63.2%), native T1 and ECV increased (1,186 ms, 15.5% vs. 1,232.44 ms, 18.68%). The main histologic findings were vacuolar changes, inflammation, interstitial edema, expansion of interstitial space, and fibrosis. In subgroup analysis, myocardial fibrosis, expansion of interstitial space scores were significantly different between the two groups (p=0.007, p=0.002). Other histologic

factors (e.g. vacuolar changes, inflammation, interstitial edema), native T1, ECV, and LVEF were not significantly different between the two groups. ECV was correlated with fibrosis (r=0.632, p=0.015), vacuolar change (r=0.705, p=0.005), and the sum of histologic scores (r=0.694, p=0.006). Native T1 was correlated with myocardial inflammation (r=0.638, p=0.012) and expansion of interstitial space (r=0.656, p=0.011)

CONCLUSION

Prominent changes in MRI parameters and pathologic findings were noted in both early and late cardiotoxicity models, even in subjects with preserved LVEF. ECV and native T1 values showed good correlations with histologic scores.

CLINICAL RELEVANCE/APPLICATION

T1 mapping MRI is a useful quantitative method to detect anthracycline-induced cardiotoxicity.

SSJ04-04 Myocardial Tissue Phase Mapping Detects Cardiac Dysfunction in a Mouse Model of Doxorubicin-Induced Cardiotoxicity

PURPOSE

Cardiotoxicity following chemotherapy is common in cancer patients treated with anthracyclines such as doxorubicin (Dox). Conventional imaging approaches to identify anthracycline associated cardiac dysfunction have targeted reductions in ejection fraction (EF) with newer approaches focusing on detecting alterations in myocardial strain. The purpose of this study was to use myocardial tissue phase mapping (TPM) to study early functional changes in a mouse model of Dox-induced cardiotoxicity.

METHOD AND MATERIALS

16 week old female C57Bl/6 mice (n = 9) were imaged at 7T. 25 mg/kg Dox was administered over 3 weeks in the form of 5 mg/kg subcutaneous pellets (Innovative Research of America, Florida, USA). Mice were imaged at baseline, 6 weeks and 10 weeks post-treatment. MRI protocol included multi-slice cine MRI covering the entire LV, and TPM in a single mid-ventricular short-axis slice. The cine images were analyzed using Segment (Medviso, AB) to calculate EF. TPM was performed using 2D cine phase contrast MRI with prospective ECG and respiratory triggering. Imaging parameters included: image/time resolution = 0.117x0.117x1 mm3x20.8 ms, tri-directional VENC=4 cm/s. TPM images were analyzed in MATLAB to measure global peak radial and longitudinal velocities at systole and diastole. Following imaging at 6 weeks, 4 mice were sacrificed for histopathologic assessment utilizing terminal deoxynucleotidyl transferase (TdT) dUTP nick-end labeling (TUNEL) to detect apoptotic cells.

RESULTS

There were no significant differences in EF (72±11% at baseline, 75±12% at 6 weeks and 63±2% at 10 weeks). Global systolic longitudinal velocity was significantly reduced at 6 weeks (p=0.03) but our power was low to detect significant differences at 10 weeks. Histopathologic results demonstrated minimal apoptosis in all mice, suggesting early-stage cardiotoxicity.

CONCLUSION

Using myocardial TPM, we detected cardiac dysfunction prior to reduction in EF and the onset of cardiomyocyte apoptosis in a mouse model of Dox-induced cardiotoxicity. Future studies comparing this technique with other myocardial tissue and functional characterization may demonstrate a role for TPM as an early biomarker of cardiotoxicity.

CLINICAL RELEVANCE/APPLICATION

In the present study, we demonstrated that longitudinal systolic velocity quantified using myocardial tissue phase mapping may represent an early imaging biomarker for doxorubicin-induced cardiotoxicity.

SSJ04-05 68Ga-Galmydar: A PET Imaging Tracer for Noninvasive Detection of Doxorubicin-Induced Cardiotoxicity

Tuesday, Nov. 27 3:40PM - 3:50PM Room: E260

PURPOSE

Doxorubicin (DOX; Adriamycin), an anthracycline analogue is widely used chemotherapeutic drug in cancer. DOX treatments are susceptible to acute and chronic cardiac anomalies, including aberrant arrhythmias, ventricular dysfunction, and heart failure. PET tracers could also provide noninvasive assessment of early and reversible metabolic changes of the myocardium. Herein, we report a preliminary investigation of 68Ga-Galmydar potential to monitor DOX-induced cardiomyopathy in vivo, ex vivo, and in cellulo employing both nuclear- and optical imaging.

METHOD AND MATERIALS

Galmydar was obtained through a ligand exchange reaction. 68Ga-Galmydar was purified on C-18 column using radio-HPLC. MicroPET imaging was performed 5 d post treatment of rats either with a single dose of DOX (15 mg/kg) or vehicle as a control (saline). For correlation of PET imaging data, post-imaging quantitative biodistribution studies were also performed. In cellulo (H9c2) dose and time dependent doxorubicin treatments were also studied using live cell optical imaging.

RESULTS

68Ga-Galmydar, micro-PET static scan (10 min acquisition; 60 min post tail-vein administration) demonstrated 1.91-fold lower uptake in hearts of DOX-treated (Standard Uptake Value; SUV: 0.92, n=3) rats compared with their vehicle treated (SUV: 1.76, n = 3) counterparts. The post imaging pharmacokinetic data demonstrated heart uptake values of 2.02 fold lower for DOX treated rats compared to control counterparts (%ID/g; DOX: 0.44 ± 0.1, n=3; Control: 0.89 ± 0.03, n=3) thus correlating well with micro-PET imaging data. Employing moderate fluorescent traits of Galmydar, live cell optical imaging indicated a gradual decrease in uptake and retention of Galmydar within mitochondria of H9c2 cells following DOX-treatment, while indicating also dose-dependent pharmacological response and time-dependent uptake profiles. Furthermore, the decreased uptake in H9c2 cells also correlated with caspase-3 expression resulting from DOX-induced cardiotoxicity and cell death. Combined data indicate that 68Ga-Galmydar could provide a sensitive and specific readout of DOX-induced cytotoxicity attributed to depolarization of mitochondrial potential in heart cells.

CONCLUSION

68Ga-Galmydar could provide a noninvasive assessment of DOX-related early and likely reversible metabolic changes that remains to be evaluated clinically.

PURPOSE

The differentiation of benign pulmonary lesions from malignant pulmonary lesions is very difficult. High resolution CT is the most commonly used radiology methods for lung. While it is limited to children, child-bearing women and disorders requiring repeated examinations over prolonged periods because of its radiation dose.The result of our previous studies showed that: comparing with routine-dose CT, the MR T1-weighted 3D Star VIBE sequence was slightly lower in differentiating the peripheral pulmonary lesions(PPL) with morphological features. MR can provide not only the morphological information, but also functional information.The apparent diffusion coefficient (ADC) value was used widely in whole body, but this research of combining MR-DWI ADC value with morphological characteristics of PPL was rare. The purpose of this study was to evaluate the no radiation-dose MR (ADC value and T1-weighted 3D Star VIBE sequence) diagnostic efficiency in differentiating the malignant PPL from benign, with the routine-dose CT as a reference standard.

METHOD AND MATERIALS

Fourty-seven patients(30 males and 17 females,mean age 64.1 years old; age range 48-83 years) were enrolled in this study, all the patients had undergone routine-dose CT,MR T1 Star VIBE and DWI with 3.0T MR sanner. These lesions were all diagnosed by transthoracic needle biopsy or surgery. Two radiologists observed the morphological signs of MR and CT images independently. The order of observation was MRI first, and followed by CT. Then the ADC value of lesions were measured. The logistic regression analysis was used to calculate the probability. The ROC curve was used to analyze the capabilities of morphological characteristics and DWI in distinguishing malignant PPL from benign.

RESULTS

There was significant difference of the ADC value between benign and malignant groups(p=0.001). The cut-off ADC value was 1197×10-6 mm2/s. Combined MR T1 Star VIBE with ADC value can distinguish PPL better than only routine-dose CT, ADC value and T1 Star VIBE alone.

CONCLUSION

The ADC value could differentiate the peripheral pulmonary lesions initially, but the distinguishability was better if combing MR T1 Star VIBE morphological characteristics with ADC value.

CLINICAL RELEVANCE/APPLICATION

We can use MR T1-weighted 3D Star VIBE and DWI to replace routine-dose CT to distinguish PSPLs in order to avoid radiation exposure.

SSJ05-03 18F-Fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (PET/CT) and Diffusion-Weighted Magnetic Resonance Imaging (DWI-MRI) Diagnostic Performance in the

PURPOSE

To perform a systematic review and meta-analysis of the diagnostic performance of DWI-MRI and 18F-FDG PET/CT in the evaluation of pulmonary lesions.

METHOD AND MATERIALS

Databases of MEDLINE and Embase were searched through December 2017. Studies published in English were included when the diagnostic performances of 18F-FDG PET/CT or DWI in detecting malignant pulmonary lesions were clearly identified in the articles. Two reviewers evaluated the study quality of all selected articles using QUADAS-2 and only those that met a minimum quality score were included. Parameters of lesion quantification were analyzed separately for each imaging modality (e.g., lesion-to-spine ratio (LSR), and apparent diffusion coefficient (ADC) for DWI-MRI). Meta-analysis using a random-effects model were conducted to calculate the pooled sensitivities, specificities, positive and negative likelihood ratios (PLR and NLR), diagnostic odds ratios (DOR) and area under the curve (AUC) for PET/CT and DWI with 95% confidence intervals (95% CI).

RESULTS

The literature search yielded 1280 results, and the inclusion criteria were met by 37 studies (23 FDG PET/CT studies, 8 MRI studies and 6 studies including both methods), with a total of 4224 participants and 4463 lesions (malignant, n = 3090, 69.2%; benign, n=1362, 30.8%). Pooled sensitivity and specificity of SUVmax (n = 25) were 0.86 (95%CI, 0.82-0.90) and 0.73 (95%CI, 0.62-0.82), respectively. For DWI-MRI, LSR studies (n = 4) showed a sensitivity of 0.81 (0.71-0.88) and a specificity of 0.90 (0.79-0.95), whereas studies utilizing ADC (n = 12) had a sensitivity and specificity of 0.83 (0.77-0.88) and 0.86 (0.76-0.92), respectively. DWI-LSR yielded the greatest diagnostic odds ratio (DOR = 38, 95%CI 12-115) compared to DWI-ADC (DOR = 30, 95%CI 14-66) and SUVmax (DOR = 17, 95%CI 10-28).

CONCLUSION

Diagnostic performance of DWI-MRI is comparable to 18F-FDG PET/CT for the evaluation of potentially malignant pulmonary lesions.

CLINICAL RELEVANCE/APPLICATION

This is the first meta-analysis to compare the diagnostic performance of DWI-MRI and 18F-FDG PET/CT in the evaluation of pulmonary lesions. Our study demonstrated that the diagnostic performance of DWI-MRI is comparable or even superior to that of PET/CT, which supports the inclusion of MRI as a low-cost and radiation-free option to the diagnostic work-up of pulmonary lesions.

SSJ05-04 Chemical Exchange Saturation Transfer (CEST) Imaging versus Diffusion-Weighted Imaging (DWI) versus FDG-PET/CT: Capability for Diagnosis of Solitary Pulmonary Nodule

yosirad@kobe-u.ac.jp

PURPOSE

To directly and prospectively compare the capability for diagnosis of solitary pulmonary nodules (SPNs) among chemical exchange saturation transfer (CEST) imaging, diffusion-weighted imaging (DWI), and FDG-PET/CT.

METHOD AND MATERIALS

113 consecutive patients (69 male and 44 female; mean age 71 year old) with 122 SPNs underwent CEST imaging and DWI at a 3T MR system, FDG-PET/CT, and pathological and/or follow-up examinations. According to final diagnoses, all SPNs were divided into malignant (n=76) and benign (n=46) SPNs. In each patient, magnetization transfer ratio asymmetry (MTRasym) was calculated from z-spectra at 3.5ppm in each pixel, and MTRasym map was computationally generated from CEST data. In each lesion, MTRasym, apparent diffusion coefficient (ADC) and SUVmax were assessed by ROI measurements. To compare all indexes between two groups, Student's t-test was performed. Then, multivariate logistic regression analyses were performed to investigate the discriminating factors of two groups. In addition, ROC analyses were performed to compare diagnostic performance among all indexes as well as combined methods. Finally, sensitivity, specificity and accuracy were compared among all methods by McNemar's test.

RESULTS

MTRasym, ADC and SUVmax had significant difference between malignant and benign SPNs ($p<0.05$). Multivariate regression analyses identified MTRasym (Odds ratio [OR]: 0.54), ADC (OR: 47.6) and SUVmax (OR: 0.47) as significant differentiators ($p<0.05$). ROC analyses showed area under the curve (Az) of MTRasym (Az=0.88) and combined all indexes (Az=0.92) were significantly larger than that of SUVmax (Az=0.77, $p<0.05$). Sensitivity (SE) and accuracy (AC) of MTRasym (SE: 81.6 [62/76] %, AC: 82.8 [101/122] %) and combined methods (SE: 85.5 [65/76] %, AC: 85.2 [104/122] %) were significantly higher than those of ADC (SE: 69.7 [53/76] %, $p<0.05$; AC: 77.9 [95/122] %, $p<0.05$) and SUVmax (SE: 64.5 [49/76] %, $p<0.05$; AC: 71.3 [87/122] %, $p<0.05$).

CONCLUSION

CEST imaging has a better potential and can improve diagnostic performance of SPNs, when compared with DWI and FDG-PET/CT.

CLINICAL RELEVANCE/APPLICATION

CEST imaging has a better potential and can improve diagnostic performance of SPNs, when compared with DWI and FDG-PET/CT.

SSJ05-05 2D-ROI and 3D-VOI Histogram Analysis of Apparent Diffusion Coefficient in Assessing Solitary Pulmonary Lesions

Tuesday, Nov. 27 3:40PM - 3:50PM Room: S404AB

Participants
Shi Y. Deng, Guangzhou, China (*Presenter*) Nothing to Disclose
Xinhua Wei, MD, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose
Xinchun Li, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

408268905@qq.com

PURPOSE

To determine the diagnostic performance of apparent diffusion coefficient (ADC) histogram analysis derived from both largest cross-sectional (2D-ROI) and whole tumor region of interest(3D-VOI) in differentiating benign from malignant solitary pulmonary lesions(SPLs).

METHOD AND MATERIALS

Sixty-nine patients with pathologically confirmed lung lesions (benign: malignant = 23:46) were included in the study. All patients underwent 3.0T diffusion-weighted imaging (DWI) with 2 b values of 0 and 600s/mm2. The histogram metrics including minimum, mean, maximum, 10th, 25th, 50th, 75th and 90th percentiles, skewness, and kurtosis were calculated from the largest cross-section and whole tumor ROI, respectively. Inter-class correlation characteristic(ICC) was used to assess inter-observer reliability. Histogram metrics were analyzed using Mann-Whitney U-test. The diagnostic performance was evaluated using receiver-operating characteristic (ROC) analysis.

RESULTS

Minimum, mean, maximum and 10th,25th,50th,75th,90th percentile ADCs with two groups were significantly lower (all $P<0.05$), except for the maximum and 25th percentile ADCs in whole-volume group ($P=0.128$, $P=0.221$) in malignant lesions compared with benign ones. The 75th and 50th percentile ADCs in two ROI setting group respectively achieved the highest AUC (single-slice: whole-volume=0.891:0.894) with cutoff value of $1.57\times10\text{-}3$ mm²/s and $1.41\times10\text{-}3$ mm²/s in differentiating solitary pulmonary lesions. ICC for the whole-volume ROIs(0.76~0.97) was better the largest-slice ROIs(0.59~0.91) .

CONCLUSION

Both single-slice and whole-volume ADCs are helpful for distinguishing malignant from benign lung lesions. Whole-volume ADC histogram analysis could have greater diagnostic properties and repeatability.

CLINICAL RELEVANCE/APPLICATION

In conclusion, ADC histogram is helpful for distinguishing malignant from benign lung lesions, and the 75th percentile ADC derived from 2D-ROI and 3D-VOI could provide better imformation in characterizing in SPLs, with no statistical difference. Moreover, placing ROIs in the largest lesion would be more suitable for clinic practice considering about saving time.

SSJ05-06 Utilization of 19F MRI for Identification of Iraqi-Afghanistan War Lung Disease

joseph.mammarappallil@duke.edu

PURPOSE

Iraq-Afghanistan War Lung Injury (WLI) describes new onset respiratory symptoms occurring in deployed soldiers to the Middle East that can ultimately lead to constrictive bronchiolitis. This study sough to determine if 19F MRI could identify patients with WLI.

METHOD AND MATERIALS

Three soldiers who presented to local VA clinics were evaluated for reactive airways disease, post deployment dyspnea, and decreased respiratory fitness. All subjects had a full pulmonary function evaluation. Inspiratory and expiratory imaging with HRCT was also obtained for each subject. For 19F MRI studies, each subject inhaled a gaseous mixture of 79% PFP mixed with 21% O2 mixture over the course of several minutes in a protocol consisting of three tidal breaths followed by a 6 second breath-hold at total lung capacity during which a 3D imaging of the lung airspaces was obtained. The image data was analyzed to generate regional wash-in and wash-out time constants (seconds) throughout the lung airspaces. Finally, the fraction of slow filling compartments was calculated as the number of volume elements exhibiting a wash-in time constant of > 100 seconds divided by the total number of lung airspace elements in the imaged [FVR1>100].

RESULTS

Two subjects were non-smokers and the third is a current smoker (11 pack-years). All three subjects were exposed to aerosolized contaminants during deployment in Iraq/Afghanistan. Spirometry for all subjects were normal FEV1% predicted (81, 109, 86), FEV1/FVC (72, 75, 73). Expiratory CT imaging was normal for subject 1, while the 2nd and 3rd subjects had mild basilar or lobular areas of air trapping. Imaging with 19F for each subject was as follows: FVR1>100 = 17.5%, 37.8%, and 24.5% for the three subjects respectfully. While the first subject's FVR1>100 was close to values seen in subjects with normal lung function the second and third subjects more resembled patients diagnosed with COPD (25->60%).

CONCLUSION

19F MRI demonstrated delayed regional filling of PFP gas in two subjects with suspected WLI when compared to data from normal subjects.

CLINICAL RELEVANCE/APPLICATION

19F MRI has the potential to detect airway abnormalities at earlier time points than current techniques. This may ultimately lead to better diagnosis of challenging airway abnormalities such as WLI and perhaps a tool for evaluation of interventions.

PURPOSE

To investigate CT utilization patterns in a major level 1 trauma center before and after the opening of a new facility with expanded ER and critical care capacity.

METHOD AND MATERIALS

A retrospective analysis of all CT scans ordered from the emergency department of a major level 1 trauma center was performed during a 36 month period spanning the opening and transition to a new facility in May of 2016. Eligible for inclusion were CT studies performed within call hours (5pm-8am weekdays, 24 hours on weekends). Data were conducted retrospectively, using ad hoc SQL query against PACS Oracle database, and classified into one of two subcategories based upon the findings 1) Type 1: critically acute findings usually necessitating hospital admission, and 2) Type 2: negative or non-critical. The incidence of Type 1 and Type 2 findings before (January 2015-May 2016) and after (May 2016-Dec 2017) transitioning to the new facility were analyzed.

RESULTS

Comparing 16 months prior and 20 months after opening of an expanded trauma center, there was a 12% increase in overall ED patient volume. There was an associated increase in overall CT utilization of 24.6%. When weighted by number of days, there was a total of 33 CT studies per day ordered before and 41 CT studies ordered per day after opening the new hospital. However, there was no significant increase in Type 1 studies (weighted average total increase of 9.2%). The increase in CT utilization was entirely accounted for by a significant increase type 2 studies which increased by 32.3% ($p<0.05$). The yield for type 1 studies (defined as the ratio of Type 1 to Type 2), decreased from 0.41 to 0.33.

CONCLUSION

Increased CT utilization following the opening of an expanded level 1 trauma center was accounted for entirely by an increase in volume of non-critical (type 2) studies. Potential contributors to this utilization pattern are explored and include overall increase in ED volume and increased proximity of CT scanners within the new emergency department.

CLINICAL RELEVANCE/APPLICATION

Hospital geography can play a role in increasing CT utilization without increasing clinical yield.

SSJ06-03 ED CT Utilization Has Increased but What Has Increased and Who Reads Them?

Tuesday, Nov. 27 3:20PM - 3:30PM Room: S402AB

Participants
Santosh K. Selvarajan, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

santosh.rad@gmail.com

PURPOSE

The growth in CT utilization is considerable and has increased across the world. The continued growth in the ED may be partly related to increased applications with improved technology and partly from inappropriate use. Our purpose was to determine the different subcategories of CT that have increased since code bundling was used only for CT of abdomen and pelvis and secondly assess the change in Non-Radiologists interpretations of CT from 2004 to 2016.

METHOD AND MATERIALS

We used the Medicare Physician/Supplier Procedure Summary Master Files for 2004-2016. The codes for ER CT were selected and the procedure volumes in ED settings were calculated. We doubled the number of bundled codes, since these would have counted as 2 exams in 2010 and before. We performed a secondary analysis of the different CT examinations by categorizing them in to head, body, spine, musculoskeletal and CT vascular. The CTA of the head and neck were assigned to the head CT to help assess the utility of neuroimaging. Then used Medicare provider specialty codes to identify those exams interpreted by Radiologists and other specialties.

RESULTS

The utilization of CT in the EDs grew in all the categories with a more substantial increase in the utilization of CT spines (+423%), CT vascular (+306%), and CT MSK (+164%). The utilization of CT body has increased by 56%. The volume of neuroimaging has significantly increased from 1,875,263 in 2006 to 3,632,617 in 2016 (+94%). A small number of cardiac CTs are performed in the ED, which has increased from 194 in 2006 to 2430 in 2016 (+1153%). Radiologists interpret 99% of the studies in all categories. The percentage of non-Radiologists interpreting CTs in the ED have reduced in all subcategories except a mild increase in the interpretation of CT spines and CT vascular.

CONCLUSION

There is substantial increase in the utilization of all CTs in the ED. The growth is predominantly in CT spine, CT vascular and CT of extremities. The utilization of CT and CTA for neuroimaging has also increased markedly.

CLINICAL RELEVANCE/APPLICATION

These trends may be partially due to defensive medicine in ED and radiologists and ED physicians need to work together to better control utilization.

SSJ06-04 The Effect of Advanced Age on the Utilization of CT in Trauma

PURPOSE

In the 1990s the most frequent mechanism of injury (MOI) in trauma was Road Traffic Accidents (RTA) with a mean age of 31; by 2013 falls from <2 meters were the predominant mechanism and the mean age had risen to 53.8. CT plays a major role in the management of trauma. The possibility exists for a delay in investigation and treatment in older trauma patients due to differences in MOI, mode of presentation and awareness.

METHOD AND MATERIALS

Trauma Audit Research Network (TARN) data from a tertiary referral urban university teaching hospital with an annual ED census of over 53,000 patients from 2012 to 2017 was analysed. Fisher's Exact test, multivariate logistic regression and Student's T Test were used for analysis in SPSS 24.

RESULTS

1422 trauma patients were included of whom 928 had CT. 721 were male and 701 were female. Mean age was 63 (range : SD) (3-99:22.2). Mean Injury Severity Score (ISS) was 13 (1-57 : 8.4). Fall <2m was the MOI in 61.5% and RTA in 15.3%. Trauma patients aged >65 were no more likely to require a CT than those <65 ($p=0.575$). Patients >65 were more likely to have a time to CT (TCT) >24 hours ($p<0.001$). This held true controlling for gender, ISS, date and time ($p<0.01$). Patients aged >65 with an ISS >15 were more likely to have a TCT >6 hours ($p=0.016$). Overall mean TCT was 262% longer ($p<0.001$) in those patients aged >65.

CONCLUSION

Trauma patients over 65 years of age wait longer for CT compared to those under 65.

CLINICAL RELEVANCE/APPLICATION

Outcomes for older trauma patients are worse in terms of morbidity, mortality and length of stay. While the cause and effect for the impact on outcomes of the delay to CT is difficult to elucidate; maximising controllable variables has the potential to benefit the patient.With the aging population and the changing face of trauma emergency departments need to plan for a different type of patient. Older patients who suffer traumatic injuries may not be identified as early and strategies should be implemented minimise delay in access to diagnostics and implementation of treatment. Emergency and radiology departments need to be accordingly resourced for this changing practise.

SSJ06-05 Defensive Medicine, Myth or Truth: The Evolution of Geriatric Trauma Imaging

Tuesday, Nov. 27 3:40PM - 3:50PM Room: S402AB

emreunal.rad@gmail.com

PURPOSE

The worldwide population is aging, and in proportion to this development the morbidity and mortality related to geriatric trauma, and its burden on healthcare is increasing. In this study, we aimed to analyze the imaging findings in a series of geriatric trauma patients admitted to our emergency department during the period of 2006-2011 and 2012-2017. We also investigated whether trauma induced pathologies or the need for imaging has changed over the years.

METHOD AND MATERIALS

We randomly selected two sets of 300 patients among 597 and 987 patients admitted to the emergency department during the time periods of 2006-2011(group I) and 2012-2017(group II), respectively. A comprehensive comparison was carried out between the groups regarding age, sex, reason for admission, associated comorbidities, Revised Trauma Score (RTS), Glasgow Coma Scale (GCS), radiological findings and number of radiological examinations, DLP values, duration of hospital stay, and trauma associated morbidity and mortality.

RESULTS

No statistically significant difference was observed between both groups regarding age and gender ($p>0.05$). Falls were the most common cause for admission in both groups, followed by traffic accidents. RTS and GCS values were similar in both groups ($p>0.05$). The number of patients who underwent X-ray and CT examinations in group II was higher compared to group I (89% vs. 82%, 73% vs. 44%, respectively, $p=0.021$). The total number of X-rays and CT scans was also higher in group II (613 vs. 310, 409 vs. 142, respectively, $p=0.01$). In 49% of patients in group I and 55% of patients in group II, CT scans were negative for a trauma related finding. In patients with radiological evidence of trauma, no significant difference was observed between the groups regarding major trauma related change ($p=0.151$). However, trauma related minor CT findings were more common in group II ($p=0.031$).

CONCLUSION

Increased need for radiological examinations over the years seem to occur as a consequence of the tendency to practice defensive medicine. In addition to increased radiation dose, unnecessary radiological examinations result in heavy burden on health care systems and radiologists' workload.

CLINICAL RELEVANCE/APPLICATION

Increased need for imaging in recent years appears to be related to 'defensive medicine' but not to Revised Trauma Score or Glasgow Coma Scale of the patients.

SSJ06-06 CT or MR for Pulmonary Embolism: 10 Years of Experience in Over 10,000 Cases in the Emergency Department

PURPOSE

We sought to determine if patient characteristics of those referred for pulmonary magnetic resonance imaging (MR) differed from those referred to computed tomographic angiography (CT) for the primary diagnosis of pulmonary embolism (PE) from our

Emergency Medicine Department (ED).

METHOD AND MATERIALS

This is a retrospective HIPPA-compliant, IRB-approved study of CT and MR performed for PE evaluation in the ED from January 1, 2009 - December 31, 2017. All ED patients with an imaging order placed and not canceled during an ED encounter were identified. Patient encounters were included if (1) study type was CT or MR and (2) study description included 'PE protocol' or study information entered by the ED clinician included a PE variant (i.e. pulm* embol*, vte). Patient factors were populated via the electronic medical record (EMR); comorbidity indices were calculated from ICD 9/10 codes. Logistic regression was used to calculate odd ratios (OR) of factors associated with use of MR versus CT.

RESULTS

There were 10,986 CT and 1,448 MR patient EMRs reviewed. MR patients were younger ($p<.001$) and female ($p<.001$). CT patients had higher morbidity indices ($p<.001$). In the patient factor model, female sex, lower age, slightly lower comorbidity index, and history of renal disease increased odds of MR use (female OR 2.7, $p<.001$; age OR 0.93, $p<.001$; Elixhauser OR 0.97, $p<.001$; renal disease OR 3.5, $p<.001$). In a separate vital signs model, slightly lower maximum respiratory rate (RR_max) and slightly higher minimum oxygen saturation (O2_min) increased odds of MR (RR_max OR 0.97, $p<.01$; O2_min OR 1.04, $p<.001$).

CONCLUSION

ED ordering of MR occurred more often in female, younger patients with lower comorbidity and more favorable vital signs. History of renal disease also significantly increased the OR of MR.

CLINICAL RELEVANCE/APPLICATION

ED clinicians have consistently utilized MR for PE evaluation since its introduction, with selection of MR in stable patients to mitigate perceived risks of CT.

sykim.radiology@gmail.com

PURPOSE

To investigate magnetic resonance imaging (MRI) features associated with transarterial chemoembolization (TACE) refractoriness in patients with HCC and to develop a prediction model.

METHOD AND MATERIALS

Among 407 patients with intermediate-stage HCC (BCLC-B) who underwent TACE as a first-line treatment from January 2012 to December 2015, 181 patients having pre-procedural gadoxetic acid-enhanced MRI were included in this study. TACE refractoriness was determined according to the Japan Society of Hepatology guidelines. Univariate and multivariable analyses were performed to investigate the association between clinical factors including MRI features and the refractoriness. A prediction scoring model was constructed by a bootstrap resampling method. The performance of the prediction model was evaluated with respect to discrimination for TACE refractoriness using the area under the receiver operating characteristic curve (AUC).

RESULTS

55 patients (30.4%) showed TACE refractoriness, while the remaining 126 (69.6%) showed good responses after TACE. Independent features associated with TACE refractoriness were alpha fetoprotein level, tumor number, maximum tumor size, atypical arterial enhancement pattern, arterial peritumoral enhancement, and presence of nonhypervascular hypointense nodule (NHHN) on hepatobiliary phase images. The prediction model derived from these variables showed good discrimination (AUC, 0.82, 95% CI, 0.75-0.89) for TACE refractoriness.

CONCLUSION

The prediction model based on the MRI features can be used to estimate the risk of TACE refractoriness in patients with HCC.

CLINICAL RELEVANCE/APPLICATION

The identification of high risk patients of TACE refractoriness can be helpful to the initiation and maintenance of TACE in patients with HCC.

SSJ07-02 Radiofrequency Ablation versus Cryoablation for Perivascular Hepatocellular Carcinoma: Local Tumor Control and Vascular Complications

Tuesday, Nov. 27 3:10PM - 3:20PM Room: S104A

Participants
Soyeon Cha, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

Tae Wook Kang, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Kyoung Doo Song, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Min Woo Lee, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Hyunchul Rhim, MD, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Hyo Keun Lim, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To compare cryoablation with radiofrequency ablation (RFA) in patients wtih perivascular HCC and to evaluate the local tumor control and vascular complications of both therapies.

METHOD AND MATERIALS

The retrospective study was approved by the institutional review board. The requirement for informed consent was waived. Between January 2015 and December 2017, 111 patients (93 men, 18 women; mean age, 62.3 years; age range, 44-48 years) who underwent percutaneous cryoablation (n=61) or FRA (n=50) were enrolled. All patients had a single perivascular HCC (mean size, 1.3 cm) that were in contact with hepatic vessels (periportal or perivenous), $\geq$ 3mm or larger in axial diameter. Cumulative local tumor progrssion (LTP) was evaluated. In addition, several procedure-related vascular complications were evaluated immediately after treatment and during follow-up images: peritumoral vessel thrombosis; transient hepatic ischemia or hepatic infarction; aggressive intrasegmental recurrence (AIR) (the simultaneous deveolpment of $\geq$ 3 nodular or infiltrative tumors).

RESULTS

The median follow-up was 18 months. Both groups did not show significant differences in terms of baseline characteristics except the proportion of periportal tumor location (40.0% in the RFA group vs. 86.9% in the cryoalblation group, p=0.031). The cumulative LTP rates at 1 and 2 years were 5.7% and 22.1%, respectively, in the RFA groups, and 6.5% and 22.7%, respectively, in the cryoablation group, without siginificant difference (p=0.918). However, peritumoral thrombosis (25% vs. 11.5%, p=0.031) and transient hepatic ischemia or hepatic infarction (24% vs. 4.95%, p=0.005) were more common in the RFA group than in the cryoablation group. Although there were not significant differences between two groups, AIR was only occurred in the RFA group (2% vs. 0%, p=0.450).

CONCLUSION

In patients with perivascular HCC, cryoablation is an effective treatment for local tumor control, comparable to RFA, with a low risk of vascular complications.

CLINICAL RELEVANCE/APPLICATION

Although cryoablation has not been included as a standard care for HCC according to the recent Barcelona Clinic Liver Cancer guidelines, based on the our results, cryoablation may be a reasonable alternative for patients with limited liver function to avoid vascular complications.

SSJ07-03 Trends in Ablative and Surgical Treatment of Hepatic Tumors in the Medicare Population, 2003-2016

ali.b.syed@jefferson.edu

PURPOSE

Percutaneous ablation of liver tumors has become increasingly accepted as a less invasive alternative to open ablation and surgical resection in patients with liver tumors. Our purpose was to assess utilization trends in these procedures in recent years.

METHOD AND MATERIALS

Using the nationwide Medicare Part B databases for 2003-2016, we selected the CPT codes for percutaneous ablation (PA), open ablation (OA), and partial lobectomy (PL) of the liver. Codes for both radiofrequency- and cryoablation were included. The databases provide volumes for each code. Medicare's specialty codes were used to identify the specialty of the provider. Trend lines were plotted for total volumes and volumes by radiologists, surgeons, and all other physicians as a group. Because these databases represent a full population, sample statistics are not required.

RESULTS

Medicare total PA volume increased from 1221 in 2003 to 2788 in 2016 (+128%), with the most rapid growth occurring from 2012-2016. Radiologists performed 99% of all PAs in 2016. Of the 2788 performed that year, 2599 were radiofrequency ablations, while 189 were cryoablations. OA volume decreased steadily from 835 in 2003 to 435 in 2016 (-48%). The vast majority of OAs were done by surgeons. PL volume increased from 2090 in 2003 to 2945 in 2016 (+41%). Again, the vast majority were done by surgeons.

CONCLUSION

OA use is declining steadily, while use of both PA and PL has increased. PA growth has been especially strong in recent years. The large majority of PAs use the radiofrequency approach, rather than cryo. Radiologists perform virtually all PAs. The data demonstrate that radiologists have assumed a major role in the treatment of hepatic tumors.

CLINICAL RELEVANCE/APPLICATION

Radiologists are virtually the only physicians performing percutaneous treatment of liver tumors, and have driven the rapid growth

of these procedures in recent years.

SSJ07-04 The Impact of Gadoxetic Acid Enhanced Hepato-Biliary MRI on Treatment Decisions in Hepatocellular Carcinoma: The SORAMIC Trial Diagnostic Cohort

Jens.Ricke@med.uni-muenchen.de

PURPOSE

SORAMIC is a RCT comprising diagnostic, local ablation and palliative studies in patients with hepatocellular carcinoma (HCC) in BCLC stages A-C. Based on the diagnostic study pts. were assigned to the local ablation or palliative cohort. The diagnostic study (reported here) was designed to determine the accuracy of treatment decisions based on hepato-biliary MRI employing Gadoxetate (hbpMRI) as compared to contrast enhanced CT (CECT).

METHOD AND MATERIALS

This multicenter trial recruited 692 pts. to receive standardized hbpMRI and CECT. Primary study objective was to confirm in a 2-step procedure hbpMRI is non-inferior (first step) or superior (second step) compared with CECT for assignment to a palliative or local ablation treatment strategy. In addition, we included a seperate set of dynamic MRI (dynMRI) sequences (obtained from the Gadoxetate data set) for comparison. Central read of all image sets was performed by 2 readergroups (R1, R2). Image criteria for CECT and dynMRI were wash-in and wash-out according to EASL. Modified HCC criteria for the hbpMRI are outlined in fig. 1. Readers determined a treatment recommendation according to standard criteria (local ablation, palliative treatment, neither recommendation; e.g. <=4 lesions <=5cm: ablation). Standard of reference was a joint truthpanel decision by a hepatologist and a radiologist with access to all available data incl. follow-ups.

RESULTS

The intention-to-treat (ITT) and the per-protocol (PP) population consisted of 530 and 442 pts., respectively. In the ITT population, the accuracy of CECT/ dynMRI was 73.8%/ 75.5% for R1 and 70.9%/ 70.4% for R2, respectively. In the PP population, the accuracy of CECT/dynMRI was 72.9%/ 76.5% (R1) and 72.2%/ 71.5% (R2). Non-inferiority (difference, -5%points; 1-sided; alpha, 2.5%) between modalities was shown for ITT as well as PP (power > 95%). For hbpMRI, the accuracy for R1/R2 was 83.4%/ 80.6% in the ITT and 82.6%/ 81.2% in the PP population. HbpMRI superiority was significant compared to CECT or dynMRI (all, $p<0.001$).

CONCLUSION

hbpMRI was superior to CECT or dynMRI for treatment decision making in HCC. Image artifacts did not affect treatment decisions in Gadoxetate based hbp MRI, dynMRI or CECT.

CLINICAL RELEVANCE/APPLICATION

Hepatobiliary MRI employing gadoxetic acid was superior to CECT or dynamic MRI for treatment decision making in pts. with BCLC stages A-C.

SSJ07-05 Diffusion-Weighted MR Imaging to Assess Immediate Response to Irreversible Electroporation in a Rabbit Liver Tumor Model: Pathologic Correlation

PURPOSE

Irreversible electroporation (IRE) is a relatively new strategy for the interventional treatment of liver tumors. Accurate follow-up imaging is critical for properly monitoring and evaluating treatment responses. The purpose of our study was to test the hypothesis that DW-MR imaging can be used to assess the immediate treatment response to IRE in animal models with liver VX2 tumors.

METHOD AND MATERIALS

New Zealand white rabbits were implanted with VX2 tumor tissue blocks in the left median and left lateral lobes of liver. Tumors were allowed to grow for 7-10 days to reach a size typically at least 10 mm in longest diameter, as verified with MR imaging. IRE electrodes were inserted, and eight 100-µsec, 2000-V square wave pulses were applied to ablate the tumor tissue in the left median lobe. Tumor in the left lateral lobe served as a control. DWI scans were performed at baseline and immediately after IRE for each animal (b= 0, 400, 800, 1200 s/mm2). Then, rabbits were euthanized and tumors harvested for hematoxylin-eosin (H-E), and caspase-3 staining. The ratio of ADC values (ADClesion/ADCnormal liver) and changes in the ADC measurements were calculated and compared. The percentage of viable tumor was calculated for treated tumors by using both radiologic methods and pathologic techniques. Pearson correlation coefficients were calculated to assess the relationship between ADC and H-E-stained measurements of viable area immediately post-IRE. The differences of apoptosis index (AI) between irreversible electroporation (IRE) zone and reversible electroporation (RE) zone were compared.

RESULTS

The ratio of ADC values, ΔADC, the mean percentage of viable tumor, and AI significantly differed between treated and untreated tumors (P<.05 for all). In treated tumors, the ratio of ADC values and AI significantly differed between IRE zone and RE zone, and there was a strong correlation between results of viable tumor measured on ADC value and pathologic techniques after IRE.

CONCLUSION

DW-MR imaging biomarkers can be used for the early evaluation of therapeutic response to IRE treatment of liver tumors in a rabbit model.

CLINICAL RELEVANCE/APPLICATION

Early changes in ADC values highlighted by DW-MRI correlate with histopathologic changes in liver tumors after IRE procedure. DWI-MRI may be helpful for timely adjustments to patient therapeutic strategies as needed to improve clinical outcomes.

Honored Educators

SSJ07-06 Therapeutic Response Monitoring After Targeted Therapy in an Orthotopic Rat Model of Hepatocellular Carcinoma Using Contrast-Enhanced Ultrasound: Focusing on Inter-Scanner and Inter-Operator Reproducibility

Tuesday, Nov. 27 3:50PM - 4:00PM Room: S104A

Participants
Hwaseong Ryu, Yangsan, Korea, Republic Of (*Presenter*) Nothing to Disclose
Jung Hoon Kim, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Seunghyun Lee, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Joon Koo Han, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To assess therapeutic responses monitoring after targeted therapy in an orthotopic rat model of hepatocellular carcinoma (HCC) using contrast-enhanced ultrasound (CEUS) with focusing on inter-scanner, and inter-operator reproducibility.

METHOD AND MATERIALS

For reproducibility evaluation, CEUS was performed using two different US scanners by two different operators in sixteen N1-S1 rat models of HCC. Using perfusion analysis software (VueBox ®), 11 parameters were collected, and intra-class correlation (ICC) was used to analyze reproducibility. Then, seventeen N1-S1 rat models of HCC were divided into a treatment group (n = 8, 30 mg/kg/day sorafenib for 5 days) and a control group (n = 9). CEUS was performed at baseline, 1 day and 7 day after the first treatment and changes of perfusion parameters were analyzed.

RESULTS

In treatment group, CEUS perfusion parameters showed significant change, and among them, peak enhancement (PE, 2.50 x103±1.68 x103vs 5.55x102±4.65x102, p = 0.010), and wash-in and wash out AUC (WiWo AUC, 1.07x105±6.48 x104vs 2.65x104±2.25x104, p = 0.009), had significantly decreased 7 day following treatment. On the contrary, in control group, CEUS parameters did not show significant change including PE (1.15 x103±7.53x102vs 9.43x102± 7.81 x102, p = 0.632) and WiWoAUC(5.09 x104±3.25x104vs 5.92 x104±3.20x104, p = 0.646). For reproducibility, the various degrees of inter-scanner reproducibility from poor to good (ICC: <0.01-0.63) and inter-operator reproducibility from poor to excellent (ICC: <0.01-0.93) were observed. However, inter-operator reproducibility was good and excellent in WiWo AUC (ICC: 0.65 and 0.88) and fair and good in PE (ICC: 0.30 and 0.65) in different scanner.

CONCLUSION

CEUS was useful for assessment of treatment response after targeted therapy using PE and WiWo AUC with fair and excellent inter-operator reproducibility.

CLINICAL RELEVANCE/APPLICATION

CEUS perfusion parameters, including PE and WiWo AUC, had significantly decreased after targeted therapy with fair and excellent

inter-operator reproducibility. However, CEUS parameters obtained by different scanner should not be used interchangeably.

hyunki@uab.edu

PURPOSE

To validate quantitative dynamic contrast enhanced magnetic resonance imaging (qDCE-MRI) with a novel perfusion phantom for predicting therapeutic response in patients with pancreatic ductal adenocarcinoma (PDAC).

METHOD AND MATERIALS

A pilot study was conducted with eight patients (7 males and 1 female; median age = 66 yrs) having either locally advanced (n=7) or metastatic (n=1) PDAC. All had two DCE-MRI exams before and 8±1 weeks after starting first-line chemotherapy. The perfusion phantom was small enough to be imaged with each patient, serving as an internal reference for accurate quantitative image analysis. Tumor boundary was demarcated by board-certified radiologist blinded to therapy and clinical response. Tumor response was assessed by RECIST criteria. Tumor perfusion was measured with Ktrans using extended Tofts model before and after phantom-based data correction. Results are presented as mean±SD and 95% confidence intervals (CI). Statistical difference was evaluated with one-way ANOVA.

RESULTS

Mean tumor long axis before therapy was 38±17 mm. Tumor-size change of the responding group (n=4) was -12±4% for 8 weeks of therapy, while that of the non-responding group (n=4) was 18±15% (p=0.010). Baseline mean tumor Ktrans before therapy was 0.090±0.032 min-1 without statistical difference between the two groups (p=0.206). Before phantom-based data correction, the Ktrans change of responding tumors was 69±23% (95% CI: 32% to 106%) at 8 weeks, whereas that of non-responding tumors was -1±41% (95% CI: -65% to 64%) (p=0.025). After correction, the data variation in each group was significantly reduced; the Ktrans change of responding tumors was 73±6% (95% CI: 64% to 82%) compared to non-responding tumors of -0±5% (95% CI: -7% to 8%) (p<0.001).

CONCLUSION

To our knowledge, this is the first clinical data to demonstrate significant perfusion increase of PDAC responding favorably to first-line chemotherapy. Use of the small perfusion phantom imaged together with the patient reduced the data variation in quantitative DCE-MRI up to 50%, enhancing precision.

CLINICAL RELEVANCE/APPLICATION

The perfusion phantom is portable, inexpensive, easily utilized, and thus has potential to enhance precision for standard-of-care early PDAC therapy monitoring.

SSJ08-02 Dynamic Contrast Enhanced MRI for Pancreatic Perfusion in Acute Pancreatitis

Tuesday, Nov. 27 3:10PM - 3:20PM Room: S102CD

Participants
Ran Hu, Chongqing, China (*Abstract Co-Author*) Nothing to Disclose
Xiaoming Zhang, Nanchong, China (*Abstract Co-Author*) Nothing to Disclose
Hua Yang, Chongqing, China (*Abstract Co-Author*) Nothing to Disclose
Xiaoxiao Chi I, Yantai, China (*Presenter*) Nothing to Disclose

PURPOSE

To assess the characteristics of perfusion for normal pancreas and acute pancreatitis (AP) by using dynamic contrast enhanced MRI (DCE MRI).

METHOD AND MATERIALS

85 patients with AP and 26 normal controls underwent routine and DCE MRI sequences on a 3.0T MRI scanner. The Omitk DCE MRI Tool was used to analyze perfusion parameters, such as Ktrans, Vp and AUC values. The perfusion parameters of pancreas between AP group and control group were compared. In AP patients, the perfusion parameters were also compared between edematous and necrotizing pancreatitis, among different grades of AP by MR severity index (MRSI) and the revised Atlanta classification.

RESULTS

The Ktrans, Vp and AUC values of AP were lower than those of control group (all $P<0.05$). According to MRSI, the Ktrans and AUC values were significant difference between mild and moderate AP, mild and severe AP ($P<0.05$), except for between the moderate and severe AP ($P>0.05$); there was no significant difference for pancreatic Vp value in the different severity grades of AP ($P>0.05$). According to the revised Atlanta classification of AP, the Ktrans value was significant difference between mild and moderately severe AP, mild and severe AP ($P<0.05$), except for between the moderately severe and severe AP ($P>0.05$); there were no significant difference for pancreatic Vp and AUC values in the different severity grades of AP($P>0.05$). And the Ktrans was significant difference between edematous and necrotizing pancreatitis ($P<0.05$), except for the Vp and AUC values ($P>0.05$).

CONCLUSION

The application of DCE MRI to evaluate pancreatic perfusion contributes to AP diagnosis and AP severity grade. Pancreatic perfusion is significantly lower in patients with AP than that in normal pancreas, and with the increase of the severity of acute pancreatitis, pancreatic perfusion tends to decrease.

CLINICAL RELEVANCE/APPLICATION

The application of DCE MRI to evaluate pancreatic perfusion contributes to AP diagnosis and AP severity grade.

SSJ08-03 Multi-Parametric MRI to Assess Focused-Ultrasound Therapy of Pancreatic Ductal Adenocarcinoma

PURPOSE

Pulsed focused ultrasound (pFUS) therapy has shown promising results in disrupting dense fibrotic stroma and decreasing high interstitial fluid pressure characteristic of pancreatic ductal adenocarcinoma (PDA). Our goal is to use multi-parametric MRI to non-invasively assess and quantitate tumor response to pFUS in PDA mouse models.

METHOD AND MATERIALS

Three murine models of PDA, including subcutaneous, orthotopic, and a genetic model (KPC) were evaluated with multi-parametric MRI at 14T (Paravision 5.1 software, Bruker Corp, Billerica, MA) to assess tumor response to ultrasound-guided pFUS (VIFU 2000 Alpinion Medical Systems; 475 W peak electric power, 1 millisecond pulse duration, 1 Hz, duty cycle 0.1%) or sham treatments. Maps for T1 and T2 relaxation, apparent diffusion coefficient (ADC), magnetization transfer ratio (MTR), and chemical exchange saturation transfer (CEST) for the amide proton and glycosaminoglycan (gag) spectrum were generated. Images were collected 48hrs pre-pFUS and immediately post-pFUS therapy. Tumors were excised and prepared for sectioning and staining with hematoxylin and eosin, Masson's trichrome, picrosirius red, and immunohistochemistry for CD31 and hyaluronan.

RESULTS

Following pFUS treatment, mean ADC increased significantly for all animal models, with the greatest increase observed in the KPC group. Mean gag CEST and T2 map quantitations decreased significantly post-treatment only for the KPC group. Mean MTR and mean amide CEST values increased 21.6% ($p<0.001$) and 14.5% ($p=0.01$), respectively for the KPC group. No significant differences were observed in sham groups. Significant increase in ADC likely reflects increased diffusivity within the treated tumors. Significant decreases in gag CEST and T2 relaxation may represent disruption of glycosaminoglycans and associated liberation of complexed water molecules. Variable changes in T1 relaxation and significantly increased MTR and amide CEST signals post-treatment most

likely represent hyperacute hemorrhage from microcapillary vessels. Histological quantifications are currently being processed.

CONCLUSION

T2 relaxation, gag CEST, and ADC may provide reliable quantitation for monitoring therapeutic effect of pFUS for PDA.

CLINICAL RELEVANCE/APPLICATION

Multi-parametric MRI may be utilized to non-invasively assess the therapeutic effects and changes in tumor composition to improve medical monitoring of pFUS treatment for patients with PDA.

SSJ08-04 Prediction of Overall Survival after Surgery of Pancreatic Cancer Using Preoperative MR Imaging, Clinical, and Histopathological Findings

Tuesday, Nov. 27 3:30PM - 3:40PM Room: S102CD

Participants
Jae Seok Bae, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Jung Hoon Kim, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Hyo-Jin Kang, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Joon Koo Han, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To predict overall survival in patients who underwent surgery for pancreatic cancer using preoperative MR imaging, clinical, and histopathological findings.

METHOD AND MATERIALS

In this retrospective study, 150 patients with pancreatic cancer who underwent MR and surgery were included. Preoperative MR findings were assessed by two radiologists. Clinical characteristics and histopathological results such as T, N stage and resection status were investigated as well. Cox proportional hazard model was used to find prognostic factors for overall survival and intraclass correlation coefficient was used to estimate interobserver agreement.

RESULTS

Median and mean survival period was 21.0 months (interquartile range, 10.0-41.3) and 31.1 ± 29.2 months in the patients. Tumor size on MR (hazard ratio (HR) 1.041, 95% CI: 1.011-1.072) and over-abutment of superior mesenteric vein on MR (HR 1.919, 95% CI: 1.177-3.130), N1 stage (HR 2.672, 95% confidence interval (CI): 1.503-4.750), macroscopic residual tumor (HR 10.340, 95% CI: 4.349-24.580), were predictors of poor survival (P<0.05). Interobserver agreement on MR was substantial for tumor size (0.682, 95% CI: 0.582-0.762) and was moderate for superior mesenteric vein involvement (0.469, 95% CI: 0.292-0.607).

CONCLUSION

Both preoperative MR findings and histopathological results are useful for prediction of overall survival after surgery for pancreatic cancer.

CLINICAL RELEVANCE/APPLICATION

Combination of preoperative MR findings and histopathological results can be useful for prediction of overall survival after surgery for pancreatic cancer.

SSJ08-05 Exploratory Study of ADC Histogram Metrics in Assessing Ampullary/Pancreatic Malignancy

Tuesday, Nov. 27 3:40PM - 3:50PM Room: S102CD

Participants
Myles T. Taffel, MD, New York City, NY (*Presenter*) Nothing to Disclose
Lyndon Luk, MD, New York, NY (*Abstract Co-Author*) Nothing to Disclose
Justin M. Ream, MD, Ann Arbor, MI (*Abstract Co-Author*) Nothing to Disclose
Andrew B. Rosenkrantz, MD, New York, NY (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

myles.taffel@nyumc.org

PURPOSE

To evaluate the utility of whole-lesion 3D-histogram apparent diffusion coefficient (ADC) metrics in the assessment of ampullary/pancreatic malignancy.

METHOD AND MATERIALS

Forty-two ampullary/pancreatic malignancies (36 adenocarcinoma, 6 neuroendocrine) underwent abdominal MRI with DWI followed by endoscopic ultrasound biopsy or surgical resection. A single radiologist used dedicated post-processing software to place 3D-volumes-of-interest encompassing the entire masses to derive whole-lesion histogram ADC metrics. Mann-Whitey tests and ROC analyses were used to assess the diagnostic performance of the histogram metrics for determining lesion histology, and among adenocarcinomas, T-stage, N-stage, and grade.

RESULTS

Whole-lesion ADC histogram metrics demonstrating significant differences between adenocarcinoma and neuroendocrine tumors were mean ADC (1.40 vs. 1.04 x10-3mm2/sec, respectively; p=0.020, AUC = 81%), mean of the bottom 10th percentile (mean0-10) (0.97 vs. 0.50; p<0.001, AUC=88%), and mean of the 10th-25th percentile (mean10-25) (1.16 vs. 0.77, p<0.001, AUC=92%). For the metric with highest AUC for histology (mean10-25), a threshold >0.94 achieved sensitivity of 94% and specificity of 83%. Metrics with significant differences between nodal status No vs. >=N1 were mean ADC (1.69 vs.1.24; p=.004; AUC = 81%), mean0-10 (1.19 vs. 0.71, p=0.012, AUC=82%), and mean10-25 (1.45 vs. 0.96; p=0.002, AUC=82%). For the metric with highest AUC for

nodal status (mean10-25), a threshold >0.94 achieved sensitivity of 94% and specificity of 83%. No metric was significantly associated with T stage (all p>0.195) or tumor grade (all p>0.215). Skewness and kurtosis were not significantly different between any groups (all p>0.087).

CONCLUSION

Volumetric ADC histogram metrics may serve as non-invasive biomarkers in assessing ampullary/pancreatic malignancy. The metric reflecting the bottom quarter of the histogram distribution outperformed the standard mean in determining lesion histology and nodal status, supporting the role of histogram analysis. More advanced methods may be needed for T stage and tumor grade differentiation.

CLINICAL RELEVANCE/APPLICATION

Although these findings require validation in larger studies, histogram diffusion metrics may be helpful in guiding prognosis and treatment selection for ampullary/pancreatic malignancy.

SSJ08-06 Noncontrast Computed Tomography Factors that Predict Outcome after Extracorporeal Shock Wave Lithotripsy in Patients with Pancreatic Duct Stones

Tuesday, Nov. 27 3:50PM - 4:00PM Room: S102CD

Participants
Ri Liu, Shanghai, China (*Presenter*) Nothing to Disclose
Jianping Lu, MD, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose
Jing Gong, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

liuri007@126.com

PURPOSE

To assess the usefulness of noncontrast computed tomography (NCCT) factors for predicting the outcome of extracorporeal shock wave lithotripsy (ESWL) in patients with pancreatic duct stone (PDS).

METHOD AND MATERIALS

We retrospectively evaluated 148 patients with multiple PDS in the pancreatic head region who had undergone ESWL therapy. All patients received NCCT examination both before and after ESWL. The following parameters are measured and recorded: patients characteristics including sex and age; NCCT parameters including mean stone length (MSL), mean stone volume before (V0) and after (V1) ESWL, mean value of CT attenuation (MSD), standard deviation of CT attenuation (SDSD), the variation coefficient of CT attenuation (VCSD), skin-to-stone distance (SSD) and pancreatic duct diameter (PDD); ESWL outcome indexes including stone clearance rate (SCR) calculated by , and the number of ESWL sessions (ESWL No.). All patients were respectively divided into A group (patients with SCR>=90%), B group (patients with SCR between 50% and 90%) and the C group (patients with SCR<50%). Analysis of variance (ANOVA) was applied among three groups to evaluate the potential predictors for SCR, and the receiver operating curve (ROC) was made for finding the cutoff value with optimal sensitivity and specificity. The Pearson correlation analysis and histogram were further used for finding factors related to ESWL No. .

RESULTS

ANOVA analysis revealed that MSD was the only significant predictor for SCR ($p < 0.05$), and ROC showed the cutoff value of +1000.45 HU, with sensitivity up to 78.0% and specificity of 48.6%. Stones with MSD lower than +1000.45 HU had higher SCR (69.3%) than that (59.6%) in higher-density ones. The Pearson correlation analysis and histogram indicated significantly positive correlation between ESWL No. and MSL (r= 0.536), MSD (r= 0.250), SDSD (r= 0.247) and PDD (r= 0.227), all with $p<0.01$.

CONCLUSION

MSD is the optimal predictor of ESWL efficacy, and PDS with lower MSD had the better clearance rate with fewer fragment sessions.

CLINICAL RELEVANCE/APPLICATION

MSD(mean stone density) is the optimal predictor of ESWL efficacy, and PDS with lower MSD had the better clearance rate with fewer fragment sessions.

PURPOSE

To measure liver attenuation automatically from low-dose lung screening CT scans to identify patients with moderate-to-severe hepatic steatosis (HS) and compare the automated method to manual region of interest (ROI) based measurement.

METHOD AND MATERIALS

This IRB-approved, HIPAA compliant study included 251 participants with a baseline low-dose CT scan with a slice thickness of <=1 mm (111 from a lung cancer screening program and 140 from the World Trade Center (WTC) cohort). Radiologists measured the liver attenuation (Hounsfield units; HU) at the level of the portal vein in four sectors defined by the Couinaud system. In each sector, the average liver HU was measured in a 1.0 cm2 circular (ROI), avoiding lesions and large vessels. The automated method samples cubic ROIs in the liver region, which is determined using a computer-based automated segmentation of the right diaphragm as the upper bound of the region, extending to 7.0 cm below the diaphragm. This region is divided into non-overlapping 1.0 cm3 cubes, and the mean intensity is computed for each cube. To account for regions that may be outside the liver or include blood vessels, cubes with mean values outside of the inner quartile range (50%) are excluded. An overall mean attenuation is computed from the remaining cubes for each CT scan. A threshold for HS was defined as the mean - 2*standard deviation from the lung screening cohort for both methods. The manual ROI measurement and automated methods were compared by using limits of agreement of average liver attenuation values and comparing the detection of HS in the WTC cohort using the established thresholds.

RESULTS

The overall mean and SD for the automated liver attenuation measurement was 51.52 HU ± 12.72 and for the manual measurement, 55.31 HU ± 11.21. The limits of agreement were (-14.09, 6.51). The threshold for HS was 40 HU for the manual method and 37 HU for the automated method; using these thresholds, 97.1% (136/140) of WTC participants had the same classification by both methods.

CONCLUSION

Automated measurement of liver attenuation from low-dose chest CT scans is feasible and shows good agreement (97%) with manual ROI based measurements for detecting HS.

CLINICAL RELEVANCE/APPLICATION

Automated identification of hepatic steatosis (HS) from low-dose lung screening CT scans has good agreement with radiologists, enabling physicians to identify patients at risk of liver disease.

SSJ09-02 Increased Adipose Tissue Attenuation on Computed Tomography (CT) Predicts One-Year Mortality in Older Adults

llenchik@wakehealth.edu

PURPOSE

To determine relationships between visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT) index and attenuation on abdominopelvic CT examinations with one-year survival in older adults.

METHOD AND MATERIALS

Relationships between adipose tissue metrics and all-cause mortality were determined retrospectively in a cohort 436 consecutive Medicare patients (52% women, mean age 75 years) who had non-contrast abdominopelvic CT exams for routine clinical indications. On CT images, VAT and SAT were segmented at the level of L3 pedicle using segmentation software (Mimics) and a threshold of -190 to -30 Hounsfield units. VAT and SAT cross-sectional area (CSA) and attenuation were measured. VAT and SAT index was determined by dividing adipose CSA by patient height in meters squared. Cox regression models were fit to determine associations between VAT and SAT metrics and one-year mortality, adjusted for age, sex, race, body mass index, smoking status, and Charlson comorbidity index.

RESULTS

Within one year of follow-up, 90 patients (20.6%) died. In the fully-adjusted models, higher values of VAT and SAT attenuation were associated with higher hazard ratios (HR) for mortality at 1 year. A 1 SD increase in the VAT attenuation was associated with a 103% increase in mortality (HR/SD=2.03; 95%CI=1.45-2.83; p<0.0001). A 1 SD increase in the SAT attenuation was associated with a 75% increase in mortality (HR/SD=1.75; 95%CI=1.40-2.19; p<0.0001). VAT index and SAT index were not associated with increased mortality.

CONCLUSION

In older adults, increased adipose tissue attenuation on abdominopelvic CT examinations was associated with increased one-year mortality, independent of other causes of death.

CLINICAL RELEVANCE/APPLICATION

Quantitative data mining for adipose tissue attenuation on abdominal CTs of older adults may help determine prognosis.

SSJ09-03 Accuracy of CT Texture versus Mean Attenuation for Quantification of Liver Fat Content

PURPOSE

To develop a CT texture prediction model to accurately and reproducibly measure liver fat content.

METHOD AND MATERIALS

Retrospective secondary analysis of a prospective study that included 50 adult participants (23 men, 27 women; mean age 57 years; BMI 27) who underwent unenhanced single energy CT and MRI proton density fat fraction (MRI-PDFF). In separate independent reading sessions, three readers measured 110 first order CT texture parameters (before and after application of median and Gaussian filters) and liver fat content on MRI-PDFF-maps. Linear regression was used to examine the association between predictors and liver fat content per MRI-PDFF (reference standard). CT texture parameters with higher reproducibility (ICC >0.60) were moved forward into development of a multivariable model. The CT texture multivariable model was built using least absolute shrinkage and selection operator (LASSO) on those significant predictors (p-0.05). The root-mean square error (RMSE) and the coefficient of determination (R) were used to assess the goodness of fit of the models. Using a subset of significant predictors, accuracy (AUROC), sensitivity and specificity for correctly classified patients with >5.56% liver fat content were calculated.

RESULTS

The CT texture model most strongly associated with liver fat content consisted of percent of pixels less than 40 HU on unfiltered images (ICC=0.97-0.98, p=0.001), mean after median filtration (ICC=0.98-0.99, p=0.0001), and percent of pixels less than 40 HU after Gaussian filtration (ICC=0.95-0.97, p=0.0001). The CT texture prediction model had less deviation from and higher correlation with the reference standard than mean attenuation (RMSE = 0.474 vs. 0.513; R = 0.77 vs. 0.72, respectively). The AUROC, sensitivity and specificity for detecting >5.56% liver fat content were 0.96, 86.5%, and 92.3% for the CT texture prediction model vs. 0.93, 83.8% and 92.3% for mean attenuation.

CONCLUSION

A CT texture prediction model is highly reproducible and more accurate than CT mean attenuation for estimating liver fat content.

CLINICAL RELEVANCE/APPLICATION

CT texture can be used to accurately and reproducibly quantify liver fat content in patients at risk for NAFLD.

PURPOSE

To assess heterogeneous hepatic injury with Gd-EOB-DTPA enhanced MRI on a novel rat model.

METHOD AND MATERIALS

This study is approved by institutional review board. Seventy male Sprague-Dawley rats were randomly divided into control group (n=10) and colchicine group (n=60). The solution with 0.25% colchicine (0.4ml/kg) was injected via the splenic vein to develop a rat model of heterogeneous hepatic injury. An equal volume of normal saline was injected via the splenic vein in the control group. After the operation, at Day 3, week 1, week 2, week 4, week 8 and week 12 ten rats of the colchicine group were selected randomly for MRI examinations respectively, then they were euthanized. The ten rats of control group underwent MRI examinations at the same time points, and were euthanized at week 12 after MRI examinations. Gd-EOB-DTPA enhanced T1WI, T2WI and diffusion weighted imaging (DWI)were used to evaluate the heterogeneous hepatic injury. The quantitative data of left and right hepatic lobes, which were calculated on MRI, were compared and correlated with the pathological result of hepatic injury, which was assessed on liver sections according to the histological scoring criteria. P value of <0.05 was considered statistically significant.

RESULTS

There was obvious pathological change of rat hepatic parenchyma after colchicine injection through splenic vein, and the hepatic injury of left and right lobes was significantly difference (P <0.05). Meanwhile there were significant difference in ADC of DWI, LMR(liver-to-muscle ratio) of T2WI and ΔLMR(the difference value of LMR between pre- and post-enhanced T1WI)between left and right lobes of colchicine groupat each time point respectively(P <0.05), and it is similarly between colchicine and control group(P <0.05). Besides, there were significant correlation between ADC, LMR, ΔLMR value and hepatic injury score, respectively (r=-0.682, P=0.000; r=-0.245, P=0.018; r =-0.807,P =0.000).

CONCLUSION

Gd-EOB-DTPA enhanced MRI is useful for evaluation of heterogeneous hepatic injuty, which induced by injection of colchicine through splenic vein. It is necessary for the further research on clinic.

CLINICAL RELEVANCE/APPLICATION

Gd-EOB-DTPA enhanced MRI is useful for evaluation of heterogeneous hepatic injuty,which is necessary for the further research on clinic.

SSJ09-05 Expanded Quantitative Ultrasound of the Liver in Healthy Adults

Tuesday, Nov. 27 3:40PM - 3:50PM Room: S104B

Participants

andrew.trout@cchmc.org

PURPOSE

Imaging techniques including ultrasound are becoming increasingly quantitative. With shear wave elastography (SWE) becoming increasingly utilized clinically, ultrasound system manufacturers are developing additional methods of tissue quantification. Two such techniques are shear wave dispersion (SWD) and attenuation imaging (ATI). SWD quantifies the variation in shear wave speed (SWS) with frequency (i.e. dispersion slope in units of (m/s)/kHz) and should provide information about viscoelasticity. ATI quantifies the ultrasound attenuation coefficient in tissue and may serve as a means to quantify hepatic steatosis. The purpose of this study was to acquire SWE, SWD, and ATI data in healthy adults to demonstrate applicability of the technique and define normal values.

METHOD AND MATERIALS

Under IRB approval, 28 healthy adults without a known personal or family history of liver disease were recruited to undergo a quantitative ultrasound of the liver including SWE, SWD and ATI. Imaging was performed by a group of experienced technologists utilizing an Aplio i800 (Canon Medical Systems, USA). 10 SWE and SWD measurements and 5 ATI measurements were obtained from the right lobe in each patient. Study population data were summarized utilizing descriptive statistics (means, medians, standard deviations and ranges).

RESULTS

Median age for the population was 45.2 years (range: 17.6-64 years) and 18 of 28 participants (64.2%) were female. Median body mass index was 24 kg/m2 (range: 20-29 kg/m2). Mean average (for the 10 measurements) SWS for the population was 1.37±0.11 m/sec (median: 1.34 m/sec, range: 1.17-1.6 m/sec). Mean interquartile range (IQR) was 0.17 for the population and mean IQR/median was 0.15. Mean SWD was 10.68±1.53 (m/s)/kHz (median: 10.15 (m/s)/kHz, range: 8.4-14.8 (m/s)/kHz) and mean attenuation was 0.59±0.09 dB/cm/MHz (median 0.59 dB/cm/MHz, range: 0.42-0.8 dB/cm/MHz).

CONCLUSION

Mean shear wave speed for adults without known liver disease on an Aplio i800 was 1.37±0.11 m/sec. SWD and ATI provide quantitative information that is additive to SWE. Data acquired in healthy adults presented here may serve as a reference against which to compare data from patients with suspected liver disease.

CLINICAL RELEVANCE/APPLICATION

Attenuation imaging and shear wave dispersion provide quantitative measures of tissue characteristics in addition to shear wave elastography. Normative values for adult liver on the Aplio i800 are provided.

amamer@uabmc.edu

PURPOSE

To validate a previously published pre-therapy conventional single energy multiphasic CT imaging biomarker that stratifies pancreatic ductal adenocarcinoma (PDAC) patients into different clinical groups and outcomes, using dual energy CT.

METHOD AND MATERIALS

IRB approved HIPAA compliant retrospective analysis of consecutive adult PDAC patients. Single operator recorded regions of interest (ROI) in tumor core, tumor border, pancreas border, normal pancreas using dedicated DECT server. ROIs were simultaneously populated to identical image locations on DECT 70 keV pancreatic parenchymal phase (PPP), single energy portal venous phase (PVP), and conventional unenhanced images. Imaging based classification of High Delta (HD-defined as increased enhancement difference across tumor-host tissue interface >= 40 HU on either 70 keV PPP or PVP) and Low Delta (LD- lower enhancement difference) was evaluated for resectable, borderline resectable (BRPC), locally advanced (LAPC), and metastatic PDAC groups and compared to outcomes using Cox proportional-hazards model.

RESULTS

158 subjects (79M, 79F, mean age 67.8) included: 93 advanced stage -50 locally advanced, 43 metastatic; 65 lower stage -48

resectable, 17 borderline resectable. 44 underwent Whipple. 28 received neoadjuvant therapy. Median overall survival (OS) was significantly shorter for HD tumors in both advanced stage patients (10.8 vs 18 months; HR, 2.03; 95%CI, 1.22 to 3.48; P= .0062) and in lower stage patients (13.5 vs 23.3 months; HR, 1.87; 95%CI, 1.01 to 3.53; P= .042). In lower stage patients, delta was associated with OS after accounting for age, tumor size, surgery, and neoadjuvant therapy (P= .04) In non-metastatic patients, HD was associated with shorter time to distant metastasis development (HR, 2.28; 95%CI, 1.04 to 5.25; P= .03).

CONCLUSION

Our results validate the prognostic value of CT-based classification of PDAC patients using DECT; those with tumors characterized by high delta have significantly shorter survival.

CLINICAL RELEVANCE/APPLICATION

As with conventional MDCT, Delta score is a visually apparent and quantifiable DECT imaging biomarker that can stratify distinct subtypes of tumors in PDAC patients.

PURPOSE

To estimate the benefit of pelvic MR imaging after a negative routine pelvic ultrasound (US) in patients with pathologically or surgically proven endometriosis.

METHOD AND MATERIALS

In this retrospective observational study, patients with surgically or pathologically proven endometriosis had routine pelvic US followed by pelvic MR imaging within six months. Patients were excluded if they had a previous history of confirmed endometriosis, were pregnant, > 18 years of age, or surgery > 1 year after MR. Clinical pelvic US and MR reports were independently reviewed to assess the ability of each modality to detect endometriosis, and to compare the detection rate based on disease location and sequela using the surgical and pathology reports as a reference standard. Examinations were considered negative if findings were normal or if a detected lesion was reported indeterminate or nonspecific.

RESULTS

83 female patients (ages 25-53) with pathologically proven endometriosis were included. The mean duration between the pelvic US and MR was 33 ± 43 days, with 64 ± 69 days between MR examination and surgery. Suspicion of endometriosis occurred in 18/83 (22%) of patients for pelvic US and 51/83 (59%) for MR examinations ($p<0.0001$). Of 65 patients with a negative pelvic US exam, 33/65 (51%) had a positive MR. Of 18 patients with a positive US exam, MR identified additional sites or sequela in the majority (14/18; 78%). Additional information on the MR examinations included extraovarian locations [e.g., fallopian tubes 7/18 (39%), uterus 7/18 (39%), uterosacral ligaments 3/18 (17%), other uterine ligaments 6/18 (33%), posterior cul de sac 5/18 (28%), pelvic side walls 5/18 (28%), abdominal wall 1/18 (6%)] and sequela [tethering of the ovaries 5/18 (28%), 6/18 bowel adhesive disease (33%), obliteration of the posterior cul de sac 2/18 (11%), hydrosalpinx 2/18 (11%), and hydronephrosis 1/18 (6%)].

CONCLUSION

Pelvic MR imaging had a higher detection rate of endometriosis and provides more information about disease location and sequela compared to routine pelvic US. In patients with suspected endometriosis, pelvic MR or endometriosis protocol US is required to identify important sequela identified at surgery.

CLINICAL RELEVANCE/APPLICATION

A substantial proportion of patients undergoing evaluation for endometriosis with a negative routine pelvic ultrasound will benefit from pelvic MR imaging.

SSJ10-04 Efficacy of MRgFUS in Treating Focal Uterine Adenomyosis After 24 Months of Follow-Up

PURPOSE

To evaluate the treatment of focal uterine adenomyosis by using MRgFUS as a mini-invasive therapy after 24 months of follow-up

METHOD AND MATERIALS

From June 2014 to June 2016, 17 patients affected by focal uterine adenomyosis (focal form), diagnosed by MRI, were subjected to a single treatment using MRgFUS. The therapeutic plan consisted of a high-energy-grid sonication. MRI was performed without and after administration of contrast medium before treatment and at 3,6,12 and 24 months from the procedure to evaluate the focal thickness of the junctional area, the uterine wall morphology and the possibility of recurrence of this pathology. Clinical symptom outcome was assessed with a symptom severity score questionnaire (UFS-QOL) obtained at baseline and after 24 months from the procedure.

RESULTS

After MRgFUS, 10/17 patients with focal adenomyosis did not show disease recurrence showing a focal thickness of the junctional area of less than 12-13 mm and a good uterine wall morphology. Furthermore, in 7/17 treated-women, we found a disease recovery with focal thickness of the junctional area greater than 12 mm. In all patients, a reduction of about 75% of the symptomatology, assessed by UFS-QOL, was observed after 24 months from MRgFUS.

CONCLUSION

MRgFUS is an important mini-invasive treatment to treat focal adenomyosis allowing to maintain the integrity of the uterus wall in a pathology with limited therapeutic possibility.

CLINICAL RELEVANCE/APPLICATION

Adenomyosis is a gynecologic medical condition characterized by the abnormal presence of endometrial tissue within the myometrium In contrast, when endometrial tissue is present entirely outside the uterus, it represents a similar but distinct medical condition called endometriosis.MRgFUS is an important mini-invasive treatment to treat focal adenomyosis.

SSJ10-05 Urge Urinary Incontinence: Spectrum of Abnormalities on Static and Dynamic MR Imaging

Tuesday, Nov. 27 3:40PM - 3:50PM Room: S404CD

Participants
Rania F. el Sayed, MD,PhD, Cairo, Egypt (*Presenter*) Nothing to Disclose
Noha M. Mokble, MD,PhD, Cairo, Egypt (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

rania729.re@gmail.com

PURPOSE

To prospectively analyze static and dynamic magnetic resonance (MR) images to determine whether urge urinary incontinence (UUI) is associated lax uterosacral ligaments (USL)

METHOD AND MATERIALS

Study included 71 women: 41 healthy continent volunteers as a control group and 30 patients with UUI. Static MRI of the 71 women was performed using PD &T2 weighted turbo spin echo sequences; MR defecography was acquired using balanced fast-field echo. A standardized grid system that allowed us to record structural observations of the USL on sequentially numbered axial MR images was used by a radiologist who then applied a 4-point grading scale to assess ligament visibility. Cumulative data from the 41 continent control subjects were compiled so that a "normal" standard appearance for the USL could be defined and then compared with that of the UUI patient. MR images were interpreted by a trained radiologist , trained urologist and revised by an expert radiologist with 20 years experience in MR imaging of the pelvic floor. The expert radiologist was not aware of the clinical data of the patients.Inter observer reliability was evaluated for the collected data by the three observers

RESULTS

In the control group the mean length of right USL= 23.88 ± 9 mms while the left USL is 21.97 ± 9 mms. In the patient group, the mean length of right USL is 35.11 ± 11 mms while the left USL is 34.03 ±11 mms. There is significant statistical difference between the lengths in both groups with longer length in the cases group (P<0.01).The highest inter observer agreement was on the image number on which origin could be visualized .The lowest agreement was on the site of insertion of USL in both control and patient group.

CONCLUSION

We found that the average length of both USLs in the cases group is significantly longer than that of the control group. Moreover, we found a correlation between the increased length of the USLs and UUI.

CLINICAL RELEVANCE/APPLICATION

Pharmacological treatments of UUI are disappointing, since they are only slightly more effective than placebo. Urologist reported that operative repair of the USL know as cervical-rectal-sacral fixation (CERESA) could cure patients withUUI

SSJ10-06 MR of the Female Pelvis on 1.5 Tesla Scanner: Image Quality and Acquisition Time Comparison Between Synthetic MR Imaging and Turbo Spin Eco Sequences

Tuesday, Nov. 27 3:50PM - 4:00PM Room: S404CD

Iacopo Carbone, MD, Montreal, QC (*Abstract Co-Author*) Nothing to Disclose
Andrea Laghi, MD, Rome, Italy (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

to compare the image quality and acquisition time of synthetic MR imaging, based on multiple-dynamic multiple-echo (MDME) sequence, and turbo spin eco (TSE) sequences on 1.5 Tesla MR study of the female pelvis.

METHOD AND MATERIALS

Fifteen women were prospectively subjected to MRI examination of the pelvis according to the clinical indication. All exams were performed on a 1.5T MR scanner. The acquisition protocol was composed of conventional TSE T2w, TSE T1w, STIR T2w acquired on the axial plane. Then, a multiple-dynamic multiple-echo (MDME) sequence was performed for synthetic reconstruction of T2w, T1w and STIR T2w images on the axial plane. Two radiologists separately evaluated image quality by using Likert scale with 5 values. A quantitative evaluation was performed by measuring the signal intensity (SI) by placing a circular ROI of 5 mm in diameter in endometrium, junctional zone and myometrium. Signal to noise ratio (SNR) for the three layers were estimated. Image acquisition time of synthetic and conventional sequences was recorded. Results of conventional and synthetic imaging were compared using noninferiority statistics.

RESULTS

Overall qualitative and quantitative scores of synthetic MR images were non inferior to conventional imaging ($p>0,05$). The cumulative scan time of conventional sequences was significantly longer than synthetic sequences($p<0,05$).

CONCLUSION

Overall imaging quality and SNR obtained with synthetic imaging were similar to those obtained with conventional sequences. Thanks to the single acquisition, this could lead to a considerable time-saving for the hospital and the patient.

CLINICAL RELEVANCE/APPLICATION

Thanks to a single acquisition there is a great time savings for the patient in terms of comfort and for department in terms of productivity

Sung Bin Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Byoung Hee Han, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

pksungbin@paran.com

PURPOSE

To assess retrospectively the usefulness of testicular volume, apparent diffusion coefficient (ADC), and normalized ADC (nADC) as measured using MRI in predicting the histopathological grade of azoospermia and in differentiating obstructive from non-obstructive azoospermia.

METHOD AND MATERIALS

A computerized search generated a list of 30 infertile men with azoospermia who had undergone both scrotal MRI and testis biopsy. MRI-determined testicular volumes, ADCs and nADCs were compared between infertile men with obstructive and those with non-obstructive azoospermia. The nADC was calculated as ADC (testis)/ADC (bladder lumen).

RESULTS

16 were obstructive azoospermia and 14 were non-obstructive azoospermia. The testicular volume in obstructive azoospermia (8.7-27.6 mL) was significantly greater than that in non-obstructive azoospermia (1.8-15.4 mL; $p < 0.001$). The area under the ROC curve for distinguishing non-obstructive from obstructive azoospermia using testicular volume was 0.92 (<= 13.06 mL, sensitivity of 85.71% and specificity of 87.5%). Testicular ADC and nADC in obstructive azoospermia (0.329×10-3 to 1.578×10-3 mm2/s for ADC, 0.113-0.449 for nADC) were significantly lower than in non-obstructive azoospermia (0.801×10-3 to 2.211×10-3 mm2/s; $p = 0.0094$ for ADC, 0.235-0.61; $p = 0.0001$ for nADC). The area under the ROC curves for distinguishing non-obstructive from obstructive azoospermia using testicular ADC and nADC were 0.741 (> 1.031×10-3 mm2/s, sensitivity of 92.86% and specificity of 56.25%) and 0.875 (> 0.425, sensitivity of 78.57% and a specificity of 93.75%).

CONCLUSION

Testicular volume, ADC, and nADC, as measured using MRI, are useful in predicting the histopathological grade of azoospermia and in differentiating obstructive from non-obstructive azoospermia.

CLINICAL RELEVANCE/APPLICATION

MRI can evaluate azoospermia with good performance, the testicular volume, ADC and normalized ADC values measured on MRI are useful in predicting the histopathologic grading of azoospermia and differentiating obstructive from non-obstructive azoospermia. Therefore, DWI seems to be a promising imaging method with great potential for the differential diagnosis of azoospermia.

SSJ11-02 Validation of Vesical Imaging Reporting and Data System (VI-RADS) in Untreated Patients with Bladder Cancer at a Single Reference Center

Tuesday, Nov. 27 3:10PM - 3:20PM Room: S403A

Valeria Panebianco, MD, Rome, Italy (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To date, several studies have evaluated the ability of Multiparametric MRI of the bladder (mpMRI) to detect and stage bladder cancer (BCa). Nevertheless, there is still no standardized reporting system. Our aim was to validate the recently developed Vesical Imaging Reporting and Data System (VI-RADS) for BCa.

METHOD AND MATERIALS

This is a retrospective study of 54 consecutive patients who underwent 3T MRI with a body-array coil for diagnostic confirmation and local staging of BCa between September 2017 and April 2018. The mpMRI protocol included T2-Weighted sequences, Diffusion-weighted images with Apparent Diffusion Coefficient Maps reconstruction and Dynamic Contrast-enhancement Imaging. The goal of the mpMRI was to exclude the presence of muscle invasive BCa (MIBCa). MpMRI exams were interpreted by two readers, blinded to cystoscopy and/or other imaging exams. Sensitivity, specificity, and agreement were calculated based on a criterion of VI-RADS score = 4. Inter-examiner agreement was determined by the weighted kappa statistic.

RESULTS

Patients' median age was 67 years. There were 42 males and 12 females. Histological findings were positive for MIBCa in 15 patients. The remaining 39 had superficial BCa. Considering a VI-RADS score of 4 as positive for MIBCa, the accuracy of each reader was 92% and 89%, respectively, and interobserver agreement was excellent (weighted $\kappa = 0.81$; 95% confidence interval: 0.73-0.88; P?=?0.023). Considering PI-RADS 2 as absence of MIBCa, the accuracy of each reader was 95% and 92%, respectively, with excellent agreement (weighted $\kappa = 0.85$; 95% confidence interval: 0.71-0.92; P?=?0.031). Sensitivity and Specificity were 91% and 94% respectively. Positive Predictive Value and Negative Predictive Value were 92% and 95% respectively.

CONCLUSION

The recently developed VI-RADS score at 3T has a high accuracy for exclusion of MIBCa, with excellent inter-reader agreement. These results are promising for improving the management of patients with BCa.

CLINICAL RELEVANCE/APPLICATION

The introduction of a standardized reporting system for multiparametric MRI of the bladder could greatly simplify its introducion in clinical practice.

SSJ11-03 Testicular Microlithiasis and Extragonadal Germ Cell Tumors: Clinical-Radiologic-Pathologic Correlation in 22 Patients

PURPOSE

The majority of germ cell tumors have testicular origin, while only 2-5% of those tumors have extragonadal location. It has been said before that the presence of testicular microlithiasis has a very strong association with extra gonadal germ cell tumors.Our purpose is to demonstrate the correlation between these two in a series of 22 cases.

METHOD AND MATERIALS

This is a retrospective observational study of prospectively collected data of 22 consecutive patients with extra gonadal germ cell tumors from a tertiary care center between 2008 and 2017. Baseline characteristics (the presence of comorbidities, hypogonadism, primary tumor site, tumor histology, and clinical stage) and testicular ultrasonographic characteristics (testicular volume and the presence of microlithiasis) were recorded for every patient. Imaging characteristics were analyzed between groups according to primary tumor site and tumor histology.

RESULTS

The median age at diagnosis was 24.6 6.5 years and 9.5 % of the patients had a history of cryptorchidia. The most common extragonadal location was mediastinum (63.6%), followed by supraselar region (18.2%) and retroperitoneum (13.6%). Non-seminomatous tumors were more frequent (75%) than seminomas. Sixteen patients had testicular ultrasound and bilateral TML was observed in 43.8% while testicular atrophy (volume <12 cc) was detected in 53.3% of the patients. Furthermore, the presence of bilateral TML was associated with testicular atrophy (85.7% v.s. 14.3%, $p<0.04$). On univariate logistic regression analysis, testicular microlithiasis was associated with testicular atrophy (OR 18, CI 1.3-255.7, $p <0.03$).

CONCLUSION

The most common primary site for EGCT was the mediastinum and the most frequent histologic type were non-semminomatous tumors. The prevalence of TML in patients with EGCT is far more common than the one reported in healthy individuals. Bilateral TML was observed in 43.8% of the patients and it was associated with testicular atrophy.

CLINICAL RELEVANCE/APPLICATION

Testicular microlithiasis has been associated with intratubular germ cell neoplasia in patients with testicular cancer. The clinical relevance of this finding in patients with EGCT remains unknown. To our knowledge, this is the largest case series in literature.

SSJ11-04 Improving Treatment Response Assessment of Bladder Cancer by Integrating Deep Learning, Radiomics and Clinical Information

Tuesday, Nov. 27 3:30PM - 3:40PM Room: S403A

PURPOSE

To evaluate the accuracy of treatment response assessment of bladder cancer using deep learning, automatically extracted radiomic features from CT scans, and clinically estimated feature.

METHOD AND MATERIALS

A deep-learning neural network (DL) was trained to recognize the patterns of bladder lesions indicative of treatment response. 47 radiomic features (RF) including pre- and post- treatment change in volume, 5 gray level and 9 shape descriptors and 32 texture features were also extracted from automatically segmented lesions. A clinically estimated feature, the bimanual exam under anesthesia (EUA), was also collected from the clinical reports. Linear discriminant analysis and max function were used to generate combined response indices (CRIs): RFs alone (CRI-RF), RFs and DL (CRI-RF-DL), RFs, DL and EUA (CRI-RF-DL-EUA). Pre- and post-chemotherapy CT scans of 98 patients with bladder cancers were collected with IRB approval. For all cases, cystectomy was performed after treatment and the disease outcome was available as reference standard of treatment response. 25% of patients had pT0 disease (complete response) at cystectomy. A radiologist marked 122 temporal pairs of primary site cancers. Stepwise feature selection and leave-one-case-out cross-validation were performed. The area under the test ROC curve (AUC) was calculated to estimate the accuracy for predicting pT0 stage (complete response) at cystectomy by the methods. Two radiologists also estimated the likelihood of pT0 stage of the tumor by reading the pre- and post-treatment paired CT scans.

RESULTS

For the 122 cancers, the AUC for DL in predicting pT0 disease at cystectomy was 0.69±0.05. The AUC for CRI-RF based on 2 Contrast and 2 RLS features was 0.75±0.05, which increased to 0.79±0.04 by adding DL (CRI-RF-DL), and further increased to 0.80±0.04 with EUA (CRI-RF-DL-EUA). The two radiologists' AUCs in predicting pT0 disease were 0.77±0.05 and 0.75±0.05. The differences in any pairs of AUCs did not reach significance ($p>0.05$).

CONCLUSION

CRI-RF, CRI-RF-DL and CRI-RF-DL-EUA performed similarly to the radiologists for estimation of treatment response. The addition of DL and EUA improved the accuracy of treatment response assessment.

CLINICAL RELEVANCE/APPLICATION

The combined response index using deep learning knowledge, the radiomic features and clinically estimated EUA has the potential to provide accurate treatment response assessment.

SSJ11-05 Evaluation of Quantitative T2-Weighted and Apparent Diffusion Coefficient Textural MRI Features to Predict Muscle Invasive Bladder Cancer (Stage >=T2) and Extravesical Extension (Stage >=T3) Prior to Surgery

limchris14@gmail.com

PURPOSE

To evaluate quantitative MRI textural features associated with muscle invasive bladder cancer (MIBC) (stage >=T2) and extravesical extension (stage >=T3) on T2-weighted (T2W) and apparent diffusion coefficient (ADC) images in patients post transurethral resection of bladder tumor (TURBT).

METHOD AND MATERIALS

This IRB-approved, HIPAA-compliant retrospective study identified 36 patients (27 men, 9 women; mean age 70.8, SD 11.1) with bladder cancer diagnosed by TURBT who subsequently underwent mp-MRI, followed by cystectomy, and without intervening

treatment, between 08/2011-08/2016. A radiologist blinded to T stage manually contoured the primary bladder cancer (BC), and extravesicular fat (EF) immediately adjacent to the tumor on T2W and ADC images using a commercially available texture analysis software (TexRAD Ltd, Cambridge, UK). Six textural features (mean, sd, entropy, mpp, skewness and kurtosis) derived from the contoured BC and AF were compared between stage T1 versus >=T2 and between stage =T3 tumors using independent sample Kruskal-Wallis or Mann-Whitney U test and multivariate logistic regression analysis (p-value <0.05).

RESULTS

Total of 72.2% (26/36) bladder cancers were stage >=T2 stage and 52.8% (19/36) were stage >=T3. BC entropy on T2W, and EF entropy on both T2W and ADC, were significantly increased in stage >=T3, compared to stage =T2, compared to stage T1, tumors on T2W and ADC ($p<0.05$) with univariate analysis; however, the difference did not persist on multivariate analysis.

CONCLUSION

Higher entropy of BC and EF may help identify >=T3 tumor on T2W and ADC. Entropy may also be different between T1 and >=T2 tumors but that difference was not significant on multivariate analysis in this pilot study.

CLINICAL RELEVANCE/APPLICATION

Staging bladder cancer with TURBT alone can be inaccurate. Entropy, a quantitative textural feature, of the bladder cancer and extravesicular fat immediately adjacent to the tumor may be predictive of higher stage cancers on multiparametric MRI, allowing for more informed management decisions.

carter.rickey@mayo.edu

PURPOSE

To examine the ability of a pseudo-reader study design to estimate the observer performance obtained using a traditional prospective, fully-crossed, multi-reader, multi-case (MRMC) study.

METHOD AND MATERIALS

The pseudo-reader study design assumes readers in an MRMC study are exchangeable (same confidence scale usage and detection ability), but uses only a fraction of the total possible reading impressions by randomly allocating what normally would be one reader's reading list to multiple readers (Fig A). To better understand the operating characteristics of the design, we compared results using a pseudo-reader study design with ten radiology trainees and four CT noise reduction methods (NRMs) (2 projection space, 2 image space) to interpretations by 10 different radiology trainees in a traditional MRMC study. Following reader training, JAFROC Figures of Merit (FOM) were calculated for each NRM and reader, and differences of FOMs were estimated using the Hillis improvement to the Dorfman, Berbaum and Metz (DBM) method under the modeling assumption of random readers - random cases using the RJafroc (v1.0.1) and mrmctools (v1.0.2) packages on R version 3.4.2.

RESULTS

The best performing NRM by the pseudo-reader approach retained the first place ranking in this traditional MRMC validation study with the highest FOM (0.71; 95% CI: 0.60 to 0.81), providing qualitative validation to the pseudo-reader approach; however, all FOMs in this traditional MRMC validation study overlapped widely with the pseudo-reader estimate but were numerically lower than that observed using the pseudo-reader with decreases ranging from 2% to 10%. Reading times in the fully crossed study dropped from 3.1 minutes to 1.9 minutes ($p<0.001$). The agreement of the readers' confidence scores, measured by the intraclass correlation, ranged from 0.60 to 0.66 across the NRM, representing moderate agreement.

CONCLUSION

The results of our fully-crossed MRMC validation study design provided qualitative agreement with the pseudo-reader estimate; however, agreement of confidence scores and changes in reading times may suggest that the operating characteristics of the pseudo-reader and fully-crossed MRMC study designs may not be the same.

CLINICAL RELEVANCE/APPLICATION

Multireader multicase studies are needed to determine observer performance; shortening trial design using a pseudoreader may be one optiojn, but requires careful attention to reader training and study design.

SSJ12-02 Which Patients with Small Renal Tumors Would Benefit Most from Preference Elicitation to Guide Management Decisions? A Quality of Life Analysis

Tuesday, Nov. 27 3:10PM - 3:20PM Room: S403B

Participants
Rahul D. Mali, MBBS,MPH, New York, NY (*Presenter*) Nothing to Disclose
Stella Kang, MD,MSc, New York, NY (*Abstract Co-Author*) Royalties, Wolters Kluwer nv

For information about this presentation, contact:

stella.kang@nyumc.org

PURPOSE

To identify patient subgroups for whom the most effective treatment for small renal masses depends upon preferences for watchful waiting, by comparing quality-adjusted life expectancy (QALE) across various treatment strategies.

METHOD AND MATERIALS

We used a state transition microsimulation model to estimate QALE for patients with mild chronic kidney disease (CKD) and small renal masses. The model compared 5 strategies: partial nephrectomy, ablation, biopsy based treatment, watchful waiting using CT, and MRI selection for watchful waiting. We incorporated renal function loss according to treatment and tumor anatomy, CKD and other comorbidities, and oncologic risk. Nephrometry Score (NS), a system for quantifying tumor anatomic complexity, was used to correlate with renal function loss after partial nephrectomy using published regression formulas. Utilities specific to health state were used to weight the quality of life. The utility for watchful waiting can vary widely due to anxiety and preferences for intervention, and we assessed the impact of varying this utility on the optimal treatment. We used sensitivity analysis to test effects of varying parameters on model results.

RESULTS

In 65-year-old men and women with anatomically simple small renal masses (NS 4-6), partial nephrectomy yielded far greater QALE (up to +3.4 months) compared with watchful waiting. For moderate anatomic complexity (NS 7-8), watchful waiting using CT surveillance yielded the highest QALE compared with the next highest QALE from biopsy based management (+1.1 months for NS of 7). In this group, the optimal treatment was dependent upon the utility related to watchful waiting. Specifically, watchful waiting using CT was the preferred treatment for patients with a utility for watchful waiting above 0.88. For high anatomic complexity (NS 9-10), watchful waiting offered greatest benefit compared with all other treatments (+1.2 months vs. ablation); ablation became favored when the utility of watchful waiting was under 0.59.

CONCLUSION

To optimize quality of life in treatment selection for patients with mild CKD, anatomically complex renal tumors warrant formal preference elicitation for watchful waiting vs. other treatment options.

CLINICAL RELEVANCE/APPLICATION

In decision making for small renal tumors, preference elicitation for watchful waiting vs. intervention likely improves longterm quality of life for patients at risk for worsening CKD after surgery.

SSJ12-03 Preference and Cost-Comparison for Iodinated and Barium-Based Oral Contrast Media: Prospective Clinical Trial in Cancer Patients with Multiple Prior CT Exams

PURPOSE

Oncological patients undergo multiple abdominopelvic CT with positive oral contrast media (CM). Aim of this study was to evaluate patient preference and cost-comparison for iodine- and barium-based CM used in abdominopelvic CT studies.

METHOD AND MATERIALS

In this prospective clinical trial, 157adults (74M, 83F; 63±12 yrs) with prior 120kVp abdominopelvic CT performed using barium-based CM (bCM; Readi-cat 2% w/v, Bracco) were enrolled. Subjects were randomly assigned to receive iodinated CM (iCM; Omnipaque 300mgI/ml, GE Healthcare) in standard concentration (iCMs 7.7mgI/ml) or 25%-reduced concentration (iCMr 5.8mgI/ml). iCM was diluted in water to obtain 900ml solution. Subjects were instructed to consume iCM in a similar protocol to bCM (900ml over 45 minutes). CT scans were performed with 100kVp single-energy-CT or dual-energy CT. A paper survey about patient's experience was conducted to rate and describe the taste of iCM on a 5-point Likert scale (1 dislike very much to 5 like very much), report adverse effects and indicate CM preference for future scans. Cost comparison of the two CM was also performed.

RESULTS

79/157 patients received iCMs and 78/157 received iCMr which was consumed over 37±10 min). Mean volume of iCM consumed was 877ml(450-900ml) and bCM was 870ml(400-900ml). 3 patients found it difficult to consume 900ml of bCM but were able to consume 900ml of iCM. Mean taste score for iCM was 3.7±1, with no significant difference between iCMs and iCMr ($p>0.05$). 77% (121/157) patients preferred iCM over bCM. Nine patients had no preference. Immediately after iCM consumption, 92% (145/157) had no adverse effects with iCM, whereas 5% (n=8/157) complained of minor gastrointestinal symptoms not requiring management (nausea-6, mild abdominal discomfort-2). Within 24 hours of iCM, 2% (4/157) patients developed diarrhea. 12 patients complained of diarrhea with bCM but not with iCM. The cost per patient for bCM was $6.86 compared with $5.30 to $6.6 for iCM, depending on the amount consumed.

CONCLUSION

Cancer patients who undergo multiple CTs as part of standard of care demonstrate a stronger preference for iCM due to its neutral taste and decreased viscosity.

CLINICAL RELEVANCE/APPLICATION

Palatable CM solutions are likely to improve patient acceptance and experience. With increased use of low kVp/keV imaging, iCM has the potential for being used as an oral CM with the advantage of being customizable and as a cost-saving alternate

SSJ12-04 Diagnostic Imaging in the Management of Patients with Possible Cerebral Venous Thrombosis: A Cost-Effectiveness Analysis

Tuesday, Nov. 27 3:30PM - 3:40PM Room: S403B

Participants
Wolfgang G. Kunz, MD, Munich, Germany (*Abstract Co-Author*) Grant, Medtronic plc
Matthias F. Froelich, MD, Munich, Germany (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

wolfgang.kunz@med.lmu.de

PURPOSE

To evaluate the cost-effectiveness of different noninvasive imaging strategies in patients with possible cerebral venous thrombosis (CVT).

METHOD AND MATERIALS

A decision model based on Markov simulations estimated lifetime costs and quality-adjusted life years (QALY) associated with the imaging strategies non-contrast CT (NCCT), CT venography (CTV), routine MRI without vascular imaging, and MR venography (MRV, Figure 1). The analysis was performed from a United States healthcare perspective. Model input parameters were based on best available and most recent evidence (Table 1), including outcome data from the International Study on Cerebral Vein and Dural Sinus Thrombosis (ISCVT). Starting age was 37 years as in ISCVT. The prior probability of CVT was set low at 1.6%, the reported frequency of CVT in consecutive brain imaging exams for isolated headaches at emergency departments. ISCVT outcome data were taken from CVT patients who also presented with isolated headache to reflect this low prior probability. Probabilistic sensitivity analyses (PSA) were performed using 10,000 Monte Carlo simulations to estimate model uncertainty. The percentage of cost-effective iterations was determined for different willingness-to-pay (WTP) thresholds.

RESULTS

The base-case analysis showed that NCCT and CTV were dominant over routine MRI and MRV. CTV led to incremental lifetime QALYs compared to NCCT (23.385 QALYs vs. 23.374 QALYs) at slightly higher lifetime costs ($5,210 vs. $5,057). CTV was the optimal strategy in the base-case analysis. In PSA, CTV was the strategy with the highest percentage of cost-effective iterations if the WTP threshold was set higher than $10,000/QALY (Figure 2). Complying with contemporary WTP thresholds and adjusting for model uncertainty, CTV was thus identified as the most cost-effective strategy. When the prior probability for CVT was set to 50%, diagnostic imaging with CTV was also preferred over MRV, routine MRI, or NCCT.

CONCLUSION

In patients at the peak age of CVT incidence yet low clinical pre-test probability of CVT, diagnostic imaging with contrast-enhanced venous CT angiography is the most cost-effective strategy.

CLINICAL RELEVANCE/APPLICATION

CTV should be the preferred imaging strategy, not only in patients with high prior probability, but also in patients with lower clinical suspicion of CVT.

SSJ12-05 Cost-Effectiveness of Thrombectomy for Ischemic Stroke in Extended Time Windows

Tuesday, Nov. 27 3:40PM - 3:50PM Room: S403B

Awards
Trainee Research Prize - Resident

wolfgang.kunz@med.lmu.de

PURPOSE

Two endovascular thrombectomy (EVT) trials have recently shown significant benefits over standard care (SC) medical management in large vessel occlusion stroke beyond 6 hours of symptom onset or last known to be well (i.e. for the first time also including the patient population with wake-up stroke). We aimed to determine the cost-effectiveness of EVT in this context.

METHOD AND MATERIALS

A decision model based on Markov simulations estimated lifetime costs and quality-adjusted life years (QALY) associated with EVT or SC (Figure 1). The analysis was performed in a United States setting from a societal perspective. Input parameters for the model were based on most recent and best available evidence (Table 1), including two recent late time window randomized clinical trials (DAWN, DEFUSE 3, Figure 2). Probabilistic sensitivity analyses (PSA) were performed using 10,000 Monte Carlo simulations to estimate overall uncertainty of the results. Incremental costs (IC), incremental effectiveness (IE), and incremental cost-effectiveness ratios (ICER) were derived. The willingness-to-pay (WTP) thresholds were set to $50,000, $100,000, or $150,000 per QALY respectively.

RESULTS

The base-case analysis identified EVT as the optimal strategy based on outcome data from DAWN (IC: -$51,561; IE: +1.90 QALYs; ICER: EVT dominant) or DEFUSE 3 (IC: -$6,905; IE: +1.63 QALYs; ICER: EVT dominant). Adjusting for all input parameter uncertainty in PSA, EVT was the preferred strategy with acceptability rates of 100% at WTP thresholds of $50,000, $100,000, and $150,000 per QALY based on DAWN or DEFUSE 3 data (Figure 3). DAWN-based simulations led to 99.9% dominant/cost-saving iterations, DEFUSE 3-based simulations to 66.1% dominant/cost-saving iterations (Figure 4).

CONCLUSION

EVT is not only a cost-effective but also long-term cost-saving therapy of large vessel occlusion stroke in patients presenting beyond 6 hours of symptom onset or last known to be well.

CLINICAL RELEVANCE/APPLICATION

Proven EVT effectiveness in late time windows will markedly increase the need for EVT procedures. Based on its cost-effectiveness, investments are justified to cover this increasing demand.

SSJ12-06 Changing Utilization of Imaging in Multiple Sclerosis Patients during Emergency Department Visits

Tuesday, Nov. 27 3:50PM - 4:00PM Room: S403B

Participants
Gelareh Sadigh, MD, Atlanta, GA (*Abstract Co-Author*) Nothing to Disclose

gsadigh@emory.edu

PURPOSE

To study the changing nature of imaging utilization in multiple sclerosis patients in US emergency departments (EDs).

METHOD AND MATERIALS

Using 2006-2014 data from the Healthcare Cost and Utilization Project (HCUP) Nationwide Emergency Department Sample (NEDS), the largest all-payer ED database in the US, we identified multiple sclerosis (MS) patients vising EDs, and studied their utilization and independent predictors of imaging tests using logistic regression.

RESULTS

Overall, an estimated total of 275,808 weighted cohort patients with a primary diagnosis of MS visited a US ED between 2006 and 2014 (mean age 44±13; 74% female), increasing from 25,815 in 2006 to 35,680 in 2014. Only 8.8% of patients underwent any imaging tests during their ED visits, and these were most commonly of the brain: CT (3.8%) and brain MRI (1.8%). ED imaging counts in MS patients increased from 1,422 in 2006 to 4,236 in 2014. Patients' primary insurance was Medicare in 34%, Medicaid in 21%, private insurance in 34%, other types in 4% and self-pay in 7%. Independent factors associated with higher utilization of ED imaging tests were age older than 45 year (OR 1.2), an ED visit year after 2009 (OR, 1.3), a primary payer other than Medicare/Medicaid (OR, 1.2), and an ED visit location in Northeast or South (OR 2.3) (All p values < 0.05).

CONCLUSION

Although uncommon overall, the use of imaging tests during ED visits for MS patients has increased over time, and most of these involve brain imaging. A variety of sociodemographic characteristics are associated with a higher likelihood of imaging utilization.

CLINICAL RELEVANCE/APPLICATION

Primary payer, location of ED and patient age are independent factors impacting increased use of imaging tests in MS patients during ED encounters.

stridan@emory.edu

CONCLUSION

Point-of-care photographs obtained simultaneously with portable radiographs can reduce wrong-patient errors. In addition, they provide clinical context improving confidence in radiograph interpretation.

Background

Wrong-patient errors in Radiology, where one patient's medical images are placed in another patient's Picture Archiving and Communications Systems folder, can cause serious problems for both patients. For example, in the State of Pennsylvania alone, 196 serious adverse events were attributed to wrong-patient errors in Radiology in 2009. To increase the detection rate of wrong-patient errors, we developed an automated system to obtain point-of-care photographs along with portable radiographs. The system is fully automated and does not require any technologist intervention.

Evaluation

Within the first 400 images that were obtained with our automated photography system, we found one potential instance of a wrong-patient error, which the photos helped to identify. The photos also helped in providing clinical context for several abdominal radiographs obtained for evaluation of feeding tube placement. In some instances, no feeding tube was seen in the radiograph, which prompted the radiologist to look at the photo: if, on the photo, no tube was seen in the nose or mouth it provided confidence that no call to the referring service needed to be made. If no feeding tube was seen in the abdomen but was was seen in the nose or mouth on the photo, this would prompt a confident call to the patient's nurse. Soft tissue injuries were also better evaluated by radiography when the concurrently obtained photos were available. The patient's face was captured in the photo along with more than 98% of chest and abdominal radiographs.

Discussion

The addition of point-of-care photographs provides an intrinsic, externally-obtained biometric identifier that can increase the detection of wrong-patient errors. This identifier is superior to identifiers such as arm-bands with bar-codes since the latter is an extrinsic identifier. In addition to providing positive patient identification, the photographs have provided clinical context and have been useful in adding confidence to the diagnosis.

PURPOSE

As part of the Medical imaging network enterprise (MiNE) initiative, an electronic repository of medical imaging data and metadata, we have examined health care consumers' opinions regarding sharing their de-identified medical images and related medical information for research purposes. We have considered the criteria that could influence patients' decision, whether or not to share their medical information, like data storage/access, and safeguards to maintain privacy and security.

METHOD AND MATERIALS

Patients from the Greater Toronto Area (GTA) attending Sunnybrook Health Sciences Centre for imaging in MRI, CT or US examination areas were invited to undertake a cross-sectional electronic survey. Patients were recruited while waiting for their examination. The survey was in an electronic format using tablet computers on site. Descriptive and parametric statistical analyses were performed.

RESULTS

Imaging clerks approached 1083 patients within the imaging areas (CT 609, US 314 & MRI 160) during patient check-in, 798 (74%) agreed to undertake the survey. Overall median age was 60 (IQR=18,Q1=52,Q3=70), 52% were females. Participants' level of education was: university degree (42%) and diplomas/certificates (34%), while 7% did not have any high school diploma. When assessing willingness to share their de-identified medical images for research, 453 (76%) were willing (agreed & strongly agreed), while 7% refused. Most patients (85%) felt comfortable with automatic storage of their images and gave unconditional data access to their family physicians (73%) and other physicians (57%). Also, 70% chose hospitals/research institutions to regulate electronic images databases. 89% of the respondents wanted safeguards against unauthorized access to their data and over 70% wanted full control over access.

CONCLUSION

Our study found that people are willing to share their clinically acquired medical images for research after full consent that clearly outlines privacy, confidentiality, security and control over permissions and duration of access. Respondents are more comfortable when medical image data warehouses/repositories are affiliated with universities/research institutions.

CLINICAL RELEVANCE/APPLICATION

Participants support sharing clinically acquired medical imaging data for research. These images could provide a great source of information when shared securely and confidentially among researchers with associated robust policies.

SSJ13-03 Using TLS (Transport Layer Security) and the ACME Protocol (Automatic Certificate Management Environment) for Securing DICOM Communications

Tuesday, Nov. 27 3:20PM - 3:30PM Room: N230B

Lawrence R. Tarbox, PhD, Little Rock, AR (*Presenter*) Nothing to Disclose
Robert Horn, Maynard, MA (*Abstract Co-Author*) Employee, Agfa-Gevaert Group

For information about this presentation, contact:

LTarbox@uams.edu

LTarbox@uams.edu

CONCLUSION

We wish to encourage sites to use the DICOM Secure Transport Connection Profiles, vendors to include the DICOM Secure Transport Connection Profiles in their product offerings, and both sites and vendors to support the ACME protocol to reduce the burden of managing and distributing security certificates.

Background

The Basic TLS (Transport Layer Security) Secure Transport Connection Profile has been part of the DICOM Standard since 1999, and has been updated over the years as technology improves. The lastest enhancements were approved this year. The Profile has also been incorporated into the IHE ATNA (Audit Trail Node Authentication) profile, and has been tested by multiple vendors at multiple IHE Connectathons. One of the barriers to deploying the Basic TLS Secure Transport Connection Profile at institutions is the need to manage security certificates. The ACME protocol (Automatic Certificate Management Environment) has the promise of simplifying the certificate management and distribution needed to properly deploy TLS-secured communications.

Evaluation

To demonstrate how to secure DICOM communications using automated certficate management, we set up an open source DICOM

archive, an ACME server for managing certificates, simulated modalities, and viewing stations. Using wire snooping software, we show how information is clearly visible on the network without encryption, and is hidden when encryption is enabled. We compare the performance of common DICOM operations both with encryption turned on and turned off. Both DIMSE based operations (DICOM binary protocol) and the new DICOM web-based, RESTful operations are demonstrated and measured.

Discussion

The use of the ACME protocol greatly simplifies the task of certificate management and distribution, which in turn makes it easier to deploy the Secure DICOM Connection Profiles. While the addition of TLS to secure DICOM communications does have a small performance hit, with modern compute speeds we feel that the additional security offered by TLS is well worth the performance hit.

SSJ13-04 The Achilles Heel of Draconian Hi-Tech Act Penalties: The Inadequacy of Current Data Encryption and Protection Technology

Tuesday, Nov. 27 3:30PM - 3:40PM Room: N230B

Diego G. Mercer, MD, Tel-Aviv, Israel (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

High-profile data breeches are now common. Penalties levied by HHS accompanying these data breeches are often in the millions of dollars. Hi-Tech Act assumes high penalties force players to use only 'breech-proof' systems and workflows. Users require workflows that are intuitive and easy to use. In data security, any skipped step may drastically increase the vulnerability of the entire system being protected. We have examined the healthcare environment to assess viability of the current technologies used in preventing data breeches.

METHOD AND MATERIALS

We examined the available data protection and encryption tools currently available to both civilian consumers and enterprises to assess the capability of storing 100% breech-proof data yet maintain high 'usability' for day-to-day use. We did not assess classified technologies not available for civilian use. We also examined some of the security workflows being enforced by large organizations to gain a realistic view of compliance versus users bypassing these protections in order to 'get their work done.' This was done by data collection of methods used by large and small healthcare organizations.

RESULTS

No single technology is yet available that allows automated, background encryption/decryption on all platforms used, Windows, MacOS, IOs and Android and include portable data transfers using USB Flash technology and other means, is yet available As organizations harden their policies and data access, both onside and remote, users become more creative and use BYOD, or even entire data sets off the enterprise or organizational servers, for access and ease of use.

CONCLUSION

Draconian Hi-Tech Act penalty assumptions appears false. Data currently cannot be 100% protected and adding stiff penalties just pushes organizations to enact harsher data access rules, forcing their own workers to bypass security systems to 'get their work done.'

CLINICAL RELEVANCE/APPLICATION

Organizational and enterprise data security today is being driven by the fear of extreme financial penalties, leading to policies and access rules that actually entice users to bypass the organizational security, weakening the overall security of the protected data.

SSJ13-05 CTrl-Alt-Radiate?

PURPOSE

Computed Tomography (CT) is an essential and commonly used X-ray generator modality that uses ionizing X-ray radiation to produce images. The CT modality consists of an ecosystem of components, which communicate with each other within the CT's ecosystem. As technology advances, the CT's ecosystem is becoming more connected to the hospital's network and the Internet, exposing it to a variety of security vulnerabilities and threats to potential cyber-attacks. The combination of ionizing radiation, potentially harmful to patients, and security vulnerabilities to cyber-attacks results in possible dangerous scenarios that compromise patients' safety. To illustrate the importance of the topic, we demonstrate how we hacked a CT.

METHOD AND MATERIALS

We present a step-by-step implementation of how we bypass current security protection mechanisms of a CT in order to manipulate its behavior, making it potentially dangerous to patients. This attack demonstrates how additional cyber-attacks on *medical imagining devices* (MIDs) can be similarly implemented. To accurately measure the potential damage to patients' health, we use a phantom device (i.e., a CT radiation measuring device), and analyze the risks that such attack can cause. Furthermore, we demonstrate how to exploit our cyber-attack covertly, so that it is difficult to detect it using current security solutions; thus, such attack may have long-term effects on a large-scale of the population.

RESULTS

A live demonstration of how we hacked a CT device and how we manipulated its behavior to create various dangerous scenarios for patients' health. Moreover, we analyze this attack in depth, to better understand the potential impacts of such attacks.

CONCLUSION

CT and MIDs are vulnerable to cyber-attacks; we demonstrate forcefully that hacking CT and MIDs is no longer theoretical. By analyzing the potential impacts to patients, we can conclude that such impacts are critical and must be dealt with urgently.

CLINICAL RELEVANCE/APPLICATION

This calls for an immediate improvement of CTs and MIDs security and further mitigation of risks to patients.

SSJ13-06 Kaleidoscope: A Series Projection Visualization Tool for Review of DICOM Images for Protected Health Information

Tuesday, Nov. 27 3:50PM - 4:00PM Room: N230B

For information about this presentation, contact:

ksmith@uams.edu

PURPOSE

Collections submitted to The Cancer Imaging Archive (TCIA) can approach one-million DICOM files. It is time consuming to review each image for burned-in-PHI, pixel data that contains names, dates, or other personal identifying information. Kaleidoscope was developed to increase throughput of visual review.

METHOD AND MATERIALS

Kaleidoscope, part of the open source Posda curation suite, displays minimum, maximum, and average projection images of a series. If the geometric information is not consistent across a series (different coordinate system) the series is divided into distinct subsets called equivalency classes to minimize image artifacts. An example of this is a longitudinal scout used to show the spatial positions of axial slices. Each equivalency class is viewed as individual sets of projection images. Kaleidoscope organizes images for review by collection. Upon review, a curator labels the series, or series equivalence class, as Good (definitely no PHI), Bad (has definite PHI), or Indeterminate (curator is unsure whether the image is ok to be included in the archive or not). A curation manager reviews Bad and Indeterminate cases and determines their final acceptance or rejection. Queries may be run to get lists of series based on the label assigned during visual review. If needed, these images may be retrieved by a query and inspected with other visualization tools. Kaleidoscope currently handles modalities CT, MR, PT, and SC.

RESULTS

To review a single image takes on average 0.7 seconds per image using the National Biomedical Imaging Archive (NBIA) quality control (QC) tool where an entire equivalency class can be reviewed using Kaleidoscope in that same amount of time. There are 203,099 series 21,082,265 CT images in the NLST collection. Reviewing NLST with the NBIA QC tool estimated 4100 hours and in practice took multiple curators weeks to complete. Using Kaleidoscope would take 1 curator about 40 hours.

CONCLUSION

Kaleidoscope is two orders of magnitude faster than using the NBIA QC tool.

CLINICAL RELEVANCE/APPLICATION

Kaleidoscope allows rapid inspection of DICOM images to ensure data are free of PHI or other personal identifying information prior to public dissemination to promote Open Science.

Moritz Wildgruber, MD, PhD, Munster, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Systemic sclerosis is an autoimmune disease with dysfunctional connective tissue repair inducing skin and internal organ fibrosis as well as vasculopathy, leading to serious complications such as digital ulcers. Microvascular dysfunction is a prognostic marker for morbidity and mortality in systemic sclerosis. However, due to a lack of functional tissue information using established imaging technologies, risk stratification remains challenging.We aimed to evaluate the clinical feasibility of a hybrid multispectral optoacoustic tomography (MSOT)/ultrasound (US) approach in systemic sclerosis.

METHOD AND MATERIALS

We used a combined handheld MSOT/US imaging system (iThera Medical, Munich) for imaging fingers D2 to D5 of systemic sclerosis patients (n=7, n=56 fingers) and healthy volunteers (n=8, n=64 fingers). In subcutaneous tissue, tissue levels of hemoglobin (deoxygenated (HbR), oxygenated (HbO2) and total (HbT)) were calculated after spectral unmixing. Furthermore, MSOT values were analysed to stratify patients with either progressive or stable disease activity. Statistical analysis was performed using unpaired t test.

RESULTS

In systemic sclerosis, MSOT values for HbR, HbO2 and HbT were significantly lower compared with healthy volunteers. On an individual basis, all patients had - as compared to healthy volunteers - a reduced ratio (<1.0) for HbO2 (ratio 0.53, $p<0.0001$) and HbT (ratio 0.49, $p<0.0001$). Additionally, in systemic sclerosis patients with a progressive disease significantly lower MSOT values were detected than in patients with a stable disease activity (HbR: 27.31 vs. 33.03 AU, HbO2: 23.87 vs. 29.22 AU, HbT: 51.18 vs. 62.24 AU; $p<0.001$).

CONCLUSION

This preliminary study demonstrates the feasibility of MSOT imaging to detect and quantify microvascular dysfunction in systemic sclerosis and to distinguish between progressive and stable disease activity. Therefore, MSOT may serve as a valuable non-invasive tool for disease stratification and therapy monitoring.

CLINICAL RELEVANCE/APPLICATION

As an easy-to-use, non-invasive and contrast-free imaging technique hybrid MSOT/US may facilitate both diagnosis and monitoring of treatment response in systemic sclerosis at the patient's bedside.

SSJ14-02 Optimization of Chest Acquisition on Whole Body PET/MRI for HCC Tumor Staging Using Non-Cartesian K Space Reconstructions

PURPOSE

To compare diagnostic performance and image quality for chest imaging of stack-of-stars T1 EG acquisition (STARVIBE) with non cartesian reconstructions of k-space, and Caipirinha 3D T1 EG acquisition, during whole-body PET-MR of HCC patients.

METHOD AND MATERIALS

33 consecutive patients referred for HCC staging in PET MRI (Biograph mMR, Siemens erlangen) were retrospectively included. All benefited from Caipirinha Dixon 3D T1 (T1EG Dixon post gadolinium) and Starvibe (post-gadolinium T1EG Dixon with radial filling of the Fourrier plan). A subjective evaluation of the image quality was performed. Detection of pulmonary nodular lesions with both sequences was compared by taking the chest CT scan as the standard of reference (Exact Fisher test). The signal-to-noise ratio of lung parenchyma (SNR) and contrast-to-noise ratio (CNR) of nodules, muscles and pulmonary vessels were compared between the two sequences (Student T-test).

RESULTS

The Starvibe sequence was judged subjectively better in 42% of cases and at least equivalent to Vibe in 88% of cases. It improved SNR (375% vs 89%, p <0.001) and CNR for muscles (53% vs 41%, p <0.001), vessels (84% vs 73%, p <0.001) and pulmonary nodules (34% vs 24%, p = 0.03). The detection of nodules was improved (sensitivity = 55% vs 41%) with a decrease in false positives (VPP = 92% vs 35%), without significant difference.

CONCLUSION

K space non cartesian reconstruction improves MRI's diagnostic performance at the chest stage by elevation of SNR and CNR.

CLINICAL RELEVANCE/APPLICATION

This new type of sequence without apnea could allow an improvement of the MRI diganostic performances especially at the thoracic stage in patients followed in oncology.

SSJ14-03 Whole-Body Functional PET-MR for Multiple Myeloma Staging: Impact of Sequence Design on Bone Marrow Infiltration and Focal Lesion Assessment

Tuesday, Nov. 27 3:20PM - 3:30PM Room: S505AB

PURPOSE

To study the impact of functional simultaneous 18FDG-PET-MR on bone marrow infiltration evaluation and focal lesion detection in initial staging of Multiple Myeloma (MM).

METHOD AND MATERIALS

25 consecutive patients referred to our centre for initial staging of a monoclonal gammopathy were included. PET-MR sequence design included whole-body T1-weighted spin-echo and T2-fat supressed DIXON weighted images (CWB-MRI) combined to whole-body Simultaneous Multi-Slice diffusion-weighted imaging (WB-DWI), 3D whole-body isotropic dynamic contrast-enhanced images (WB-DCE) and 3D-T1 weighted images combined with PET (T1-PET) acquisition using 4-5 MBq/kg of 18FDG-glucose. In the first part of the evaluation, the mean apparent diffusion coefficient (mADC), the mean enhancement (mE) and mean maximal standard uptake value (mSUV) of the bone marrow measured at the posterior part of the ischium, the lowest lumbar vertebral, and lowest thoracic vertebral possible outside of focal lesions were measured. The second part of the evaluation comprised the counting of focal lesions on CWB-MRI, CWB-MRI combined with WB-DWI, CWB-MRI combined with WB-DCE, CWB-MRI combined with PET, and PET-MR. Based on these findings, each patient was allocated a specific staging for bone marrow infiltration (BMI) and the number of focal lesions.

RESULTS

Functional imaging significantly impacted assessment of BMI; Compared to CWB-MRI, WB-DWI upstaged 7 and down staged 8 patients, WB-DCE upstaged 17 and down-staged 5 patients, PET upstaged 6 and down-staged 4 patients. Correlation between functional imaging and percentage of plasma cell infiltration were [r=0.7655, p<10^-6], [r=0.549 p<0.005], [r=0.678, p=0.0001] for mADC, mE, and mSUV. Compared to CWB-MRI, PET-MRI detected 30 additional focal lesions among 8 patients and upstaged 6 of them. 4 patients were upstaged from MGUS to stage 1 Multiple Myeloma (MM), 1 patient from stage 1 to stage 2 MM, and 1 patient from stage 1 to stage 3 MM. The detection of additional focal lesions did not modify staging for 2 patients.

CONCLUSION

PET-MRI modifies initial staging of patients with a monoclonal gammopathy. Further studies are necessary to improve medullary infiltration evaluation as well as prospective longitudinal studies to evaluate the prognostic value of these modifications.

CLINICAL RELEVANCE/APPLICATION

Functional PET-MRI significantly impacts initial staging of patients with suspected MM.

SSJ14-04 Multispectral Optoacoustic Tomography of Vascular Malformations

Tuesday, Nov. 27 3:30PM - 3:40PM Room: S505AB

Michel Eisenblaetter, MD, Muenster, Germany (*Abstract Co-Author*) Nothing to Disclose
Moritz Wildgruber, MD, PhD, Munster, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Differential diagnosis and treatment of congenital vascular anomalies is challenging and misdiagnosis is frequent. A novel non-invasive imaging approach combining not only visualization of anatomical features but also quantitative assessment of molecular tissue biomarkers would aid both diagnosis and monitoring of treatment response of vascular anomalies. We aimed to evaluate the feasibility of hybrid ultrasound (US) and multispectral optoacoustic tomography (MSOT) for non-invasive, real-time imaging of vascular malformations.

METHOD AND MATERIALS

In this pilot study 6 patients with arteriovenous (AVM) and 6 patients with venous (VM) malformations were investigated with a clinical hybrid MSOT/US system before and after either endovascular embolization (AVM) or percutaneous sclerotherapy (VM). All patients were diagnosed with AVM or VM according to the classification system of the International Society for the Study of Vascular Anomalies (ISSVA). Region of interest analysis of the lesion and contralateral healthy tissue revealed quantitative values for oxygenated (HbO2) and deoxygenated hemoglobin (HbR). Ratios of HbO2 over HbR were calculated for all vascular malformations and healthy tissue before and after treatment.

RESULTS

HbO2/HbR ratio was significantly higher for AVM versus VM and compared with healthy tissue (1.82±0.08 vs. 1.12±0.04 vs. 0.89±0.03, all p-values<=0.001). Therefore MSOT provided intrinsic biomarker patterns to distinguish arteriovenous from venous malformations. After therapy the HbO2/HbR ratio decreased in correlation to treatment success validated by MRI and angiography.

CONCLUSION

Different types of vascular malformations are clearly distinguished by MSOT-based, non-invasive assessment of hemoglobin levels in vascular malformations. Therapy effects could be instantly visualized and quantified.

CLINICAL RELEVANCE/APPLICATION

As an easy-to-use, non-invasive and contrast-free imaging technique hybrid MSOT/US may facilitate both diagnosis and monitoring of treatment response of vascular malformations at the patient's bedside.

SSJ14-05 Ultra-Fast Whole-body PET/CT Enabled by Digital Photon Counting PET Detector Technology: Findings from a Phase II Clinical Trial

knopp.16@osu.edu

PURPOSE

To assess in a Phase II study the clinical feasibility of ultrafast whole body PET imaging using the new generation digital photon counting PET and to compare by intraindividual comparison the diagnostic and quantitative findings to current clinical whole body PET acquisition.

METHOD AND MATERIALS

52 patients scheduled for FDG whole body PET/CT were imaged using three separate acquisitions as part of an intra-individual comparison study to compare a new genertaion digital system, dPET/CT (Vereos) with a current generation conventional sytem, cPET/CT (Gemini). Standard cPET imaging was performed at ~75 min p.i. of 13mCi FDG with investigational dPET imaged at ~55 min p.i. The first dPET acquisition was performed using 90s/bed position, immediately followed by a 9s/bed position acquisition lead to average table times of ~15 and ~2 min and compared with 90s/bed position cPET ~20 min . The 9s/bed dPET were reconstructed using a previously optimized methodology. All other aspects of image acquisition were kept identical. Three blinded reviewers

evaluated the data sets regarding visual characteristics, diagnostic confidence and semi-quantitative readouts.

RESULTS

All ultrafast scans were classified to be assessible. As expected, visual assessment scores were significant higher for 90s/bed dPET whole body (p<.01), while no significant between the ultra-fast wholebidy and the cPET scans were reported. The ultra-fast scan presented with slightly increased background noise levels. The ultra-fast scans also presented with substantially less motion artefacts including bowl movements. A county density regularized reconstruction approach is essential to achieve the acceptable image quality on a consistent basis.

CONCLUSION

Next generation digital photon counting detector technology enabled consisten accepatable image quality even for ultra-fast wholebody imaging with a whole body acquistion time of 2 min. The concept of ultra-fast whole-body acquisition is feasible, however requires count density adaptive, regularized reconstruction, New PET workflow concepts, improved patient comfort, minimized patient motion and whole-body pseudo dynamic imaging of tracer were demonstated as feasible.

CLINICAL RELEVANCE/APPLICATION

Ultra-Fast Wholebody PET/CT with 2 min acquisition time was shown to be feasible using a new generation digital photon counting PET/CT system

SSJ14-06 SiPM-Based versus LYSO-based 68Ga-DOTA-TATE PET/CT: Comparison of Semi-Quantitative Measurements in Normal Tissues and Lesions

lbaratto@stanford.edu

PURPOSE

To compare the performance of a silicone photomultiplier (SiPM)-based PET/CT scanner (DMI) and a LYSO-based PET/CT scanner (D690) used in our clinic and to determine any differences in semi-quantitative measurements.

METHOD AND MATERIALS

We prospectively enrolled patients referred for 68Ga-DOTA-TATE PET/CT. All patients underwent a single 68Ga-DOTA-TATE injection dual imaging protocol: they were randomly scanned first on the D690 or the DMI scanner. SUVmax of detectable lesions and SUVmean of different normal tissues were measured independently by two Nuclear Medicine Physicians, from data acquired using both scanners.

RESULTS

Data from 61 patients (35-80 year-old; 36 women, 25 men) was analyzed. Thirty-one patients out of 61 (51%) underwent DMI as first scan and a total of 95 lesions were detected on both scanners; the average SUVmax measurements for all 95 lesions were higher on DMI than D690 (28.1 and 25.2, respectively, r = 0.944, p<0.001, 95% CI, 1.382 to 4.375). Thirty patients out of 61 (49%) performed D690 PET/CT as first scan and a total of 84 lesions were seen on both scanners; the average SUVmax measurements for all 84 lesions were higher on DMI than D690 (38.3 and 33.8, respectively, r = 0.991, p<0.001, 95% CI, -6.139 to -2.879). Mean lesion:aortic arch ratios were higher on DMI than D690 (47.1 vs 42.7, and 26.6 vs 26.4 when D690 was performed first and when DMI was done first, respectively), but differences were not statistically significant (p<0.006 and p<0.877, respectively). The agreement analysis for different background organs indicated that scanners are similar in normal tissues uptake regardless of scan order.

CONCLUSION

We observed higher SUVmax values for lesions measured from DMI compared to D690 regardless of the order of the scan, while the measurements were similar for normal tissues. While delayed imaging can lead to higher SUVmax values in cancer lesions, in the series of lesions identified when DMI was performed as first scan this was not seen; therefore, the data suggests superior performance of the DMI scanner.

CLINICAL RELEVANCE/APPLICATION

DMI PET/CT new generation scanner have better performance on standard of care PET/CT scanners. This would allow to reduce the injected dose or the scan time without missing images quality.

PURPOSE

To evaluate the diagnostic performance of a dual-energy computed tomography (CT) virtual non-calcium (VNCa) technique for the detection of bone marrow edema in patients with acute knee trauma.

METHOD AND MATERIALS

Data from 41 patients with acute knee trauma who had presented to a level 1 trauma center emergency department were retrospectively included. Subjects had undergone clinically indicated third-generation dual-source dual-energy CT and 3-T magnetic resonance imaging (MRI) of the knee within 7 days between January 2017 and March 2018. Six blinded radiologists independently evaluated conventional grayscale dual-energy CT series for the presence of fractures; after 8 weeks, readers reevaluated all cases using color-coded dual-energy CT VNCa reconstructions for the presence of bone marrow edema for six femoral and six tibial regions. Quantitative analysis of CT numbers on VNCa reconstructions was performed by a seventh blinded radiologist. Results from MRI evaluated by two separate blinded experienced radiologists (20 and 32 years of experience in musculoskeletal imaging) served as standard of reference. Diagnostic performance was calculated taking into account clustering.

RESULTS

MRI revealed a total of 136 areas with focal posttraumatic bone marrow edema in 492 regions (61/246 femoral, 75/246 tibial). Fractures were present in 12 patients. In the subjective analysis, VNCa showed high overall sensitivity (95.6%), specificity (96.6%), positive predictive value (PPV, 91.5%) and negative predictive value (NPV, 98.3%) for the detection of bone marrow edema. Area under the curve was 0.959 (femur) and 0.962 (tibia). Inter-reader agreement was excellent (κ=0.91). CT numbers obtained from VNCa were significantly different in areas with or without edema (p<0.001). A cut-off value of -35 HU provided a sensitivity of 92.3%, specificity of 93.1%, PPV of 87.3% and NPV of 95.2% for the differentiation of bone marrow edema.

CONCLUSION

Dual-energy CT VNCa reconstructions yield excellent diagnostic performance for the detection of posttraumatic bone marrow edema compared to MRI in patients with acute knee trauma by enabling direct color-coded visualization.

CLINICAL RELEVANCE/APPLICATION

Presence and extent of bone marrow edema may be visualized during dual-energy CT performed for detection of fracture in patients with acute knee trauma by using color-coded VNCa reconstructions, potentially replacing MRI in patients with contraindications.

SSJ15-02 Identification of Bone Marrow Edema of the Ankle and Foot: Diagnostic Accuracy of Dual-Energy CT and Virtual Non-Calcium Techniques

gfoti81@yahoo.it

PURPOSE

To evaluate the diagnostic accuracy of dual-energy Computed Tomography (DECT) and virtual non calcium (VNC) techniques to identify bone marrow edema of the ankle and foot

METHOD AND MATERIALS

This prospective institutional review board-approved study included 38 consecutive patients (21 males and 17 females; mean age of 62.3, range 26-79 years) studied between January 2017 and January 2018. All patients underwent DECT (80 kV and tin filter 150 kV) and MRI with Short Tau Inversion Recovery images (STIR) within 7 days. DECT data were postprocessed on a dedicated offline workstation (SyngoVia® VB20; Siemens, Erlangen, Germany) by using a three-material decomposition algorithm for generating noncalcium images of the ankle and foot. Two radiologists, blinded to clinical and MRI data (25 and 11 years of experience, respectively) evaluated the presence of abnormal attenuation of each ankle on dedicated color-coded maps and on grey scale images. STIR images served as standard of reference. Diagnostic accuracy values of the DECT maps and of the CT numbers (quantitative assessment) by using receiver operator curves (ROC) and relative area under the curve (AUC) were calculated. Inter-observer and intra-observer agreement were calculated with k-statistics. Continuous and categorical variables were evaluated by using t test and x2 or Fisher exact test, as appropriate. A value of $p<0.05$ was considered statistically significant

RESULTS

MRI revealed the presence of bone marrow edema in 25/38 cases (65.8%). DECT numbers were significantly different between positive (mean -12.6 ± 29.6 HU) and negative cases (mean -64.2 ± 34.5 HU) with a p value <0.001. The ROC curve analysis revealed an AUC of 0.896 (95% confidence interval: 0.764-0.942). By using -20HU cutoff to identify bone marrow edema, the sensitivity, specificity, PPV and NPV and accuracy of DECT were 88.0, 92.3, 95.6, 80.0 and 89.5%, respectively. The interobserver and intraobsever agreement were near perfect (k=0.88 and k=0.91, respectively)

CONCLUSION

DECT represents a reliable imaging tool for demonstration of bone marrow edema of the ankle and foot

CLINICAL RELEVANCE/APPLICATION

DECT represents a fast and reliable imaging tool for demonstration of bone marrow edema of the ankle and foot and could be proposed as an alternative imaging modality in patients with contraindications for MRI

SSJ15-03 Sub-Milisievert Ultralow-Dose CT of the Cervical Spine: A Feasibility Study in Human Cadavers

Tuesday, Nov. 27 3:20PM - 3:30PM Room: E350

PURPOSE

To compare radiation dose and image quality of a standard-dose (SD) and four different reduced-dose (RD) computed tomography (CT) protocols of the cervical spine using filtered back-projection (FBP) and iterative reconstruction (IR) in human cadaver specimen.

METHOD AND MATERIALS

The cervical spine of 29 human cadavers (15 male) was examined using different RDCT protocols (P) with decreasing reference tube currents (P1:70; P2:50; P3:30; P4:10 mAs) at a tube voltage of 140 kV while a clinical SDCT protocol (120 kV, 160 mAs) served as reference. Raw data was reconstructed using FBP and two increasing levels of IR (4&6). Two radiologists assessed image quality for the upper (C1-4) and lower (C5-7) cervical spine. Images were evaluated for overall image quality and visibility of three separate anatomical structures according to a 5-point Likert scale. Additionally, diagnostic acceptability was evaluated. Results were compared using a linear mixed-effects regression model. This study was HIPAA compliant and was approved by our institutional review board, the need for informed consent was waived.

RESULTS

Image quality did not significantly differ between SDCT and RDCT P1-4 using IR 4&6 ($p>0.05$). Subjective image quality of the upper cervical spine was diagnostic for SDCT and all four RDCT protocols using FBP and IR except for only two cadavers in RDCT P4 using

FBP. Image quality of the lower cervical spine was rated as non-diagnostic in RDCT P3 (n=8/29) and RDCT P4 (n=22/29) reconstructed with FBP and in RDCT P4 (n=10/29) reconstructed with IR 4&6. Compared with the SDCT all RDCT protocols resulted in a significant effective dose reduction (SDCT:1.5±0.7 mSv; RDCT P1:1±0.6 mSv; P2:0.7±0.4 mSv; P3:0.4±0.2 mSv; P4:0.2±0.1 mSv; p<0.001).

CONCLUSION

Diagnostic acceptable sub-milisievert CT of the cervical spine is feasible with a reference mAs of 30 at 140 kV with iterative reconstruction.

CLINICAL RELEVANCE/APPLICATION

RDCT of the cervical spine with an effective dose of 0.4 mSv is feasible and should be implemented in clinical routine. Further dose reduction is possible, but IR seems not to compensate for image quality loss at the lower cervical spine.

SSJ15-04 Bone Marrow Imaging Using Dual Energy CT for the Evaluation of Diffuse Infiltrative Lesions of Multiple Myeloma: Correlation with the Severity of Marrow Infiltration Assessed by MRI

Tuesday, Nov. 27 3:30PM - 3:40PM Room: E350

Participants
Qin Wang, MD, Beijing, China (*Presenter*) Nothing to Disclose
Huadan Xue, MD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To assess the feasibility of using dual-energy CT(DECT) with virtual noncalcium(VNCa) technique for the evaluation of the severity of diffuse marrow infiltration of multiple myeloma, using MRI as reference standard.

METHOD AND MATERIALS

22 consecutive patients with plasma disorders were recruited prospectively, including active MM(n=12), MM in complete remission(n=2), MGUS(n=4) and systemic amyloidosis(n=4). All patients underwent whole-body DECT scan (80kV/Sn150kV) and MRI evaluation, including T1-weighted sequence, short TI inversion recovery sequence and fat fraction(FF) map quantified by six-echo volume interpolated breath-hold gradient echo Dixon sequence. VNCa CT numbers, regular CT numbers and FF of vertebral bone marrow were measured. The severity of marrow infiltration was graded as "normal", "moderate" and "severe", according to marrow signal intensities on T1-weighted images. The relationship between VNCa and severity of marrow infiltration was evaluated by Spearman correlation. ROC analysis was performed for the diagnosis of diffuse infiltration.

RESULTS

A total number of 173 vertebrae were measured. VNCa CT numbers were significantly positive correlated with the severity of marrow infiltration(r=0.580, P=0.000) and significantly negative correlated with FF of bone marrow (r=-0.546, P=0.000). The AUCs of VNCa(0.958) were significantly higher than that of regular CT numbers(0.472) for the diagnose of marrow infiltration. With the cut-off value of -34HU, the sensitivity and specificity of VNCa was 97.2% and 85.4%, respectively.

CONCLUSION

VNCa based on DECT is feasible for the evaluation of diffuse marrow infiltration of MM. A significant correlation was observed between VNCa and the severity of marrow infiltration assessed by MRI.

CLINICAL RELEVANCE/APPLICATION

VNCa technique based on DECT may severe as an alternative method for the evaluation of the severity of marrow infiltration in MM patients.

SSJ15-05 Diagnostic Accuracy Values of Dual-Energy CT and Virtual Non-Calcium Techniques to Evaluate Bone Marrow Edema in Vertebral Compression Fractures

PURPOSE

To evaluate the ability of dual-energy Computed Tomography (DECT) to identify bone marrow edema in vertebral compression fractures of thoracic and lumbar spine

METHOD AND MATERIALS

This prospective institutional review board-approved study included 76 consecutive patients (29 males and 47 females; mean age of 62.3, range 51-82 years) studied between February 2017 and February 2018. All patients underwent DECT (80 kV and tin filter 150 kV) and MRI with Short Tau Inversion Recovery images (STIR) within 7 days. DECT data were postprocessed on a dedicated workstation (SyngoVia® VB20; Siemens) by using a three-material decomposition algorithm for generating noncalcium images of

vertebral bodies. Two radiologists blinded to clinical data (25 and 11 years of experience, respectively) evaluated the presence of abnormal attenuation of each vertebral body on dedicated color-coded maps. STIR images served as standard of reference. Diagnostic accuracy values of the DECT maps (qualitative assessment) and of the CT numbers (quantitative assessment) by using receiver operator curves (ROC) and relative area under the curve (AUC) were calculated. Inter-observer and intra-observer agreement were calculated with k-statistics. Continuous and categorical variables were evaluated by using t test and x2 or Fisher exact test, as appropriate. A value of $p<0.05$ was considered statistically significant

RESULTS

MRI revealed 61/774 (7.9%) edematous vertebrae and 52/774 (6.7%) collapsed non edematous vertebrae. The sensitivity, specificity, PPV and NPV and accuracy of the DECT maps were 88.6, 92.3, 93.1, 87.3 and 90.3%, respectively. DECT numbers were significantly different between positive (mean -23 HU, range -189, 29 HU) and negative cases (mean -126 HU, range -321, -66 HU) with $p<0.001$. The ROC curve analysis revealed an AUC of 0.886 (95% confidence interval: 0.722-0.913). By using -50HU cutoff to identify vertebral edema, the sensitivity, specificity, PPV and NPV and accuracy of DECT were and 91.8, 90.4, 91.6, 90.4 and 91.1%, respectively. The interobserver and intraobsever agreement were near perfect ($k=0.87$ and $k=0.83$)

CONCLUSION

DECT represents a reliable imaging tool for demonstration of bone marrow edema in vertebral compression fracture

CLINICAL RELEVANCE/APPLICATION

DECT could be proposed as an alternative imaging modality in the suspect of vertebral compression fracture in patients with contraindications for MRI

SSJ15-06 Is CT-Based Cinematic Rendering Superior to Volume Rendering Technique in the Preoperative Evaluation of Complex Lower Extremity Fractures?

Tuesday, Nov. 27 3:50PM - 4:00PM Room: E350

Participants
Lena Marie Wollschlaeger, Duesseldorf, Germany (*Presenter*) Nothing to Disclose
Johannes Boos, MD, Dusseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Christoph Schleich, MD, Dusseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Pascal Jungbluth, Dusseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Gerald Antoch, MD, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Benedikt M. Schaarschmidt, MD, Essen, Germany (*Abstract Co-Author*) Stockholder, Bayer AG; Stockholder, General Electric Company; Stockholder, Siemens AG; Stockholder, Teva Pharmaceutical Industries Ltd

PURPOSE

Cinematic rendering (CR) is a recently launched, FDA-approved 3D reconstruction technique which converts conventional CT images into almost photorealistic 3D reconstructions using a unique lightning model. The purpose of this study is to compare CR and volume rendering technique (VRT) in complex lower extremity fractures and to evaluate the value of CR for traumatologists to improve preoperative planning.

METHOD AND MATERIALS

In this retrospective, IRB approved study, 41 consecutive patients (female: n=13; male: n=28; mean age: 52.3±17.9y) with complex lower extremity fractures (calcaneus: n=16, tibial pilon: n=19, acetabulum: n=6) were included. All datasets were acquired using a 128-row dual-source CT. CR and VRT images were reconstructed on a dedicated workstation. Two experienced board-certified traumatologists trained in special lower extremity trauma surgery reviewed VRT and CR images in independent sessions. Image quality, anatomical accuracy and fracture visualization were rated using a 6-point Likert scale (1=non-diagnostic to 6=perfect visualization). Furthermore, the additional value of CR in comparison to conventional VRT images on preoperative planning was assessed. For each score, median values between both readers were calculated. A Wilcoxon-Ranksum test was performed to compare both reconstruction methods. $p<0.05$ indicated statistical significance.

RESULTS

In comparison to VRT, CR had a higher image quality (VRT: 2.5; CR: 6.0; $p<0.001$), a higher anatomical accuracy (VRT: 3.5; CR: 5.5; $p<0.001$) and provided a more detailed visualization of the fracture (VRT: 2.5; CR: 6.0; $p<0.001$). Furthermore, both readers reported an additional value of CR images for preoperative planning in 65.9% (27/41) of all patients in comparison to VRT.

CONCLUSION

CR provides a more detailed visualization of complex lower extremity fractures compared with VRT. Additionally, CR is a useful tool for traumatologists to improve preoperative planning.

CLINICAL RELEVANCE/APPLICATION

Cinematic rendering is superior to volume rendering technique in the preoperative evaluation of complex lower extremity fractures.

Ogonna K. Nwawka, MD, New York, NY (*Presenter*) Research Grant, General Electric Company

PURPOSE

This study aims to evaluate the use of ultrasound in detecting traumatic lesions of the brachial plexus, comparing them to magnetic resonance (MR) imaging findings.

METHOD AND MATERIALS

Patients with symptoms suggestive of post-traumatic brachial plexopathy were recruited to undergo high resolution magnetic resonance (MR) imaging and ultrasound (US) of the brachial plexus. 30 patients fit criteria for study inclusion. Standard high resolution MR and US imaging was performed. The brachial plexus was imaged from the paravertebral region through the infraclavicular region on both MRI and US. Evaluation of radiographic findings were performed by two fellowship-trained musculoskeletal radiologists expert in brachial plexus imaging, of which one focused on MR imaging and one on US evaluation. MR and US findings were compared for characterization of injury at the root, trunk, division, cord and terminal branch level using kappa coefficient measurements.

RESULTS

On MR imaging, brachial plexus injury was detected in 25 of 30 patients, including 9 with high-grade lesions (neuroma, root avulsion or nerve transection). On US imaging, brachial plexus injury was detected in 28 patients, including 6 patients with high-grade lesions. False-negative US findings, were related to a limited field of view, obscuring of the field by bony structures, and limited mobility of patients. False-positive US findings were related to scarring. MR imaging suffered from hardware susceptibility effects in 3 patients and motion artifacts in 1 patient. Kappa values were >0.75 for the C5-C8 nerve roots, trunks, divisions, cords, and the suprascapular, median and ulnar nerves, indicating excellent agreement. The kappa values were < 0.75 for the T1 nerve root (0.30), axillary (0.74), radial (0.70) and musculocutaneous nerve (0.29). All kappa values were statistically significant ($p < 0.001$).

CONCLUSION

US and MRI demonstrate excellent agreement in the evaluation of brachial plexus trauma. Ultrasound detection is limited in regions obscured by bony structure and in patients with limited mobility. MRI evaluation is limited by hardware susceptibility artifacts and patient motion.

CLINICAL RELEVANCE/APPLICATION

As ultrasound demonstrates excellent agreement with MRI in the detection of traumatic brachial plexus lesions, it can serve as an alternative to MRI for evaluation of traumatic brachial plexopathy, particulary useful in patients who cannot tolerate MR imaging.

SSJ16-02 Shear Wave Elastography Demonstrates Reduced Patellar Tendon Elasticity in Jumping Athletes with Patellar Tendinopathy Compared to Activity-Matched Healthy Jumping Athletes

Tuesday, Nov. 27 3:10PM - 3:20PM Room: E353B

For information about this presentation, contact:

s.breda@erasmusmc.nl

PURPOSE

Patellar tendinopathy (PT) is characterized by localized patellar tendon pain and decreased performance in athletes. Morphologic changes and neovascularization are sequelae of PT, however sometimes subtle or absent. Evaluating elastic properties of the patellar tendon could improve the sonographic diagnosis of PT. Shear wave elastography (SWE) is a quantitative ultrasound-based imaging method measuring tissue elasticity. To explore the diagnostic performance of SWE to visualize PT, we evaluated patellar tendon elasticity in athletes with PT compared to activity-matched healthy jumping athletes.

METHOD AND MATERIALS

Athletes aged 18-30 years, playing tendon-loading sports at least 3 times per week were included for clinical and radiological evaluation of the patellar tendon. Symptomatic athletes underwent both clinical examination and sonographic evaluation (conventional ultrasound and power Doppler) to confirm the diagnosis of PT. SWE was performed in supine position with extended knees using a GE Logiq E9 ultrasound system. Activity-matched healthy controls without history of knee pain were recruited for ultrasound of both knees. Primary outcome was mean elastic modulus of the proximal patellar tendon measured in kilopascal (kPa). Tendon thickness was a secondary outcome measure. To compare tendon elasticity in healthy versus affected tendons, a Mann-Whitney U test was used. Linear regression analysis was performed to determine the association between tendon thickness and elasticity.

RESULTS

We included 37 athletes (30 affected with PT). Median elastic modulus of the proximal patellar tendon was 76.5 kPa [IQR 59.2-106.9] in PT, compared to 35.4 kPa [IQR 31.9-42.3] in healthy controls ($p<0.001$). Increased tendon thickness was associated with reduced tendon elasticity in jumping athletes with PT after adjustments for age and sex, ß=9.7 (95%CI 5.5-13.8), $p<0.001$.

CONCLUSION

Patellar tendon elasticity is reduced in jumping athletes with patellar tendinopathy compared to activity-matched controls. Furthermore, tendon elasticity is associated with tendon thickness. Further research is ongoing to explore the potential of SWE as an imaging biomarker to monitor treatment response in a randomized clinical trial.

CLINICAL RELEVANCE/APPLICATION

SWE is a promising quantitative imaging tool to visualize patellar tendinopathy and is currently evaluated to monitor treatment effects.

SSJ16-03 Simultaneous Multi-Band Fast Spin Echo MRI: Scan Time and Image Quality Improvement for Peripheral Nerve Imaging

Tuesday, Nov. 27 3:20PM - 3:30PM Room: E353B

Participants
Erin C. Argentieri, BS, New York, NY (*Abstract Co-Author*) Institutional research agreement, General Electric Company
Darryl B. Sneag, MD, Plainview, NY (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

sneagd@hss.edu

PURPOSE

To determine whethere a novel, fast spin echo (FSE) MR acquistiion using a multiband (MB) excitation, which has a minimal noise penalty, provides equivalent image quality at reduced scan time compared to a standard of care FSE acquistiion for evaluating peripheral neuropathies.

METHOD AND MATERIALS

This was an IRB-approved study of 8 patients (5F/8M), mean age 41.7± 14.5 years, who presented in clinic for routine MRI evaluation of peripheral neuropathy and who provided written consent. Data was acquired in: 4 knees, 1 elbow, 1 pelvis and 2 lower legs. For the knees and lower legs, evaluation was focused on the saphenous, tibial and commo peroneal nerves, while the ulnar nerve was evaluated for the elbow, and the lumbosacral plexus and sciatic nerves were the focus for the pelvis. All MRIs were performed at 3T (MR750 GE Healthcare, Waukesha WI), using a 16-channel flex-coil for all exams except the pelvis where a 32-channel torso coil was used. Axial proton density (PD) and T2-weighted fat saturation (T2-FS) standard-of-care (SOC)-FSE and MB-FSE scans were acquired with matching scan parameters: FOV:11-30 cm;512x352 (freq x phase); 26-62 slices; PD TR/TE: 4500/24 ms, T2-FS TR/TE 4800/86 ms; NEX:2.

RESULTS

No appreciable differences betweeen MB-FSE and SOC-FSE acquisitions were observed between qualitative evaluations of image quality based on the 5-point scale. All grades of MB-FSE image quality were ± 1 point of the corresponding SOC-FSE images: 38% of grades were + 1, and 50% of grades indicated that MB-FSE and SOC-FSE image sets were of equal image quality. Comparsions of MB-FSE and SOC-FSE image sets with identical imaging parameters revealed that the utilization of a MB-FSE acquisition saved, on average, 1.5 min. of scan stime (min: 30 sec; max: 2.5 min 27 sec).

CONCLUSION

Preliminary results of this pilot study indicate that the MB-FSE acquistion provides similar imaging quality compared to SOC-FSE acquisitions. MB-FSE accelerates FSE imaging without the noise penalty associated with in-plane acceleration techniques. For peripheral nerve imaging, where SNR and resolution are paramount, decreased scan time can be traded off to significantly improve image quality.

CLINICAL RELEVANCE/APPLICATION

Multi-band fast spin echo (FSE) MRI may provide similar image quality to conventional FSE within a shorter scan time, faciliating the acquistion of higher spatial resolution sequences for detecting peripheral neuropathies.

SSJ16-04 MR Neurography for the Evaluation of Peripheral Nerves and Associated Neurogenic Muscle Atrophy in Non-Systemic Vasculitic Neuropathy

PURPOSE

Non-systemic vasculitic neuropathy (NSVN) is a frequent cause of chronic progressive axonal peripheral neuropathy. Nerve biopsies can demonstrate axonal damage with asymmetric loss of nerve fibers. In contrary, diagnosis and evaluation of the clinical course remain difficult by non-invasive techniques (e.g. electroneurography (ENG) or electromyography (EMG)). Thus, the objective of this prospective clinical study was to evaluate MR neurography at 3T as a potential diagnostic tool for diagnosis and follow-up. NSVN causes damage of nerve fiber integrity, therefore diffusion tensor imaging (DTI) was evaluated to detect changes in NSVN patients. Since NSVN causes neurogenic muscle atrophy, the second aim of this study was to quantify the intramuscular fat fraction using proton density fat fraction (PDFF) mapping.

METHOD AND MATERIALS

In this prospective study, patients with NSVN and healthy controls (HC) were investigated by MR neurography at 3T (n = 9 respectively). In all patients tibial nerves were examined by DTI and fractional anisotropy (FA) was calculated. Secondly, fat fractions of the soleus muscle (SM) and gastrocnemius muscle (GM) were analysed by PDFF mapping. MR neurography data was correlated with clinical follow-up by ENG and EMG.

RESULTS

In tibial nerves of NSVN patients FA values were significantly lower compared to healthy controls (0.33 vs 0.42 respectively, p=0.002). Muscle PDFF showed significantly higher values in NSVN compared to healthy controls, thus detecting fatty muscle atrophy reliably. Mean values measured 5.74% vs 10.78% respectively for SM (p=0.003) and 4.17% vs 23.71% for GM (p<0.001).

CONCLUSION

In this study, MR neurography at 3T proved as a reliable biomarker for the affection of peripheral nerves in NSVN. Fractional anisotropy allows for a reliable distinction between healthy and functionally impaired nerves while PDFF reliably detects fatty neurogenic muscle atrophy as an indirect surrogate marker in those patients. This is possible without the administration of iv contrast agent.

CLINICAL RELEVANCE/APPLICATION

In patients with NSVN, the combination of DTI and PDFF detects nerve damage and neurogenic muscle atrophy and might be helpful to guide treatment.

SSJ16-05 Lumbar Plexus in Patients with Chronic Inflammatory Demyelinating Polyradiculoneuropathy: Evaluation with Simultaneous T2 Mapping and a Neurography Method with SHINKEI

Tuesday, Nov. 27 3:40PM - 3:50PM Room: E353B

Hiroshi Honda, MD, Fukuoka, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

MR neurography (MRN) is a useful technique with which to evaluate abnormal conditions of the peripheral nerves such as chronic inflammatory demyelinating polyradiculoneuropathy (CIDP). We have developed a simultaneous T2 mapping and MRN method with 'nerve-sheath signal increased with inked rest-tissue rapid acquisition of relaxation enhancement imaging' (SHINKEI). The purpose of this study was to evaluate the usefulness of this technique in lumbar plexus to distinguish patients with CIDP from healthy controls.

METHOD AND MATERIALS

Ten patients with CIDP (7 males and 3 females; age range 11 - 68-year-old; median 47.5 year) from 2015 to 2017 were studied along with five healthy controls (4 males and 1 female; age range 27 - 45-year-old; median 41 year). MRI was conducted on a 3T clinical scanner. Typical imaging parameters were as follows; TR = 2500 ms, TE = 51 ms, FOV = 290 x 290 mm, ETL = 90, matrix =

256 x 245, Acquisition voxel size = 1.13 x 1,18 x 4.0 mm3, Reconstructed voxel size = 0.60 x 0.60 x 2.0 mm3, b = 10 s/mm2, iMSDE duration = 36 and 72 ms, acquisition time = 5 min 45 s. The T2 relaxation time and the size of the dorsal root ganglia and nerves of the lumbar plexus at L3-S1 were measured on coronal plane. Statistical analyses were performed with the Mann-Whitney U-test and a receiver operating characteristics (ROC) analysis.

RESULTS

The T2 relaxation times of the dorsal root ganglia and the nerves of the lumbar plexus were longer in the CIDP patients (133.34 ± 41.36 msec and 130.40 ± 47.78 msec) compared to the healthy controls (114.69 ± 24.90 msec and 83.72 ± 17.51 msec, p=0.0265 and p<0.0001, respectively). The sizes of the nerves were larger in the CIDP patients (6.19 ± 2.28 mm) compared to the controls (4.54 ± 0.86 mm, p<0.0001). However, there was no significant difference between the sizes of the ganglia in the CIDP patients and the controls. The ROC analysis revealed that the T2 relaxation time of the nerves was best at distinguishing the CIDP patients from the controls (Az = 0.848).

CONCLUSION

Patients with CIDP could be distinguished from healthy controls using simultaneous T2 mapping and MRN method with SHINKEI in lumbar plexus.

CLINICAL RELEVANCE/APPLICATION

With our new method we could obtain high resolution neurography with simultaneous T2 mapping. CIDP could be distinguished from controls using our technique.

SSJ16-06 Quantitative Ultrasound Measures in the Patellar Tendon are Associated with VISA-P Scores of Collegiate Basketball Players Over One Season of Play

Tuesday, Nov. 27 3:50PM - 4:00PM Room: E353B

Participants

nwawkao@hss.edu

PURPOSE

This study of collegiate basketball players evaluated change over time (COT) in ultrasound shear wave (SW) elastography metrics across the basketball season, and correlated to morphologic changes on conventional ultrasound imaging, and VISA-P scores.

METHOD AND MATERIALS

In eleven male collegiate basketball players (mean age 19, age range 18-21), patella tendon (PT) ultrasound and SW elastography of both knees were performed at pre-season and post-season time points, and players reported their VISA-P scores throughout the season. Patella tendinopathy grade and SW metrics were correlated to VISA-P scores using Spearman correlation coefficients. Paired t-test was used to assess differences in mean SW metrics at pre-and post-season timepoints, accounting for leg dominance.

RESULTS

6 of 11 players (54.5%) had baseline patella tendinopathy on ultrasound progressing in 4 players. The mean change in VISA-P score was 15.18 (+/-8.55). No significant correlation was seen between ultrasound grades of tendinopathy and VISA-P. Pre-season SW velocities did not significantly correlate with baseline VISA-P scores. Post-season SW values and SW COT demonstrated strong correlation with change in VISA-P score in dominant and non-dominant knees. Although not statistically significant, there was a trend towards higher SW velocity for tendinopathy in both dominant and non-dominant knees at both study visits.

CONCLUSION

SW metrics of the PT correlated to change in VISA-P scores in the dominant and non-dominant knees, whereas conventional ultrasound grades of patella tendinopathy did not. There was a trend towards higher SW velocities in patella tendinopathy which may indicate detection of change in intrinsic tissue stiffness.

CLINICAL RELEVANCE/APPLICATION

These results showed significant correlation between SW values and patella tendinopathy symptom scores, demonstrating the benefit of this quantitative imaging technique over conventional ultrasound imaging in the characterization of clinically symptomatic patella tendinopathy.

SSJ17-02 An Updated and Validated PET/CT Volumetric Prognostic Index for Non-Small Cell Lung Cancer

Tuesday, Nov. 27 3:10PM - 3:20PM Room: S504CD

Participants
Joshua H. Finkle, MD, Chicago, IL (*Presenter*) Nothing to Disclose
Bill C. Penney, PhD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
Yonglin Pu, MD, PhD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Whole-body metabolic tumor volume (MTVWB) and TNM staging are independent prognostic factors for overall survival (OS) in non-small cell lung cancer (NSCLC). We aimed to update and validate the PET/CT volumetric prognostic index (PVP index) using the new 8th edition TNM staging system to evaluate its prognostic power versus TNM staging and MTVWB alone.

METHOD AND MATERIALS

This study was a retrospective analysis of 949 non-small cell lung cancer (NSCLC) patients diagnosed between 2004 and 2014. Clinical TNM stage, MTVWB, age and gender, tumor histology type at the initial staging PET/CT exam, as well as treatment history and long-term survival data were obtained. Patients were randomly assigned to modeling or validation group. Univariate and multivariate Cox regression analyses were performed to compare PVP index, TNM stage, and MTVWB in the validation group.

RESULTS

The updated PVP index included the 3 variables TNM stage, and MTVWB and age. Univariate Cox models showed significant association of PVP index with overall survival (OS) in patients with NSCLC (with Hazard ratio HR= 2.88 in the validation group, $p<0.001$). The C-statistic of the PVP index (C-statistic = 0.71 in the validation group) was significantly greater than that of 8th edition TNM staging (C-statistic = 0.68, $p=0.029$), MTVWB (C-statistic = 0.68, $p=0.001$), and patient age (C-statistic = 0.53, $p<0.001$). Multivariate Cox regression analyses demonstrated significant association of PVP index with OS (with HR= 2.80, $p<0.001$) after adjusting patient's gender and tumor histology.

CONCLUSION

The updated PVP index provides a quantitative risk assessment for NSCLC patients using 8th edition TNM staging, MTVWB, and age. The index provides a simple and practical way for the care team to incorporate the independent prognostic value of both the TNM stage and MTVWB. This approach can further improve the accuracy of overall survival prognosis.

CLINICAL RELEVANCE/APPLICATION

The PVP index combines the prognostic power of the TNM stage, whole-body metabolic tumor volume and age, offering prognostic accuracy superior to whole-body metabolic tumor volume or TNM stage alone.

SSJ17-03 Prospective Comparison of 18F-FDG PET/MRI and 18F-FDG PET/CT for Thoracic Staging of Non-Small Cell Lung Cancer

PURPOSE

To compare the diagnostic performance of 18F-FDG PET/MRI and 18F-FDG PET/CT for primary and locoregional lymph node staging in non-small cell lung cancer (NSCLC).

METHOD AND MATERIALS

In this prospective study a total of 84 patients (51 men, 33 women, mean age 62.5 ± 9.1 years) with histopathologically confirmed NSCLC underwent 18F-FDG PET/CT followed by 18F-FDG PET/MRI in a single injection protocol. Two readers independently assessed T and N staging in separate sessions according to the seventh edition of the American Joint Committee on Cancer staging manual for 18FFDG PET/CT and 18F-FDG PET/MRI, respectively. Histopathology as reference standard was available for N staging in all 84 patients and for T staging in 39 patients. Differences in staging accuracy were assessed by McNemars chi2 test. The maximum standardized uptake value (SUVmax) and longitudinal diameters of primary tumors were correlated using Pearson's coefficients.

RESULTS

T stage was categorized concordantly in 18F-FDG PET/MRI and 18F-FDG PET/CT in 38 of 39 (97.4%) patients. Herein, 18F-FDG PET/CT and 18F-FDG PET/MRI correctly determined the T-stage in 92.3% and 89.7% of patients, respectively. N-stage was categorized concordantly in 83 of 84 patients (98.8%). 18F-FDG PET/CT correctly determined the N stage in 78 of 84 patients (92.9%), while 18F-FDG PET/MRI correctly determined the N stage in 77 of 84 patients (91.7%). Differences between 18F-FDG PET/CT and 18F-FDG PET/MRI in T and N staging accuracy were not statistically significant ($p > 0.5$, each). Tumor size and SUVmax measurements derived from both imaging modalities exhibited excellent correlation ($r=0.963$ and $r=0.901$, respectively).

CONCLUSION

18F-FDG PET/MRI and 18F-FDG PET/CT showed an equivalently high diagnostic performance for T and N staging in patients suffering from NSCLC.

CLINICAL RELEVANCE/APPLICATION

PET/MRI as a dose-saving alternative to PET/CT proved coequal to the current gold standard for thoracic staging of NSCLC. Thus, clinicians might use PET/MRI instead of PET/CT for this purpose. However, considering the longer examination times and higher expenses of PET/MRI, a general recommendation in favor of PET/MRI cannot be drawn from this study.

SSJ17-04 The Relationship Between PET/CT Imaging Features and Pathological Types and Gene Mutations of Primary Lung Cancer: A Study of 213 Untreated Lung Cancer Patients with Bone Metastases

Tuesday, Nov. 27 3:30PM - 3:40PM Room: S504CD

Participants
Xiaomeng Li, MD, Beijing, China (*Presenter*) Nothing to Disclose
Ning Wu, MD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

dora1327@163.com

PURPOSE

To evaluate the relationship between 18F-FDG PET/CT image characteristics and pathological types and gene mutations of primary lung cancer in untreated lung cancer patients with bone metastases.

METHOD AND MATERIALS

A total of 213 untreated lung cancer patients with bone metastases were enrolled in this study. All patients underwent 18F-FDG PET/CT examination, pathological and gene mutation examination of primary lung cancer. Spearman's correlation test was performed to evaluate the association between primary tumors and bone metastases. Single factor analysis of variance was used to compare groups.

RESULTS

(1)A total of 213 cases were evaluated. The mean SUVmax of primary lung cancer was 7.9±4.7; that of bone metastases was 8.2±4.3. The SUVmax of primary lesions had a significantly positive correlation with the SUVmax of bone metastases ($r = 0.622$; $p = 0.000$). Osteolytic metastasis was the most common type. (2)The SUVmax of primary lung lesions with different pathological types were statistically different (all $P = 0.000$): squamous cell carcinoma > small cell carcinoma > adenocarcinoma. Their SUVmax were 11.7±3.7, 9.3±3.1, and 6.7±4.6, respectively. (3)In non-small cell lung cancer (NSCLC), the gene mutation rates of epidermal growth factor receptor (EGFR), K-ras and anaplastic lymphoma kinase (ALK) were 35.7%, 10.1% and 3.8%, respectively. There was no statistical difference in SUV*max* of primary lung cancer between gene mutation type and wild type ($P>0.05$).

CONCLUSION

The SUVmax of primary lung lesions with different pathological types were statistically different. Squamous cell carcinoma was the highest, and adenocarcinoma was the lowest. The SUVmax of primary lung cancer had a significantly positive correlation with the SUVmax of bone metastases. In NSCLC, the mutation rate of EGFR is the highest. There was no statistical difference in SUVmax of primary lung cancer between gene mutation type and wild type.

CLINICAL RELEVANCE/APPLICATION

The SUVmax of primary lung cancer is suggestive of its pathological type. But the SUVmax of primary lung cancer is not helpful to predict the gene mutations in NSCLC.

SSJ17-05 Local and Whole-Body Staging in Patients with Primary Breast Cancer: A Comparison of One-Step to Two-Step-Staging-Algorithms Utilizing PET/MRI

PURPOSE

To compare the diagnostic value of a one-step to a two-step staging algorithm for local and whole-body staging utilizing 18F-FDG PET/MRI in breast cancer patients.

METHOD AND MATERIALS

A total of 38 patients (37 females and one male, mean age 57 ± 10 years; range 31-78 years) with newly diagnosed, histopathologically proven breast cancer were prospectively enrolled in this trial. All PET/MRI examinations were assessed for local tumor burden and metastatic spread in two separate reading sessions: (1) One-step algorithm comprising supine whole-body 18F-FDG PET/MRI, (2) Two-step algorithm comprising a dedicated prone 18F-FDG breast PET/MRI and supine whole-body 18F-FDG PET/MRI.

RESULTS

On a patient based analysis the two-step algorithm correctly identified 37 out of 38 patients with breast carcinoma (97%), while 5 patients were missed by the one-step 18F-FDG PET/MRI algorithm (33/38; 87% correct identification; p=0.37). On a lesion-based analysis 56 breast cancer lesions were detected in the two-step algorithm and 44 breast cancer lesions could be correctly identified in the one-step 18F-FDG PET/MRI (79%), resulting in statistically significant differences between the two algorithms (p=0.0015). For axillary lymph node evaluation sensitivity, specificity and accuracy was 93%, 95 % and 94%, respectively. Furthermore, distant metastases could be detected in 7 patients with both modalities.

CONCLUSION

The results demonstrate the necessity and superiority of a two-step 18F-FDG PET/MRI algorithm, comprising dedicated prone breast imaging and supine whole-body imaging, when compared to the one-step algorithm for local and whole-body staging in breast cancer patients.

CLINICAL RELEVANCE/APPLICATION

Two-step 18F-FDG PET/MRI comprising dedicated breast and whole-body imaging enables high-quality local and whole-body staging in patients with breast cancer.

SSJ17-06 Multimodal Radiomic Imaging: Comparison of PET and MRI-pCM Heterogeneity in Breast Cancer

Tuesday, Nov. 27 3:50PM - 4:00PM Room: S504CD

Participants
Bert-Ram Sah, MD, London, United Kingdom (*Presenter*) Nothing to Disclose
Marta Bogowicz, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Christian Leissing, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Stephanie Tanadini-Lang, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Patrick Veit-Haibach, MD, Zurich, Switzerland (*Abstract Co-Author*) Research Grant, Bayer AG Resaarch Grant, F. Hoffmann-La Roche Ltd Research Grant, General Electric Company

PURPOSE

This study investigated the value of pre-treatment F-18-Fluorodeoxyglucose (FDG)-positron-emission-tomography (PET) radiomics in comparison to T1-weighted-post-contrast-magnetic-resonance-imaging (MRI-pCM) radiomics in patients with breast cancer.

METHOD AND MATERIALS

Following IRB approval and informed consent, a total of 30 patients with histologically proven breast cancer were prospectively recruited. Patients were injected 225+/-55 MBq FDG intravenously. PET and MRI-pCM were acquired on the same machine. 154 radiomic features of first, second, and higher order were extracted from the primary tumor. Dimensionality of features was reduced with a Principal Component Analysis. The relationship of selected features to staging and histological parameters was determined. Association of features between the different modalities was compared (Spearman "ρ").

RESULTS

Selected radiomic features of PET showed moderate correlation to T-stage ($-0.52 < \rho < 0.54$) and weak correlation to N-Stage ($-0.35 < \rho < 0.38$). Selected radiomic features of MRI-pCM showed moderate correlation to T-stage ($-0.64 < \rho < 0.57$) and to N-stage ($-0.52 < \rho < 0.54$). Correlation of radiomic features of both modalities to hormone receptor status is shown in Table 1. Comparison between PET and MRI-pCM showed moderate to strong correlation for the comparison of all radiomic features (-0.66 <

ρ < 0.68) (Figure 1), whereas the correlation for the comparison of a respective radiomic parameter was only weak to moderate (0.22 < ρ < 0.56) (1st diagonal in Figure 1).

CONCLUSION

Radiomics in a multimodality approach might be a complementary tool for non-invasive pre-therapeutic characterization of breast cancer.

CLINICAL RELEVANCE/APPLICATION

Combining radiomic features from different imaging modalities may help in non-invasive specification of breast cancer.

PURPOSE

With rapid growth and increasing use of brain MRI, there has been a significant interest in automated image processing and classification of brain MRI scans to supplant human interpretation and improve workflow. In this study we aim to assess the diagnostic accuracy of an AI 3D pipeline in classifying multi-parametric brain MRI to normal vs. abnormal.

METHOD AND MATERIALS

A total of 1,516 consecutive clinical brain MRI studies including sagittal T1W and axial FLAIR, ADC and B1000 sequences were selected from our institution HIPAA compliant imaging registry. Brain MR studies were obtained using standardized protocol across 1.5T MR scanners from two manufacturers (GE and Siemens). Each sequence was reformatted to common resolution to accommodate for differences between vendors. A board certified neuroradiologist assigned each case to normal vs. abnormal based on the review of clinical report of each case. Consequently, 88% of the MRI scans were marked as abnormal. A 3D AI pipeline was developed: first, a deep reinforcement learning based landmark detection was used to estimate positioning and brain coverage. Brain was extracted using an adversarial dense image-to-image based technique then sequence-independent dense convolutional networks were trained in a supervised way, with data augmentation (random rotation, translation and added noise at each iteration), and merged to flag abnormal cases. Training was performed on 1,566 cases (200,448 images - 85% abnormal) with class weights to address class imbalance, testing included 175 cases (22,400 images - 84% abnormal).

RESULTS

Receiver operating characteristic (ROC) analysis showed that an area-under-the-curve (AUC) of 0.90 with accuracy of 86%, sensitivity of 85%, and specificity of 89% for our detection pipeline.

CONCLUSION

Our proposed intelligent pipeline accurately identifies abnormal brain MRIs from the individual patients. If its potential is realized, it can be used as a clinical tool to flag abnormal MRIs, allowing for improved triage and timely interpretation of abnormal scans in a busy and large clinical practice.

CLINICAL RELEVANCE/APPLICATION

Our proposed automated and intelligent 3D pipeline can flag abnormal brain MRI scans, catering available human expertise in interpreting abnormal cases in a timely manner.

SSJ18-02 Multi-Metric Characterization of Resting-State Functional Connectivity for Machine Learning Classification in Major Brain Networks

Tuesday, Nov. 27 3:10PM - 3:20PM Room: E451B

Participants
Rosaleena Mohanty, MS, Madison, WI (*Presenter*) Nothing to Disclose
Veena A. Nair, PhD, Madison, WI (*Abstract Co-Author*) Nothing to Disclose
Vivek Prabhakaran, MD, PhD, Fitchburg, WI (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Population differences have been identified based on resting-state functional connectivity (FC) derived from blood-oxygen-level-dependent (BOLD) response using machine learning classification. While Pearson's correlation is the conventional metric used to quantify FC, it may not capture the true dynamic and non-linear relationship between BOLD responses from distinct brain regions. This motivates the need for a more complete notion of FC for better classification performance.

METHOD AND MATERIALS

Ten-minute eyes closed functional MRI were acquired on 3T GE MR750 scanner from 50 right-handed healthy participants consisting of 25 older (age=57.5±7.1 years; 13 females; education=16.68 years) and 25 younger (age=23.9±5.9 years; 13 females; education=16.76 years) participants. Data were preprocessed using standard steps on SPM12 to extract the BOLD time courses in 6 major brain networks. Network-wise FC was computed based on 8 distinct metrics: cross-correlation, coherence, mutual information, dynamic time warping (DTW) distance, Euclidean distance, cityblock distance, wavelet coherence and the conventional Pearson's correlation. Individual and combined discriminatory power of the metrics was assessed using a linear support vector machine classifier to differentiate between the older and younger groups for each network. Neighborhood component analysis and leave-one-out cross-validation were used for feature selection and evaluation of classification performance respectively.

RESULTS

Groups were significantly different in age (p-value<0.001) but not in gender distribution or education. Comparative results showed that Pearson's correlation may not always be the optimal choice for FC. The combined metric performed comparable/better than individual metrics for each network. This could imply that a more meaningful definition of FC encompassing linear, non-linear, dynamic, time-, frequency- and wavelet-domain information could be created for classification by drawing contributions from multiple metrics.

CONCLUSION

Combining the inter-dependencies in BOLD signals in time, frequency and wavelet domains could provide a more comprehensive notion of FC for population-based classification using machine learning.

CLINICAL RELEVANCE/APPLICATION

Multi-metric characterization offers a more complete definition of FC and could be useful in delineating group differences between patient and healthy population using machine learning classification.

SSJ18-03 Use of a Deep Convolutional Neural Network for Automated Detection of Intracranial Hemorrhage

Tuesday, Nov. 27 3:20PM - 3:30PM Room: E451B

For information about this presentation, contact:

Chad.Farris@bmc.org

PURPOSE

The purpose of this study is to investigate the possibility of automated detection of all varieties of intracranial hemorrhage (ICH), including epidural (EDH), subdural (SDH), subarachnoid (SAH), intraparenchymal (IPH), and intraventricular (IVH) on unenhanced head CT examinations (HCT) using a deep residual convolutional neural network (DRCNN) in all possible clinical scenarios, including initial HCT for diagnosis of ICH, follow-up HCT for known ICH, and post-operative HCT after surgical intervention.

METHOD AND MATERIALS

IRB approved retrospective HIPAA compliant study with requirement for informed consent waived. Included cases were identified through a keyword search of our RIS for HCT with ICH and normal HCT (NHCT) between 7/1/2014-7/1/2016. A total of 95 ICH cases and 46 NHCT cases were included in this study. The hemorrhages in the ICH cases were segmented by hand using an inhouse MATLAB annotation tool. The DRCNN was trained using 60 annotated ICH cases and validated with 5 ICH cases. The trained DRCNN was then tested on 30 ICH cases (with many of the cases including different types of hemorrhage for a total of 56 hemorrhages) and 46 NHCT cases using two different DRCNN thresholds for hemorrhage detection and minimal post-processing of the DRCNN output. The percentage of hemorrhages detected, and the false positive rate (FPR) were evaluated at each of the DRCNN thresholds. For the lower DRCNN threshold, a minimum number of DRCNN identified pixels containing hemorrhage was employed to consider the case positive for hemorrhage to limit the FPR.

RESULTS

The DRCNN with a high threshold (HT) for ICH detection correctly detected 70% (39/56) ICH including, 0% (0/1) EDH, 60% (6/10) SDH, 50% (6/12) SAH, 81% (17/21) IPH, and 83% (10/12) IVH. The DRCNN with a low threshold (LT) for ICH detection correctly

detected 89% (50/56) ICH including, 100% (1/1) EDH, 80% (8/10) SDH, 83% (10/12) SAH, 90% (19/21) IPH, and 100% (12/12) IVH. The DRCNN with a HT for ICH detection had a FPR of 2% (1/46 NHCTs evaluated). The DRCNN with a LT for ICH detection had a FPR of 28% (13/46 NHCTs evaluated).

CONCLUSION

DRCNNs can be trained to successfully detect all types of ICH on HCT examinations in all possible clinical scenarios.

CLINICAL RELEVANCE/APPLICATION

Automated detection of intracranial hemorrhages could potentially be used clinically to help triage completed unread examinations and assist with detection of subtle hemorrhages.

SSJ18-04 Substantially Shortened Brain and Lumbar Spine MR Scan Times with a Machine Learning-Based Iterative Image Reconstruction Algorithm

Tuesday, Nov. 27 3:30PM - 3:40PM Room: E451B

PURPOSE

To evaluate the scan time shortening potential of a novel 3D image enhancement algorithm for brain and lumbar spine MRI exams.

METHOD AND MATERIALS

Fifty-six subjects (mean age 48+/-16 years) were scanned on four 1.5T scanners (Philips-Ingenia: 18 brain, 6 spine; Siemens-Aera: 9 brain, 2 spine; General Electric Signa-HDxt: 10 brain, Optima MR450w 11 spine), at three different sites using the site's routine clinical protocols as well as an average of ~30% shorter scan time-reduced variants. The time-reduced variant protocols were set by altering routine acquisition parameters, trading scan time reductions, mainly, for decreased signal to noise ratio. The faster, SNR challenged scans were processed with a novel 3D image enhancement algorithm (iQMR by Medic Vision Ltd.) and compared with the corresponding sites' routine scans (153 brain scans and 43 lumbar spine scans). Independent, blinded, side-by-side comparisons of diagnostic quality, visual image quality, presence of artifacts and brain gray-white matter differentiation were performed by six neuroradiologists for brain data and three neuroradiologists for spine data, using a 5-point Likert-scale (3= equal, >3 processed image is superior).

RESULTS

The processed-reduced scan time images (614 brain reads, 129 lumbar spine reads) were rated higher or equal to the conventional routine scans with respect to diagnostic quality (brain: median=3, mode=3, mean=2.94+/-0.39; spine: median=3, mode=3, mean=3.05+/-0.39), visual image quality (brain: median=3, mode=3, mean=2.83+/-0.69; spine: median=3, mode=3, mean=3.14+/-0.77), the presence of artifacts (brain: median=3, mode=3, mean=2.91+/-0.54; spine: median=3, mode=3, mean=3.11+/-0.66) and for brains, gray-white matter differentiation (median=3, mode=3, mean=2.91+/-0.46).

CONCLUSION

iQMR processed, reduced scan time images were similar in overall image quality to standard protocols with a reduction of MRI exam scan time of about 30%.

CLINICAL RELEVANCE/APPLICATION

iQMR can produce clinically acceptable MR images at significantly shorter scan times, facilitating patient comfort and clinical practice workflow. Faster scans could potentially decrease motion artifacts and reduce the need for repeat scans.

SSJ18-05 Radiomics-Based Prediction of Malignant Potential in Patients with Parotid Gland Cancer

Tuesday, Nov. 27 3:40PM - 3:50PM Room: E451B

PURPOSE

Prediction of malignant potential (low+intermediate and high grades) in patients with parotid gland cancer (PGC) is crucial in determination of treatment approaches. Although the fine needle aspiration cytology (FNAC) is performed for prediction of malignant

potential for PGC, various researchers have reported the prediction accuracy of malignant potential in PGC by the FNAC, which depends on the operator experience, was from 69 to 92%. Therefore, we developed the radiomics-based prediction of malignant potential in patients with parotid gland cancer.

METHOD AND MATERIALS

A total of 972 radiomic features (statistic, texture, wavelet-based features) were extracted from tumor regions in preoperative T1- and T2-weighted images of 42 PGC patients. Radiomic signatures for prediction of malignant potential in PGC patients were generated by using least absolute shrinkage and selection operator (LASSO), which is one of sparse coding approaches that performs both feature selection and regularization to avoid the curse of dimensionality. Malignant potential for PGC was predicted by using Gaussian support vector machine (G-SVM), which is a machine learning classifier. The accuracy and the mean area under the receiver operating characteristic curve (AUC) of G-SVM model by a leave-one-out cross validation test were evaluated.

RESULTS

The 5 features, which included T1_LLH_Skewness, T1_HLH_Min, T2_gray-level non-uniformity (GLN), T2_LLH_Long Run Emphasis (LRE), and T2_LLH_Small Zone High Gray-Level Emphasis (SZHGE), were selected by LASSO as the radiomic signatures for the malignant potential for PGC. The prediction accuracy of the malignant potential for PGC by using the G-SVM based on the selected 5 features was 90.5%, and the AUC was 0.96 with a sensitivity of 0.90 and a specificity of 0.90.

CONCLUSION

The proposed approach demonstrated high accuracy in classification of the malignant potential for PGC. Our results suggested that the proposed approach based on radiomics using preoperative MR images could be feasible to predict the malignant potential for PGC.

CLINICAL RELEVANCE/APPLICATION

The proposed approach contributes to the higher accuracy and lower intra- and inter-observer variabilities for prediction of malignant potential in parotid gland cancer.

SSJ18-06 Brain Tumor Segmentation on Fluid-Attenuated Inversion Recovery MRI Using Transfer Learning on U-Net

Tuesday, Nov. 27 3:50PM - 4:00PM Room: E451B

nabahrami@ucsd.edu

PURPOSE

Lesion assessment of glioma hyperintense volumes on fluid-attenuated inversion recovery (FLAIR) MRI is important for surgery, treatment planning, and genomic analysis. Manual delineation of the hyperintense region is time-consuming and subject to inter- and intra-operator variability. The purpose of this study is to assess the feasibility of FLAIR hyperintense region segmentation using a fully automated convolutional neural network (CNN) technique.

METHOD AND MATERIALS

We retrospectively collected 151 patients (363 time points) with low and high-grade gliomas. Each of the patients had a 3D T2-weighted FLAIR sequence with TE/TR = 126/6000 ms, TI = 863, and FOV = 24 cm. Prior to analysis, raw data were corrected for bias field and distortion, image registration, and skull stripping. FLAIR hyperintense volumes were segmented semi-automatically (Amira software package, Visage Imaging) on the co-registered images by two trained image analysts and approved by a board-certified neuro-radiologist with expertise in neuro-oncology. We developed a 2D U-net algorithm for segmentation and serially trained the model with images containing large lesions, small lesions, and no lesions. Three hundred of the cases were used for training and sixty-three were used for validation. We evaluated our model using Dice coefficients between the manually segmented and CNN-derived FLAIR volumes on the validation set.

RESULTS

Our proposed model segmented the hyperintense regions with the average Dice coefficient of 0.85. In 79% of patients, the dice coefficient was more than 0.8. Prediction of FLAIR volume from our cascaded U-net model closely matched with expert annotation (ρ=0.91).

CONCLUSION

In this study, we demonstrate the utility of a fully-automated CNN technique for segmenting the hyperintense region on FLAIR. We increased the performance of our model with transfer learning from images with large hyperintense regions to the images with no lesion. Implementation of this CNN into the clinical workflow may help improve the ROI drawing performance and reduce the discrepancies among image analysts.

CLINICAL RELEVANCE/APPLICATION

We present a fully automated technique for tumor segmentation of the FLAIR MRI of the patients with gliomas. Our model will increase accuracy of clinical interpretations by standardizing and quantifying the determination of the FLAIR hyperintense volume as a crucial part of Response Assessment in Neuro-Oncology (RANO).

PURPOSE

Dopamine transporter imaging such as 18F-FP-CIT PET (CIT PET) is needed to assess presynaptic dopaminergic function, but its accessibility and cost are limited. We sought to compare nigrosome-1 susceptibility map-weighted imaging (SMWI) with 0.8-mm isovoxel NMI for predicting presynaptic dopaminergic function.

METHOD AND MATERIALS

We enrolled 79 subjects who underwent both MRI and CIT PET for parkinsonism. Oblique axial 0.5×0.5×1.0-mm3 SMWI and 0.8-mm isovoxel 3D T1-weighted NMI were obtained at 3T. SMWI was resliced in 0.5-mm increments. Below the red nucleus, 4 consecutive SMWI images (2-mm slab) and were only assessed. Three NMI images (2.4-mm slab) that encompassed the slab of the 4 SMWI images were also included for analysis. For SMWI, the pixels less than the mean background (decussation of the superior cerebellar peduncle) signal intensity (SImean) - 3SD (SMWI3SD) and those less than SImean - 7SD (SMWI7SD) were separately selected in a semi-automated manner. For NMI, the pixels greater than SImean + 3SD (NMI3SD) and those greater than SImean (NMImean) were selected in a similar way. The volume ratios of SMWI7SD to SMWI3SD and NMI3SD to NMImean were calculated. Each side of the basal ganglia was separately assessed on CIT PET and was served as the reference standard for per substantia nigra (SN) analysis. For per participant analysis, more affected side was chosen on each MRI.

RESULTS

Patients were diagnosed as Parkinson's disease (n=54; advanced stage [n=16]) and drug-induced parkinsonism (n=25) based on clinical and imaging findings (106 abnormal basal ganglia on CIT PET). For per SN analysis, NMI showed sensitivity of 86.8% and specificity of 88.5% (AUC=0.896[95% CI, 0.838-0.939]; criterion<=0.424); SMWI demonstrated sensitivity of 89.6% and specificity of 75.0% (AUC=0.846[95% CI, 0.780-0.898]; criterion>0.368), showing no significant difference (*P*=0.2593). For per participant analysis, NMI showed sensitivity of 96.3% and specificity of 92.0% (AUC=0.939[95% CI, 0.861-0.980]; criterion<=0.385); SMWI demonstrated sensitivity of 92.6% and specificity of 72.0% (AUC=0.881[95% CI, 0.789-0.43]; criterion>0.4), showing no significant difference (*P*=0.3404).

CONCLUSION

For predicting presynaptic dopaminergic function, SMWI and high-spatial-resolution NMI were comparable.

CLINICAL RELEVANCE/APPLICATION

Both SMWI and NMI can serve as a screening imaging tool for patients who need further evaluation by dopamine transporter imaging.

SSJ19-02 MR Fingerprinting: A Possible Source for Imaging Biomarkers in Parkinson's Disease

PURPOSE

Parkinson's Disease (PD) is a neurodegenerative disease with increasing incidence but currently limited availability of an MRI-based diagnosis or monitoring by imaging biomarkers. MR fingerprinting (MRF) is a recently developed quantitative MR acquisition and post-processing technique, which may have the potential to both significantly shorten MR protocols and detect PD-specific alterations of T1 and T2 signal relaxation times.

METHOD AND MATERIALS

25 PD patients (18m/7f, mean age±SD 69.6±6.9 yrs) and 25 healthy controls (HC; 13m/12f, mean age±SD 67.5±4.3 yrs) participated after informed consent. A new FISP-based MRF sequence (TR 15ms, TE 3.5ms, two spiral interleaves / layer; starting with an adiabatic inversion pulse; scan time: 3.2 min.) was added to the 3T standard MRI protocol (scan time: 28 min). The MRF dictionary used the extended phase graphs algorithm to generate B1-corrected MRF-qT1 and qT2 maps. The registration and segmentation of substructures was performed with FSL. Independent T-tests were applied to compare regional T1 and T2 values between PD and HC. Each participant was evaluated by a neurologist including the minimal mental state test (MMST).

RESULTS

PD patients and HC did not differ significantly with regard to age, sex and MMST score (p=0.2, 0.08, 0.28 respectively).MRF-qT1 mapping, but not MRF-qT2, identified significant differences between PD patients and HC: Gray matter: (PD: 1408.6±42.7ms vs. HC: 1435.9±39.3ms, p=0.02); white matter: (PD: 1053.9±45.1ms vs. HC: 1010.8 ± 65.8ms, p = 0.01); left amygdala: (MP: 1517.9 ± 81.3 ms vs. HC: 1579.7±95.7ms, p=0.02); right amygdala: (PD: 1523.1±111.6ms vs. HC: 1601.7±87.8ms, p=0.01).

CONCLUSION

MR fingerprinting-based T1 mapping seems to be a promising tool to identify PD patients. The regions identified as abnormal, including white matter and the amygdalae, indicate that PD affects the brain globally rather than being limited to the basal ganglia.

CLINICAL RELEVANCE/APPLICATION

We are in need for reliable MR tools to diagnose and monitor PD by MRI. This study indicates that MR fingerprinting is a method worth following as a solution to achieve this goal. Future studies need to go deeper into machine learning applications of MRF for PD.

SSJ19-03 Clinical Application of Quantifying Consecutive Dopamine Neuronal Changes in the Substantia Nigra Pars Compacta During the Development of Early Parkinson's Disease Using Neuromelanin and Diffusion Tensor Imaging

Tuesday, Nov. 27 3:20PM - 3:30PM Room: E351

Noriyuki Tomiyama, MD,PhD, Suita, Japan (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation

PURPOSE

Early Parkinson's disease (PD) develops from rapid eye movement sleep behavior disorder (RBD) which has been previously reported as a precursor of PD. Our aim was to assess the utility of consecutive dopamine neuronal changes in the substantia nigra pars compacta (SNpc) with MRI in evaluating the early stages of PD development.

METHOD AND MATERIALS

Eighteen patients (PD group) with early PD (Hoehn and Yahr scale: 1-2), 13 patients with RBD (RBD group) and 20 age-matched healthy controls (HC group) underwent neuromelanin imaging and diffusion tensor imaging (DTI) on a 3T magnetic resonance imager. The neuromelanin SNR (signal-to-noise rario) and the DTI value [mean diffusivity (MD) and fractional anisotropy (FA) values] of the SNpc were calculated using an automatic volumetric region of interest selection method. The significance of the intergroup differences using analysis of variance with Tukey's post hoc test was tested for each neuromelanin area with an SNR higher than that of the background and DTI value. The correlation between the neuromelanin area and the DTI value of all the groups was assessed. Logit (p) was used to estimate the probability of each RBD and early PD in relation to the neuromelanin area

and the DTI value, and the diagnostic performance of each value for RBD and early PD was assessed using receiver operating characteristic (ROC) analysis.

RESULTS

The neuromelanin area was significantly less and the MD value was significantly higher in both RBD and PD group than in HC group ($P < 0.05$), whereas, no significant intergroup difference was shown in the FA value. A moderate correlation between the neuromelanin area and the MD value was found ($|r|$: 0.47). The respective areas under the ROC curve for neuromelanin area/MD value were 0.76/0.79 for RBD and 0.80/0.80 for the early PD. The respective areas under the ROC curve for logit (p) in relation to neuromelanin area and MD value were 0.81 for RBD and 0.85 for the early PD. (See optional figure)

CONCLUSION

Quantifying consecutive dopamine neuronal changes in the SNpc using both neuromelanin and MD values may be a useful technique in the evaluation of the early stages of PD.

CLINICAL RELEVANCE/APPLICATION

Comprehensive MRI assessment for PD-related consecutive dopamine neuronal changes in the SNpc can provide a high diagnostic accuracy of the early stages of PD.

SSJ19-04 Differentiation of Atrophy Patterns and Diagnosis of Parkinsonian Syndromes Based on Combination of Manual and Automated Brain Measurements

PURPOSE

To retrospectively assess the value of magnetic resonance (MR) imaging automated volumetric measurements of midbrain, pons, cerebellum, third ventricle, putamen and manual magnetic resonance (MR) imaging indexes to study the different atrophy patterns of Parkinsonian syndromes and differentiate progressive supranuclear palsy (PSP) from Parkinson's disease (PD) and multiple system atrophy (MSA).

METHOD AND MATERIALS

Brain volumetric ratios adjusted for intracranial volume (ICV) of pons, midbrain, cerebellum, third ventricle and putamen were automatically measured by segmentation tool Accubrain on 3D T1-weighted MR images in 56 consecutive patients with PSP (39 male, 17 female; mean age, 70.9 years), 69 with PD (36 male, 33 female; mean age, 63.9 years), 15 with MSA (9 male, 6 female; mean age, 58.2 years), and 50 healthy controls (30 male, 20 female; mean age, 66.1 years). MR parkinsonism index and midbrain-pons short axis ratio (M/P) were also manually calculated. Differences in MR imaging volumetric measurements among groups were evaluated with Kruskal-Wallis H test and differences between two groups were evaluated with Mann-Whitney U test. Receiver operating characteristic curve analysis was used to define cutoff values in PSP.

RESULTS

Pons volumetric ratio in MSA was smaller than that in PD (P=0.0007) and control (P=0.0006). Midbrain volumetric ratio in PSP was smaller than that in PD (P 0.52 and 34 patients (60.71%) whose MRPI 13.55. In our study, midbrain-pons short axis ratio (M/P) of 0.57 (specificity 86.57%, sensitivity 76.54%) and MRPI of 10.81 (specificity 82.84%, sensitivity 78.57%) were the more proper cutoff values for PSP.

CONCLUSION

Combination of manual and automated cerebral measurements can present different brain atrophy features in Parkinsonian syndromes and help distinguish PSP from other Parkinsonian degenerative disorders.

CLINICAL RELEVANCE/APPLICATION

Different brain atrophy features of Parkinsonian Syndromes may help clinically differentiate these degenerative disorders and the more accurate cutoff values for diagnosis of PSP was newly set in our study

SSJ19-05 Quantifying Consecutive Changes in Dopaminergic Nigrostriatal System During the Early Stages of Parkinson's Disease Development Using Diffusion Tensor Imaging

Tuesday, Nov. 27 3:40PM - 3:50PM Room: E351

Noriyuki Tomiyama, MD,PhD, Suita, Japan (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation

PURPOSE

The development of Parkinson's disease (PD) is characterized pathologically by dopaminergic neurodegeneration in the substantia nigra pars compacta (SNpc) and resulting in dopamine neuronal dysfunction in the striatum. Recently, rapid eye movement sleep behavior disorder (RBD) has been reported as a precursor of PD. Our aim was to access the clinical application of measuring water diffusivity in consecutive changes in dopaminergic nigrostriatal system during the early stages of PD development.

METHOD AND MATERIALS

Eighteen patients (PD group) with early PD (Hoehn and Yahr scale: 1-2), 13 patients with RBD (RBD group) and 20 age-matched healthy controls (HC group) underwent diffusion tensor imaging (DTI) and three-dimensional T1W imaging on a 3T magnetic resonance imager. All MR imaging data were transferred to a computer. For highly reproducible image analysis, an automatic volumetric region of interest selection method was developed with the voxel-based morphometric technique. By using this method, the DTI value [mean diffusivity (MD) and fractional anisotropy (FA) values] of each SNpc and putamen was calculated. The significance of the intergroup differences using analysis of variance with Tukey's post hoc test was tested for the DTI value of each SNpc and putamen.

RESULTS

In the SNpc, the MD value in both RBD and PD group was significantly higher than in HC group ($P < 0.05$), while no significant intergroup difference was shown in the FA value. In the putamen, the MD value in PD group was significantly higher than in both HC and RBD group and the FA value was significantly higher in RBD group than in HC group and significantly less in PD group than in RBD group ($P < 0.05$). (See optional figure)

CONCLUSION

The measurement of water diffusivity in dopamine neuron in the SNpc can significantly differentiate patients with both RBD and early PD from healthy subjects. Meanwhile, the measurement of water diffusivity in the putaminal dopamine neuron may be useful in not only differentiating patients with both RBD and early PD from healthy subjects but also, in evaluating the evolution of RBD to early PD.

CLINICAL RELEVANCE/APPLICATION

Quantifying consecutive changes in dopaminergic nigrostriatal system with DTI technique can be useful in monitoring the early stages of Parkinson's disease development.

SSJ19-06 Individual Classification of Parkinson Disease with Diffusion Magnetic Resonance Imaging

Tuesday, Nov. 27 3:50PM - 4:00PM Room: E351

Participants
Wenliang Fan, BMedSc,PhD, Wuhan, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

fanwenliang168@163.com

PURPOSE

To investigate the feasibility and performance of the PD classification using diffusion MRI of different machine learning methods.

METHOD AND MATERIALS

A total of 285 PD patients and 135 healthy controls were included and underwent diffusion tensor imaging scans. DTI images were processed with the FSL toolbox to get the parameters such as fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), radial diffusivity (RD). Values of each brain areas in stereotaxic white matter atlas were extracted by the ICBM template as the raw features for subsequent machine learning based classifiers. All of the PD patients and healthy controls were separated to training data sets and testing data sets. Feature optimization was performed by the LASSO and principal component analysis. And both the filter- and wrapper-based feature selection models were used to get the final features used in the last classifier. The k-nearest neighbor algorithm (KNN), naïve Bayes algorithm and support vector machine (SVM) models were trained on the training data sets and the performance of these models were evaluated by the testing data sets.

RESULTS

Compared to healthy control subjects, PD patients showed significantly alteration of white matters in wide spread brain regions. The machine learning analyses showed that the SVM model performs best than KNN and naïve Bayes algorithm with an overall accuracy of 86.7%, sensitivity of 83.3% and specificity of 89.0% when discriminated PD patients from healthy controls.

CONCLUSION

The combination of DTI and machine learning methods is a promising method to discriminate PD patients from healthy controls. These findings may be useful for future incorporation of DTI and machine learning methods for disease classification, or as a useful tool for clinical diagnosis by diffusion MRI.

CLINICAL RELEVANCE/APPLICATION

DTI-based machine learning methods can help to better PD diagnosis.

SSJ20-01 Comparative Trends in Utilization of Cervical Spine Imaging: A Reflection of Shifting Trends in Outpatient Imaging to the ED?

Tuesday, Nov. 27 3:00PM - 3:10PM Room: E352

Participants
Gabriela T. Bober, Philadelphia, PA (*Presenter*) Nothing to Disclose
Adam E. Flanders, MD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose
Laurence Parker, PhD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose
David C. Levin, MD, Philadelphia, PA (*Abstract Co-Author*) Consultant, HealthHelp, LLC; Board Member, Outpatient Imaging Affiliates, LLC
Vijay M. Rao, MD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To study utilization trends in CT, MRI, and plain radiography (XR) of the cervical spine (CSP) among outpatients in the Medicare population.

METHOD AND MATERIALS

The nationwide Medicare Part B Physician/Supplier Procedure Summary databases for 2004 to 2016 were queried. Medicare's location codes were used to identify CSP imaging examinations done in EDs, outpatient offices, and hospital outpatient departments (HOPDs). These are the 3 locations where virtually all outpatients will undergo imaging. CPT-4 codes were selected for CT, MRI, and plain XR of the CSP. For each code, the database provides procedure volume; utilization rates per 100,000 beneficiaries were then calculated. Utilization trends were studied between 2006 and 2016. As this database represents a complete population, sample statistics are not required.

RESULTS

In EDs, the CSP CT rate per 100,000 enrollees increased from 217 in 2004 to 2031 in 2016 (+836%). The ED CSP XR rate decreased from 783 in 2004 to 261 in 2016 (-67%). ED CSP MRI utilization rate also increased, rising from 13 in 2004 to 47 in 2016 (+262%). In HOPDs the rate changes from 2004 to 2016 were as follows: CT 154 to 335 (+117%); MRI 555 to 791 (+43%); XR 1109 to 1142 (+3%). In private offices the rate changes were as follows: CT 64 to 96 (+50%); MRI 616 to 700 (+14%); XR 1497 to 1495 (no change). In all 3 outpatient locations together, the CSP rate changes were: CT 435 in 2004 to 2462 in 2016 (+466%); MRI 1184 in 2004 to 1538 in 2016(+30%); XR 3389 in 2004 to 2898 in 2016 (-14%). In 2004, CT and MRI comprised 21% and 1.3% of CSP imaging in the ED, which increased to 71% and 1.6% respectively in 2016.

CONCLUSION

The utilization rate of outpatient CSP CT imaging is increasing rapidly, especially in EDs. The utilization rate of CSP MRI has more than doubled but is well below that of CT. CSP XR utilization is declining. By 2016, the CT rate was almost as high as the XR rate.

CLINICAL RELEVANCE/APPLICATION

Among Medicare population outpatients who undergo imaging of the CSP, the utilization rate of cross sectional imaging is increasing rapidly, especially in EDs, while the utilization rate of XR is declining. The proportion of the increase in ED utilization may represent a shift of outpatient imaging to the ED.

SSJ20-02 Evaluation of Dual-Energy Metal Artifact Reduction Methods for Patients with Instrumented Spines

PURPOSE

Spine hardware causes artifacts in CT imaging due to beam hardening, photon starvation, scatter, noise, and non-linear partial volume effect. This study aims to evaluate three dual-energy CT (DECT) metal artifact reduction methods in patients with instrumented spines.

METHOD AND MATERIALS

20 patients with instrumented spines who underwent DECT were retrospectively identified. All scans were performed on a dual-source 128-slice scanner (SOMATOM Flash, Siemens Healthcare) using 100/140Sn kV pair with CARE Dose4D. In addition to the original DE linearly mixed images, images were reconstructed using iterative metal artifact reconstruction algorithm (DE iMAR), virtual monochromatic imaging (DE Mono+) at 130 keV, and a combination of the two methods (DE iMAR Mono+). Slice thickness and reconstruction kernel were kept the same. The four image series were anonymized and randomized for a reader study. Four experienced neuroradiologists rated them in terms of artifact scores for four relevant anatomical regions and an overall image quality score for both bone and soft tissue display window settings. In addition, a quantitative analysis was performed to assess the performance of the three metal artifact reduction methods by counting artifact-contaminated pixels that were recovered by the metal artifact reduction methods.

RESULTS

There were statistically significant differences in the artifact scores and overall image quality scores among the four image sets (both $p < 0.001$). DE iMAR Mono+ showed the best artifact scores and quality scores (all $p < 0.001$). Intraclass correlation coefficient among the readers was 0.779 and 0.892 for the overall quality score using the bone display window and soft tissue window, respectively (both $p < 0.001$). In addition, DE iMAR Mono+ reduced the artifacts by the greatest amount in the quantitative analysis.

CONCLUSION

DE iMAR Mono+ method demonstrated the best performance for spine metal artifact reduction using DECT data. These results may be specific to this CT vendor and spine implant types.

CLINICAL RELEVANCE/APPLICATION

A dual-energy CT metal artifact method was identified to best reduce metal artifacts for patients with spinal hardware, which would benefit spine and other CT exams affected by spine metal artifacts.

SSJ20-03 Osteoporosis Identification and Treatment Among Previously Undiagnosed Patients with Vertebral Fractures

PURPOSE

Unexplained fractures are an accepted indication for osteoporosis screening. Our aim was to determine how often patients without prior histories of osteoporosis undergo bone densitometry (DEXA scans), receive their initial diagnoses, or start osteoporosis medication after imaging studies demonstrated vertebral fracture.

METHOD AND MATERIALS

We used data from a pragmatic cluster randomized trial, consisting of adult patients from four integrated health care systems who received lumbar spine plain films, CT or MRI ordered by primary care providers from 10/2013 through 9/2016. We identified men $\geq$ 50 and women $\geq$ 52 years old with at least one vertebral fracture on their index imaging exams. We excluded patients with histories within the previous 12 months of severe trauma, diagnosis codes for osteoporosis/osteoporotic fractures or cancer, and/or bone densitometry procedure codes. Prior prescriptions for osteoporosis medications will be added as an exclusion factor, as well as an

outcome, before presentation. We report the proportion of patients with subsequent osteoporosis diagnoses, defined as having at least one of the following within 12 months: CPT code for DEXA; ICD diagnosis code for osteoporosis; or prescription for an osteoporosis medication. (Patients with any of these on day 0 were considered to be newly diagnosed, and therefore were classified as outcomes, rather than excluded.)

RESULTS

Of the 23,199 patients who had fractures on index imaging (10% of the entire cohort), 56% (n=12,935) met inclusion criteria. After 12 months, 16% (n=2130) had bone densitometry scans and 23% (n=2999) received osteoporosis diagnoses; 29% (n=3772) had at least 1 of these outcomes, and 10% (n=1357) had both.

CONCLUSION

Only 29% of primary care patients who underwent lumbar spine imaging and had vertebral fractures received *de novo* osteoporosis diagnoses and/or bone densitometry scans within the next year. A large proportion of patients who have potentially identifiable osteoporosis remain undiagnosed.

CLINICAL RELEVANCE/APPLICATION

A large proportion of patients who present with vertebral fractures and are at risk for osteoporosis remain undiagnosed.

PURPOSE

The aim of the present study is to evaluate the utility of MR-based radiomic analysis to quantify microstructural changes created by the cordotomy lesion and predict outcome in patients undergoing percutaneous cordotomy for medically refractory cancer pain.

METHOD AND MATERIALS

This is a retrospective interpretation of prospectively acquired data in 10 patients (5 males, age range 43-76 years) who underwent percutaneous CT-guided high cervical cordotomy for medically refractory cancer pain between 2015-2016. All patients underwent MR imaging of the cordotomy lesion on postoperative day 1. Aftersegmentation of T2-weighted images, 310 radiomic features were extracted. Pain outcomes were recorded on postoperative day 1 and day 7 using the visual analog scale. R software was used to build statistical models based on MRI radiomic features for prediction of pain outcomes.

RESULTS

Six of 10 patients (60%) showed decreased pain on postoperative day 1, and all patients had decreased pain on postoperative day 7. Twenty relevant radiomic features were identified using the mRMR method. Radiomics predicted postoperative day 1 pain scores with an accuracy of 90% (p-value= 0.046), 100% sensitivity, 75% specificity, 85.7% positive predictive value and 100% negative predictive value. The radiomics model also predicted if the postoperative day 1 pain score was sustained on postoperative day 7 with an accuracy of 100% (p-value= 0.02825), 100% sensitivity, 100% specificity, and 100% positive and negative predictive value.

CONCLUSION

MR-based radiomic analysis of the cordotomy lesion was predictive of pain outcomes at 1 week after percutaneous cordotomy for intractable cancer pain.

CLINICAL RELEVANCE/APPLICATION

MR-based radiomic analysis can non-invasively characterize microstructural changes created by the cordotomy lesion.

SSJ20-05 How Can Inter-Observer Reliability of Cervical Central Spinal Stenosis Evaluation and Cord Compression Be Improved?

PURPOSE

To evaluate the potential value of quantitative analysis of the bony canal size and CSF space to improve the quality and consistency of the standard qualitative visual assessments of cervical spinal stenosis (CSS).

METHOD AND MATERIALS

IRB-approved retrospective review of 39 levels of CSS from 20 patients were qualitatively assessed independently by 3 radiologists to rate the degree (mild, moderate, or severe) of CSS. The degree of CSS was then separately assessed quantitatively using calipers and categorized by the reduction of the bony canal level relative to the assumed normal diameter (10 mm): 7-10 mm (<30%), 4-6 mm (31-60%) and <4 mm (>61%), respectively. Similarly, quantitative analysis of the CSF space was assessed at the levels of CSS with different parameters of the thecal sac, including AP diameter, Left-right (LR) diameter and CSF area. Inter-reader agreement among the 3 readers was evaluated using Light's kappa and the intraclass correlation coefficient (ICC). The non-parametric bootstrap was used to calculate confidence intervals (CIs) and compare kappa/ICC values.

RESULTS

Inter-reader agreement of the qualitative assessment of the degree of CSS was fair with unweighted kappa 0.39 (95% CI: 0.23-0.57). Inter-reader agreement for the quantitative analysis of bony canal narrowing was significantly higher than that for qualitative degree of CSS (p=0.005), with unweighted kappa 0.69 (95% CI: 0.46, 0.86). For the quantitative analysis of the CSF space, there was also good inter-reader agreement on CSF AP diameter (ICC 0.80, 95% CI: 0.65-0.86) and CSF axial areas (ICC 0.75, 95% CI: 0.50-0.90), though agreement was lower for CSF LR diameter (ICC 0.50, 95% CI: 0.25-0.64).

CONCLUSION

Consistency of qualitative visual analysis of CSS can be improved with quantitative measurements of the bony canal diameter, although this 'one size fits all' approach to CSS evaluation does not account for individual size variation of the spinal canal and cord. Quantification of the CSF space has great potential since it can be performed consistently by different readers, accounts for thecal sac deformity and size variations of the bony canal and cord, and provides direct visualization of cord compression.

CLINICAL RELEVANCE/APPLICATION

Qualitative evaluation of cervical spine stenosis suffers from inconsistent interpretation and individual anatomic variation which can be improved by quantitative analysis of bony canal and CSF space.

SSJ20-06 Over-Reliance on Fluoroscopy Guided Lumbar Punctures Can Negatively Impact Neuroradiology Training in Radiology Residency: An Analysis and Potential Solution through Establishing Departmental Guidelines for Referring Clinicians

Tuesday, Nov. 27 3:50PM - 4:00PM Room: E352

richartj33@gmail.com

PURPOSE

Requests for fluoroscopy guided lumbar punctures have increased over the past decades. They are primarily performed by radiology trainees in many academic institutions. We evaluated the impact of the number of fluoroscopy guided lumbar punctures performed on the number of cross-sectional neuroimaging studies residents dictated during their neuroradiology rotation. We also evaluated the effect that introducing department guidelines for lumbar punctures had on the number of lumbar puncture referrals we received in our neuroradiology division.

METHOD AND MATERIALS

We retrospectively reviewed the fluoroscopy guided lumbar punctures and myelograms performed and neuroimaging studies dictated by radiology residents on our neuroradiology service from July 2008 - December 2017. We used Poisson regression analysis to directly examine the relationship between the number of fluoroscopy guided lumbar punctures performed and neuroimaging studies (CT and MRI) dictated per day by residents. We developed and instituted guidelines for ordering fluoroscopy guided lumbar punctures and evaluated its effect on the number of these procedures performed before and after institution of the guidelines.

RESULTS

Radiology residents (n=84) performed a total of 3436 fluoroscopy guided lumbar punctures and myelograms and interpreted 33,402 cross-sectional studies. For each fluoroscopy guided lumbar puncture or myelogram performed, there was an estimated factor reduction in the total number of neuroimaging studies dictated of 0.77 for both first year residents and all residents (p<0.001). After institution of the guidelines, there was a statistically significant decrease in the number of fluoroscopy guided lumbar punctures performed (p<0.001).

CONCLUSION

We demonstrated that performing fluoroscopy guided lumbar punctures has an inverse relationship with the number of neuroimaging studies radiology residents dictate on the neuroradiology rotation. We instituted department guidelines which significantly decreased the number of fluoroscopy guided lumbar punctures performed.

CLINICAL RELEVANCE/APPLICATION

Performing fluorscopy guided lumbar punctures significantly decreases the number of cross-sectional neuroimaging studies read by radiology residents, which could potentially delay the development of their diagnostic neuroradiology skills.

PURPOSE

To develop a new performance informatics platform, called 'METrology for Imaging Systems (METIS)', that enables both radiation safety and image quality monitoring for prospective and retrospective assessments of dose and quality

METHOD AND MATERIALS

METIS has been developed with multi-year input and pilot trials at a large academic medical center. This data-centric platform integrates a multi-infrastructure workflow for collecting patient data and clinical images from the PACS, imaging workstations (CT, Mammography, Radiography, and Fluoroscopy), and electric health record system (Epic). Dose and image quality metrics are implemented from previously validate algorithms in a modality context-specific fashion. Device-, protocol-, and size-specific reference levels are established with supervised machine learning technologies. High-dimensional data analysis is performed to provide multi-dimensional visualizations to aid users in evaluating clinical performance and highlighting inconsistencies. All metrics and image data are managed in a MySQL-MongoDB hybrid database.

RESULTS

METIS was deployed in clinical operation since 2016. Dose data from 460,000 CT, 350,000 Mammography, 300,000 Radiography, and 10,000 Fluoroscopy exams are recorded. Over 500 dose reference lines are created for CT outlier identification. Over 60,000 chest radiographs are automatically evaluated to simulate radiologists' perceptual evaluation process. 1000 adult and 1000 pediatric CT scans are sampled from contrast and non-contrast enhanced CT chest/abdomen/pelvis exams to build the dose-quality metrics by using measured image noise, spatial resolution, contrast, and dose. A web-based dashboard with high-dimensional data visualization is developed to provide a holistic performance view, consolidating large-scale diverse clinical and operational data into a single graphics.

CONCLUSION

METIS offers the first strategy for combined dose and image quality monitoring. Adding quality-dose metrics and advanced prospective and retrospective data analysis, it provides opportunities for assessing and addressing the aggregate aspects of clinical imaging practice to ensure rigorous patient safety and consistent imaging quality.

CLINICAL RELEVANCE/APPLICATION

METIS fulfills an unmet need for a prospective and retrospective dose monitoring, along with image quality and device performance assessment, to ensure rigorous patient safety and consistent image quality.

SSJ21-02 Signal and Noise Performance of the Apodized-Aperture Pixel (AAP) X-Ray Detector Design to Increase Detective Quantum Efficiency (DQE)

Tuesday, Nov. 27 3:10PM - 3:20PM Room: N229

Participants
Tomi Nano, London, ON (*Presenter*) Nothing to Disclose
Ian A. Cunningham, PhD, London, ON (*Abstract Co-Author*) Founder, DQE Instruments Inc

For information about this presentation, contact:

tnano@uwo.ca

PURPOSE

Recent studies from screening programs have shown significantly higher detection rates attributed to higher detector performance. X-ray detector performance, in terms of signal-to-noise ratio (SNR) for a given amount of radiation, is quantified by the detective quantum efficiency (DQE). Current clinical detectors have low DQE (<30%) at high-frequencies which are important for visualization of small image features. We have developed a novel x-ray detector design, called Apodized-Aperture Pixel (AAP), that could achieve high DQE at high-frequencies. The purpose of this research is to determine AAP performance in the presence of correlated or uncorrelated noise due to x-ray interactions or converter blur.

METHOD AND MATERIALS

Conventional x-ray detectors have the same element and pixel size. AAP design separates physical elements from image pixels by using micro-elements (0.01-0.025mm) to produce current clinical pixel sizes (0.07-0.2mm). Conventional and AAP designs were modeled with cascaded system analysis including x-ray interactions, converter blur, collection efficiency and readout noise. DQE was measured to evaluate proof-of-concept experiments with radiography and mammography detectors. Simulations of sinusoidal patterns and demonstration x-ray images were acquired for visual comparison.

RESULTS

Excellent agreement was found between theoretical and experimental results. AAP design provides 1.5x greater MTF at high frequencies than conventional design. For cases when detector DQE is dominated by converter blur (ie. pixel size is smaller than converter blur), x-ray reabsorption or element size, high-frequency DQE of the AAP design was 1.5x greater, 1.8x greater and 2.5x greater respectively compared to conventional design.

CONCLUSION

Compared to conventional design at high-frequencies, the AAP design has greater MTF from use of a micro-elements and greater DQE due to reduced noise aliasing. MTF and DQE improvement is greatest when x-ray reabsorption and converter blur effects are minimal. Simulations and x-ray images with the AAP design (Fig. 1) show increased contrast and reduced aliasing artifacts. The AAP design can achieve a flat-DQE that approaches an 'ideal detector' which was not previously possible.

CLINICAL RELEVANCE/APPLICATION

The Apodized-Aperture Pixel (AAP) x-ray detector design can increase high frequency MTF by 1.5x and DQE by 2.5x with the implication that this may help increase cancer detection rates.

SSJ21-03 Validation and Performance Evaluation of a Remote and Automated QC Program for Digital Radiography

For information about this presentation, contact:

arreom@radiology.ufl.edu

PURPOSE

This study evaluates the performance viability of the Remote QC program as well as comparing the performance of ATIA with other established image quality assessment tools.

CONCLUSION

The easy-to-use ATIA provides results that are in agreement with those obtained by established methods. The results show the great applicability of the Remote QC program in monitoring trends. The results also show that however, caution needs to be used as not to damage the QC phantom and avoid using different image filtering, the consistent results will be still reproducible upon using the same phantom and acquisition protocol.

CLINICAL RELEVANCE/APPLICATION

Insufficient qualified medical physics support in some parts of the world may lead to an ineffective quality control program for digital radiography systems. To mitigate this situation a remote QC program package (ATIA) including a simple, yet data-rich phantom and software tool was developed in order to quantitative image assessment which remotely informs the medical physicists of issues in trend analysis.

SSJ21-04 Assessment of Scatter Emitting From the Exit Window of Interventional X-Ray Tubes

Fetterly.Kenneth@mayo.edu

PURPOSE

Radiation safety practices have been based on the tenet that the primary source of occupational radiation dose to interventional radiologists is from the patient. The purpose of this work was to quantify the contribution of scatter emitting from the exit window of the x-ray tube to occupational radiation dose.

METHOD AND MATERIALS

Air kerma (KA) to the average location of the upper body of an interventional physician (height = 150cm) was measured with and without a 25 cm thick anthropomorphic phantom positioned in the x-ray beam. The experimental technique allowed isolation of radiation dose emitting from the phantom versus directly from the X-ray tube. KA measurements were normalized by dose area product. Experimental geometry was consistent with that of PA imaging during thoracic and abdominal interventional procedures. No accessory radio-protective shields were used. Scatter from x-ray tubes by three manufacturers was assessed and systems were configured to produce similar quality beams (81 kVp, filtration: 0.2 mm Cu or 0.1 mm Cu + 1 mm Al). Further, scatter from a selected X-ray tube was reassessed following the addition of 0.5 mm Pb to the inside surface of the collimator assembly housing.

RESULTS

The magnitude of scatter originating from within the phantom was equivalent for all systems. Considering all x-ray tubes and variable distance from the central ray, scatter emitting from the beam exit window of the tubes accounted for 20% to 55% of the total scatter. There was a minimum of 20% tube scatter at all distances with respect to the central axis of the X-ray beam, with some tubes exhibiting increased tube contribution as the measurement point was moved toward the central axis. The X-ray tube scatter originated from interaction of the x-ray beam with x-ray collimator assembly components, including the DAP meter. The addition of 0.5 mm Pb to the collimator assembly housing provided an approximately 50% reduction of tube scatter to the location of an interventional physician.

CONCLUSION

X-ray scatter originating from within the x-ray collimator assembly was found to contribute substantially to the radiation dose measured at a typical location of the upper body of an interventional physician.

CLINICAL RELEVANCE/APPLICATION

The primary source of occupational radiation dose was thought to be from the patient. However, our study shows that X-ray tube scatter is in fact a significant contributor to occupational dose.

PURPOSE

ICU patients are often too unstable to move for CT imaging. In these cases, portable chest radiographs (CXR) are used to assess pathology. Tomosynthesis can provide additional diagnostic information, but is not readily available at the bedside. The primary goal of our study was to compare the stationary digital chest tomosynthesis (s-DCT) system to portable CXR in the evaluation of patients with various lung pathologies.

METHOD AND MATERIALS

Patients undergoing clinically indicated chest CT were recruited to have a portable CXR and s-DCT scan, with our carbon nanotube (CNT) x-ray source array. Three thoracic radiologists evaluated the images. Readers scored the imaging on a scale of 1-5 based on 10 criteria; visualization of lung fields, vasculature, trachea, proximal bronchi, retrocardiac lung, diaphragm, costophrenic angles,

ribs, spine, and hardware. Readers were asked to rate their confidence in interpreting the scans on a scale of 1-7. Furthermore, readers evaluated whether s-DCT gave them more information than CXR. A t-test for independent means was used to analyze the data.

RESULTS

A total of twenty-two patients were successfully imaged. The average age was 64.7 +/- 8.5 years. All readers gave s-DCT statistically higher scores when evaluating vasculature, proximal bronchi, and the spine (p: <0.00026). Readers 1 and 2 rated the ribs higher on s-DCT (p: <0.00001). Reader 2 gave statistically higher scores to s-DCT for the trachea, retrocardiac lung, and costophrenic angles (p: <0.0033). Reader 3 gave CXR higher scores for visualization of the diaphragm (p: 0.018). Confidence scores were not statistically different between techniques for readers 1 and 3. Reader 2 gave higher confidence scores to s-DCT (p: <0.00001). Readers 1 and 3 stated that s-DCT gave them information that CXR did not 36% and 41% of the time. While reader 2 indicated that s-DCT gave additional information 95% of the time.

CONCLUSION

Portable stationary-DCT in the ICU setting should be possible with our CNT s-DCT system. Tomosynthesis imaging improves visualization of thoracic structures compared to portable CXR. Reader confidence in s-DCT can be comparable or higher to CXR, and in a significant number of cases s-DCT gives information that is not provided by CXR.

CLINICAL RELEVANCE/APPLICATION

Stationary digital chest tomosynthesis is a potentially superior alternative to portable chest x-ray for patients in the ICU setting that cannot undergo CT examination.

SSJ21-06 Virtual Dual-Energy (VDE) Imaging: Separation of Bones from Soft Tissue in Chest Radiographs (CXRs) by Means of Deep Residual Learning (DRL)

PURPOSE

Lung nodules that overlap ribs and/or clavicles in CXRs can be difficult to be detected by radiologists, as well as by computer-aided detection (CAD) systems. Our purpose was to develop a new VDE imaging technique to separate ribs and clavicles from lung nodules and soft-tissue in CXRs by means of our newly developed DRL.

METHOD AND MATERIALS

We developed a novel DRL model employing our neural network convolution (NNC) framework in a residual convolutional manner to convert a standard CXR to an image that looks like a dual-energy (DE) bone image; thus, term VDE imaging. Our model consisted of 2 convolutional layers and 9 residual blocks, resulting in a deep 20-layer network. Each residual block contained two convolutional layers with batch normalization, and a shortcut connection, passing information from finer to coarser image features. Our DRL model was trained in an image-based fashion to learn the relationship between input CXRs and the corresponding "teaching" DE bone images. We used a large database of 118 CXRs with nodules with corresponding "gold-standard" DE images acquired with a DE imaging system (FCR 9501 ES, Fuji Medical Systems, CT). We trained and evaluated our model with a nested 2-fold cross validation protocol. Once trained, our technology no longer required DE images, and it provided VDE bone images where soft tissue was substantially attenuated, while bony structures were preserved. This image was then subtracted from the corresponding CXR to provide a VDE soft-tissue image from which bones were removed. We performed quantitative evaluation of our results by using the structural similarity (SSIM) image-quality index.

RESULTS

Our VDE technology was able to separate ribs and clavicles from lung nodules and soft-tissue structures very accurately in 118 CXRs and provided bone and soft-tissue images. Comparing to a state-of-the-art bone-suppression technique, our new VDE soft-tissue images had higher (t-test; P<.01) similarity (SSIM from 0.90 to 0.93) to the "gold-standard" DE soft-tissue images.

CONCLUSION

Our new DRL model converted CXRs to VDE soft-tissue images, where bones were separated from soft-tissue accurately, which offered the improved conspicuity of lung nodules and vessels.

CLINICAL RELEVANCE/APPLICATION

VDE technology requiring only a "single" CXR without requiring specialized equipment or additional radiation dose would be beneficial to radiologists as well as CAD in detection of lung nodules in CXRs.

PURPOSE

Recent theoretical and experimental studies about CT number accuracy in low dose CT have shown that filtered backprojection (FBP) and conventional model based iterative reconstruction (MBIR) methods are biased by an amount that is dose and contrast dependent. This work validates that the data weighting scheme in the MBIR framework is the culprit for both these biases and that a more optimal weighting scheme has been found to eliminate bias across all dose and contrast levels.

METHOD AND MATERIALS

Raw CT data was acquired for two phantoms on a benchtop CT system using a photon counting detector (XC-HYDRA FX50, XCounter AB, Sweden). The Catphan phantom (Catphan 600, Phantom Laboratory, Salem, New York) was scanned at several dose levels in the range 69-367 mAs, with 50 repeated scans for each dose level. A customized head phantom was also scanned in the range 40-400 mAs, with 30 repeated scans for each dose level. Reference images for each phantom were obtained by averaging the pre-log projections for the highest dose level across all repetitions, and then performing FBP reconstruction. These references served as the experimental ground truth. For each dose level and reconstruction method (FBP, MBIR, proposed MBIR), bias images were calculated by subtracting the reference image from the mean of the reconstructions of each repeated scan. Bias was measured in 4 small inserts of varying contrast in the Catphan phantom. Bias images of the Catphan and head phantoms were also assessed across the image field of view (FOV).

RESULTS

There are three main results: 1) The theoretical relationship bias=±a/mAs*(1+ßΔHU) was validated experimentally for both FBP (positive polarity) and conventional MBIR (negative polarity). 2) The proposed MBIR method, which uses a modified weighting scheme, eliminates bias for each contrast and dose level in the Catphan phantom. 3) The proposed MBIR method demonstrates promising preliminary results for reducing bias across the FOV in a more complex anthropomorphic head phantom.

CONCLUSION

The proposed MBIR method maintains CT number accuracy of varying contrast across dose levels by using a theoretically based modified data weighting scheme.

CLINICAL RELEVANCE/APPLICATION

Certain tasks, e.g. detection of acute cerebral venous sinus thrombosis (CVST), rely on CT number estimation. It is critical the CT reconstruction method maintains accurate HU values.

SSJ22-02 Joint Reconstruction of Low-Count PET and Undersampled MR in PET/MR Using Deep Learning

Tuesday, Nov. 27 3:10PM - 3:20PM Room: N227B

Participants

Junshen Xu, Beijing, China (*Presenter*) Nothing to Disclose
Tuoyu Cao, PhD, Houston, TX (*Abstract Co-Author*) Employee, Medical Device Manufactor

Kui Ying, PhD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Acquiring low-count PET and undersampled MR can shorten PET/MR scan time, which, however, may also lead to noisy PET images and MR images with artifacts. The goal of this report is to evaluate whether deep learning method can reconstruct high-quality PET/MR images from its low-quality counterpart, potentially enabling shorter scan time in PET/MR. We also compared the proposed model with single modality models to investigate whether the resulting image quality can benefit from sharing features of the two modalities in the network.

METHOD AND MATERIALS

We developed a fully convolutional encoder-decoder network to predict high quality PET and MR images from low-count PET and undersampled MR. Concatenate skip connections and strategy of residual learning is adopted to restore high resolution details. Brain PET/MR data are acquired with a simultaneous PET/MR system (uPMR790, United Imaging Healthcare) from 50 patients who received 0.12 mCi/kg FDG. To generate low-count PET, the PET list-mode data was randomly undersampled for 10% events. Both standard-count and low-count PET images were reconstructed with OSEM (4 iterations, 20 subsets). Undersampled T1 weight MR is generated using radial sampling in k-space with sampling rate equal to 10%. Standard-count PET and fully sampled MR were taken as ground-truth in network training.

RESULTS

Models were trained on 40 patients and evaluated on the other 10 patients. The proposed joint model gains 4.5/7.9dB in peak signal-to-noise ratio (PSNR) and 0.036/0.42 in structural similarity index (SSIM) compared with low-count PET/undersampled MR. When compared with the single modality model of PET/MR, results shows that our joint model has an improvement of 0.97/0.15dB in PSNR and 0.006/0.0012 in SSIM.

CONCLUSION

Using a deep learning algorithm, we can estimate high-quality PET and MR images from low-count PET and undersampled MR images. Results also showed that joint reconstruction of PET and MR by sharing features in network can improve image quality of two modalities compared with single modality model.

CLINICAL RELEVANCE/APPLICATION

This method was demonstrated promising in greatly reducing the scan time in PET/MR imaging by up to 90%.

SSJ22-03 Implementation of a CT Reference Library Containing Manufacturer-Neutral Projection Data, Images, and Clinical Metadata

PURPOSE

A manufacturer-neutral CT projection data (PD) format (DICOM-CT-PD) has been previously developed and used to allow access to CT PD and the scanner information required for image reconstruction. Access to such data was not previously possible, limiting the ability of reconstruction scientists to work with patient data. In this work, we aim to construct a reference DICOM-CT-PD library containing patient PD with corresponding images and clinically relevant metadata, and to publish this library for public access.

METHOD AND MATERIALS

CT images and PD were acquired from three different manufacturers for three clinical scanners at routine dose levels for head, chest and abdomen exams. The PD were converted to the DICOM-CT-PD format and a lower dose exam was simulated for each PD set using a validated noise-insertion method. Radiologists reviewed each case and marked lesion locations and diagnosis. Reference truth was obtained from the patient medical record, either from histology or subsequent imaging. Metadata such as lesion location, diagnosis, and source of truth were acquired for each case and formatted into a reference report. Each case was anonymized to remove protected health information for transfer to an NCI-hosted public data archive, The Cancer Imaging Archive (TCIA).

RESULTS

450 total cases from Siemens (n=150), GE (n=150), and Philips (n=150) scanners were obtained, including both negative and positive patient cases. PD are available for two dose levels, routine full dose and simulated low dose (25% of routine dose for head and abdomen cases and 10% of routine dose for chest cases). Routine dose image series are available for all of the cases, and reduced dose images are additionally available for exams acquired on a Siemens scanner. Clinical metadata are organized in an easy to use spreadsheet. The assembled projection, image and clinical data provide a rich data library with which CT image reconstruction scientists can validate their algorithms.

CONCLUSION

A large patient library containing manufacturer-neutral PD, the corresponding full dose images, and clinical reference information has been developed and is being made available through the TCIA.

CLINICAL RELEVANCE/APPLICATION

The successful implementation of this library will provide open source CT PD with correlated images and clinical information to investigators for reconstruction research and development.

SSJ22-04 Motion Compensation in Liver SPECT using Simultaneous X-Ray and Nuclear Imaging

Tuesday, Nov. 27 3:30PM - 3:40PM Room: N227B

Participants
Martijn Dietze, Utrecht, Netherlands (*Presenter*) Nothing to Disclose
Remco Bastiaannet, Utrecht, Netherlands (*Abstract Co-Author*) Nothing to Disclose
Britt Kunnen, Utrecht, Netherlands (*Abstract Co-Author*) Nothing to Disclose

Hugo W. de Jong, PhD, Utrecht, Netherlands (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Quantitative accuracy of liver SPECT/CT is crucial for e.g. dosimetry in radioembolization, but due to respiratory motion limited in precision. Motion can be compensated for in the reconstruction, but in clinical practice this requires an external device for the tracking of the motion signal and a prior motion vector field estimate to link the motion signal to organ movements, complicating the acquisition. A device under development, which simultaneously measures x-ray and nuclear projections, could be used to retrieve both measures intrinsically. Such a data-driven approach eliminates the need for external devices and provides a real-time vector field. The purpose of this work is to evaluate the performance of the proposed motion compensation technique using simulations.

METHOD AND MATERIALS

Nuclear and x-ray projections of a realistic digital phantom with respiratory motion were generated using Monte Carlo simulations for several breathing patterns. X-ray projections were sampled at 1 to 5 Hz; nuclear projections were acquired continuously. Total x-ray imaging dose was varied from 1 to 1000 µGy. The motion signal was extracted from x-ray projections by calculation of the center of mass and then used to bin the projections into gates. The x-ray gates were individually reconstructed and registered onto each other, resulting in the vector field to be included in the nuclear reconstruction.

RESULTS

The respiratory motion signal was accurately extracted from the x-ray projections, provided the x-ray sampling rate was greater than 2 Hz and the motion was stable in amplitude. The total minimally required dose for x-ray sampling was 10 µGy for a 5 minute scan. The inclusion of motion correction into the SPECT reconstruction improved contrast-to-noise ratio, in comparison with no motion correction, from 11.9 ± 0.5 to 19.1 ± 0.7.

CONCLUSION

The proposed motion compensation technique has the potential to improve quantitative SPECT reconstructions. Additionally, the need for external devices and a prior vector field estimate are eliminated. Only a limited amount of dose is required to obtain significantly improved results, paving the way for clinical use.

CLINICAL RELEVANCE/APPLICATION

Liver radioembolization requires quantitative SPECT to study the activity distribution. In order to improve accuracy and personalize dosimetry, motion should be accounted for in reconstructions.

SSJ22-05 Motion Compensated Reconstruction of the Aortic Valve for Non-Gated Helical CT Scans

Michael Grass, PhD, Hamburg, Germany (*Abstract Co-Author*) Employee, Koninklijke Philips NV

PURPOSE

Precise CT imaging is prerequisite for reliable planning of transcatheter aortic valve implantation (TAVI). Especially in non-gated CT scans, cardiac motion leads to severe artifacts in the reconstructed CT images. Blurring of the valve and the neighboring vascular anatomy potentially result in incorrect device sizing. A second pass motion correction method for non-gated helical CT scans with a pitch <1 is introduced here.

METHOD AND MATERIALS

The new post-processing method was applied to five non-gated clinical datasets acquired with a 256-slice CT scanner (Brilliance iCT, Philips Healthcare). Redundancy in the helical projection data was used to generate three image volumes at identical spatial positions, but different time points. During each reconstruction a subset of detector rows was selected which may be either overlapping or fully separated depending on the pitch size. The 3D edge-filtering scheme included Gaussian smoothing for noise reduction, gradient calculation for edge enhancement, non-maximum-suppression and hysteresis thresholding for reduction of incoherent edges. The sparse filter results were taken as input for an elastic registration to estimate the displacement of each

voxel between the given time points. Reconstructed datasets were evaluated with a TAVI planning software (IntelliSpace Portal, Philips Healthcare) by two blinded readers.

RESULTS

The method achieved significant motion artifact reduction in CT aortic valve reconstructions. A removal of doubled structures at the aortic boundaries could be observed, as well as reduced blurring compared to the uncompensated reconstructions.

CONCLUSION

Motion compensated reconstruction is feasible for non-gated helical CT scans using edge filtering and image based registration for motion estimation. Reconstructed CT image datasets may improve planning and device selection for TAVI procedures.

CLINICAL RELEVANCE/APPLICATION

Motion compensated reconstruction yields reduced artifact levels at the aortic valve in non-gated helical CT scans with a pitch <1.

SSJ22-06 Multi-Channel GAN: A Machine Learning Approach to Parallel MRI Reconstruction

Tuesday, Nov. 27 3:50PM - 4:00PM Room: N227B

Participants
Pengyue Zhang, Stony Brook, NY (*Presenter*) Nothing to Disclose
Fusheng Wang, Stony Brook, NY (*Abstract Co-Author*) Nothing to Disclose
Yulee Li, Greenvale, NY (*Abstract Co-Author*) Nothing to Disclose

pengyue.zhang@stonybrook.edu

PURPOSE

Magnetic resonance imaging (MRI) has a low imaging speed. MRI acceleration relies on undersampling that may introduce aliasing artifacts in image reconstruction. Here we propose a machine learning approach that can automatically learn parallel MRI mechanisms underlying multi-channel k-space data and reconstruct high-quality MR images from undersampled data.

METHOD AND MATERIALS

Parallel MRI is a standard approach to imaging acceleration on clinical MRI scanners. This approach can effectively suppress aliasing artifacts associated with undersampling, but requires an additional calibration procedure that limits the overall imaging speed. Here a deep learning based neural network model, multi-channel generative adversarial network (multi-channel GAN), is developed to process multi-channel raw MRI data. This model can learn parallel MRI reconstruction mechanisms underlying a large amount of multi-channel k-space data. The trained model can be used to reconstruct images from undersampled data without calibration, thereby providing a higher imaging speed than conventional parallel MRI. In our approach, the basic unit of multi-channel GAN has two sub-networks: a generator network which learns the relationship between undersampled and fully-sampled data and a discriminator network which justifies if the generated data are real. The whole model consists of the same number of basic unit networks as that of radiofrequency channels on the MRI scanner for parallel MRI reconstruction. The training process uses a stochastic gradient descent and back-propagation algorithm. The trained multi-channel generator network is used to perform image reconstruction.

RESULTS

We evaluate the proposed method with a total of 170 sets of 2D multi-channel brain MRI images. Figure 1 shows an example of reconstruction results with an undersampling factor of 5. It is found that the machine learning method outperforms other state-of-the-art parallel MRI reconstruction methods.

CONCLUSION

We demonstrate a machine learning approach to parallel MRI reconstruction.This approach can generate high-quality images from undersampled data without calibration, providing a higher imaging speed than conventional parallel MRI.

CLINICAL RELEVANCE/APPLICATION

The machine learning approach to parallel MRI reconstruction can enhance diagnostic MRI quality, shorten clinical MRI procedures and improve clinical MRI throughput.

qcao@jhmi.edu

PURPOSE

Quantitative evaluation of bone mineral density (BMD) using cone-beam CT (CBCT) is challenged by a high level of artifacts typically associated with CBCT. We apply a polyenergetic model-based iterative reconstruction (MBIR) with a material mixing model to obtain accurate and reproducible density estimates in extremity CBCT.

METHOD AND MATERIALS

An ideal solution model was used in polyenergetic MBIR (MBIR-poly, Elbakri PMB 2003) to account for mixing of Ca and marrow in bone. The model was calibrated using BMD inserts of known concentration (Gammex 467, 472). Scans were acquired at 90 kVp on a test-bench emulating the geometry of extremity CBCT. Monte Carlo scatter estimates obtained from water-corrected FBP were subtracted from projection data. Artifact reduction and quantitative accuracy were evaluated in water phantoms with muscle, adipose and BMD inserts (from 20 mg/cc to 500 mg/cc Ca). MBIR-poly reconstructs the density map of the object and thus the reconstructed voxel values were compared with measured physical densities of the inserts. To assess robustness to imaging conditions (essential in longitudinal studies), we compared density estimates in cortical and trabecular regions-of-interest (ROI) of a cadaveric ankle imaged in the following configurations: ankle alone (C1), ankle+water+2 BMD inserts (C2), ankle+water+2 BMD inserts+2 cm shift (C3).

RESULTS

With MBIR, the error in density was <0.009 g/cc across all BMD inserts. The magnitude of streak artifacts (departure from uniformity in a water region) was reduced by 96% compared to FBP with water-correction only. The spread (standard deviation) of mean cortical and trabecular density across configurations C1-C3 was reduced by 78% and 51%, respectively. The estimates of physical BMD insert density remained accurate when imaged in the presence of the ankle (configurations C2 and C3), with errors<0.015 g/cc.

CONCLUSION

MBIR-poly with an ideal solution mixture model yielded correction of beam hardening artifacts and provided quantitatively accurate estimates of object density in extremity CBCT. The density estimates were reproducible across a variety of imaging conditions.

CLINICAL RELEVANCE/APPLICATION

A polyenergetic model-based reconstruction algorithm yields accurate and reproducible estimates of tissue density in extremity CBCT, enabling quantitative studies of bone mineralization.

SSJ23-02 Two-Dimensional Anti-scatter Grids for CBCT: Transmission Properties of High Grid Ratio 2D Grid

Prototypes

caltunbas@gmail.com

PURPOSE

CT number accuracy and low contrast resolution can be poor in CBCT images due to high levels of scattered radiation. To reduce scatter, we have been investigating the utility of 2D antiscatter grids for flat panel detector based CBCT. In this study, we developed two prototypes, and characterized their scatter and primary transmission performance in a CBCT system for image guided radiation therapy.

METHOD AND MATERIALS

Two prototypes with grid ratio of 12 (R12) and 16 (R16) were developed and fabricated by using direct metal laser sintering process. Both grids have 2 mm grid pitch, and 0.1 mm septal thickness, and their grid cells were focused towards the x-ray source, in offset detector CBCT geometry. Prototypes were integrated with the flat panel detector in a clinical CBCT system. Primary and scatter transmission properties were measured using PMMA phantoms and beam-stops, at tube voltages of 80, 125, and 140 kVp. To benchmark the performance of prototypes, a fluoroscopic 1D antiscatter grid with a grid ratio of 21 (R21) was also evaluated under identical imaging conditions.

RESULTS

At 140 kVp, scatter-to-primary ratio (SPR) at 40 cm phantom thickness was 10.1 without a grid. SPR was reduced to 0.36 and 0.29 with our R12 and R16 prototypes, whereas SPR was 1.47 with the 1D grid. Scatter transmission fraction (Ts) with R12 and R16 prototypes were 3.1% and 2.4%, and Ts for 1D grid was 10.8%. When tube voltage increased for 80 to 140 kVp, Ts values increased by 13% for both 2D grids, whereas Ts increased by 31% for the 1D grid. Similar trends were observed for all grids when phantom thickness was varied between 10 and 40 cm. Average primary transmission fraction of R12, R16 prototypes, and 1D grid were 83%, 71%, and 70%, respectively.

CONCLUSION

Scatter transmission of our 2D grids were up to factor of 4.5 lower than a conventional antiscatter grid, while providing higher primary transmission. Thus, lower scatter transmission provided by 2D grids may lead to higher CT number accuracy and improved contrast resolution in CBCT. Lower scatter transmission may also play an important in the context of dual-energy CBCT, where highly accurate projection images are required.

CLINICAL RELEVANCE/APPLICATION

Scattered radiation is one of the leading causes of image quality degradation in CBCT imaging, limiting the utility of CBCT in a range of clinical applications. Our research on 2D antiscatter grid development aims to address this problem.

SSJ23-03 Deep Scatter Estimation (DSE) for Truncated Cone-Beam CT (CBCT)

Tuesday, Nov. 27 3:20PM - 3:30PM Room: N226

joscha.maier@dkfz.de

PURPOSE

To correct for x-ray scatter in truncated CBCT in real time.

METHOD AND MATERIALS

Cone-beam CT (CBCT) acquisitions suffer from scatter artifacts. To correct for these artifacts, we recently developed the deep scatter estimation (DSE) that trains a deep convolutional neural network to reproduce Monte Carlo (MC) scatter estimates. Once trained, DSE combines both real-time capability and high accuracy. Applied to non-truncated data, DSE turned out to be equivalent to MC while outperforming known scatter estimation approaches. In the present work, however, we deal with truncated data as they occur in interventional C-arm CBCT or dental CBCT. In this case MC simulations are not possible because the object, which is needed as input to the MC simulation, cannot be fully reconstructed. To overcome this drawback, we developed the truncated DSE which uses a U-net architecture to reproduce the outcome of MC simulations from non-truncated objects given only the truncated projection data as input. Here, DSE is trained on 10800 simulated truncated projection images (pelvis, abdomen, and thorax). The training is performed on a GeForce GTX 1080 for 100 epochs using an Adam optimizer and the mean absolute error between the output and the MC scatter distribution as loss function. The performance of DSE was evaluated for simulated and measured testing data of a truncated CBCT system and compared against a kernel based scatter estimation (KSE).

RESULTS

Considering simulated data, the accuracy of KSE and DSE scatter estimates was quantified by calculating the mean absolute error (MAE) with respect to the simulated ground truth scatter distribution. Here, we observe a MAE of 19.2 % (KSE) and 1.8 % (DSE).

To quantify the performance for measured data, a slit scan measurement was performed as reference. Compared to the slit scan, CT reconstructions that were corrected using DSE show an almost similar CT value distribution while there are discrepancies of up to 150 HU using KSE.

CONCLUSION

DSE is able to derive highly accurate scatter estimates very close to MC simulations. Compared to conventional scatter estimation approaches DSE shows a superior performance while requiring similar processing time (20 ms / projection).

CLINICAL RELEVANCE/APPLICATION

Scatter correction is crucial to maintain the diagnostic value of CBCT examinations. DSE can overcome the drawback of existing approaches that are optimized for performance at the cost of accuracy.

SSJ23-04 Daily Edge Deformation Prediction Using a Conventional Neural-Network Regression for Low Dose Prior Contour Based Total Variation CBCT Reconstruction (PCTV-CNN)

Tuesday, Nov. 27 3:30PM - 3:40PM Room: N226

yingxuan.chen@duke.edu

PURPOSE

Previously we developed a PCTV reconstruction method to enhance the edge sharpness of low-dose CBCT. PCTV deforms the edge map from planning CT to on-board volumes to obtain the on-board edge information for enhancement in TV reconstruction. However, the deformable registration used for deforming the edge is time consuming and prone to errors due to the low quality of CBCT. This study aims to develop a novel method for predicting daily on-board edge deformation using deep conventional neural networks (CNN) to bypass deformable registration to improve the PCTV reconstruction efficiency.

METHOD AND MATERIALS

The new method uses patch-based CNN deformation prediction and PCTV reconstruction. Deformation vector field (DVF) registered from CT to full-sampling CBCTs and retrospectively under-sampled low-dose CBCT are obtained on the first day to train the model, which is then updated with following days' data. The model predicts DVF for low-dose CBCT acquired on the following day to generate on-board contours for PCTV reconstruction. Specifically, 3D patches are extracted from the same location in the planning-CT and low-dose CBCT as the inputs. Only DVF and voxels at the edge regions of planning-CT are selected for the prediction model. The CNN model is developed in MATLAB using 4 convolutional layers interleaved with pooling layers to directly learn the mapping from the input image patch pair. The method is evaluated using lung SBRT patient data. The first n-1 day's CBCTs are used for CNN training to predict nth day edge information (n=2, 3, 4, 5). 45 half-fan projections covering 360° from nth day CBCT is used for reconstruction. Results from Edge-preserving (EPTV), PCTV and PCTV-CNN are compared.

RESULTS

The cross-correlations between predicted and reference edge maps are 0.9734, 0.9706, 0.9624 and 0.9477, for day 2-5 respectively. PCTV-CNN enhanced bone edges in CBCT compared to EPTV and achieved comparable image quality as PCTV while avoiding time-consuming deformable registration process.

CONCLUSION

Preliminary results demonstrated the feasibility to use CNN to predict daily deformation of on-board edge information for PCTV based low-dose CBCT reconstruction.

CLINICAL RELEVANCE/APPLICATION

PCTV-CNN has a great potential for enhancing the edge sharpness with high efficiency for low dose 3D CBCT or 4D CBCT to improve the precision of on-board target localization and adaptive radiotherapy.

SSJ23-05 A Robust Fully Automatic Method for Intrinsic Respiratory and Cardiac Gating for Cone-Beam CT Scans of the Thorax Region

Tuesday, Nov. 27 3:40PM - 3:50PM Room: N226

Participants
Andreas Hahn, Heidelberg, Germany (*Abstract Co-Author*) Nothing to Disclose
Michael Knaup, PhD, Heidelberg, Germany (*Abstract Co-Author*) Nothing to Disclose
Marc Kachelriess, PhD, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To automatically extract a respiratory and a cardiac signal from cone-beam CT (CBCT) rawdata.

METHOD AND MATERIALS

Due to the relatively slow acquisition speed of CBCT systems, patient respiration and cardiac motion lead to motion blurring. This can be compensated using motion-compensated image reconstruction in 4D and in 5D [Brehm et al., MedPhys 42(4)] which requires accurate motion information. Without an external signal, motion surrogates have to be retrieved intrinsically from the rawdata. While there are several methods for respiratory gating, only few are dedicated to cardiac gating but are not very robust. We propose a robust method that is able to retrieve a respiratory and a cardiac signal fully automatically. The respiratory signal is retrieved by analyzing the mean signal over the whole detector as a function of the projection angle. The cardiac signal starts from

50×50×50 uniformely distributed grid points in the field of measurement to which x-y-circles of radius r are attached. We iterate over radii between 3 cm and 5 cm in steps of 2 mm and compute the intersection of the x-ray that runs through the tangent of each circle with the detector. The intersection points are centers of rectangular ROIs of about 8 cm by 4 cm whose mean value serves as a surrogate for the cardiac motion phase. The most regular signal after band pass filtering is selected as the cardiac surrogate. The method was tested on 10 patient thorax scans acquired with a Varian True Beam system and compared to the AS method [Van Herk et al., ICCR 07] (M1) and the method of reference [Hahn et al., SPIE Medical Imaging 2016] (M2).

RESULTS

The proposed method, M1 and M2 determined the correct number of respiratory peaks. While the proposed method showed good results for the cardiac gating with a maximum error of 1 heart beat, M2 showed good results for 6 patients (max. error 1), it did not perform well for 4 patients (max. error 23). M1 cannot detect cardiac motion.

CONCLUSION

The proposed method is able to acquire a respiratory and cardiac surrogate in a fully automatic way for CBCT scans of the thorax region and outperformed M2 in terms of robustness.

CLINICAL RELEVANCE/APPLICATION

Clinically, intrinsic gating will be useful in cases where no gating signals are available, such as it is the case in many interventional imaging scenarios. With intrinsic gating those cases can benefit from motion-compensated reconstruction and thus from better image quality.

SSJ23-06 Multi-Structure Segmentation of Hard Tissues, Maxillary Sinus, Mandible, Mandibular Canals in Cone Beam CT of Head and Neck with 3D U-Net

PURPOSE

we proposed automatic segmentation method on four facial structures including hard tissues, maxillary sinus, mandible, and mandibular canals using 3D U-Net with convolutional neural net (CNN) in CBCT.

METHOD AND MATERIALS

We obtained 100 data sets of i-Cat CBCT scans (Imaging Science International, Hatfield, PA, USA).The training and validation dataset of hard tissues, maxillary sinus and mandible consists of 7 and 4 cases, 20 and 4 cases, and 20 and 4 cases, respectively. The training, and validation dataset of mandibular canals consist of 40 and 15 cases, respectively. Each test dataset was used in the same 7 patients. Depending on the structures, the segmentation result as gold standard was made differently. The hard tissues and mandibular canals were manually drawn by an expert and confirmed by an expert dentist. The initial mandible and maxillary sinus mask was created by in-house software with conventional image processing techniques including 3D sculpting and thresholding. These masks were filled per slice, and manually corrected by experts. Before training,we pre-processed images to change brightness (window level = 450) and contrast (window width = 5000). Also, the number of each dataset was augmented by flip and rotation. We used the 3D U-Net, one of the most widely used CNN architectures for image segmentation.

RESULTS

For the evaluation metrics, the Dice similarity coefficient (DSC), Jaccard similarity coefficient (JSC), mean surface distance (MSD) and Hausdorff surface distance (HSD) were 82.60±0.04%, 70.47±0.06%, in hard tissues, 86.60±0.01%, and 92.80±0.01%, and 82.00±0.07%, 0.35±0.29mm, 0.49±0.09mm in maxillary sinus, 90.00±0.04 %, 0.89±0.66 %, 11.29±10.21mm, 3.21±2.56mm and 18.42±19.72mm, in mandible, respectively. In the mandibular canals, mean error distances were 0.89±0.40mm.

CONCLUSION

In this study, we proposed an automatic 3D segmentation method, demonstrated very fast segmentation results with reasonable accuracies of multi-facial structures in CBCT including hard tissues, maxillary sinus, mandibular, and mandibular canals.

CLINICAL RELEVANCE/APPLICATION

This study could be used to the planning of dental implant and orthognathic surgeries.

ben1dost@yahoo.com

PURPOSE

To evaluate normal organ doses in rectal cancer patients treated with neoadjuvant radiotherapy using dose escalated SIB with three-dimensional conformal radiotherapy (3DCRT) and volumetric modulated arc therapy (VMAT).

METHOD AND MATERIALS

Treatment planning CT images of 88 rectal cancer patients (F: 31, M: 57) were included. Median patient age was 60 (30-85). Patients with inguinal lymph nodes in the treatment field were excluded. Two treatment plans were done for each patient using SIB with VMAT and 3DCRT techniques. Normal organ and target volume doses in two plans were dosimetrically compared. CTV-tumor volume was covering GTV plus 2 cm proximally and distally, and mesorectum radially. Pelvic lymph node dose was 50.4 Gy with 1.8 Gy/fx and PTV-tumor dose was 56 Gy with 2 Gy/fx in 28 fractions, for both plans. Maximum target volume doses (Dmax), homogeneity index (HI) and conformity number (CN) for target volumes (PTV-Tumor and PTV-Total), maximum bladder dose (Dmax), bladder volumes receiving 40 Gy (V40), 50 Gy (V50), 56 Gy (V56), maximum bowel dose (Dmax), doses to 90 ml (D90), 130 ml (D130) and 230 ml (D230) bowel, mean femoral head (FH) doses (Dmean) and FH volumes receiving 40 Gy (V40), and 50 Gy (V50) were compared between two plans.

RESULTS

Median bladder and bowel volumes were 393 (43-1128) and 1629 (280-4792) cm3, respectively. For both PTV volumes, HI ($p<0.02$) and CN ($p<0.01$) were significantly better in VMAT plans and Dmax was ($p<0.65$) not significantly different between two plans. Bladder and bowel Dmax were not significantly different between VMAT and 3DCRT plans. Bladder V40, V50, V56 volumes and bowel D90, D130 and D230 doses were significantly lower in VMAT plans compared with 3DCRT plans ($p<0.01$). FH Dmean and V40, V50 were significantly lower in VMAT plans compared with 3DCRT plans ($p<0.05$).

CONCLUSION

Except bladder and bowel Dmax, VMAT decreases all normal organ doses compared with 3DCRT in rectal cancer patients treated with neoadjuvant radiation therapy using dose escalated SIB. Clinical studies are needed to evaluate these results' clinical impact on treatment side effects.

CLINICAL RELEVANCE/APPLICATION

VMAT decreases normal organ doses compared with 3DCRT in rectal cancer patients treated with neoadjuvant radiotherapy using dose escalated simultaneous integrated boost, but maximum bladder and bowel doses do not change. Clinical studies needed to evaluate impact of these results on treatment side effects.

SSJ24-04 Fat-Free Muscle Mass Predicts Overall Survival of Patients Undergoing Radioembolization of Colorectal Cancer Liver Metastases

Tuesday, Nov. 27 3:30PM - 3:40PM Room: E261

PURPOSE

Sarcopenia is associated with poor prognosis in various types of cancer. We therefore aimed to investigate the clinical potential of fat-free muscle mass as a marker for outcome prediction in patients with liver-predominant metastatic colorectal cancer undergoing radioembolization (RE) with 90Yttrium-microspheres.

METHOD AND MATERIALS

Patients with liver-predominant metastatic colorectal cancer who underwent RE between June 2008 and August 2014 at our department were included in this retrospective study. Medical records were reviewed and several clinical parameters were determined. Using standard liver magnetic resonance imaging (MRI) scans, the total erector spinae muscle area and the intramuscular fat tissue area were measured and subtracted to calculate the fat-free muscle area (FFMA). Sarcopenia was defined as FFMA less than 3653 mmSquared and 2866 mmSquared for men and women, respectively. The main outcome was overall survival (OS). Univariate and multivariate Cox-regression analyses were performed comparing various variables with potential impact on OS (e.g. age at RE, bodyweight, ascites prior to RE, cholestasis, clinical scores, tumor burden).

RESULTS

Seventy-seven patients (49 male, mean age 59.9±10.8 years) were investigated. Mean time between MRI and RE was 19±38 days. Mean FFMA was 2878±613 mmSquared in female patients and 3706±779 mmSquared in male patients. Median OS after RE was 200 (range: 25-1650) days. In patients without sarcopenia OS was significantly longer compared to patients with sarcopenia (mean 348±48 vs. 226±36 days, p=0.006). On multivariate Cox-regression analysis, OS was best predicted by FFMA (p<0.001, HR 2.692, 95% CI 1.559-4.648), Model for End-Stage Liver Disease (MELD) (p<0.001, HR 1.165, 95% CI 1.089-1.245), and pattern of tumor manifestation (solitary, oligofocal, multifocal, diffuse) (p<0.001, HR 2.006, 95% CI 1.418-2.840).

CONCLUSION

Fat-free muscle mass might be a new prognostic biomarker for survival prognosis in patients receiving RE for treatment of colorectal liver metastases.

CLINICAL RELEVANCE/APPLICATION

This study offers an easy-to-apply MRI-based measurement of fat-free muscle mass as a marker of sarcopenia which can predict OS in patients receiving RE for treatment of colorectal liver metastases.

SSJ24-05 Stereotactic Body Radiotherapy (SBRT) in Pancreatic Cancer Patients Aged 70 and Older

Tuesday, Nov. 27 3:40PM - 3:50PM Room: E261

rtobillo2015@health.fau.edu

PURPOSE

Over 50% of pancreatic cancer is diagnosed in people over the age of 70, many of whom have limited treatment options due to preexisting comorbidities. This study reports on the outcomes and tolerability of stereotactic body radiation therapy (SBRT) in patients aged 70 and older with pancreatic cancer.

METHOD AND MATERIALS

Twenty-six and 2 patients aged >=70 with pancreatic and ampullary cancer respectively, treated with SBRT +/- chemotherapy and surgery at one institution from 2009 to 2017 were retrospectively reviewed. Patients without up-to-date records or at least 6-months of follow-up were excluded. Patients were analyzed for treatment toxicity, local recurrence, and distant metastases. Kaplan-Meier was used to estimate overall survival, defined as date of diagnosis to date of death or last follow-up.

RESULTS

Median age was 84 years (range 70-94), and median follow-up was 6.9 months. Twenty-five (89%) patients had locally advanced disease and 3 (11%) had metastatic disease. Most common doses delivered were 30, 32.5, 35 and 37.5 Gy (20-45 Gy), most commonly in 5 fractions. Twenty-four (86%) patients were treated at time of initial diagnosis and 4 (14%) were treated for recurrence. Six patients had pre-radiation surgery, either with a Whipple procedure (14%) or an endoscopic resection (7%). Two patients had previously been treated with external beam radiation therapy (EBRT) before SBRT. Nineteen patients (68%) were

treated with some form of chemotherapy. Twenty-one (75%) patients had an acute toxicity grade of 1-2, and 3 patients had an acute toxicity grade of 3, 2 with GI symptoms and 1 with sepsis and fatigue (CTCAE V5.0). Most common acute toxicities were GI symptoms (57%) and fatigue (36%), while most common late morbidities were GI symptoms (68%), fatigue (68%), and nutritional disorders (50%). There were no acute or late grade 4+ toxicities. Fourteen (50%) patients recurred locally, 14 (50%) patients developed distant metastases, and 10 (36%) had both. Median overall survival was 15.0 months.

CONCLUSION

SBRT for pancreatic cancer seems to be a safe and effective method for treatment of elderly patients who decline surgery, have unresectable disease, or comorbidities precluding surgery.

CLINICAL RELEVANCE/APPLICATION

The literature on treatment of elderly patients with pancreatic cancer is sparse. SBRT appears to be safe and effective for those who cannot undergo surgery.

SSJ24-06 Evaluation in Predicting Tumor Sensitivity on Radiotherapy for Esophageal Cancer Using Magnetic Resonance Diffusion Kurtosis Imaging

feinier_1989@sina.com

PURPOSE

To evaluate magnetic resonance diffusion kurtosis imaging (MR-DKI) values for predicting the tumor sensitivity on radiotherapy for esophageal cancer.

METHOD AND MATERIALS

There were 40 Eca-109 nude mice models with esophageal cancer xenogrfts before and during radiotherapy (test group=24; control group=16) used in this study. The test group was given 6MV-X line 15Gy single dose during radiation therapy. The control group did not undergo any radiation or other treatments. Sixteen time points included at 1 day before and 1 day after radiotherapy and then very two days during radiotherapy until 29th day. In the time points, mice models in both test and control groups were performed on MRI scan with T1WI, T2WI, and multiple b-value DWI values. Tumor volume, MR-DWI ADC value, MD value and MK value in test group were compared with the control group.

RESULTS

The tumor volume was double at the 5th day in the control group and at the 17th day in the test group after the radiotherapy. At the 7th day after radiotherapy and then, the volume of the transplanted tumor was significantly smaller in the test group (1.729±0.906 mm3) than that in the control group (2.671±0.915 mm3) ($P<0.05$). ADC values in test group rapidly increased at the 3rd day (reached highest point at the 7th day) and then gradually decreased and returned to pre-therapy levels from the 17th day. In the control group, the ADC values gradually decreased from the first day and kept at a low level from the 9th day. The MK values in the test group decreased after radiotherapy (reached lowest point on the 9th day), and then gradually increased to the pre-therapy level from the 17th day. In the control group, the MK values gradually increased (high level since the 17th day). The changes of the MD values were similar to those in ADC values in both groups.

CONCLUSION

MR-DKI values could change prior to tumor morphological features in esophageal cancer during radiotherapy in an animal experimental study, and may have the potential in predicting tumor sensitivity for clinical tumor patients during their radiation or chemotherapy.

CLINICAL RELEVANCE/APPLICATION

(dealing with MR-DKI) 'MR-DKI values could change prior to tumor morphological features in esophageal cancer during radiotherapy in an animal experimental study, and is recommended in predicting tumor sensitivity for clinical tumor patients during their radiation or chemotherapy.'

PURPOSE

The ability to quantify the blood flow rate in a particular vessel using two-dimensional digital subtraction angiography (DSA) remains an elusive goal. Proceduralists could use such a technique to plan and define quantitative endpoints for interventions involving embolization and recanalization among others. Dialysis fistula interventions are an ideal testbed since alternative validated techniques, such as thermodilution, are commonly used. This study aims to assess the precision of simple, rapid geometric flow estimation techniques applied to in vitro acquisitions mimicking dialysis fistulagrams.

METHOD AND MATERIALS

The true flow rate through a phantom with 9.5mm internal diameter was measured by collecting the outflow. Triplicate DSA acquisitions were performed using a fixed contrast injection protocol. Flow rates were calculated by dividing the cylindrical volume of the tube (based on linear measurements from each acquisition) by transit time determined using three methods: (1) visual estimation of contrast arrival time on DSA ("DSA"), (2) automated measurement of time of arrival using parametric color-coded angiography ("TOA"), (3) automated measurement of time-to-half-peak using parametric color-coded angiography ("TTHP"). Results were analyzed using Bland-Altman plots and ANOVA.

RESULTS

True flow rates through the phantom ranged from 620-1210 ml/min. The normalized variance was 0.023 for DSA, 0.031 for TOA, and 0.013 for TTHP ($p<0.05$), with a significant pairwise difference only between TOA and TTHP. Bland-Altman analysis showed the normalized 95% confidence interval for a given measurement was 0.75 to 1.34 for DSA, 0.67 to 1.36 for TOA, and 0.70 to 1.16 for TTHP. The normalized bias of each measurement technique was +0.047 for DSA, +0.016 for TOA, and -0.070 for TTHP.

CONCLUSION

Any proceduralist using any angiographic system without advanced post-processing software can quickly perform a geometric calculation to obtain an estimate of blood flow rate using the DSA method. In this preliminary in vitro study, the margin of error for such a calculation was ±15%. Using a parametric color-coded angiography tool that calculates time-to-half-peak can reduce this margin of error to ±11%.

CLINICAL RELEVANCE/APPLICATION

This preclinical study demonstrates a rapid, accessible estimation technique. In vivo characterization is necessary in both healthy

and diseased vessels at a wider range of flow rates and frame rates.

SSJ25-02 Transjugular Access for Interventions in Upper Extremity AV Fistulas

Tuesday, Nov. 27 3:10PM - 3:20PM Room: S503AB

Participants
Maria A. Kotarska, PhD, Chicago, IL (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

majakotarska@me.com

PURPOSE

Describe our experience using a transjugular venous approach for endovascular interventions in patients with dysfunctional hemodialysis AV fistulas.

METHOD AND MATERIALS

This is an IRB approved, retrospective study. The imaging files of all patients who underwent a hemodialysis access intervention between January 2015 and May 30, 2017 were reviewed. Patients who underwent the procedure using a transjugular approach were selected for analysis. A total of 600 upper extremity hemodialysis intervention procedures were performed and 30 were performed using a transjugular approach (5 %). Technical procedural details were recorded.

RESULTS

The technical success rate was 97 % (29/30). An additional puncture into the AV fistula was necessary in 13% (4/30) cases to enable retrograde access to the circuit. Indications for the use of the transjugular approach included: Declotting: (13/30) juxta-anastomotic stenosis (13/30), non-maturing AV fistula (2/30) and bleeding pseudoaneurysm (2/30). Most procedures were initially performed using an ipsilateral jugular venous approach, however, most of our recent procedures have been performed using a contralateral approach as it appears to be technically easier. A temporary dialysis catheter can be inserted after the procedure in case of a technical failure or in case the fistula is not ready for use immediately after intervention. No major complications were encountered. There was no post-procedural jugular vein thrombosis.

CONCLUSION

The transjugular approach is safe and effective for interventions in dysfunctional or clotted upper extremity AV fistulas. In selected case, this approach may be better than using the direct access technique.

CLINICAL RELEVANCE/APPLICATION

AVFs have lowest morbidity and mortality among choices for hemodialysis and well-functioning vascular access is the crucial to performing efficient AV fistula intervention.

SSJ25-03 Prospective, Randomized Single-Center Trial to Compare the Efficacy of Ultrasound-Guided Supraclavicular Brachial Plexus Block to Reduce Pain During Angioplasty of Dysfunctional Arteriovenous Fistulas

PURPOSE

To evaluate the efficacy and safety of ultrasound-guided supraclavicular brachial plexus block (BPB) for reducing pain during angioplasty of dysfunctional arteriovenous fistulas (AVFs).

METHOD AND MATERIALS

Eighty patients (mean age, 64.6 years) were enrolled in this study. Forty were randomized to receive regional BPB (0.75% ropivacaine and 2% lidocaine) prior to undergoing angioplasty and forty to receive local anesthesia (2% lidocaine). Pain was assessed on a 10-point visual analog scale after the procedure. Both patient and operator satisfactions were examined.

RESULTS

There were no significant differences in the baseline demographics between the two groups. The mean block execution time was 5.1 minutes and the mean time to achieve complete block was 10.7 minutes. The mean time to fully recover from the BPB was 476 minutes. BPB group showed profoundly lower average pain scale compared to the control group (0.93 vs 6.40, $p<0.001$). Patient satisfaction ($p<0.001$), and operator satisfaction ($p<0.001$) were significantly higher in the BPB group. There were no significant differences in procedure time ($p=0.084$), fluoroscopy time ($p=0.059$), and cumulative dose area product ($p=0.869$). There were no major complications and two patients experienced minor complications of self-limited nausea. In 6 months follow up periods there were no delayed complications.

CONCLUSION

Compared with conventional local anesthesia, ultrasound-guided BPB provides excellent benefit of reducing pain with acceptable safety profile during angioplasty of dysfunctional AVFs.

CLINICAL RELEVANCE/APPLICATION

US-guided BPB is a superior method of pain control compared to local anesthesia during angioplasty of dysfunctional AVFs.

SSJ25-04 Single-Center Experience of IVC Filter Placement and Retrieval Practice Patterns

Tuesday, Nov. 27 3:30PM - 3:40PM Room: S503AB

adam.fang@health.slu.edu

PURPOSE

To compare practice patterns in the placement and retrieval of inferior vena cava filters (IVCF) at a single academic center over four years (2013-2017).

METHOD AND MATERIALS

Retrospective analysis of 238 patients (136 M,102 F; mean age, 58.6±16.8 y) who underwent IVCF placement and retrieval at a single academic center from 2013-2017. Variables assessed were placement indication, filter type, fluoroscopy time, dwell time, and placement and retrieval differences over time and between services (interventional radiology [IR] or vascular surgery [VS]).

RESULTS

We identified 233 IVCF placements and 44 retrievals from 2013-2017. IVCF placement for classic indications increased compared to extended or prophylactic indications (85% in 2013 vs 96% in 2017). There was an increase in the percent of filters retrieved (17% in 2013 vs 30% in 2015) and the percent of filters placed and retrieved by the same service (13% in 2013 vs 28% in 2015). Filter dwell time decreased over the years ($p<0.0001$). The percent of IVCF placed by IR increased with time (76% in 2013 vs 92% in 2016) and decreased for VS (24% in 2013 vs 8% in 2016). IR preferred placing Bard Denali IVCF (53%) while VS preferred placing Optease IVCF (33%). IR used venograms for IVCF placement more often than VS (84% vs 16%, $p<0.0001$), while VS used intravascular ultrasound more often than IR (82% vs 18%, $p<0.0001$). Mean fluoroscopy time (min) was 3.8 [95%CI (2.6,4.9)] for IR IVCF placement and 1.4 [95%CI (1.0,1.8)] for VS IVCF placement ($p=0.001$). IVCF retrievals paralleled placement trends, with IR rates increasing (8% in 2013 vs 22% in 2016) and VS rates decreasing (27% in 2013 vs 0% in 2016) over time. The percentages of placed filters retrieved were similar between IR and VS. IVCF placed by IR had shorter dwell times compared to those placed by VS (median 503 vs 975 days, $p<0.05$).

CONCLUSION

Within four years at a single academic center, changes in IVCF placement and retrieval patterns over time and between services were observed. Increasing contribution of a single service may not only improve patient follow-up and oversight, but may also provide a more consistent patient experience, including the use of similar pre-procedure modalities and filter types.

CLINICAL RELEVANCE/APPLICATION

Single service placement and retrieval of IVC filters may lead to better patient follow-up and improve patient experience.

SSJ25-05 Transvenous Pulmonary Chemoembolization (TPCE) for Palliative and Neoadjuvant Treatment of Lung Metastases

PURPOSE

To evaluate tumor response, local tumor control and patient survival after the treatment of pulmonary metastases using transvenous pulmonary chemoembolization (TPCE) in palliative and neoadjuvant intent.

METHOD AND MATERIALS

143 patients (mean: 56.7±13.4 years) underwent repetitive TPCE (mean: 5.8±2.9 sessions) between August 2004 and April 2017 for the treatment of unresectable lung metastases not responding to systemic chemotherapy. Patients had predominant lung metastases with bilateral lung involvement in 80.4% of the cases. Regional delivery of the chemotherapeutic agents was performed through selective catheterization of the tumor-supplying pulmonary arteries with subsequent injection of iodized oil and/or microspheres. Patients who underwent subsequent ablation (n=51) either for all lesions (complete) or for dominant lesions

(incomplete) were in the neoadjuvant group, and those who underwent TPCE alone were in the palliative group (n=92). The response was assessed according to the revised RECIST criteria.

RESULTS

Partial response was achieved in 11.9% (n=17), stable disease in 66.4% (n=95) and progressive disease in 21.7% (n=31). The mean survival time and time to progression were 24.5±1.7 and 7.5±0.5 months, respectively. The mean survival time was shorter for the palliative group (19.7±2 months) compared to the neoadjuvant group (30.1±2.6 months). The use of TPCE alone or with incomplete ablation had a significantly decreased 4.6-fold (p=0.002) and 3.1-fold (p=0.027) hazard of death in comparison with TPCE with subsequent complete ablation.

CONCLUSION

TPCE has the potential to improve local tumor control and to prolong survival with a neoadjuvant potential when combined with thermal ablation.

CLINICAL RELEVANCE/APPLICATION

Combined TPCE and thermal ablation therapy can improve local tumor control and survival versus TPCE alone.

PURPOSE

To determine the clinical impact of CT-guided Pulsed Radiofrequency in the management of pa-tients with acute or sub-acute neuro-radicular pain from lumbar disc herniation, refractory to pro-longed conservative treatment.

METHOD AND MATERIALS

We conducted a single center, prospective, randomized trial (1:1) in patients with acute or sub-acute neuro-radicular low back pain (EMG confirmed), refractory to usual care (conservative). Pulsed radiofrequency (pRF) treatment was performed using a 22-20 G needle-electrode with probe tip directed to the symptomatic dorsal root ganglion under CT guidance; E-pulsed radiofre-quency (Cosman G4) was administered for 10 min at 45V with constant local temperature of 42°C. Masking group received 1 to 3 sessions of CT-guided steroid injection on the same anatomi-cal target. Primary outcome was clinical efficacy measured with Visual Analogue Scale (VAS), Oswestry Disability Index (ODI) and Roland-Morris (RM) score for quality of life assessment; all questionnaires were obtained at baseline and at 1-week, 1-3-6 and 12-month follow-up. Analyses were performed on a per-protocol basis.

RESULTS

Of 260 patients enrolled, 128 patients received Pulsed Radiofrequency, 120 were treated with in-jection only strategy treatment. Median VAS scores decreased linearly in both groups; patients that received radiofrequency obtained greater significant overall improvement in pain and disabil-ity scores during the first year ($P<0.001$). Relief of leg pain was faster for patients assigned to pRF ($P<0.001$). Patients assigned to pRF also reported a faster rate of perceived recovery (hazard ratio, 1.97; 95% confidence interval, 1.72 to 2.22; $P<0.001$). The probability of perceived recovery after 1 year of follow-up was 95% in the pRF group and 61% in the injection only group. There were 6 patients considered partial responders that required a second PRF session. Eight pa-tients required further surgical management.

CONCLUSION

The 1-year outcomes demonstrated CT-guided Pulsed Radiofrequency superior to injection only strategy. pRF is an effective and repeatable percutaneous treatment option for patients with acute or sub-acute neuro-radicular low back pain.

CLINICAL RELEVANCE/APPLICATION

The results of this study are superior to those reported from literature for usual care strategies and injections and may avoid surgery for a substantial number of patients with sciatic disc com-pression.

SSJ26-02 Treatment of Osteoid Osteomas with Magnetic Resonance Guided Focused Ultrasound: Evaluation of the Prognostic Value of Post-Treatment Perfusion Differences for Pain Reduction and Bone Remodeling

Tuesday, Nov. 27 3:10PM - 3:20PM Room: S502AB

hansperasmus@gmail.com

PURPOSE

Magnetic Resonance guided focused ultrasound (MRgFUS) has proven a safe, feasible and effective treatment modality for osteoid osteoma (OO). To date, however, there are no proven factors to evaluate the patient's prognosis during /immediately after treatment. To address this question, this study evaluated the role of perfusion scans and the gained data to assess the likelihood of pain reduction and bone remodeling after treatment.

METHOD AND MATERIALS

A total of 42 consecutive patients with symptomatic osteoid osteomas were treated with MRgFUS from 2011 to 2018. MR (inc. perfusion scan) and CT scans of the lesion were acquired before and immediately after the treatment; follow-up MR and CT scans were acquired at 3, 6, 12, 24 and 36 months and 12 months, respectively. Visual Analog Scale (VAS) score was used to assess pain and was evaluated over the same time periods and, additionally, at 1 week post-treatment. 3 patients were lost during follow-up. Statistical analysis of the correlation with the perfusion data (namely, KTrans) was performed using Spearman's rho.

RESULTS

In the overall study, the mean age was 25 ± 13.5 years, and 77% of patients were male. 4 patients were retreated with MRgFUS. Mean pre-treatment VAS score was 8.4 ± 1.0 months and 0.6±1.4, 0.1±0.3, 0.1±0.3 0.1±0.2 and 0.1±0.2 at 3, 6, 12, 24 and 36 months, respectively. The median VAS dropped to 0 at 1 week from 8 before treatment and stayed there during the entire follow-up. Mean KTrans was 0.69±0.7 pre-treatment and 0.15±0.13, 0.20±.25, 0.12±0.1, 0.07±0.05, 0.13±0.08 and 0.1±0.08 immediately after treatment and at 3, 6, 12, 24 and 36 month follow-up. Spearman's rho showed a positive correlation for a >50% KTrans reduction and significant pain reduction, as well as for >90% KTrans reduction and both pain reduction and bone remodeling. Age appeared to be an additional factor with an inverse correlation to bone remodeling. No adverse events were recorded.

CONCLUSION

The current study demonstrated that KTrans could be a good prognostic tool to evaluate the patient's likelihood of pain remission and bone remodeling.

CLINICAL RELEVANCE/APPLICATION

In the future, evaluation of KTrans could allow for more reliable treatment efficacy and patient satisfaction after treatment of OO with MRgFUS.

SSJ26-03 O2-O3 Chemiodiscolysis: Any Issues for Spine Biomechanics? 5 Years MRI Imaging Follow Up

PURPOSE

O2-O3 dyscolysis is a well-validated technique for the treatment of symptomatic lumbar disc herniation. Although it is a highly effective procedure, up to now there are only a few evidences about long-term changes on disc treated and on biomechanical changes of the lumbar spine "in toto" after O2-O3 dyscolysis treatment. Indeed, dehydration of a lumbar disc with subsequent volume loss could lead to the same alteration of a degenerative pathology. The purpose of our study was to compare long-term follow-up MR images of patients treated by O2-O3 dyscolysis and long-term follow-up MR images of patients affected by lumbar disc herniation treated without intradiscal administration of O2-O3

METHOD AND MATERIALS

We recalled 80 patients for an MRI follow-up treated in our department with O2-O3 mixture 5 years earlier; 40 patients treated

We recalled 80 patients for an MRI-follow-up treated in our department with O2-O3 mixture 5 years earlier: 40 patients treated with dyscolysis and the remaining 40 treated by intraforaminal injection of steroids only as the control group. We compared T2 sagittal and axial images of MR exams performed before the procedure and after 5 years during our follow-up imaging. In all patients in each affected level, we evaluated: disc height, disc area, disc protrusion beyond the vertebral posterior wall, the degree of disc degeneration (according to Pfirmann classification), degenerative changes in adjacent vertebral discs, endplate Modic changes, facet joint changes (Weishaupt classification)

RESULTS

Our analysis showed a significant decrease in disc height and protrusion (respectively mean of 15% and 37,42%) in patients treated with intradiscal O2-O3, despite a decrease of circumferences of 4,72%, differently from control group findings. There was no significant difference in the degree of disc degeneration between the two groups (even more pronounced in patients not treated by dyscolysis), as in both groups we found the same endplate changes (Modic) in about 20% of cases. Analysis of facet joint degeneration shows significant alteration according to Weishaupt classification in both groups, and no significant differences in comparison

CONCLUSION

Compared with control group, patient treated by O2-O3 dyscolysis didn't show significant difference in lumbar disc degeneration, despite a stable shrinkage of the disc herniation

CLINICAL RELEVANCE/APPLICATION

Our findings reveal that O2-O3 dyscolysis don't determine significant differences in biomechanical changes compared with the natural course

SSJ26-04 A Matched Case-Control Study of MR-Guided Focused Ultrasound (MRgFUS) versus CT-Guided Radiofrequency Ablation (RFA) for the Clinical Evaluation of Patients with Osteoid Osteoma

roberto.scipione@uniroma1.it

PURPOSE

To examine and compare the clinical outcome of MR-guided focused ultrasound (MRgFUS) and CT-guided Radiofrequency Ablation (RFA) in patients with painful non-spinal osteoid osteoma (OO).

METHOD AND MATERIALS

Patients with clinical and radiological findings suggestive for OO were included in this multicenter study; eligible patients had pain scores >=4 (assessed with Visual Analogue Scale, VAS) and could safely undergo both MRgFUS and RFA. Vertebral locations were excluded as considered inaccessible by MRgFUS. Selected participants were assigned to receive either MRgFUS or RFA according to a matched case-control protocol; the two groups were homogeneous in terms of age, gender distribution, pain onset and pain level. Patients underwent periodical three-month follow-ups over a period of 1 year. Safety (rate of complications), clinical effectiveness (Visual Analogue Scale [VAS] pain score reduction) and durability (stability of results over time) of MRgFUS were assessed and compared between the two arms.

RESULTS

112 patients (M: 61; F: 51) were enrolled and assigned to MRgFUS or RFA. In the RFA arms, 2 complications were recorded (1 skin burn, 1 infection at the skin entry site); no treatment-related complications were observed in the MRgFUS arm. No statistically significant difference was recorded between the two arms in terms of efficacy: a complete clinical response (VAS 0) was obtained in 50 patients treated with MRgFUS (89.3%) and in 52 patients treated with RFA (92.9%) at 3-month follow-up ($p>0.05$). Clinical results were stable over the whole period of follow-up, and no pain recurrence was recorded in both groups.

CONCLUSION

MRgFUS has shown similar clinical results compared to RFA in the management of OO, with the advantage of complete safety. MRgFUS is limited to non-spinal locations.

CLINICAL RELEVANCE/APPLICATION

MRgFUS non-invasiveness provides relevant advantages in the treatment of this impairing disease affecting mostly young population: no ionizing radiation, no incisions or needles, and no complications.

SSJ26-05 The Role of Multi-Modal Analgesic Cocktail for Pain Control in Patients Undergoing Microwave Ablation

Tuesday, Nov. 27 3:40PM - 3:50PM Room: S502AB

momodon@mgh.harvard.edu

PURPOSE

There has been significant advancement in techniques and outcomes in various aspects of interventional radiology with much emphasis on radiological procedural advances and innovations. However research in pain management of these patients has taken a back seat. Procedures such as microwave ablation may result in significant post procedural pain and increased opioid use. There have been significant advances in the treatment of pain and enhancing recovery which may be applicable to interventional radiology patients. The goal of this study is to compare post procedural pain in patients who received regular monitored anesthesia care during microwave ablation to those who received a multimodal analgesic cocktail (consisting of Gabapentin, Toradol and Dexamethasome) prior to microwave ablation. A secondary goal is to familiarize the audience with the Enhanced Recovery After Surgery protocols offered by anesthesia.

METHOD AND MATERIALS

A retrospective analysis was performed on 34 patients who underwent microwave ablation for liver and renal cancer with anesthesia services. The patients were in either of 3 groups: (1) standard monitored anesthesia care, (2) multimodal analgesic cocktail only (with Toradol, Gabapentin and Dexamethasome) and (3) combination of regional block and multimodal analgesics. Post procedure pain scores and opioid consumption (dilaudid and oxycodone) were recorded.

RESULTS

Multimodal pre-procedural cocktail consisting of Gabapentin, Toradol and Dexamethasome is associated with decreased pain and opioid consumption in the immediate post-procedure recovery.

CONCLUSION

Patients undergoing liver and renal microwave ablation receiving the multimodal analgesic cocktail generally have less pain scores using the visual analogue scale. They also required less immediate post procedural anesthesia.

CLINICAL RELEVANCE/APPLICATION

This multimodal cocktail consisting of Gabapentin, Toradol and Dexamethasome is associated with decreased pain and opioid consumption post microwave ablation

SSJ26-06 Histologic Diagnosis of Incidentally Discovered Parotid Lesions: Should Biopsy Be Pursued?

Tuesday, Nov. 27 3:50PM - 4:00PM Room: S502AB

Participants
Sarah N. Eberson, MD, Houston, TX (*Presenter*) Nothing to Disclose
Hassan Al-Balas, MD, Houston, TX (*Abstract Co-Author*) Nothing to Disclose
Zeyad A. Metwalli, MD, Bellaire, TX (*Abstract Co-Author*) Nothing to Disclose
David Sada, MD, Houston, TX (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Purpose: With increased utilization of imaging in evaluation of head and neck conditions, there has been an increase in the detection of incidental parotid lesions. This study compares the pathology of incidentally discovered parotid lesions to a cohort of symptomatic parotid lesions.

METHOD AND MATERIALS

Materials and Methods: A single institution retrospective review of all patients who underwent percutaneous biopsy of parotid lesions between January 2010 and December 2017 was performed. 143 patients were identified and divided into two groups: patients with symptomatic parotid lesions and patients with incidentally detected parotid lesions. Patient demographics, lesions characteristics and final histologic diagnosis were recorded and compared between the two groups. Histologic diagnosis in resected lesions was considered the final diagnosis in patients who underwent parotidectomy.

RESULTS

Results: Of the 143 study patients, 64 (44.8%) had symptomatic parotid lesions and 79 (53.2%) had incidentally discovered parotid lesions. Histologic diagnosis in the symptomatic group included 27 Warthin tumors (42%), 7 pleomorphic adenomas (11%), 3 intra-parotid lymph nodes (5%) and 27 (42%) with miscellaneous pathology (mucoepidermoid carcinoma, sialadenitis, lymphoepithelial lesion, oncocytoma and equivocal pathology). Histologic diagnosis in the incidental group included 34 Warthin tumors (43%), 14 pleomorphic adenomas (18%), 5 intra-parotid lymph nodes (6%) and 26 (33%) with miscellaneous pathology. There was no significant difference in final histologic diagnosis between the two groups ($p = 0.34$).

CONCLUSION

Conclusion: Incidentally detected asymptomatic parotid lesions have a similar histologic profile to symptomatic lesions and tissue diagnosis is warranted.

CLINICAL RELEVANCE/APPLICATION

Clinical Relevance: The distribution of histologic diagnoses of incidentally discovered parotid lesions is similar to that of symptomatic lesions and tissue diagnosis should be pursued.

PURPOSE

We developed a deep-learning-based "virtual" higher-dose (VHD) technology for radiation dose reduction in DBT. The purpose of our study was to compare the image quality of our VFD images generated from half-dose acquisitions to that of real clinical full-dose images in DBT.

METHOD AND MATERIALS

Our deep-learning-based VHD technology employed our original patched-based neural network convolutional deep learning to convert lower-dose (LD) to higher-dose (HD) tomosynthesis images. To evaluate our VHD technology, we collected half-dose (50% of the standard dose: 32±14 mAs at 33±5 kVp) and full-dose (100% of the standard dose: 68±23 mAs at 33±5 kvp) images of 51 clinical screening cases with a DBT system (Selenia Dimensions, Hologic, Inc, Bedford, MA) at University of Iowa Hospitals & Clinics. We applied our VHD technology to the 51 cases to convert half-dose images to VFD images. We invited 35 breast radiologists to participate in our observer rating study to rate and distinguish blinded VFD and real full-dose DBT images of 10 of the 51 cases. A VFD image and its corresponding real full-dose image were shown on two clinical LCD monitors (EIZO RadiForce GX540) in a blinded manner. Radiologists were asked to rate the image quality on a 0-to-100 scale and to provide their choices as to which one was better in image quality.

RESULTS

Among the 35 breast radiologists, 21 (60%) radiologists either preferred our VFD DBT images over the real full-dose images or could not distinguish between the two in our observer rating study. The mean scores of the image quality of our VFD images and the real full-dose images were 83.2±3.2 and 84.0±3.0, respectively. The difference in image quality between VFD and real-full dose images was not statistically significant (p=0.37).

CONCLUSION

Our blinded observer study with 35 breast radiologists demonstrated that our deep-learning-based VFD images generated from half-dose acquisitions were equivalent to real full-dose DBT images. Thus, our VHD technology achieved 50% dose reduction without sacrificing the image quality.

CLINICAL RELEVANCE/APPLICATION

Substantial radiation dose reduction with the observer-study-proven VHD technology would benefit patients by reducing the lifetime risk of radiation-induced cancer from DBT screening.

SSK01-02 Comparison of DM/Tomosynthesis and Synthesized DM/Tomosynthesis False Negative Cancers in a Population-Based Breast Cancer-Screening Program

PURPOSE

Synthesized 2D imaging (s2D) is replacing 2D digital mammography (DM) in digital breast tomosynthesis (DBT) screening to reduce radiation dose. However, there have been reports of decreased rates of detection of in situ carcinomas with s2D/DBT screening. The purpose of this study is to compare screening outcomes as well as false negative rates and lesion types in DM/DBT versus s2D/DBT screening.

METHOD AND MATERIALS

Recall rate percentage (RR), cancer detection (CDR) and false negative (FN) rates per 1000 screened, false negative cancer subtype (invasive versus in situ) and the method of detection of the false negative cancer (symptomatic versus by another imaging modality) were compared for 37,184 women screened with DM/DBT from 10/3/2011-1/6/2015 and 37,996 women screened with s2D/DBT from 1/7/2015-1/6/2018. Differences were compared using chi-squared tests at the standard a=0.05 significance level with Yates correction. All statistical tests were two-sided.

RESULTS

RR decreased with s2D/DBT versus DM/DBT screening - 6.9% versus 8.9% ($p<0.001$). CDR for DM/DBT and s2D/DBT screening were not statistically different (6.0/1000 vs. 5.5/1000, p=0.37). However, FN rate doubled for s2D/DBT (0.84/1000, n=32) versus DM/DBT screening (0.40/1000, n=15), p=0.02. While not statistically significant, there was a trend of more asymptomatic FN cancers detected by other modalities (i.e., MR, US, CT) in the s2D cohort than in the DM/DBT cohort (13/32 (41%) versus 5/15 (33%), p=0.11) and a trend of higher proportion of DCIS in the s2D cohort than in the DM cohort (9/32 (28%) versus 3/15 (20%), p=0.16).

CONCLUSION

s2D/DBT maintains CDR with the benefit of decreased recall rates. However, the FN rate increased with s2D/DBT compared to DM/DBT with both in situ and invasive FN cancers increased in the s2D cohort. While not statistically significant, a greater proportion of s2D FN cancers were detected by other modalities in asymptomatic patients. The increase in false negative rates is multifactorial and may be intrinsically related to the new technology and/or a learning curve in implementing the s2D technology.

CLINICAL RELEVANCE/APPLICATION

The replacement of DM with s2D in a large DBT breast cancer screening program maintained cancer detection rates and decreased recall rates, but increased false negative rates.

SSK01-03 Integration of Digital Breast Tomosynthesis into Breast Cancer Screening Practices in the United States: A Comparative Modeling Analysis

PURPOSE

To project long-term outcomes and cost-effectiveness of transitioning from breast cancer screening using digital mammography (DM) to digital mammography with digital breast tomosynthesis (DBT) in the United States.

METHOD AND MATERIALS

Two established breast cancer models were used to simulate two scenarios: complete transition from DM to DBT for all women ages 40+ between 2011-2020 versus continued use of DM alone. Screening utilization was based on observed dissemination patterns from national surveillance datasets. We assumed current screening and treatment patterns continued, and women were followed for their remaining lifetimes. DM and DBT performance was based on screening data from the NCI's Population Based Research Optimizing Screening through Personalized Regimen (PROSPR) consortium from 2011-2014. Costs and quality of life weights were based on US national averages and published literature. Outcomes included life-years (LY), quality-adjusted life-years (QALYs), breast cancer deaths, false positive exams (FP), costs (2017 US$) and incremental cost-effectiveness ratios (ICER). Analyses were performed from the payer perspective. Results were summarized within and across models.

RESULTS

Transition to DBT had the greatest impact on FP screening mammograms, which reduced FP exams by 278-288/1,000 women. The small difference in test sensitivity observed in the PROSPR data translated to minimal differences in breast cancer deaths and LY gains, with a reduction in deaths from 0 to 0.03/1,000 women and LY gains from -1 to 0.05 years/1,000 women. Total costs increased by $5.64-$5.66 million, with ICERs of $193,634-$217,532/QALY with DBT relative to DM. In sensitivity analyses, ICERs were sensitive to both the test performance and costs of screening DBT. For example, ICERs decreased to $141,043/QALY with 2% absolute improvement in DBT sensitivity; ICERs decreased to $163,092/QALY and $59,872 with $20 and $40 reductions in cost of DBT exams, respectively.

CONCLUSION

The transition from DM to DBT for routine breast cancer screening in the U.S. reduces FP results, but substantially increases costs assuming current estimates of performance and reimbursement rates.

CLINICAL RELEVANCE/APPLICATION

Digital breast tomosynthesis for routine breast cancer screening in the U.S. reduces false positive exams, but substantially increases costs based on current estimates of performance and reimbursement rates.

SSK01-04 Interval Cancers at Digital Breast Tomosynthesis (DBT) and Full-Field Digital Mammography (FFDM) in a Hybrid Imaging Environment

Wednesday, Nov. 28 11:00AM - 11:10AM Room: E451A

PURPOSE

To review imaging features and histopathology of interval cancers (IC) on screening full-field digital mammography (FFDM) and screening digital breast tomosynthesis (DBT) in a hybrid imaging environment.

METHOD AND MATERIALS

This HIPAA-compliant IRB approved retrospective review of consecutive screening exams (9,828 DBT and 41,713 FFDM exams) from October 2012-September 2014 identified interval cancers by cross reference to the institutional cancer registry. Interval cancer was defined as cancer detected within 365 days of a negative screening exam. During the study period a hybrid imaging environment for screening existed, using both FFDM and DBT. Three breast radiologists reviewed prior mammograms of all IC in consensus. Cancers were classified as missed (actionable), minimal signs (non-actionable), or true negative. Mammographic lesion features and breast density were described. Electronic medical record review of patient demographics and histopathology was performed. Percentages were compared using Fisher's exact test.

RESULTS

There were 34 interval cancers (20 FFDM, 14 DBT). IC were considered missed, actionable in 2/20 (10%) FFDM and 2/14 (14%) DBT; minimal signs, non-actionable in 3/20 (15%) FFDM and 0/14 (0%) DBT, and true negative in 15/20 (75%) FFDM and 12/14 (86%) DBT (p-value = 0.4061). Of the 5 cancers visible (2 missed, 3 minimal signs) on prior FFDM, 3 were asymmetries, 1 calcifications, and 1 architectural distortion. Both cancers visible (both missed) on prior DBT were spiculated masses. Most IC on both FFDM and DBT were moderate-to-high grade invasive carcinoma (n=29): 17/20 (85%) FFDM and 12/14 (86%) DBT (p-value = 0.9999). 1 case of pure intermediate grade DCIS, presenting as nipple discharge, was missed on FFDM; the remaining four, 2 FFDM and 2 DBT, were grade 1 invasive carcinoma. Most IC were in Category 3 and 4 dense breasts (n=26): 15/20 (75%) FFDM and 11/14 (79%) DBT (p-value = 0.9999).

CONCLUSION

In this hybrid FFDM/DBT screening environment, most IC are mammographically occult at prior imaging, occur in dense breast tissue, and are moderate to high grade invasive cancers.

CLINICAL RELEVANCE/APPLICATION

Because FFDM and DBT techniques both rely on lesion morphology for detection, IC on each technique have similarities, occurring in dense tissue and with moderate to high grade invasive histopathology.

SSK01-05 Evidence Supporting Digital Breast Tomosynthesis as Primary Mammographic Screening Tool: Sustained Improved Outcomes over 7 Consecutive Years

Wednesday, Nov. 28 11:10AM - 11:20AM Room: E451A

Participants

liane.philpotts@yale.edu

PURPOSE

Digital breast tomosynthesis (DBT) has shown promise in multiple individual, multi-institutional and population based practices to improve screening metrics, particularly reduce recall rates and improve cancer detection. The sustainability of the early results has not yet been well demonstrated. Long term results are needed to demonstrate if the technology is the preferred screening tool compared with 2D full field digital mammography (FFDM). The purpose of this study was to assess screening metrics with DBT over a 7 year period.

METHOD AND MATERIALS

DBT screening (Dimensions, Hologic, Inc, Bedford, MA) was offered to all women free of charge at a dedicated academic breast center starting in August 2011 and 3 out-patient satellite offices that obtained DBT units in the following years. Over a 7 year period, 124,669 screening DBT exams were performed. Screening metrics were obtained from the breast imaging electronic database (PenRad, MN) and assessed by one-year intervals starting in August 2011. Recall rate (RR), Cancer detection rate (CRD), positive predictive value of screening recall (PPV1) and of biopsy (PPV3) were assessed. Comparison with historic 2D rates (8/1/08 though 7/31/11) were performed.

RESULTS

The RR was significantly reduced over 2D and showed a decreasing trend for each consecutive year: 7.9%, 8.8%, 7.8%, 7.5%, 6.9%, 6.7%, 6.2% (2D = 11.4) ($p<0.0001$). The CDR (per 1000) showed a stable trend that was statistically significantly improved over 2D: 5.8, 5.2, 5.4, 5.6, 6.6, 5.6, 5.1 (2D = 3.8)($p<.0001$). The PPV1 showed a sustained significant improvement over 2D: 7.2, 5.8, 7.0, 7.5, 9.5, 8.4, 8.2 (2D=3.3) ($p<.0001$). The PPV3 also showed a striking significant increase over 2D and an upward trend over consecutive DBT years: 35%, 31%, 36%, 37%, 47%, 42%, 44% (2D=29%) ($p<0.05$).

CONCLUSION

Screening metrics with DBT over 7 years were sustainably significantly improved over 2D rates and further demonstrate favorable trends of improvement over time. This may reflect learning curve and/or increasing availability of prior comparison tomosynthesis exams.

CLINICAL RELEVANCE/APPLICATION

The sustained use of DBT demonstrates that there are fewer false positive screening recalls and biopsies which is essential for shifting the harms and benefits of screening.

SSK01-06 Impact of Using Digital Breast Tomosynthesis in Diagnostic Mammography

emcinto8@jhmi.edu

PURPOSE

The use of digital breast tomosynthesis (DBT) in the screening setting has been shown to decrease recall rate and improve cancer detection. This study evaluates the impact of using DBT in the diagnostic setting at a large academic institution.

METHOD AND MATERIALS

All diagnostic mammograms performed from 7/1/2013 to 8/24/2017 were reviewed. Diagnostic mammograms performed to further evaluate calcifications were excluded, as spot magnification views, rather than DBT views, are typically used for diagnostic evaluation in these cases. Studies were divided into two groups: those performed with at least one DBT view and those performed with only full field digital mammography (FFDM). We compared the frequency of a negative/benign assessment (BI-RADS 1 or 2), a probably benign assessment (BI-RADS 3), and a suspicious or highly suspicious assessment (BI-RADS 4 or 5) between the two groups. We also compared positive predictive value 2 and cancer detection rate between the two groups. The Chi-squared test was used for statistical analysis.

RESULTS

12,324 studies were included in the DBT group and 11,775 studies were included in the FFDM group. There was a significantly higher percentage of BI-RADS 1 or 2 assessments (77.8% vs. 74.9%, p<0.001) and a significantly lower percentage of BI-RADS 3 assessments (10.6% vs. 12.9%, p<0.001) in the DBT group compared to the FFDM group. There was no significant change in the percentage of BI-RADS 4 or 5 assessments (biopsy recommendations) between the two groups (12.1% vs. 11.6%, p=0.20). Both PPV2 and CDR were significantly higher for studies performed with DBT compared to FFDM (PPV2: 36.1 vs. 26.6, p<0.001; CDR: 41.8 vs. 32.3, p<0.001).

CONCLUSION

In our study, using DBT in the diagnostic setting led to more studies being assessed as normal with less frequent need for short-term follow-up, implying decreased associated cost of follow-up and decreased stress and anxiety for patients. While the number of biopsy recommendations was similar between the groups, PPV2 and CDR increased when DBT views were included, suggesting improved accuracy of biopsy recommendations.

CLINICAL RELEVANCE/APPLICATION

Routine use of digital breast tomosynthesis for diagnostic mammography may result in more confident assessments, and could lead to resource savings and improved patient-centered care.

SSK01-07 Architectural Distortion (AD) on Digital Breast Tomosynthesis (DBT): Outcomes, Histopathology, and Predictive Features of Malignancy

cdenison@bwh.harvard.edu

PURPOSE

1) To determine histopathologic outcomes for architectural distortion (AD) detected on tomoshynthesis (3D) mammography, (2) to investigate imaging features predictive of malignancy.

METHOD AND MATERIALS

A HIPAA-compliant IRB approved retrospective review of a mammography screening database between 12/2012-5/2015 identified 297 consecutive screening mammograms classified as BI-RADS 0 for AD. All breast imaging available for cases classified as BI-RADS 4 and 5 at diagnostic work-up were reviewed in consensus by 3 breast radiologists. Imaging features and biopsy accuracy were assessed. Medical records were reviewed for patient demographics, histopathology and follow-up imaging. Chi-square tests were performed with <0.05 significance.

RESULTS

Of 297 BI-RADS category 0 screening detected AD on DBT, 45 (15.2%) were subsequently categorized as BI-RADS category 4-5. Cases were excluded if the finding was a mass rather than AD alone (n=3) or if no pathology results were available (n=2). Within the study population of 40 cases, 20/40 (50%) were malignant (18/20 [90%] invasive, 2/20 [10%] ductal carcinoma in situ), 3/40 (7.5%) atypical ductal hyperplasia, and 17/40 (42.5%) benign. 31/40 (77.5%) cases of AD were visible on 3D only and 9/40 (22.5%) were seen on 2D and 3D. Malignancy was found in 15/31 (48.4%) 3D only AD and 5/9 (56%) AD visible on 2D and 3D (p=1.00). While presence of a sonographic correlate did not increase likelihood of malignancy (US correlate in 33 cases [17 benign, 16 malignant] and no US correlate in 7 cases [3 benign, 4 malignant] [p=1.00]), the specific finding of a mass was more likely malignant than non-mass findings (17 masses [4 benign, 13 malignant] and 16 non-mass [13 benign, 3 malignant] [p=0.0016]. Diagnostic MRI was performed in 7/40 (17.5%) cases, of which 3/7 (1 malignant, 2 benign) had a correlate for AD and 4/7 (0 malignant) did not.

CONCLUSION

The majority of AD cases in this series were seen on 3D only, although risk of malignancy for 3D only visible compared to 2D plus 3D visible was similar. AD is more likely to represent invasive disease than in situ and is more likely malignant if a sonographic mass is present. Given the high malignancy rate, negative US or breast MRI should not obviate the need for biopsy of mammographic detected AD.

CLINICAL RELEVANCE/APPLICATION

Given the high malignancy rate associated with AD detected on 3D mammography, lack of US or MRI correlate should not obviate biopsy.

PURPOSE

The purpose of this study was to assess the clinical performance of *stationary* 3D mammography, which is a new approach to digital breast tomosynthesis that uses a fixed array of carbon nanotube-based x-ray sources to acquire the projection views.

METHOD AND MATERIALS

Women with a suspicious abnormality (BIRADS 4 lesion) identified by screening digital mammography were recruited for the study, which involved imaging by *stationary* 3D mammography prior to biopsy. Pre-clinical testing has demonstrated that *stationary* 3D mammography offers a higher spatial resolution than commercially-available 3D mammography devices, since it solves the problem of source blur. In this study, the *stationary* 3D mammography device collected 15 projections over an angular span of 28°. Four radiologists were asked to evaluate the likelihood of malignancy and rate breast density (BIRADS 1-4) when interpreting the standard mammogram and *stationary* 3D mammography images. Using pathology as ground truth, reader performance was quantified as the area under the receiver operating characteristic curve (AUC), while multivariate analysis with a fitted linear mixed-effect model was used to relate breast density to reader performance.

RESULTS

43 women [average age: 56.7 (35 to 83) years] provided a lesion-enhanced image set, in which malignancy was found to be present in 28% of participants by pathology. On average, readers were more accurate identifying malignancy when interpreting the *stationary* 3D mammography images compared to the standard mammograms, as demonstrated by the significantly higher ($p<0.0001$) mean AUC for *stationary* 3D mammography. This higher accuracy was present and statistically-significant across the full range of breast densities.

CONCLUSION

In this first-in-human study, readers were more likely to identify malignancy correctly when interpreting *stationary* 3D mammography images compared to the standard digital mammogram. Given these encouraging findings, as well as the results of pre-clinical testing, future trials are being designed to compare the performance of *stationary* 3D mammography to commercially-available 3D mammography devices in the clinic.

CLINICAL RELEVANCE/APPLICATION

Stationary 3D mammography may prove to be a valuable clinical tool, as readers were more accurate identifying malignancy when interpreting its images compared to the standard digital mammogram.

SSK01-09 Molecular Characterization of Breast Cancers: Could It Change Potential Overdiagnosis Analysis?

Wednesday, Nov. 28 11:50AM - 12:00PM Room: E451A

Participants
Francesca Caumo, MD, Padua, Italy (*Presenter*) Nothing to Disclose
Gisella Gennaro, PhD, Padua, Italy (*Abstract Co-Author*) Nothing to Disclose
Giovanna Romanucci, Verona, Italy (*Abstract Co-Author*) Nothing to Disclose
Marco Zappa, Firenze, Italy (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To compare the amount of potentially overdiagnosed breast cancers in two screening populations using tomosynthesis (DBT) and digital mammography (FFDM) considering only tumor stage or also molecular features.

METHOD AND MATERIALS

Cancers detected within a prospective screening trials using DBT were compared with those obtained from an historical FFDM screening cohort. The amount of potentially overdiagnosed breast cancers in the two cohorts was calculated according to two different assumptions: (1) stages 0 and 1 cancers (DCIS, IDCs, ILCs); (2) considering low-grade DCIS and IDCs/ILCs that are simultaneously grade 1, stage IA or IB, luminal A subtype. Rates (Fisher exact test) were used to compare the two hypotheses of potential overdiagnosis. A p-value lower than 0.05 was considered statistically significant. The same analysis was performed on the complementary subgroups for the two hypotheses: (1) stage > 1 tumors; (2) any other combination of features with the exception of that defined with the second assumption.

RESULTS

Cancers detected in the two screening populations was 322 from the DBT trial and 153 from the FFDM cohort. Considering only tumor stage, cancers potentially overdiagnosed were 268 with DBT and 116 with FFDM, equivalent to 83.2% and 75.8%, respectively. Comparing rates, DBT found 7.9/1000 stage 0/1 cancers vs. 4.0/1000 found by FFDM (P<0.0001), with an incidence rate ratio (IRR) equal to 1.99 (95%CI = [1.60-2.50]. Rates of cancers with stage >1 were 1.6/1000 with DBT vs. 1.3/1000 with FFDM, not significantly different (P=0.2817); the IRR was 1.26 (95%CI = [0.81-1.97]). Including in the definition of potentially overdiagnosed cancers also molecular features, the numbers become 61/322 (18.9%) with DBT and 13/153 (8.5%) with FFDM; rates of overdiagnosed cancers with the second assumption were 1.8/1000 with DBT and 0.4/1000 with FFDM (P<0.0001) corresponding to an IRR of 4.04 (95%CI = [2.20-8.02]). Rates of any other cancers (not overdiagnosed) were 7.7/1000 with DBT vs. 4.8/1000 with FFDM (P<0.0001), with an IRR of 1.61 [95%CI = [1.30-1.99]].

CONCLUSION

DBT increased the amount of potentially overdiagnosed cancers with both definitions. However, the second assumption (inclusion of stage, grade, and molecular features) showed that cancers detected by DBT were mostly not overdiagnosed.

CLINICAL RELEVANCE/APPLICATION

Overdiagnosis by DBT is overestimated using only cancer stage as metric for overdiagnosis.

PURPOSE

Mean percentage density assessed visually by two independent readers using Visual Analogue Scales (VAS) has a strong association with breast cancer risk, but is resource-intensive and impractical for stratified screening. We describe a fully-automated method for predicting this mammographic percent density measure from raw (for processing) or processed (for presentation) mammograms, and compare association of predicted VAS score with risk.

METHOD AND MATERIALS

Convolutional Neural Networks (CNNs) were trained using 67520 whole-image mammograms from 16968 women, each labelled with the average VAS score of two independent readers. The networks learned a mapping between mammographic appearance and mammographic density so that they can predict density for unseen images. To evaluate its use for risk assessment, we tested on case-control datasets of contralateral mammograms of screen detected cancers (SDC) and prior screening mammograms of women with cancers detected subsequently. Each cancer was matched to three controls on age, menopausal status, parity, HRT and BMI. The test datasets contained 366 cancers (SDC) and 338 (priors). Odds ratios between the top and bottom quintile were derived, and matched concordance indices were estimated. All images were acquired on GE Senographe systems, and none of the images from the case-control test sets were used in the training process.

RESULTS

For density estimates derived from raw images, odds ratios of cancer in the highest vs lowest quintile were 3.07 (95%CI: 1.97 - 4.77) for SDC and 3.52 (2.22 - 5.58) for priors, with matched concordance indices of 0.59 (0.55 - 0.64) and 0.61 (0.58 - 0.65) respectively. For processed images we obtained odds ratios of 3.22 (2.06 - 5.03) for SDC and 3.65 (2.27 - 5.88) for priors. Matched concordance indices were 0.58 (0.53 - 0.62) for SDC and 0.61 (0.57 - 0.65) for priors.

CONCLUSION

Our fully automated method demonstrated encouraging results on both raw and processed mammographic images, indicating that either image type could be used for screening stratification.

CLINICAL RELEVANCE/APPLICATION

Mammographic density is one of the most important risk factors for breast cancer. Our fully automated method could provide a pragmatic solution for population-based stratified screening.

SSK02-02 Breast Density Classification with Deep Convolutional Neural (DCN) Networks Utilizing 200,000 Screening Mammograms

Wednesday, Nov. 28 10:40AM - 10:50AM Room: E451B

PURPOSE

To develop a DCN network to reliably assess mammographic breast density

METHOD AND MATERIALS

In this retrospective study, we trained a multi-column DCN network on 200,000 digital screening mammograms performed at our institution from 2010-2016 to assess breast density. We extracted the textual reports associated with each exam to obtain the breast density as determined by the original interpreting radiologist. The algorithm was trained on 80% of the data sets, validated on a separate 10%, and tested on the remaining 10%. Once this convolutional neural network classifier was trained, we performed a reader study comparing our model to 3 radiologists. All readers independently evaluated the breast density in 100 mammograms in a randomized order. Breast density was assessed using the conventional BI-RADS categories: Class 0 - fatty, Class 1 - scattered fibroglandular densities, Class 2 - heterogeneously dense, and Class 3 - extremely dense. Performance of the model and the readers were assessed using the area under the ROC curve (AUC). Kappa score was used to assess for intra-observer and inter-observer variability.

RESULTS

Both the radiologists and our DCN model achieved a fair agreement (k = 0.34 - 0.51) with the labels in the reader study. The agreement between the predictions of our model and the labels in the data were higher (k = 0.65 - 0.72) compared to the inter-observer agreement between the radiologists. There was higher agreement for the fatty and extremely dense breast tissue. Comparing our CNN model to an average of the radiologists, the CNN achieved AUC of 0.934 (class 0: 0.971, class 1: 0.859, class 2: 0.905 and class 3: 1.000) while the radiologists achieved an AUC of 0.892 (class 0: 0.960, class 1: 0.812, class 2: 0.807 and class 3: 0.990) (Figure 1).

CONCLUSION

The level of agreement between the trained classifier and the classes in the data was found to be similar to that between the radiologists and the classes in the data, as well as among the radiologists.

CLINICAL RELEVANCE/APPLICATION

The classifier provides quantitative, reproducible prediction of breast density, while there is often poor intra-reader and inter-reader correlation in the qualitative assessment of breast density.

SSK02-03 Improving Radiologists' Breast Cancer Detection with Mammography Using a Deep Learning-Based Computer System for Decision Support

PURPOSE

To compare the breast cancer detection performance of radiologists reading mammography exams unaided versus reading using an interactive deep learning-based computer system for decision support (DS).

METHOD AND MATERIALS

A retrospective, fully-crossed (two sessions >4 weeks apart), multi-reader multi-case (MRMC) study was performed. 240 cases (100 cancers, 40 false positive recalls, 100 normals) were scored by 14 MQSA-qualified radiologists, once with and once without using DS. For each case, a forced BI-RADS® score and a level of suspicion (1-100) were provided. When reading with the DS system (Transpara, Screenpoint Medical, Nijmegen, The Netherlands), radiologists could activate the DS for a specific breast region by clicking on it and the system then displayed a cancer likelihood score (1-100). Additionally, traditional computer-aided detection was available to prompt calcification and soft tissue lesion markers. Area under the receiver operating characteristic curve (AUC), specificity and sensitivity, and reading time were compared using MRMC Analysis of Variance.

RESULTS

On average, with the DS system, the AUC increased significantly from 0.866 to 0.886 (P=0.0019) compared to unaided reading. Sensitivity increased from 83% to 86% (P=0.046), while specificity only slightly improved from 77% to 79% (P=0.061). Considering lesion type, AUC increased for soft tissue lesions (0.886 to 0.902, P=0.033), and calcifications (0.878 to 0.898, not significant, P=0.1021). Reading time per case was similar in both situations (unaided = 146 s, with DS = 149 s, P=0.147). As a stand-alone, the computer system had an equal detection performance (AUC=0.887) than the average of radiologists (P=0.333).

CONCLUSION

Radiologists significantly improved their cancer detection in mammography when using a deep learning-based computer system for decision support without taking more time.

CLINICAL RELEVANCE/APPLICATION

The use of decision support might prevent overlook and interpretation errors that are relatively common in the reading of mammography. The increase in performance when concurrently using DS does not lengthen radiologists reading time per case, as opposed to traditional computer-aided detection systems. The use of single-reading in combination with the computer system might achieve a performance similar to double human reading considering that the stand-alone performance of the system is similar to the average of radiologists.

PURPOSE

Previously, we demonstrated data-driven imaging biomarker in mammography (DIB-MMG; an imaging biomarker that is derived from large-scale mammography data by using deep learning technology) for detection of malignant lesions. Now, we assess the feasibility of DIB-MMG as a diagnosis-support-tool for radiologists.

METHOD AND MATERIALS

Total 96,191 exams of 4-view digital mammograms were retrospectively collected from two institutions. All cancer exams were proven by biopsy. Benign exams were proven by biopsy or at least 1 year of follow-up mammography, and normal exams were proven by at least 1 year of follow-up mammography. 90,637 exams of training data (16,086 cancer, 31,237 benign, and 43,314 normal exams) and 5,554 exams of test data (1,692 cancer, 2,780 benign, 1,082 normal cases) were used for developing the DIB-MMG. Sensitivity, specificity, and AUC of the final DIB-MMG on the test data were 82.6%, 93.3%, and 0.94, respectively. Total 120 exams of mammograms (38 cancer and 82 non-cancer exams) were independently collected for reader study, and five radiologists participated. For each exam, readers first read the exam without the help of DIB-MMG and Task-1) annotate the most suspicious lesion with DMIST 7-pt scores and Task-2) decide recall or not per breast. After reading of each exam, readers modify their decision based on the heat-map of DIB-MMG which denotes the likelihood of malignancy.

RESULTS

Per-breast standalone performance of DIB-MMG for 120 exams was 0.942 of AUC in Task-1, and 89.7% of sensitivity, 89.6% of specificity in Task-2. Average performance of five radiologists without DIB-MMG was 0.807 of AUC in Task-1, and 70.8% of sensitivity, 86.2% of specificity in Task-2. With DIB-MMG, the average performance was improved to 0.879 of AUC (p=0.024) in Task-1, and 79.5% of sensitivity, 86.5% of specificity in Task-2. Fig.1 shows exemplary DIB-MMG heat-maps.

CONCLUSION

This retrospective reader study showed the potential of DIB-MMG as a diagnosis support tool for radiologists in breast cancer screening. Further clinical validation with prospective study is needed.

CLINICAL RELEVANCE/APPLICATION

DIB-MMG is purely based on data-driven features from a large-scale mammography data instead of manually designed features of conventional computer-aided detection (CAD) algorithms. With further clinical validation, DIB-MMG can be practically used as a diagnosis support tool for radiologists in breast cancer screening.

SSK02-05 Generative Neural Network Inserting or Removing Cancer into Mammograms Fools Radiologists and Deep Learning Alike: Example of an Adversarial Attack

PURPOSE

To investigate whether a cycle-consistent generative adversarial network (CycleGAN) can insert or remove cancer-specific features into mammographic images in a realistic fashion.

METHOD AND MATERIALS

From two publicly available datasets (BCDR and INbreast) 680 mammographic images from 334 patients were selected, 318 of which exhibited potentially cancerous masses, and 362 were healthy controls. We trained a CycleGAN, using two pairs of generator and discriminator networks to convert cancerous breast images to healthy and back, and vice versa for the controls, without the need for paired images. The network, implemented in TensorFlow, was trained for 40 epochs on an augmented dataset enlarged ten-fold by random rotation, scaling, and contrast perturbations. To investigate how realistic the images appear, we randomly selected 20 image pairs of original and generated images, and 10 single images of each category (60 images in total). The images were presented to three radiologists (5 and 3 years of experience, and PGY-5 resident) who rated them on a 5-point Likert-like scale and had to indicate whether the image was real or generated/modified. The readout was analysed with a receiver-operating-characteristics (ROC) analysis, performance was expressed as area under the ROC curve (AUC).

RESULTS

For the most experienced radiologist, the modifications introduced by CycleGAN reduced diagnostic performance, with the AUC dropping from 0.85 to 0.63 (p=0.06), respectively, while the two less experienced ones seemed unaffected at a lower baseline performance (AUC 0.75 vs. 0.77 and 0.67 vs. 0.69). None of the radiologists could reliably detect which images were real and which were modified by CycleGAN (AUC 0.50-0.66).

CONCLUSION

CycleGAN can inject or remove malignant features into mammographic images while retaining their realistic appearance. These artificial modifications may lead to false diagnoses.

CLINICAL RELEVANCE/APPLICATION

Modern adversarial attacks may go undetected by humans as well as deep learning algorithms, and could be used in cyber warfare. It is vital to secure healthcare devices and information systems against such attacks mediated by neural networks.

SSK02-06 Deep Learning for Detection of Breast Cancer and Negative Screening Exams Using an In-House Million Mammogram Dataset

PURPOSE

Breast cancer is the second leading cause of cancer death in women in the US. Screening mammography is effective for early detection, however suffers from unnecessary recall imaging and biopsies. Deep learning shows promise in medical image recognition tasks, but requires large-scale, robustly-annotated datasets. We expand upon our previously described end-to-end process of constructing a million mammogram dataset using routine clinical data and present results of two preliminary deep learning models for cancer detection and the identification of true negative images.

METHOD AND MATERIALS

923,685 DICOM images and 37,730 free-text pathology reports were used to generate an in-house database labeled with ground-truth pathology results.The first deep learning model was created for cancer detection only in biopsy proven specimens - the most difficult subset of data as each image contained a suspicious finding. The model was comprised of two components: patch-based pre-training and end-to-end fine tuning. Training set size was 34,390 images (12,251 positive, 22,139 negative), and test set size was 6,778 images equally split.The second model was designed to have a high NPV for screening and diagnostic studies. An attention-based object detection network was used, with potential abnormalities identified by a region-proposal network and resolved by a separate head classifier network. The model was trained with 359,574 images (4,738 positive, 354,837 negative).

RESULTS

The first model achieved an AUC of 0.81, sensitivity of 0.764, and specificity of 0.797. The second model when tested on 100 positive and 100 negative cases achieved an AUC of 0.90, sensitivity of .866, and specificity of .873 . If the test cases were

changed to a more clinically relevant distribution of 99% benign and 1% cancer, the AUC increased to 0.96.

CONCLUSION

We demonstrate the efficacy of deep learning for mammography in both cancer detection and the identification of negative studies. Future work includes enrichment of the dataset with further clinical data such as history of breast cancer, prior surgeries, and hormone replacement therapy. We also aim to improve model performance and efficiency through novel model architectures.

CLINICAL RELEVANCE/APPLICATION

We develop novel deep learning models for mammography using routine clinical data from a single institution with the potential to decrease recall imaging and unnecessary biopsies.

SSK02-07 Improved Cancer Detection using Artificial Intelligence: A Retrospective Evaluation of Missed Cancers on Mammography

PURPOSE

To determine whether artificial intelligence-based (AI) software can be used to improve radiologists' sensitivity in breast cancer screening and detection.

METHOD AND MATERIALS

A set of 2-D Digital Mammograms originally interpreted with R2 ImageChecker CAD (Hologic, Sunnyvale, CA) and performed between October 2011 to March 2017 was collected from a community facility. Of the 317 cancer patients with available prior mammograms, 139 had retrospective findings, and 90 of those were deemed actionable. A blinded retrospective study was performed with a panel of seven radiologists comprised of false negative actionable mammograms obtained up to 5.8 years prior to diagnosis and 32 normal studies. Each radiologist viewed the cases without and then with benefit of cmAssist TM (CureMetrix, La Jolla, CA) AI based computer-aided detection (AI-CAD) flags and neuScore TM (quantitative AI-based probability for malignancy of flagged lesions, 1-100 scale). Reader decision making changes in true and false positive recalls with and without AI were analyzed.

RESULTS

All radiologists showed a significant improvement in their cancer detection rate (CDR) with the use of AI-CAD and neuScore ($p = 0.0069$, C.I. = 95%). With the assistance of AI software, the sensitivity of less experienced general radiologists improved to a level higher than a fellowship-trained academic mammographer. The readers detected between 25% and 71% (mean 51%) of the early cancers without assistance. With AI software results,, overall reader CDR was 41% to 76% (mean 62%). Overall, there was less than 1% increase in the readers' false positive recalls with use of the AI software.

CONCLUSION

There was a statistically significant improvement in radiologists' sensitivity for cancer detection in this enriched data set of primarily false negative mammograms with the benefit of the AI-CAD with neuScore. The percentage increase in CDR for the radiologists in the reader panel, ranged from 6% to 64% (mean 27%) with the use of AI-CAD, with negligible increase in false positive recalls.

CLINICAL RELEVANCE/APPLICATION

This study shows a measurable, significant benefit for radiologists in mammography interpretation with the use of artificial intelligence (AI) based computer-aided detection software with quantitative scoring. The use of AI in clinical practice may potentially expedite workflow, enhance earlier detection of cancer, and reduce false negative mammograms.

SSK02-08 Data-Driven Imaging Biomarker for Breast Cancer Screening in Digital Breast Tomosynthesis

PURPOSE

To assess feasibility of a data-driven imaging biomarker in digital breast tomosynthesis (DIB-DBT) using the deep learning technology and evaluate its potential for detection of breast cancer.

METHOD AND MATERIALS

We retrospectively collected 49,577 exams of 4-view digital mammograms (MMG) and 1,196 exams of 4-view digital breast tomosynthesis images (DBT) from a single institution. We also collected 41 (10 cancer, 16 benign, 15 normal) exams of 4-view DBT retrospectively from another institution for external validation. 49,577 exams of MMG consists of 47,719 (5,599 cancer, 17,971 benign, and 24,149 normal) and independent 1,858 (619 cancer, 620 benign, 619 normal) exams of training and validation data, respectively. 1,196 exams of DBT consists of 996 (822 cancer, 40 benign, 134 normal) and independent 200 (120 cancer, 30 benign, 50 normal) exams of training and validation data, respectively. Previously, we assessed the feasibility of DIB-MMG as a screening tool for breast cancer detection in mammograms through external validation and pilot reader study. Thus, we exploit DIB-MMG for developing DIB-DBT in this study. Training of DIB-DBT consists of two stages - semi-supervised pre-training with partially-annotated large-scale MMG followed by fully-supervised fine-tuning with fully-annotated small-scale DBT. Residual network for image recognition is used as a baseline model. Diagnostic accuracy of DIB-DBT was assessed using receiver operating characteristic analysis.

RESULTS

Area under the curve (AUC) on the internal validation dataset of DIB-DBT with and without the pre-training stage of DIB-MMG was 0.9227 and 0.9081, respectively. AUC of the external validation dataset of DIB-DBT with and without the pre-training stage of DIB-MMG was 0.9710 and 0.9232, respectively.

CONCLUSION

This study showed the feasibility of DIB-DBT as a screening tool for breast cancer detection in DBT. This research also showed the potential of DIB-MMG as a base model for DIB-DBT. Further clinical validation of DIB-DBT is needed for using it as a reliable screening tool for breast cancer screening.

CLINICAL RELEVANCE/APPLICATION

With further clinical validation, DIB-DBT could be practically used as a second-reader to help radiologists detecting and diagnosing breast cancer in DBT efficiently.

SSK02-09 Improved Performance of Machine Learning-Based Analysis of Mammography by Using Digital Breast Tomosynthesis Versus 2D Mammography

Wednesday, Nov. 28 11:50AM - 12:00PM Room: E451B

sorensen@deep.health

PURPOSE

Digital Breast Tomosynthesis (DBT) has been shown to be clinically superior to both full-field digital mammography and synthetic two-dimensional mammography (2D) for breast cancer detection. However, few studies to date have compared machine learning (ML) algorithmic performance in DBT versus 2D in large data sets. Technically, the much larger size of a DBT acquisition could actually be a hindrance for training convolutional neural networks (CNNs), for example via overfitting. Such technical issues could in turn imply impracticality of ML for DBT or a need for much larger training datasets. We sought to implement CNNs for both DBT and synthetic 2D X-ray mammograms and compare their performance.

METHOD AND MATERIALS

We compiled two separate datasets consisting of de-identified images and linked reports, collected from multiple mammography centers following an IRB-approved protocol. Data originated from equipment from the same manufacturer across all sites, and included presentation DBT and synthetic 2D images. We developed a novel CNN architecture and trained this model on the first dataset consisting of 22,000 DBT studies (323 cases of confirmed malignancy), where radiology reports and MQSA outcome data were used as estimates of ground truth. To simulate a more realistic evaluation scenario, the CNN was then tested on the second dataset collected from a different center. Using a test set of 1,750 screening DBT studies (94 confirmed cancers), receiver operating characteristic (ROC) curves and the corresponding area-under-the-curve (AUC) were calculated on both the full DBT study, and on just the synthetic 2D data alone.

RESULTS

AUC values for performance on the test dataset were: 2D: 0.894. DBT: 0.915. ($p < 0.01$ for difference between 2D and DBT on the full test dataset). At typical operating points (sensitivity 0.75 to 0.90) this corresponds to an average 19.6% relative decrease in model callback rates for the model (e.g., at sensitivity=0.8, from ~15% to ~11%).

CONCLUSION

ML can be applied successfully to DBT and results in improved performance over synthetic 2D mammography.

CLINICAL RELEVANCE/APPLICATION

Machine learning could play an important role in screening mammography, not only for traditional 2D mammography, but also when used with DBT; thus, ML is not in conflict with DBT but complementary and could further improve breast cancer screening performance.

PURPOSE

To determine the sensitivity, specificity, and predictive value of cardiac CT angiography (cCTA), cardiac MR (CMR), and transthoracic echocardiography (TTE) for stroke recurrence in patients with suspected cardioembolic stroke.

METHOD AND MATERIALS

163 patients (55% men, 61.9±16.9 years) with suspected cardioembolic stroke who underwent TTE, CMR, or cCTA between January 2013 and May 2017 were retrospectively analyzed. The presence of left atrial thrombus, left ventricular thrombus, complex aortic plaque, cardiac tumors, and valvular vegetation was evaluated. The patient electronic medical records were used to determine if the patient suffered a recurrent stroke. The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated for each imaging modality and the diagnostic accuracy was compared using receiver operating characteristic analysis.

RESULTS

cCTA was performed in 82 patients, CMR in 81 patients, and TTE in 151 patients. 28 recurrent strokes occurred (cCTA- n=14; CMR- n=14; TTE- n=26). The sensitivity, specificity, PPV and NPV were: 14%, 79%, 12.5%, and 81.5% for CMR; 28.5%, 88.2%, 33.3%, and 85.7% for cCTA; and 11.5%, 88.8%, 17.6%, and 82.8% for TTE. There was no significant difference in diagnostic accuracy between CMR (0.53, 95% CI [0.42, 0.64]), cCTA (0.56, 95% CI [0.43, 0.69]), and TTE (0.50, 95% CI [0.43, 0.57]).

CONCLUSION

cCTA, CMR, and TTE demonstrated comparably high specificity and NPV for the exclusion of cardioembolic stroke recurrence.

CLINICAL RELEVANCE/APPLICATION

The comparable performance of cCTA, CMR, and TTE in predicting recurrent cardioembolic stroke allows physicians to choose a preferred imaging modality for patients with suspected cardioembolic stroke.

SSK03-02 Quantitative Assessment of Myocardial Infarction with Computed Tomography (CT) Using a Bolus Contrast Injection Scheme: Comparison Between Extravascular Contrast Distribution Volume (ECDV) and Extracellular Volume Fraction (ECV)

Wednesday, Nov. 28 10:40AM - 10:50AM Room: S102CD

PURPOSE

Myocardial viability can be assessed with CT by delineating the infarcted tissue with a higher degree of contrast retention in the late phase after bolus injection of iodinated contrast. In this study, we investigated the effectiveness of two metrics for the quantification of late iodine enhancement in myocardium for viability assessment.

METHOD AND MATERIALS

Reperfused acute myocardial infarction was induced in four farm pigs with 1-hr occlusion of the left anterior ascending artery (LAD) with a balloon catheter, and CT studies were performed within 2 weeks after the interventional procedure. After bolus injection of contrast at 3 mL/s and 0.7 mg/kg followed by saline flush, a 4-phase dynamic acquisition covering 10 min was performed with a GE Healthcare Revolution CT scanner at 100 kV, 100 mA, 280 ms/rot: 1st phase: 22 axial scans every 1-2 diastoles; 2nd: 6 scans every 15 s; 3rd: 4 scans every 30 s; 4th: 6 scans every 60 s. Dynamic images were analyzed with a model-based deconvolution approach, with the modified Johnson-Wilson-Lee tracer kinetic model used to describe the contrast exchange among the cellular and interstitial and vascular spaces in myocardium to derive ECDV in ml/g. The difference images were also generated by subtracting the images acquired at 10 min post contrast injection by the baseline images to obtain enhancement in the myocardium (ΔHUmyo) and left ventricular blood pool (ΔHUblood). ECV was then calculated as (1-Hematocrit)·(ΔHUmyo/ΔHUblood). ECDV and ECV in normal (LCx territory) and infarcted myocardium (LAD territory) were compared.

RESULTS

Mean ECV in normal and infarcted myocardium were 0.27±0.11 and 0.52±0.11 respectively. The corresponding mean ECDV calculated from the dynamic images covered up to 3 min post contrast injection were 0.28±0.07 ml/g and 0.60±0.10 ml/g respectively. Infarcted myocardium exhibited a higher percentage increase in ECDV from normal myocardium (114%) compared to ECV (93%).

CONCLUSION

ECDV may be a more sensitive marker of myocardial viability compared to ECV due to the larger difference exhibited between the normal and infarcted tissues, and can be measured with only 1/3 of the time required for ECV (3 min vs. 10 min post contrast injection).

CLINICAL RELEVANCE/APPLICATION

With bolus contrast injection, ECDV measurement could provide a faster and more reliable assessment of myocardial viability after acute myocardial infarction compared to conventional ECV measurement.

SSK03-03 Feasibility of Myocardial Extracellular Volume Fraction Quantification Using Dual-Energy CT

Wednesday, Nov. 28 10:50AM - 11:00AM Room: S102CD

PURPOSE

To assess the feasibility of Dual Energy CT (DECT) to derive myocardial extracellular volume (ECV) and detect ECV differences without the need for a true non-contrast scan compared to Single Energy CT (SECT) results.

METHOD AND MATERIALS

A total of 35 patients were included in this IRB-approved, HIPAA-compliant study; 8 control patients, 17 infarct patients (focal fibrosis), and 10 cardiomyopathy patients (diffuse fibrosis). All scans were acquired using a 2nd or 3rd generation dual source CT system. A true non-contrast and delayed acquisition were used to calculate SECT-ECV, while only the delayed acquisition in dual energy mode and derived virtual non-contrast images were used to calculate DECT-ECV. In the control and diffuse fibrotic groups, a region of interest (ROI) encompassing the entire left ventricular myocardium was used to calculate ECV. Two ROIs were placed in the focal fibrotic group; one in normal myocardium and one in fibrotic myocardium.

RESULTS

The median ECV was 33.4% (IQR, 30.1-37.4) for the SECT approach and 34.9% (IQR, 31.2-39.2) for the DECT approach (p =

0.401). For both SECT-ECV and DECT-ECV, focal fibrotic and diffuse fibrotic tissue had significantly higher ECV values compared to normal myocardium (all p < 0.021). No systematic bias was observed between SECT and DECT measurements, with limits of agreement calculated at ± 9.4% (p = 0.348). The DECT acquisition had a lower radiation dose than the SECT scan by 1.1 mSv (p < 0.001), which was likely caused by the absence of the true non-contrast acquisition in the DECT approach.

CONCLUSION

Measurement of ECV with only a delayed acquisition is feasible using the DECT approach. The DECT approach provides similar results at a lower radiation dose compared to a SECT protocol.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the feasibility of DECT for myocardial ECV measurements using only a delayed acquisition, thus eliminating the need for a true non-contrast scan and consequently reducing radiation dose.

SSK03-04 Accuracy of Myocardial Blood Flow Quantification with Dual-source CT: Validation in Human Using 15O-Water PET

masa-tkfj@clin.medic.mie-u.ac.jp

PURPOSE

Myocardial CT perfusion has emerged as a potential method for absolute quantification of myocardial blood flow (MBF). However, there is no standardized technique for CT MBF quantification, and dual-source CT MBF values have never been compared against positron emission tomography (PET), which is an established technique for non-invasive quantification of MBF. The aim of this study was to assess the accuracy and usefulness of absolute MBF values quantified with dual-source CT by comparing them with those quantified with 15O-water PET.

METHOD AND MATERIALS

Dynamic CT perfusion and 15O-water PET were performed in 26 patients (70+/-9 years, 22 male) with known/suspected coronary artery disease with a median interval of 48 days (interquartile range: 29-73 days). Hyperemic MBF in AHA 16 segments were quantified with a dual-source CT and its dedicated software (Force/VPCT body, Siemens). For the quantification of hyperemic MBF using 15O-water PET, non-commercial software (Carimas) was used. Comparison of hyperemic MBF quantified by CT and PET was performed on segment (n=377), vessel (n=77), and patient (n=26) levels after exclusion of 7 segments out of FOV and 32 segments with transmural myocardial infarction.

RESULTS

CT results showed excellent linear correlation with PET results at segment (r=0.87, p<0.0001), vessel (r=0.91, p<0.0001), and patient level (r=0.93, p<0.0001). Area under the receiver-operating characteristics curve for detecting reduced MBF (<2.3 mL/min/g) on 15O-water PET was 0.88, 0.91, and 0.92 at segment, vessel, and patient level, respectively. Although CT demonstrated significantly lower hyperemic MBF than PET (1.16 ± 0.29 mL/min/g vs 2.46 ± 1.56 mL/min/g, p<0.0001), there was good per-vessel sensitivity (79.5%), specificity (92.1%), negative predictive value (81.4%) and positive predictive value (91.2%) for diagnosing reduced PET-derived MBF with a CT-derived MBF cutoff value of 1.09 mL/min/g.

CONCLUSION

Hyperemic MBF quantified by CT demonstrated excellent correlation with MBF estimated by 15O-water PET, and yielded high diagnostic accuracy for detecting abnormal perfusion.

CLINICAL RELEVANCE/APPLICATION

CT MBF quantification has potential to provide objective assessment of perfusion abnormality in patients with known or suspected CAD with high accuracy comparable to 15O-water PET.

SSK03-05 Relationship Between Epicardial Adipose Tissue and Coronary Vascular Function in Patients with Normal Myocardial Perfusion by 82Rb PET/TC

PURPOSE

We assessed the relationship between epicardial adipose tissue (EAT) and coronary flow reserve (CFR) in patients with suspected or known coronary artery disease (CAD) and normal myocardial perfusion imaging (MPI).

METHOD AND MATERIALS

The overall population consisted of 272 subjects referred for the evaluation of suspected or known CAD to stress-rest 82Rb PET/CT and showing normal MPI. CAC score was measured according to the Agatston method. Using unenhanced CT images for CAC, EAT volume was measured (cm3). The ln(CAC+1) score and lnEAT transformation were used to reduce heteroscedasticity. Myocardial perfusion was assessed using standardized segmentation of 17 myocardial regions. The summed stress, summed rest and summed difference scores were automatically calculated. Myocardial perfusion was considered normal when the summed stress score was <3. Absolute myocardial blood flow (MBF) was computed (in milliliters per minute per gram) from the dynamic rest and stress imaging series. CFR was defined as the ratio of hyperemic to baseline MBF; CFR 2 was considered reduced.

RESULTS

In the overall population, 95 (35%) patients showed reduced and 177 (65%) normal CFR. Compared to patients with normal CFR, those with reduced CFR were older (60±11 vs. 67±9, P<0.05) and showed higher values of ln(CAC+1) (3.9±3 vs. 4.7±3, P<0.05) and lnEAT volume (4.5±1 vs. 4.7±.1, P<0.05). At univariable logistic regression analysis age, ln(CAC+1) and lnEAT resulted significant predictors of reduced CFR. At multivariable analysis, only age and lnEAT volume were independently associated with reduced CFR (hazard ratio 1.05 and 1.89 and 95% confidence interval 1.02-1.08 and 1.01-3.54, P<0.005). The addition of lnEAT to clinical data significantly increased the global chi-square of the model (from 23.8 to 28.6, P<0.05) in predicting reduced CFR.

CONCLUSION

In patients with suspected and known CAD and normal myocardial perfusion, age and EAT are strongly associated with reduced CFR confirming that visceral fat depot may directly influence coronary vascular function. Thus, EAT evaluation may play a major role in the identification of coronary vascular dysfunction in patients with normal perfusion.

CLINICAL RELEVANCE/APPLICATION

In patients with suspected and known CAD and normal myocardial perfusion, age and EAT are associated with impaired CFR confirming that visceral fat may directly influence coronary vascular function.

SSK03-06 Beyond CT-Fractional Flow Reserve (FFR): Non-Invasive Assessment of Instantaneous Wave Free Ratio (iFR), Coronary Flow Reserve (CFR) and Hyperemic Stenosis Resistance Index (HSR) from CTA

Wednesday, Nov. 28 11:20AM - 11:30AM Room: S102CD

dmitsouras@alum.mit.edu

PURPOSE

Although FFR can be assessed by CTA, patient management in the cathlab uses eg, iFR to avoid pharmacologic stress, or CFR and HSR to assess other factors associated with increased risk of major adverse cardiac events, such as microvascular disease or endothelial dysfunction. Estimating these metrics from CTA requires matched baseline and hyperemic simulations (ie, stress simulated using results obtained from rest simulation), which no technology to date provides. We sought to determine if coupling rest/stress computational fluid dynamics (CFD) simulations from CTA is feasible, and whether resulting metrics agree with known relationships of those metrics to reference-standard FFR.

METHOD AND MATERIALS

Rest-stress hemodynamics from CTA were performed for 50 patients with invasive FFR in intermediate lesions in <90d of CTA. Rest CFD was performed using only CTA data (myocardial mass, Murray's law). Stress CFD was then performed by coupling the epicardial arteries to a microvascular resistance model using the resistances estimated by the rest CFD for each myocardial territory. Hemodynamic metrics were calculated at the same location as invasive FFR as follows: CT-FFR=stress P/aortic stress P; CT-iFR=rest P/aortic rest P; CT-CFR from average peak velocity (APV), CFR=stress APV/rest APV; and CT-HSR=(aortic stress P-stress P)/stress APV. Correlation to FFR and receiver operating characteristic area-under-the-curve (AUC) to predict FFR<=0.8 was determined for each metric.

RESULTS

Target lesion DS was 46.8±8.7%, and 40% had FFR<=0.8. Pearson correlations against invasive FFR of CT-FFR, CT-IFR, CT-CFR and CT-HSR were r=0.70, 0.69, 0.35, and -0.71, respectively (all p<0.01). Diagnostic accuracy to detect FFR<=0.8 was 0.87 (95%CI:0.77-0.98), 0.86 (95%CI:0.75-0.97), 0.72 (95%CI:0.56-0.88), and 0.9 (95%CI:0.8-0.99), respectively. These match reported relationships between invasive FFR and iFR, CFR and HSR (eg, Pearson r~0.75 for iFR and r~0.34 for CFR compared to FFR, and AUC of FFR to predict significant HSR of ~0.94).

CONCLUSION

Coupling baseline and hyperemic simulations enables key physiologic parameters dependent on both pressure and flow to be estimated non-invasively from standard retrospective CTA.

CLINICAL RELEVANCE/APPLICATION

Evaluation of coronary artery disease by CTA can non-invasively assess coronary physiology beyond FFR, delivering key physiologic

information that is used in clinical decision making for patients with angina

PURPOSE

Commercially available CT scanners can achieve gantry rotation times of 0.3 s (~3 frames per second). However, the temporal resolution might not be sufficient to calculate blood flow and velocity in the coronary arteries, which are important for the diagnosis of coronary artery disease (CAD). Currently, ~1000 projection images are acquired during each gantry rotation. The purpose of this study was to determine the feasibility of a new reconstruction technique called 4D CTA, which calculates a 3D time frame for each projection image and therefore provides high temporal resolution for flow calculations in the coronary arteries.

METHOD AND MATERIALS

The previously described 4D DSA technique (Davis, 2013) was extended for the time-resolved 3D reconstruction of coronary arteries (CA). A pig study was retrospectively analyzed, where continuous axial CT acquisitions (64 slices) were performed with a 0.4 s gantry rotation time over a period of 50 s during intravenous contrast injection. A 3D image of the vasculature was reconstructed using a short scan (235 degrees) during diastole and the CA were manually segmented. A constrained back-projection was then performed for each projection image to create a 3D time frame. The reconstructed time attenuation curves were used to calculate the blood flow and velocity in the CA based on the mean transit time. The velocity and flow values were compared to values from literature and the flow conservation was determined.

RESULTS

In the first order branches, the average diameter, velocity and flow were 4.12 mm (3.28 mm), 110.43 mm/s (128 mm/s), and 1.44 ml/s (1.07 ml/s) respectively. The same measurements for the second order branches were 1.31 mm (1.70 mm), 63.34 mm/s (46.10 mm/s) and, 0.32 ml/s (0.10 ml/s) respectively. Values given in brackets are from literature as reported in Kassab et al. (1997) The flow conservation in the measured branches of the CA was 96.71 %.

CONCLUSION

Calculated coronary arterial velocity and flow correlated well with previously reported values from the literature suggesting that flow determination from 4D CTA is feasible. Additionally, the high flow conservation shows that the calculated values are consistent.

CLINICAL RELEVANCE/APPLICATION

The presented technique could provide both anatomical and functional information in diagnostic settings as well as cath labs using existing CT systems to detect pathologies of the coronary arteries.

SSK03-08 Deep Learning Reconstruction of Non-Contrast Magnetic Resonance Coronary Angiography at 3T Machine

Wednesday, Nov. 28 11:40AM - 11:50AM Room: S102CD

PURPOSE

Dedicated T2 preparation pulse have enabled non-contrast magnetic resonance coronary angiography (MRCA) at 3T system; however, the vascular contrast-to-noise ratio (CNR) is still inadequate for clinical use. The deep learning reconstruction (DLR) is a novel technique to improve the image quality. The purpose of this study was to investigate the effects of DLR on the image quality of 3T non-contrast MRCA.

METHOD AND MATERIALS

We enrolled 10 volunteers (2 female, mean age 48 years) with no known coronary artery disease. Non-contrast MRCA was performed on a 3T MR scanner (Galan 3T ZGO, Canon medical) with following parameters: 3D fast FE, TR/TE =5.3/1.9ms, flip angle = 12°, slice thickness = 1.7mm with ECG trigger and real time motion correction. DLR images at moderate level and high level were generated by using dedicated workstation. In the quantitative evaluation, we measured signal-to-noise ratio of 3 coronary vessels (proximal and distal segments). In the qualitative evaluation, the 2 observers graded the vessel visualization and artifacts on a 4-point scale (worst, 1; best, 4).

RESULTS

The CNR (original MRCA) was 31 ± 7 and 16 ± 5 in the proximal and distal vessel, respectively. The corresponding CNR (moderate-level DLR) was 46 ± 9 and 24 ± 10; and the CNR (high-level DLR) was 85 ± 20 and 45 ± 14. The visual scores for overall image quality and image noise were significantly better in DLR images than original images. The vessel sharpness scores were comparable among 3 reconstructions (3.4, 3.8, and 3.8 for original, moderate DLR, and high DLR, respectively). The visual scores for image noise/graininess was significantly better in DLR (2.4, 3.8, and 4.0 for original, moderate DLR, and high DLR, respectively).

CONCLUSION

Non-contrast MRCA at 3T using DLR provides higher CNR without degrading the vessel sharpness.

CLINICAL RELEVANCE/APPLICATION

The deep learning reconstruction technique contributes in improved visualization of coronary arteries in non-contrast MR coronary angiography, enabling noninvasive scrutiny of the heart.

SSK03-09 Clinical and Transthoracic Echocardiography Predictors of Non-Detectable Left Ventricular Thrombus: When Is Cardiac Magnetic Resonance Necessary

Wednesday, Nov. 28 11:50AM - 12:00PM Room: S102CD

Participants

For information about this presentation, contact:

rolf.symons@uzleuven.be

PURPOSE

Currently, transthoracic echocardiography (TTE) remains the most commonly used technique for the identification of LV thrombi. However, not all thrombi are visualized with TTE. Therefore, the purpose of our study was to identify predictors of unsuccessful TTE thrombus visualization and to develop a risk score to stratify which patients may benefit from cardiac magnetic resonance (CMR) to reliably detect or exclude LV thrombus.

METHOD AND MATERIALS

We performed a retrospective search of our CMR database including 10300 patients and identified 118 patients with LV thrombus and a time interval between CMR and TTE of <72h. Univariate logistic regression analysis was used to assess the association between baseline characteristics and TTE parameters with the primary endpoint (i.e. unsuccessful LV thrombus visualization on TTE). Variables with P<0.10 at univariate analysis were included as covariates in the multivariate logistic regression analysis. Receiver-operating characteristic (ROC) curve analysis was performed to examine differences in performance of each variable for prediction of the primary endpoint. A two-sided P-value<0.05 was considered to represent a significant difference.

RESULTS

In multivariate analysis, body mass index (BMI), LV end-diastolic diameter (EDD), and mitral valve regurgitation (MVR) were identified as significant predictors of unsuccessful LV thrombus visualization by TTE (all P<0.001). ROC analysis showed BMI >=26.9 kg/m2, LVEDD >=52 mm, and MVR >=2/4 to be the optimal cutoff points for prediction of the primary endpoint. The combination of the independent predictors allowed generation of a gradient response risk score of unsuccessful LV thrombus visualization by TTE (0/3 present: 0% missed; 1/3 present: 33.3% missed; 2/3 present: 79.5% missed; 3/3 present: 100% missed) (P<0.001).

CONCLUSION

Individual clinical and TTE parameters can predict the sensitivity of TTE for the successful detection of LV thrombus in heart disease. By using the presented risk score, a cost-effective strategy may be implemented by selectively referring patients to CMR when these risk factors are present.

CLINICAL RELEVANCE/APPLICATION

Clinical and TTE parameters can predict unsuccessful detection of LV thrombus in heart disease. These findings may lead to a cost-effective referral of certain patients to CMR to rule out LV thrombus.

PURPOSE

Aortic stenosis(AS) have a quite proportion of low-flow, low-gradient(LF/LG) AS, defined as small aortic valve area(AVA<1.0cm2) but a low mean pressure gradient(PG<40mmHg) and low flow(stroke volume<35ml/m2). Diagnosis of AS has been based on a valve area, mean PG and a peak flow velocity measured on echocardiography. However, there was a discrepancy between the measured AVA on cardiac CT and degree of AS on echocardiography. The purpose of this study was to evaluate the discrepancy between CT and echocardiography, and show the role of CT to detect LF/LG AS.

METHOD AND MATERIALS

Between June 2011 and Mar 2016, 465 patients with AS underwent CT for preoperative evaluation of aortic valve replacement. On CT, aortic annulus, AVA and aortic root size were measured. Clinical information including echocardiography findings was retrospectively collected. On echocardiography, severe AS was defined as peak velocity >4 m/s or mean PG <40mmHg. On CT, severe AS was defined as AVA <1.0 cm2. Patients were classified into four groups: Group 1) severe AS on both CT and echocardiography (n=282); Group 2) Severe AS on CT alone (n=49); Group 3) Severe AS on echocardiography alone (n=99); and Group 4) non-severe AS on both CT and echocardiography (n=35). Echocardiography and CT findings were compared among the groups.

RESULTS

AVA in both group 1 and 2 were similar (0.8 and 0.8cm2, respectively, P=0.99). However, in group 2, left ventricular ejection fraction (LVEF) (59.3 vs. 54.1%, P=0.02) and mean PG (67.5 vs. 28.5mmHg, P<0.001) ware significantly low compared to those in group 1, suggests LF/LG severe AS. Peak velocity was also smaller in group 2 (5.2 vs. 3.1m/s, P<0.001). LV mass index and B-type natriuretic peptide were no significant difference among the four groups.

CONCLUSION

In 32% of patients who required AVR due to AS, there was a discrepancy between the measured AVA on CT and degree of AS on echocardiography. Patients who showed peak velocity <4m/s or mean PG <40mmHg on echocardiography and AVA<1.0cm2 on CT show significantly lower EF, peak velocity, and mean PG, which suggests characters of LF/LG AS. CT may be useful to detect LF/LG AS.

CLINICAL RELEVANCE/APPLICATION

Since echocardiography is useful for functional evaluation of LV and CT can accurately measure the AVA, we can accurately evaluate the characteristics of AS using both modalities. The use of two modalities may help to risk stratify AS patients and to make therapeutic decision.

SSK04-02 Bioprosthesis Thrombosis After Transcatheter Aortic Valve Replacement: Cardiac Computed Tomography Findings

Wednesday, Nov. 28 10:40AM - 10:50AM Room: S103AB

Participants
Hyun Jung Koo, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Joon-Won Kang, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

donghyun.yang@gmail.com

PURPOSE

To evaluate post-transcatheter aortic valve replacement (TAVR) findings such as thrombosis and leaflet dysfunction using cardiac computed tomography.

METHOD AND MATERIALS

Among 397 post-TAVR patients, 133 patients underwent cardiac CT. After excluding immediate post-TAVR CT, 49 patients (23 CoreValve, 23 Sapien XT, and 3 Sapien 3) with CT obtained more than one month after TAVR were retrospectively reviewed. Leaflet opening limitation, bioprosthesis thrombosis, leaflet degeneration, and stent eccentricity were analyzed. Baseline immediate and follow-up echocardiography parameters were collected and analyzed.

RESULTS

Median intervals between TAVR and CT was 13 months (range: 9.4 - 24.5 months). Minimal subvalvular rim-like soft tissue thickening (n= 27, 55%) and mild thickening of leaflets (n=2, 4%) are detected, but the patients are asymptomatic without hemodynamic disturbance. Leaflet opening limitation is noted in 11 (22%, 7 mild, 3 moderate, and 1 severe reduction) patients, however, there was no correlation with echocardiography parameters. TAV thrombosis is noted in 9 (18%) patients. In the patients with TAV thrombosis, transvalvular peak velocity (2.9 vs. 2.5 m/sec) and pressure gradient (20.7 vs. 13.6 m/sec) are higher than the others, but without statistical significance (P<0.05). One patient who showed highest peak velocity and pressure gradient on echocardiography (5.4 m/sec and 71 mmHg) had extensive subvalvular and valvular soft tissue thickening on CT even though she have managed with intense anticoagulation. One infective endocarditis is occur. The smaller the size of the stent lumen at the valve level, the more the peak velocity and pressure gradient increases (r=-0.4, P=0.008).

CONCLUSION

Leaflet thrombosis, subvalvular soft tissue thickening and leaflet opening limitation following TAVR is not uncommon findings in patients who performed cardiac CT. Cardiac CT can demonstrate post-TAVR findings such as subvalvular soft tissue, valve thrombosis, leaflet opening limitation and stent lumen size.

CLINICAL RELEVANCE/APPLICATION

Although the majority of patients who present leaflet thrombosis, subvalvular soft tissue thickening or leaflet opening limitation following TAVR show subclinical conditions without hemodynamic disturbance on echocardiography, follow-up cardiac CT may help to detect early complications of TAVR.

SSK04-03 Dynamic Evaluation of 3D Mitral Annular Anatomy in Primary and Functional Mitral Regurgitation Patients Using Multiphase Cardiac CT: Implications for Trans-catheter Mitral Valve Replacement Planning

Wednesday, Nov. 28 10:50AM - 11:00AM Room: S103AB

PURPOSE

To date, there is a relative lack of data regarding the use of CT to characterize dynamic geometry of the mitral valve (MV) in patients with MV disease. The aims of this study are: 1) to obtain 3D CT measurements of the mitral annulus throughout the cardiac cycle using a prototype mitral evaluation tool, and 2) to compare these measurements among patients with primary mitral regurgitation (PMR), functional (secondary) MR (FMR), and control patients without MR.

METHOD AND MATERIALS

Patients were retrospectively identified who underwent ECG-gated cardiac CT using a dual-source scanner (SOMATOM Definition, Siemens Healthcare). Multiphasic CT data was loaded into our prototype software. Multiple anatomical parameters were recorded in 3D space throughout the cardiac cycle (0-95%, at 5% increments), and included: annular circumference, planar surface area (PSA), anterior-posterior (A-P) or inter-commissural diameter, anterolateral-posteromedial (AL-PM) or septo-lateral diameter, and annular ellipticity. Comparisons were made among the three groups, with p<0.01 considered statistically significant.

RESULTS

A total of 145 subjects (age: 63.5±14.0 years, 64% males) were included in this study: 50 control, 50 with PMR, and 45 with FMR.

Mitral annular dimensions were significantly higher in the PMR group, followed by FMR and control groups, with circumference (144±11 vs. 131±14 vs. 117±8mm), PSA (1533±247 vs. 1229±269 vs. 1005±142mm2), A-P diameter (38±4 vs. 35±5 vs. 32±2mm), and AL-PM diameter (47±4 vs 41±4 vs. 39±3mm) (all p<0.001). Notably, different patterns were observed among the three groups regarding the change in annular dimensions across cardiac phases, with FMR maintaining relatively similar size while control and PMR both had substantial size changes, but with maximal and minimal sizes at different cardiac phases. However, no statistically significant difference was demonstrated for annular ellipticity among control versus pathological groups (p>0.01).

CONCLUSION

Multiphase cardiac CT affords assessment of mitral annular dynamicity in response to various types of MV disease. The dramatic variability in annular dimensions across the cardiac cycle demonstrates the significance of obtaining multiphasic 3D measurements.

CLINICAL RELEVANCE/APPLICATION

Multiphase ECG-gated cardiac CT offers dynamic, pre-procedural evaluation of complex 3D mitral valve geometry for catheter-guided prostheses in patients with various types of mitral valve disease.

SSK04-04 Differentiation of Pannus From Other Prosthetic Valve Abnormalities Using Computed Tomography Texture Analysis

PURPOSE

The purpose of this study was to determine whether quantitative computed tomography (CT) texture analysis features can differentiate the cause of prosthetic valve obstruction (PVO) in patients who had undergone prosthetic valve replacement.

METHOD AND MATERIALS

We retrospectively included 46 subprosthetic masses in 39 patients who were clinically suspected prosthetic valve dysfunction and underwent cardiac CT scan from March 2010 to December 2017. The cause of PVO was assessed by redo-surgery and follow-up imaging findings as standard reference, and classified as pannus, thrombus or vegetation. CT texture analysis was performed with drawing region-of-interests of subprosthetic mass using an in-house texture analysis software and features such as first-order statistics, size and volume, and gray-level co-occurrence matrix (GLCM) features were extracted. Features on texture analysis were compared between two groups (pannus vs. thrombus or vegetation) using Mann-Whitney U test. Logistic regression analysis was performed to investigate association between quantitative CT features and pannus formation.

RESULTS

Of 46 subprosthetic masses, there were 19 cases with pannus, 14 cases with thrombus, and 13 cases with vegetation. Patients with pannus tended to be female, and had higher mean and standard deviation of CT attenuation, percentile value of the cumulative histogram (Perc25, 50, 75, 90, 95), and GLCM features (moments and contrast), and smaller volume, with statistical significance (P<0.05).On multivariate logistic regression analysis, mean CT attenuation (OR: 5.71; 95% CI: 0.48, 68.43; p=0.1691), volume (OR: 5.52; 95% CI: 0.88, 34.59; p=0.068), GLCM moments and GLCM contrast (OR: 6.00; 95% CI: 0.72, 50.40; p=0.0987 and OR: 12.07; 95% CI: 1.31, 110.90; p=0.0277) of subprosthetic mass were significantly associated with pannus.

CONCLUSION

Quantitative features on CT texture analysis may help differentiating pannus from thrombus or vegetation in patients with suspected PVO.

CLINICAL RELEVANCE/APPLICATION

Quantitative CT texture analysis can differentiate pannus from other causes of prosthetic valve obstruction and may diminish the subjectivity of visual analysis.

SSK04-05 CT Virtual Endoscopic Findings of Bicuspid Aortic Valve in Patients with Severe Aortic Stenosis: Comparison with Surgical Diagnosis

Wednesday, Nov. 28 11:10AM - 11:20AM Room: S103AB

PURPOSE

CT has been known to have high diagnostic accuracy for bicuspid aortic valve (BAV). However, CT findings of BAV remain unclear,

CT has been known to have high diagnostic accuracy for bicuspid aortic valve (BAV). However, CT findings of BAV remain unclear. The aim of our study was to evaluate diagnostic characteristics of CT findings for BAV compared with surgical diagnosis as the reference standard.

METHOD AND MATERIALS

This retrospective study included 112 consecutive patients with severe aortic stenosis who underwent preoperative cardiac CT, followed by surgical aortic valve replacement (57% woman, mean age, 70 years [range, 27-92]). All CT images were acquired using retrospective ECG-gated helical scan, from the aortic arch to the heart. Optimal stationary systolic and diastolic phase images were reconstructed at the slice thickness of 0.5 mm, and surgical-view virtual endoscopic images were reconstructed on a workstation. CT findings included shape of orifice (oval or the letter 'Y') and the number of leaflet (2 or 3) on systolic images, and balance of leaflet size (central angle of >= 150¬° or 120-149° in the largest leaflet) and the number of commissure (2 or 3) on diastolic images. For each CT findings, oval orifice, 2 leaflets, central angle of >= 150° or 2 commissures were defined as BAV.

RESULTS

BAV was surgically found in 37% (41/112) of patients. Accuracy, sensitivity, specificity and area under the curve (AUC) (95% confidence interval) for the detection of BAV were as follows; number of leaflets, 0.86 (0.80-0.87), 0.98 (0.91-1.00), 0.79 (0.69-0.83) and 0.88 (0.82-0.93); orifice shape, 0.93 (0.87-0.96), 0.93 (0.82-1.00) 0.93 (0.87-0.99) and 0.93 (0.86-0.96); central angle, 0.92 (0.86-0.95), 0.76 (0.59-0.88), 0.98 (0.95-1.00) and 0.87 (0.79-0.93); and number of commissures, 0.87 (0.81-0.87), 0.63 (0.46-0.78), 1.00 (1.00-1.00) and 0.82 (0.73-0.88), respectively. Although there was no difference in accuracy (p = 0.147 by Cochran's Q test), sensitivity of the number of commissure or specificity of number of leaflet were the lowest among the CT findings (adjusted $p < 0.05$ for all by post-hoc Dunn's test with Bonferroni correction, respectively). AUC of number of commissure was lower than orifice shape and central angle ($p < 0.05$ for both by DeLong's test).

CONCLUSION

Although CT findings have high accuracy for detection of BAV, number of commissure showed lower sensitivity and AUC, and number of leaflet showed lower specificity.

CLINICAL RELEVANCE/APPLICATION

Knowledge of morphological CT characteristics of BAV may help diagnosis in patients with severe aortic valve stenosis.

SSK04-06 3D Printing of the Aortic Annulus Based on Cardiovascular Computed Tomography: Preliminary Experience in Pre-Procedural Planning for Aortic Valve Sizing

PURPOSE

to determine reliability and reproducibility of measurements of aortic annulus in 3D models printed from cardiovascular computed tomography (CCT) images.

METHOD AND MATERIALS

Retrospective study on the records of 20 patients who underwent aortic valve replacement (AVR) with pre-surgery annulus assessment by CCT and intra-operative sizing by Hegar dilators (IOS). 3D models were fabricated by fused deposition modelling of thermoplastic polyurethane filaments. For each patient, two 3D models were independently segmented, modelled and printed by two blinded "manufacturers": a radiologist and a radiology technician. Two blinded cardiac surgeons performed the annulus diameter measurements by Hegar dilators on the two sets of models. Matched data from different measurements were analyzed with Wilcoxon test, Bland-Altmann plot and within-subject ANOVA.

RESULTS

No significant differences were found among the measurements made by each cardiac surgeon on the same 3D model (p=0.48) or on the 3D models printed by different manufacturers (p=0.25); also, no intraobserver variability (p=0.46). The annulus diameter measured on 3D models showed good agreement with the reference CCT measurement (p=0.68) and IOH sizing (p=0.11). Time and cost per model were: model creation 10-15 min; printing time 60 min; post-processing 5min; material cost 1 euro.

CONCLUSION

3D printing of aortic annulus can offer reliable, not expensive patient-specific information to be used in the pre-operative planning of AVR or TAVI.

CLINICAL RELEVANCE/APPLICATION

3D models of aortic annulus printed from CCT may offer a reliable, not expensive, patient-specific pre-operative planning opportunity: they provide the final user with a unique interactive platform for both visual and tactile experiences, which are critical

for simulation of the procedure, but are not available in imaging data per se.

SSK04-07 Improving the Diagnostic Performance of 18F-FDG PET/CT in Prosthetic Heart Valve Endocarditis

PURPOSE

18F-Fluorodeoxyglucose (FDG) Positron-Emission Tomography/Computed Tomography (PET/CT) was recently introduced as a new tool for the diagnosis of prosthetic heart valve (PV) endocarditis (PVE). Previous studies reporting a modest diagnostic accuracy may have been hampered by unstandardized image acquisition and assessment, as well as several confounders. The aim of this study was to improve the diagnostic performance of FDG PET/CT in patients suspected of PVE by identifying and eliminating possible confounders, using both visual and standardized quantitative assessments.

METHOD AND MATERIALS

In this multicentre study, 160 patients with a PV who underwent FDG PET/CT for suspicion of PVE, as well as 77 patients with a PV who underwent FDG PET/CT for other indications (negative control group), were included. Their scans were reassessed by two independent observers blinded to all clinical data, both visually and quantitatively on EARL reconstructions. Confounders were identified using a binomial regression model, and subsequently eliminated.

RESULTS

Visual assessment of FDG PET/CT had a sensitivity/specificity/PPV/NPV for PVE of 74%/91%/89%/78%, respectively. Low inflammatory activity (CRP <40mg/L) at the time of imaging and use of surgical adhesives during PV implantation were significant confounders, while recent valve implantation was not. After elimination of significant confounders, diagnostic performance values of the visual assessment increased to 91%/95%/95%/91%. As a semi-quantitative measure of FDG uptake, an EARL-standardized SUVratio of >=2.0 was a 100% sensitive and 91% specific predictor of PVE.

CONCLUSION

Both visual and quantitative assessment of FDG PET/CT have a high diagnostic accuracy in patients suspected of PVE. FDG PET/CT should be implemented early in the diagnostic work-up to prevent negative confounding effects of low inflammatory activity (e.g. due to prolonged antibiotic therapy). As a quantitative measure of FDG uptake, an EARL-standardized SUVratio of >=2.0 is a 14 100% sensitive and 91% specific predictor of PVE. Recent valve implantation was not a significant predictor of false positive interpretations, but surgical adhesives used during implantation were.

CLINICAL RELEVANCE/APPLICATION

FDG PET/CT should be implemented early in the diagnostic work-up to prevent negative confounding effects of low inflammatory activity.

SSK04-08 Aortic Regurgitation in Hypertrophic Cardiomyopathy: A Cardiac Magnetic Resonance Study

PURPOSE

We sought to investigate the prevalence, mechanism and risk factors of AR in patients with HCM by cardiac magnetic resonance(CMR).

METHOD AND MATERIALS

This is an retrospective study of 105 consecutive patients (49±16 years, 70% male) with HCM who underwent CMR between April to November, 2017. Cardiac morphological, functional paremeters and AR were evaluated by multi-plane cine images and velocity-encoded phase contrast images.Patients were divided into 2 groups by AR. The clinical and CMR characteristics were compared between the 2 groups, and predictors of AR assessed on multivariable logistic regression analysis.

RESULTS

AR was identified in 38 (36%) HCM patients including 25 (66%) with left ventricle outflow tract obstruction (LVOTO). AR was also more prevalent in obstruction group than that in non-obstruction group (52% vs. 23%, *p*=0.002). Patients with AR showed older age (58± 11 vs. 45±16 years, *P*<0.001), the higher prevalence of hypertension, mitral regurgitation (MR) and aortic valve thickening (55% vs. 33%, *P*=0.03; 90% vs.61%, *P*=0.006 and 40% vs. 9%, *P*<0.001, respectively). The distance of interventricular septum that protruded into the LVOT(D1), anterior mitral leaflet (AML) and left atrial diameter were greater and LVOT effective width (D3) were shorter in patients with AR than without it (13.5± 4.4 vs.10.6±4.0 mm, *P*=0.001; 25.5± 3.6 vs. 23.5±4.1mm, *P*=0.013 and 43.6± 8.6 vs. 39.1± 8.4mm, *P*=0.01; 10.2±5.3 vs. 13.7±5.9mm, *P*=0.003, respectively). On multivariable logistic regression analysis, the independent risk factors of AR were LVOTO and age.

CONCLUSION

This study has demonstrated that AR is not an uncommon consequence secondary to HCM. Age and LVOTO are the most probably risk factors of this pathophysiology consequence.

CLINICAL RELEVANCE/APPLICATION

(dealing with CMR) 'AR is a quite common comorbidity of HCM especially in patients with LVOTO . An earlier and better control of blood pressure and relieving LVOTO are required as early as possible to delay the progress of aortic valvular degeneration.'

SSK04-09 T1 Mapping as a Predictor for Persisting Valvular Cardiomyopathy in Patients with Chronic Aortic Regurgitation After Aortic Valve Repair

PURPOSE

Left ventricular (LV) dysfunction is associated with poor prognosis in patients presenting with chronic aortic regurgitation. Unfortunately, LV-dysfunction often persists even after successful aortic valve (AV) repair. We aimed to evaluate the value of native T1 mapping by cardiac MRI as a predictor of valvular cardiomyopathy in patients with severe aortic regurgitation.

METHOD AND MATERIALS

31 consecutive patients (mean age 49.5±11.5 years, 52% men) with severe bicuspid (n=18) or tricuspid (n=13) aortic valve regurgitation and without previous history of coronary artery disease underwent 1.5 Tesla cardiac MR imaging. Native T1 mapping was performed using a modified Look-Locker inversion-recovery (MOLLI) sequence for quantification of diffuse interstitial myocardial fibrosis prior to AV repair and correlated with echocardiographic LV parameters before and after surgery.

RESULTS

Mean native T1 relaxation time of myocardium was 1025±44 ms (range: 898-1109 ms). There was no significant correlation between native T1 and preoperative LVEF (r=-0.1, p=0.6), LVEDD (r=-0.2, p=0.4), LVESD (r=-0.03, p=0.9), LVEDV (r=-0.02, p=0.9) and regurgitation fraction (r=-0.17, p=0.6). Fourteen patients (45%) had a postoperative decrease in LVEF more than 10% as compared to preoperative LVEF values. These fourteen patients showed significantly longer preoperative native T1 as compared to native T1 of patients with preserved postoperative LVEF (1056 ± 32 ms vs. 1019 ± 40 ms, p=0.03).

CONCLUSION

Native T1 mapping might be a promising predictor of postoperative LVEF decrease after AV repair for chronic severe aortic regurgitation.

CLINICAL RELEVANCE/APPLICATION

T1 mapping before aortic valve repair may guide and optimize aortic valve repair surgery in the future.

PURPOSE

The low dose CT (LDCT) screening criteria used in National Lung Screening Trial (NLST) has a 26.6% false positive rate at baseline. Even when updated more stringent Lung RADS criteria was retrospectively applied to the NLST data, the false positive rate remained at 12.8%. Deep learning, a form of artificial intelligence, has the potential to improve risk stratification of pulmonary nodules. The purpose of this study is compare the performance of deep learning vs. radiologists in the risk stratification of pulmonary nodules.

METHOD AND MATERIALS

264 patients with one solid nodule reported in NLST database up to 20mm (mean±standard deviation: 7.5±3.4mm) in size (223 benign, 41 malignant) were retrospectively selected from the NLST baseline LDCT (T0). All malignant nodules were confirmed pathologically and benign nodules were diagnosed based on pathology or clinical follow-up by NLST investigators. The nodules were semi-automatically segmented using our in-house software. 3D deep convolutional networks (CNN) was used for the deep learning classification of malignancy based on 64x64x64 input patch bounding intramodular and perinodular areas. 4-fold cross-validation was performed. Data augmentation by scaling and rotating was used to increase the number of training dataset. Two radiologists who were blinded to the diagnosis reviewed the cases independently and scored the nodules based on Lung RADS criteria. Scores 1 and 2 were considered negative and scores >= 3 were considered positive.

RESULTS

The selected cohort was 62.0±5.1 year-old-patients at T0 (150 male and 114 female). The average accuracy, sensitivity, and specificity of the review of radiologists were 0.67, 0.73, and 0.67, respectively. 4-fold cross validation result of deep learning was 0.88, 0.90, and 0.88 in the same terms of accuracy, sensitivity, and specificity. Especially, the false positive rate showed significant improvement from 0.33 to 0.12, which represents to reduce false positive cases from 73 to 27, using CNN.

CONCLUSION

Deep learning achieved improved sensitivity, specificity, and accuracy in risk stratification of pulmonary nodules compared with radiologists.

CLINICAL RELEVANCE/APPLICATION

Deep learning can improve the accuracy in risk stratification of pulmonary nodules compared with radiologists. This has the potential of achieving earlier cancer detection and reducing unnecessary work up in the lung screening population.

PURPOSE

To investigate the diagnostic performance of a deep learning method with a convolutional neural network (CNN) for the differentiation of pathologic grades in lung adenocarcinomas (ADs) manifesting as solitary lung nodules.

METHOD AND MATERIALS

This clinical retrospective study comprised preoperative CT image sets of lung ADs pathologically confirmed to be one of three grades (grade A, patterns with low metastatic potential [AIS, MIA, and lepidic-predominant]; grade B, patterns with intermediate metastatic potential [acinar and papillary]; and grade C, patterns with high metastatic potential [solid and micropapillary]). Supervised training was performed using 26,321 CT images (2390 sets) obtained between 2014 and 2016 (a total of 1066 image sets; 278, 718, and 70 nodules for grades A, B, and C, respectively; 609 enhanced and 457 non-enhanced). Image sets were augmented (rotated, parallel-shifted, strongly enlarged, and horizontal flipped images were generated from the original images) by a factor of 4 in images from grade A tumors and by a factor of 8 from grade C tumors. A CNN composed of 151 convolutional, two maximum pooling, and one fully connected layers was tested using independent 1268 image sets (762 enhanced and 506 non-enhanced) obtained between 2007 and 2013 (578 men and 690 women; mean age, 62.7 years ± 10.1; mean mass size, 23.5 mm ± 14.4; 400, 709, and 159 lung ADs of grades A, B, and C, respectively). Accuracy in categorizing lung ADs using the CNN model and the area under the ROC curve (AUC) for differentiating grades A vs. B+C, grade A vs. B, grade A vs. C, and grade B vs. C were calculated.

RESULTS

For the differentiation of grades A vs. B+C, diagnostic accuracy was 79.1% and AUC was 0.77 in the test data. For differentiating grades A vs. B, A vs. C, and B vs. C, diagnostic accuracies were 73.4%, 78.8%, 70.1% and AUCs were 0.77, 0.91, and 0.62, respectively.

CONCLUSION

Deep learning with CNN demonstrated high diagnostic performance in differentiating the pathologic grade of lung ADs.

CLINICAL RELEVANCE/APPLICATION

The CNN model can be useful in differentiating the pathologic grade of lung ADs, however, further study is warranted to correlate patients' prognoses with the output of CNN.

SSK05-04 Deep Machine Learning for Automatic Analysis of Chest X-Rays: Effect of Clinically Relevant Pathology Class Label Definition

Wednesday, Nov. 28 11:00AM - 11:10AM Room: N227B

Participants
Anas Z. Abidin, MS, Rochester, NY (*Presenter*) Nothing to Disclose
Adora M. D'Souza, MSc, Rochester, NY (*Abstract Co-Author*) Nothing to Disclose
Axel Wismueller, MD, PhD, Rochester, NY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To quantitatively analyze the effect of radiologically relevant pathology class label definition on deep machine learning results for automatic analysis of chest x-rays.

METHOD AND MATERIALS

With >100,000 frontal-view chest radiographs, the ChestX-ray14 data (Wang et al, 2017) is currently the largest publicly available annotated dataset for automatic chest x-ray analysis. Annotations consist of one or more of 14 thoracic pathology labels, e.g. Consolidation (C), Infiltration (I), Pneumonia (P) and 11 others. As radiologists cannot distinguish between C, I and P based on imaging findings alone, the stratification of these 'Opacity' entities into separate classes suggests a non-existent crispness of reported pathology class labels. To circumvent this key limitation of the ChestX-ray14 dataset and to investigate its effect on machine learning performance, we resampled data belonging to the 3 'Opacity' and 'No findings' classes, resulting in a 2-class classification problem with 63,000 chest x-rays. Images were resized to 10242 without preserving aspect ratio. Ensuring strict training/test (80%/20%) data separation, we fine-tuned a pre-trained ResNet-34 convolutional neural network with batch normalization, cross-entropy loss function, and last layer sigmoid activation. We also performed classification for all 14 individual pathology labels using the full dataset. Diagnostic accuracy was quantified using Area Under the receiver operating characteristics

Curve (AUC).

RESULTS

For 'Opacity/No Findings' classification, we obtained AUC=0.78. This is close to the best performance obtained for original labels I, C, P with AUCs of 0.72, 0.81, 0.73, respectively. For the remaining 11 class labels, AUCs were comparable to, and for some labels, slightly better than the best published results of current state-of-the art methods (Rajpurkar et al 2017).

CONCLUSION

Our results suggest that radiologically relevant pathology label definition is important for training deep machine learning systems for automatic chest x-ray analysis, as it can influence their performance. Merging visually indistinguishable pathology classes can address a key limitation of the ChestX-ray14 data by alleviating the effect of 'structured noise'.

CLINICAL RELEVANCE/APPLICATION

It is critical that the datasets being used for training artificial intelligence recapitulate the characteristics of datasets encountered in a radiology setting as closely as possible.

SSK05-05 Evaluating the Use of a Deep Learning Algorithm for Radiology Quality Assurance in Out-Patient Chest X-Ray Reporting

Wednesday, Nov. 28 11:10AM - 11:20AM Room: N227B

drsahuamit@gmail.com

PURPOSE

To evaluate the accuracy of a deep learning algorithm - 1. To assist with screening of chest X-rays in the wellness check/primary care setting with predominantly normal X-rays 2. To help optimize the quality assurance (QA) process by selecting X-rays for review

METHOD AND MATERIALS

For this retrospective study, we used 3945 de-identified chest X-rays with the accompanying radiologist reports, randomly selected from the natural distribution of scans from adult patients attending OPD for a wellness check at 5 urban centers. Language processing algorithms were used to extract an initial ground truth of either 'normal' or 'abnormal' from the report impressions. A commercial deep learning-based chest X-ray screening system was then evaluated versus this ground truth. X-rays with a discordance between the original radiology report and the algorithm output were re-read by a panel of 3 radiologists. The majority opinion of the 3 radiologists was used as a new ground truth, to evaluate accuracy on this discordant set.

RESULTS

3274 of 3945 (82.9%) X-rays were normal, based on the original radiology report. Algorithm accuracy on the original dataset was 80%, with an AUC of 0.8, sensitivity of 0.63 and specificity of 0.83 on the detection of abnormal X-rays. Of the 789 discordant X-rays, 405were read by the panel of 3 radiologists. On this discordant dataset, the 3 radiologist-consensus agreed with the algorithm results in 64.9% of the cases, and with the original radiology report in the remaining 35.1%.

CONCLUSION

Among the discordant scans, the consensus ground truth was closer to the algorithm results than to the original report. Deep learning algorithms can effectively select chest X-rays for review during radiology quality control

CLINICAL RELEVANCE/APPLICATION

Artificial intelligence algorithms can be used for automated selection of chest X-rays for review during the radiology QA process, potentially increasing its effectiveness.

SSK05-06 Performance Validation of a Deep Learning-Based Automatic Detection Algorithm for Major Thoracic Abnormalities on Chest Radiographs

PURPOSE

To evaluate the performance of a deep learning-based automatic detection (DLAD) algorithm for major thoracic abnormalities

To evaluate the performance of a deep learning-based automatic detection (DLAD) algorithm for major thoracic abnormalities including malignant pulmonary nodules/masses, tuberculosis, pneumonia, and pneumothorax on chest radiographs (CRs) in comparison with physicians.

METHOD AND MATERIALS

DLAD was developed using a 27-layer deep convolutional neural network. External validation of its diagnostic performance was conducted using 2 separate datasets from 2 institutions (normal: abnormal = 97:103 and 100:84). For comparison with physicians, an observer performance test was conducted using 1 of the datasets including 15 physicians (5 non-radiology physicians, 5 board-certified radiologists, 5 thoracic radiologists). All physicians reviewed each CR twice, without and with DLAD, and determined the presence of clinically significant thoracic abnormalities on a 5-point scale. Performance measurements were done using area under the receiver operating characteristic (ROC) curves for image-wise classification and area under the alternative free-response ROC curves for lesion-wise localization.

RESULTS

Image-wise classification performances of DLAD for abnormal CRs were 0.983 and 0.993 and lesion-wise localization performances were 0.974 and 0.985 on the two external validation datasets. Without DLAD, average classification performances of non-radiology physicians, board-certified radiologists, and thoracic radiologists were 0.813, 0.896, and 0.932, and average localization performances were 0.781, 0.870, and 0.907, respectively. DLAD demonstrated significantly higher performance in image-wise classification and lesion-wise localization compared with all reader groups (all *P*s <0.05). With DLAD, physicians' diagnostic performances were significantly improved in classification (0.904, 0.939, 0.958; all Ps <0.05) and localization (0.873, 0.919, 0.938; all *P*s <0.05) in all reader groups.

CONCLUSION

DLAD demonstrated excellent performance in image-wise classification and lesion-wise localization on CRs with major thoracic abnormalities, outperforming physicians, and enhancing the physician's diagnostic performance when used as a second reader.

CLINICAL RELEVANCE/APPLICATION

Our DLAD algorithm can accurately classify abnormal CRs and localize abnormal findings, and has the potential to improve diagnostic accuracy, patients' safety, and clinical workflow efficacy.

SSK05-07 Deep Learning-Based Automatic Detection Algorithm for the Detection of Major Thoracic Abnormalities on Chest Radiographs

sgpark@lunit.io

PURPOSE

To develop a deep learning-based automatic detection (DLAD) algorithm for major thoracic abnormalities including nodule/mass, tuberculosis (TB), pneumonia and pneumothorax on chest radiographs (CRs) using a large-scale CR dataset and evaluate its diagnostic performance.

METHOD AND MATERIALS

We collected a total of 89,832 CRs comprising 54,221 normal CRs and 35,641 abnormal CRs with major thoracic abnormalities including malignant pulmonary nodules/masses (n=13,925), pulmonary TB (n=6,798), pneumonia (n=6,903) and pneumothorax (n=8,015). Thereafter, all CRs were randomly split into three datasets; training dataset (n=84,072; 53,393 normal and 30,679 abnormal CRs), validation dataset (n=750; 300 normal and 450 abnormal CRs), and test dataset (n=750; 300 normal and 450 abnormal CRs). DLAD was designed using deep convolutional network consisting of 27 layers and 12 residual connections, and trained with 71,376 label-only CRs and 12,696 annotated CRs for which 15 thoracic radiologists marked the locations of the individual abnormalities. Diagnostic performance of the DLAD was investigated using receiver-operating characteristic (ROC) curve analysis for per-CR classification performance and jackknife alternative free-response receiver-operating characteristic (JAFROC) curve analysis for per-lesion detection performance. All CRs in the validation and test datasets were annotated by 5 out of 15 thoracic radiologists, and the final determination of the location of each abnormality was made by majority decision.

RESULTS

In the test dataset, DLAD showed an area under the ROC curve (AUC) of 0.9811 for per-CR classification performance and an area under the JAFROC curve of 0.9656 for per-lesion detection performance. The AUCs and JAFROCs of each disease category were 0.9674 and 0.9494 for malignant pulmonary nodule/mass, 0.9902 and 0.9742 for tuberculosis, 0.9854 and 0.9740 for pneumonia, and 0.9937 and 0.9800 for pneumothorax, respectively.

CONCLUSION

Our deep learning-based automatic detection algorithm demonstrated excellent, cutting-edge performances both in terms of differentiating normal and abnormal CRs and localizing individual abnormalities on CRs.

CLINICAL RELEVANCE/APPLICATION

DLAD can augment the diagnostic performance of radiologists both in terms of image-wise diagnosis and lesion-wise detection, thereby improving diagnostic accuracy, patients' safety, and work-flow efficacy.

SSK05-08 Participants

"Change" versus "No-Change": Can Machine Learning Driven Algorithm Detect Stability or Change in Chest Radiographs?

PURPOSE

Chest radiograph is the most commonly performed imaging; changes, or lack thereof, of radiographic findings have tremendous implications on patient care. We compared accuracy of machine learning (ML) algorithm (Qure AI) and thoracic radiologists for assessing stability or change in findings over serial chest radiographs.

METHOD AND MATERIALS

We parsed the publicly available, de-identified, frontal-view chest radiographs from the NIH to identify 300 baseline and follow-up radiographs from 150 adult patients both with and without change in radiographic findings. Two thoracic radiologists reviewed all 300 radiographs to establish ground truth for radiographic findings [such as pleural effusions (EF), lung opacities (LO), hilar prominence (HP), and cardiomegaly (CM)]. All radiographs were processed with Qure AI ML to generate prediction scores and heat maps for each finding. Then, two different thoracic (test R1 and R2) radiologists independently recorded their findings, unaware of the ground truth and ML findings. Data were analyzed to determine accuracy and area under curve with free-choice receiver operating characteristics (FROC) analyses.

RESULTS

Respective percentage changes in findings on follow-up radiographs for EF, CM, HP and LO were 15% (21/138), 9% (13/150) , 5% (8/150), 25 % (33/132) for ground truth; 20%(28/138), 13%(20/150), 12% (18/150), 27% (36/132) for R1; 19%(26/138), 7% (11/150), 4.7%(7/150), 25% (33/132) for R2; and 25%(34/138), 23% (34/150), 23% (35/150), 40% (53/132) for ML. The AUC of ML algorithm for detecting lack of change in findings were 0.867 (EF), 0.904 (C), 0.872 (HP), 0.742 (LO). Accuracy of ML for detecting change in radiographic findings was also high with corresponding AUC of 0.804 (EF), 0.923 (C), 0.839 (HP), 0.758 (LO). Although both test radiologists had AUC similar to ML for stable radiographic findings, their AUC [0.867-0.878 (EF), 0.815-0.904 (CM), 0.635-0.872 (HP), 0.742-0.854 (LO) for change in findings were lower compared to corresponding AUC for ML.

CONCLUSION

ML algorithm can accurately predict stability and change in radiographic findings on follow up radiographs. Its accuracy varies across different types of findings, and is highest for cardiomegaly and lowest for lung opacities.

CLINICAL RELEVANCE/APPLICATION

ML can enable stratification of chest radiographs on basis of change or stability of findings, thus expediting interpretation of radiographs with important changes.

PURPOSE

Assess the efficacy of deep learning in determining endotracheal tube (ETT) position on chest radiographs.

METHOD AND MATERIALS

23,079 de-identified frontal chest radiographs with an ETT were split into 12 categories, which included bronchial insertion, and distance from the carina at 1.0cm intervals (e.g. 0.0-0.9cm, 1.0-1.9cm...) and lastly >=10cm. Ground truth ETT position was determined by two board certified radiologists (original author and a second radiologist for QA confirmation). Images were split into

training (80%, 18467 images), validation (10%, 2306 images), and test (10%, 2306 images). The ETT was re-measured on 100 random images from the test data to assess inter-observer variability. The pretrained Inception V3 convolutional neural network was utilized to a) predict ETT distance from the carina in cm and b) categorize images as low ETT (< 2cm of carina), satisfactory (2-7cm above carina), or high (>= 7cm above carina). Image normalization and auto-cropping about the carina was performed prior to model training. Real-time data augmentation was employed, and an ensemble of 10 Inception V3 models was used in the final classification. Receiver operating characteristic (ROC), area-under-the-curves (AUC), sensitivity and specificity on test data were used to assess the models.

RESULTS

The predicted ETT distance from carina had a mean difference of 0.79cm (±0.56) from the ground truth, and the two radiologists had a mean difference of 0.44cm (±0.44). On the test data, the AUC was 0.97 (95%CI: 0.96-0.98) for differentiating ETT<2cm from carina from all others. The AUC was 0.96 (95%CI: 0.95-0.98) for differentiating high ETT>=7cm from all others. 4 bronchial insertions and ETT 0-0.9cm from carina were missed of 385 true positives (sensitivity: 99.0%). There were 86 false positives of 1921 true negative cases (specificity: 95.5%). However, threshold cases near a category were sometimes missed; for example, 43 cases of 1-1.9cm above carina were misclassified as >=2cm above carina, usually as 2-3cm above carina. Similarly, threshold cases of 6-6.9cm were predicted as 7-7.9cm above carina or vice-versa. The sensitivity of the model drops to 87.8% when including these threshold cases as misclassified.

CONCLUSION

Deep learning shows promise in assessing ETT position and predicts postion within 1cm in most cases.

CLINICAL RELEVANCE/APPLICATION

Automatic identification of ETT position may reduce time to identification of critical placement.

PURPOSE

The purpose of this study was to investigate the potential value of dual-energy CT (DECT) in differentiating vascular invasion rectal cancer from non-vascular invasion rectal cancer.

METHOD AND MATERIALS

90 consecutive untreated patients (56 men, 34 women; mean age, 62.95 years) were enrolled and underwent DECT before biopsy. DECT image metrics including iodine (water) concentration (IC) and effective atomic number (eff-Z) were measured. Data were analyzed statistically by the independent-samples t test and were correlated with pathological findings.The receiver operating characteristics (ROC) analysis was also carried to evaluate the efficacy of these parameters for differentiating rectal cancers with or without vascular invasion.

RESULTS

Pathological results showed that there were 41 vascular invasion rectal cancer and 49 non-vascular invasion rectal cancer.The IC values of the vascular invasion rectal cancer in the venous phase were 2.42±0.55mg/ml, significantly higher than that of the non-vascular invasion rectal cancer with 2.13±0.52mg/ml ($P<0.05$). The eff-Z of the vascular invasion rectal cancer in the venous phase was 17.85±3.731, which was also higher than that of the non-vascular invasion rectal cancer with 16.19±3.638 ($P<0.05$). However, there were no significant differences in those parameters in the arterial phase ($P>0.05$). Based on the ROC curves, the optimal cut off value for the IC was 2.25mg/ml which yielded a sensitivity of 70.7% and a specificity of 67.3% for differentiating rectal cancers with or without vascular invasion.

CONCLUSION

It is feasible to differentiate a vascular invasion rectal cancer from the non-vascular invasion rectal cancer using dual energy CT, especially the iodine concentration measurement in the venous phase.

CLINICAL RELEVANCE/APPLICATION

Dual energy CT appears to be an efficient CT technique for a possible method to evaluate vascular or non-vascular invasion of rectal cancer.

SSK06-03 Low Anterior Resection Syndrome (LARS): Imaging Characteristics of Rectal Cancer and Anorectal Anatomy

zx333232@163.com

PURPOSE

To identify risk factors associated with LARS severity based on the imaging characteristics of rectal cancer and anorectal anatomy defined by magnetic resonance imaging (MRI) pre-operation.

METHOD AND MATERIALS

Between August 2016 and August 2017, patients who had pathological-proved rectal cancer and underwent low anterior resection (LAR) were collected in this retrospective study. Patients need to be followed-up at least 9months after operative. All patients were divided into non-major LARS group and major LARS group based on LARS score. The tumor morphological characteristics were measured and recorded as the following: the distance between tumor and anal margin, the distance between tumor and puborectal muscle, the length of tumor involvement, the tumor stage, the lymph nodes stage, and circumferential resection margin. In addition, morphological characteristics of rectal-anal canal were measured and recorded, including anorectal angle (ARA), levato-anal angle (LAA), levator plate angle, thickness of internal anal sphincter, levator plate angle(°), thickness of rectal wall(mm), thickness of obturator internus(mm), thickness of external anal sphincter (mm), thickness of internal anal sphincter(mm), thickness of puborectal muscle(mm), and thickness of illiosacrum muscle(mm). The differences of measurement between non-major and major LARS groups were analyzed by t-test and x2-test.

RESULTS

Thirty-three patients were enrolled in the final cohort including 22 patients (66.7%) with non-major LARS (score 0-20) and 11 patients (33.3%) with major LARS (score 30-42, n=11). The distances of tumor and anal margin and the distance of tumor and puborectal muscle of patients with major LARS was significantly lower than patients with non-major LARS (<= 7cm, P =0.017 and <= 5 cm P=0.009). The LAA and the ARA of patients with major LARS were larger than patient with non-major LARS and significances were seen (>=100°, P=0.049 and >=125°, P=0.025).

CONCLUSION

The lower tumor, larger ARA and LAA was identified as risk factors may be associated with major LARS for patients with rectal cancer after Low Anterior Resection.

CLINICAL RELEVANCE/APPLICATION

Identification of risk factors associated with LARS severity by MRI pre-operation may help surgeons change the strategy of operation to avoid LARS and, therefore, the life quality of patients may be improve after surgery.

SSK06-04 Preoperative Staging for Rectal Cancer: Comparison of Whole Body MR-PET and Standard Protocol

PURPOSE

To measure the concordance of rectal cancer clinical staging between whole body MR-PET including dedicated liver and rectal MRI (WB MR-PET) and the current standard care protocol (chest/abdominopelvic CT and rectal MRI).

METHOD AND MATERIALS

This IRB-approved prospective study enrolled 71 patients (M:F = 43:28, mean age 60.9 years) with newly diagnosed mid to lower rectal cancer. Clinical staging and effective dose were compared between standard protocol and WB MR-PET protocol according to AJCC 7th staging. In addition, incidence of further study recommendation and incidental findings were recorded.

RESULTS

Regarding with the presence of metastasis, two protocols were consistent in 67.6% (48/71), and discordant in 4.2% (3/71). In the remaining 28.2% (20/71), standard protocol did not conclude presence or absence of metastasis or extent of metastasis (IVa or IVb) due to indeterminate lesions in lung, liver, or retroperitoneal lymph nodes. In these patients, standard protocol recommended followings for lesion characterization: chest CT follow up in 20% (4/20), liver MRI in 20% (4/20), PET-CT in 45% (9/20) and liver MRI with chest CT follow up for multiple indeterminate lesions in 15% (3/20). In these 20 patients, WB MR-PET protocol suggested presence or absence of metastasis in 25% (5/20) and 75% (15/20), respectively. Compared with clinical follow-up results within 6 months, 14 of 15 patients with WB MR-PET negative findings did not show metastasis. In 5 patients with WB MR-PET positive

findings, all liver lesions were correctly classified, but one false positive and one false negative cases for lung nodules were observed. There were 13 cases with incidental findings including incidentally detected tonsillar cancer with neck lymph node metastasis (n=1) and incidentally detected Warthin's tumor in the parotid gland (n=1). Effective dose was significantly lower in WB MR-PET than standard protocol (6.18±1.06 mSv vs. 10.70±5.45 mSv, P<0.0001).

CONCLUSION

WB MR-PET protocol showed low discrepancy rate with the standard protocol for metastasis evaluation in patients with rectal cancer and it served as problem-solving modality for indeterminate lesions.

CLINICAL RELEVANCE/APPLICATION

Compared with the standard protocol, WB MR-PET with dedicated rectal and liver MRI may facilitate the staging work-up with less inconvenience in a short period.

SSK06-05 Application of Dynamic Dual-Energy CT Imaging In Colorectal Cancer for Assessing the Correlation Between Blood Perfusion and Iodine Uptake on 320-Row Multidetector CT

Wednesday, Nov. 28 11:10AM - 11:20AM Room: S502AB

m13940431957@163.com

PURPOSE

To evaluate the characteristics of blood perfusion and iodine uptake in colorectal cancer using dynamic dual-energy imaging on 320-row CT.

METHOD AND MATERIALS

29 patients with colonic adenocarcinoma diagnosed by colonoscopy were enrolled. Each patient was scanned for 10 dual-emerge acquisition phases, with 3-second intervals for 1 to 7 phases, 5-second intervals for 8 to 10 phases, and total scanning time was 53s. Iodine map and perfusion map were generated, and iodine uptake peak (IUP), arterial flow (AF, ml/min/100ml), blood volume (BV,ml/100ml) and permeability (ml/min/100ml) of tumor were measured.

RESULTS

The IUP, AF, BV and permeability of tumor were 71.46±2.19, 158.26±80.40, 17.33±17.80, 60.14±20.59, respectively. The IUP of tumor was significantly associated with the AF (r=0.440, P<0.05) and BV (r=0.382, P<0.05) There was no significant correlation between IUP and permeability(P>0.05). The average DLP of dynamic dual-energy CT imaging was 1104 mGy•cm with an effective radiation dose of 16.56 mSv.

CONCLUSION

Dynamic dual-energy CT imaging can generate dynamic iodine map and perfusion map at the same time. The correlations of iodine uptake peak and perfusion parameters AF and BV of colorectal cancer are significant.

CLINICAL RELEVANCE/APPLICATION

Dynamic dual-energy CT imaging of coloractal cancer provides iodine uptake and perfusion data in just one scan. It can be used to evaluate the hemodynamic characteristics of colorectal cancer and provide more diagnostic information for the clinical doctors.

SSK06-06 Predictors of Surgical Outcome, DFS and OS in Mid and Low Rectal Cancer Undergoing Laparoscopic Resection After Neoadjuvant Chemoradiation Therapy: Impact of Pretreatment and Re Staging MRI

PURPOSE

To assess (1) the impact of restaging MRI as a predictor of surgical difficulties and survival and (2) the diagnostic accuracy of re-staging MRI against final pathological assessment.

METHOD AND MATERIALS

Between 1/2010 and 1/2016, patients with histologically proven locally advanced (AJCC stages I to IIIc) rectal cancer of the mid or lower third of the rectum, who underwent MRI including DWI before (pre-treatment MRI) and after neo-adjuvant chemo-radiotherapy (re-staging MRI) followed by either elective laparoscopic anterior resection (LAR) with total mesorectal excision or laparoscopic abdominoperineal (L-APR) resection were included. Pelvimetry was performed on pre-treatment MRI providing transverse, sagittal, angles and surface measures. On pre and post-treatment MRI, T stage, N stage and EMVI status were assessed. On re-staging MRI, the MR tumor regression grade score (mrTRG) was determined. Sensitivity, specificity, PPV and NPV of restaging MRI for mrTRG prediction were assessed. Binary, multimodal, or linear regression analyses were performed to assess predictors of surgical difficulties (i.e., estimated on operative time, blood loss, and conversion rate) and surgical success (i.e., postoperative complications and successful resection rate).

RESULTS

170 patients (mean age 59±13) were included. Tumor volume and tumor height on re-staging MRI were associated respectively with operative time and blood loss. Conversion was predicted by tumor volume, interischial distance and pubic tubercle height. A circumferential resection margin> 2 mm was found as a protector of postoperative complications and unsuccessfull resection. The quality of the surgical resection was found as a predictor of overall and disease-free survival. On re-staging MRI, the PPV of ymrT for ypT0 stage, ypT1/T2 stages, and ypT3/T4 staging was 83%, 55.7% and 68.8% respectively. The PPV of ymrN for ypN0 and ypN+ staging was 87.7% and 62.5% respectively. The sensitivity, specificity, PPV, and NPV of ymrEMVI was respectively 68.4%, 78.8%, 28.8% and 95.2%. The sensitivity and specificity of tumor regression grade (mrTRG) 1 to identify pathologic complete response was 76.9% and 89.3%, respectively, with a PPV of 68.2% and NPV of 92.8%.

CONCLUSION

Pelvimetry and re-staging MRI may be useful to predict surgical difficulties and surgical outcomes.

CLINICAL RELEVANCE/APPLICATION

Pelvimetry and re-staging MRI can predict outcome in rectal cancer.

SSK06-07 The Tram Track Sign and the Railroad to Complete Response after Neoadjuvant Therapy in Rectal Cancer

ines.santiago@neuro.fchampalimaud.org

PURPOSE

To measure the diagnostic performance of the tram track sign for the identification of sustained complete response (SCR) after neoadjuvant therapy on re-staging magnetic resonance (MR) T2-weighted imaging (T2-WI) in patients with locally advanced rectal cancer.

METHOD AND MATERIALS

Institutional review board approval was obtained for this retrospective study and patient informed consent requirement was waived. Fifty-eight consecutive patients with locally advanced rectal cancer who underwent neoadjuvant therapy were enrolled. Two radiologists blindly and independently reviewed restaging pelvic MRs and analyzed 3 features: a distinct morphologic pattern of tumour response - the tram track sign (TTS) -characterized by the presence of 2 hypointense rims at previous tumour location separated by a variable amount of homogeneously intermediate or high signal intensity on T2-WI; the relative proportion of intermediate signal intensity on T2-WI; and the relative proportion of high signal intensity on high b-value diffusion-weighted images (DWI). Endoscopic response grading from the same timepoint was retrieved. Qui-Square test was employed in search for any associations between SCR and TTS, T2-WI, DWI or endoscopy. Interrater agreement of MR parameters was estimated using Cohen´s Kappa statistic (k).

RESULTS

TTS was significantly associated with SCR, with specificity=0.97/0.97, sensitivity=0.52/0.64, PPV=0.93/0.94, NPV=0.73/0.78 and AuROC=0.78/0.83, for observers 1/2, respectively. DWI was significantly associated with SCR for observer 2, with specificity=0.76, sensitivity=0.60, PPV=0.65, NPV=0.71 and AuROC=0.69. No significant differences were found for T2-WI or endoscopy. Interobserver agreement was substantial for TTS (k=0.69), moderate for DWI (k=0.46) and poor for T2-WI (k=0.17).

CONCLUSION

The tram track sign is a specific and reliable tool for the early identification of SCR after neoadjuvant therapy in rectal cancer. Its diagnostic performance exceeds that of endoscopy and conventional T2-WI and DWI assessment.

CLINICAL RELEVANCE/APPLICATION

The tram track sign may outperform standard T2-WI, DWI and endoscopic assessment in the early identification of sustained complete response after neoadjuvant therapy in rectal cancer.

SSK06-08 Diffusion-Weighted MR-Volumetry and High-Resolution MR-Volumetry Association with Lymphovascular Invasion and N-Stages in Resectable Rectal Cancer

Wednesday, Nov. 28 11:40AM - 11:50AM Room: S502AB

lihang111222@126.com

PURPOSE

Purpose: To determine whether diffusion-weighted imaging (DWI)-volumetry and high-resolution T2-weighted imaging (T2WI) MR-volumetry could predict lymphovascular invasion (LVI) and N-stages in resectable rectal cancer.

METHOD AND MATERIALS

Materials & Methods: 50 consecutive patients with rectal cancer who underwent radical surgery in 1-week after DWI and high-resolution T2WI were retrospectively identified. Gross tumor volume (GTV) was evaluated on DWI and high-resolution T2WI. Univariate and multivariate analyses were performed to determine whether GTV could predict LVI and lymph node metastasis (LNM). Mann-Whitney U test was performed to compare GTV among N-stages. Cutoffs of GTV were investigated using area under the receiver operating characteristic curve (AUC) analysis for predicting LVI and N-stages.

RESULTS

Results: DWI-GTV and T2WI-GTV increased with LVI (r=0.750 and 0.710,P<0.0001,respectively) and increasing of N stage(r=0.780 and 0.755,P<0.0001,respectively). Univariate analysis showed DWI-GTV and T2WI-GTV could predict LVI (P<0.0001). Multivariate analyses indicated only DWI-GTV as an independent risk factor of LVI (P=0.005, odds ratio=1.207) and LNM (P=0.005, odds ratio=1.420). The Mann-Whitney U test showed DWI-GTV and T2WI-GTV could distinguish N0 from N1, N0 from N1-2, N0-1 from N2 (P<0.0001). DWI-GTV could predict LVI (cutoff,11.05cm3;AUC,0.899), and distinguish N0 from N1 (cutoff,10.86cm3;AUC,0.865), N0 from N1-2 (cutoff,10.46cm3;AUC,0.934), N0-1 from N2 (cutoff,17.7cm3;AUC,0.932). T2WI-GTV could predict LVI (cutoff,13.74cm3;AUC,0.877), and distinguish N0 from N1 (cutoff,12.25cm3;AUC,0.827), N0 from N1-2 (cutoff,13.36cm3; AUC,0.911), N0-1 from N2 (cutoff,20.43cm3; AUC,0.927).

CONCLUSION

Conclusion: High-resolution T2WI-GTV and DWI-GTV of resectable rectal cancer were correlated well with the LVI and LNM, but the latter is a potentially more promising non-invasive technique that can help predict the preoperative LVI and distinguishing N-stages.

CLINICAL RELEVANCE/APPLICATION

Diffusion-weighted MR-volumetry of resectable rectal cancer are correlated well with the lymphovascular invasion and lymph node metastasis, and is recommended as a potentially more promising non-invasive technique for predicting the preoperative lymphovascular invasion and distinguishing N-stages.

SSK06-09 Comparison of Polyp Surface Tagging Performance of Barium plus Diatrizoate Meglumine/Diatrizoate Sodium Solution versus Barium plus Iohexol during CT Colonography

PURPOSE

The detection of polyps at CT colonography (CTC), especially serrated adenomas, is contingent on polyp surface tagging. The purpose of this study is to investigate differences in surface tagging performance of barium when combined with either diatrizoate meglumine/diatrizoate sodium solution (DM-DS) versus iohexol.

METHOD AND MATERIALS

A retrospective review was conducted of 338 polyps detected at CTC with two different tagging regimens: barium plus either DM-DS or iohexol. The degree of coating of each polyp was graded on a 0-4 scale (no coating to heavy coating) and correlated to polyp histologic subtype and tagging agent. Polyp histology was classified into: hyperplastic, sessile serrated or non-serrated adenoma. Performance of coating scores were analyzed with univariate logistic regression and Wilcoxon rank sum tests.

RESULTS

338 polyps were included, 255 tagged with DM-DS and 83 with iohexol. Across all polyps, coating score of SSA (3±2) was significantly higher than in NSA (1± 3) (p<.0001). However, the coating score was only significantly higher for SSA compared with NSA within the DM-DS group (3±2 versus 1±2) (p<.0001). No statistical difference was seen for the iohexol group (3±1 versus 1±3) (p=.0603). Using all polyps (and in sub-analysis of DM-DS and iohexol groups) there was a statistically significant difference in tagging of SSA (N=70) versus benign HP (N=71) (p < .0001). Of note, there is a significantly higher percentage of serrated adenomas compared with all adenomas (30.8%, 61/198) detected in the DM-DS group compared with iohexol group (15.3%, 9/59)

(p=.0185).

CONCLUSION

CT colonography using both an iodine and barium oral tagging regimen allows for detection of polyps by the presence of surface tagging. We demonstrated that DM-DS demonstrates a significantly higher coating score of serrated adenomas when compared with non-serrated adenomas. Although a similar difference was seen for iohexol, it was not statistically significant. Of concern, there is a significantly higher percentage of serrated adenomas (as compared to all adenomas) detected in the DM-DS group. This may suggest a lower sensitivity for serrated adenomas with iohexol.

CLINICAL RELEVANCE/APPLICATION

Combined with barium, DM-DS results in greater surface tagging of serrated compared with nonserrated adenomas. Although no difference in tagging was seen, Iohexol resulted in lower SSA detection.

Verena.Hofmann@usb.ch

PURPOSE

The aim of this study was to compare parameters of liver fat quantification derived from single source twin beam dual energy computed tomography (deCT) and magnetic resonance imaging (MRI).

METHOD AND MATERIALS

We retrospectively analyzed 50 patients (28 male, 22 female, mean age 65 years) who underwent both abdomino-pelvic twin beam deCT (SOMATOM Definition Edge, Siemens, Germany) and abdominal MRI examinations. Region of interests were drawn on CT and MRI in each liver segment. The fat fraction (FF) and the virtual unenhanced attenuation values (VUE) derived from portal-venous phase deCT were quantified using commercially available software (Syngo.via, Siemens, Germany) and compared to the changes in signal intensity (SI) on in-phase (SIIP) and out-of-phase images (SIOP), as well as the signal intensity on the fat only images (SIF) (DIXON sequence). A p-value less than 0.05 was considered to indicate statistical significance.

RESULTS

456 of 459 liver segments were included in this analysis. 188 segments were classified as steatotic according to MRI. The FF in steatotic segments averaged 13.5±11% compared to 2.2±7.9% in non-steatotic segments ($p<0.001$). The FF was significantly correlated to the VUE attenuation vales ($r=-0.94$), changes in SIIP to SIOP ($r=0.62$), as well as SIF ($r=0.5$) ($p<0.001$). The color coded FF map readily indicated diffuse of focal fatty liver disease.

CONCLUSION

Quantitative analysis of liver fat fraction using single source twin beam dual energy computed tomography shows a strong correlation to the standard imaging parameters of fatty liver disease.

CLINICAL RELEVANCE/APPLICATION

Fatty liver disease should be reported due to increased risk for developing e.g. cirrhosis. Since steatosis can be easily missed on portal venous phase CT, deCT derived liver FF analysis improves the evaluation of liver parenchyma.

SSK07-02 Quantification of Fat in Hepatocellular Carcinoma (HCC) Using Multimaterial Decomposition (MMD) Analysis of Fast-Kilovolt-Peak Switching Dual-Energy CT Data: Comparison with Chemical Shift MR Imaging

Wednesday, Nov. 28 10:40AM - 10:50AM Room: S402AB

PURPOSE

Recent study showed that the multimaterial decomposition (MMD) analysis can accurately quantify hepatic fat in dual-energy CT (DECT) data. However, intratumoral fat quantification in hepatocellular carcinoma (HCC) by the MMD algorithm has not been evaluated yet, although there are some differences in component materials between liver parenchyma and HCC. The purpose of the study was to quantify HCC fat with the MMD algorithm using DECT, comparing with chemical shift MRI.

METHOD AND MATERIALS

Thirty-one consecutive patients having HCC (22 males; 9 females, mean age 66.5 ± 7 years) underwent non-enhanced and four-phases dynamic contrast-enhanced DECT (80 and 140 kVp) and MRI before liver surgery. Fat volume fraction (FVFDECT) images were generated by using the MMD algorithm on DECT data to quantify HCC fat and liver fat. Additionally, fat fraction (FFMRI) were measured for HCC and liver on dual-echo sequence using 1.5 or 3T MRI. The correlation between FVFDECT and FFMRI was evaluated using Pearson's correlation test. Real non-contrast-enhanced FVFDECT were compared with four-phases contrast enhanced FVFDECT to prove the reproducibility of MMD by using one-way ANOVA.

RESULTS

FVFDECT and FFMRI exhibited moderate correlations for HCC in all phases (r = 0.51, 0.47, 0.42, 0.47, 0.45, respectively; all P <0.05), and strong correlations for liver parencyma in all phases (r = 0.68, 0.65, 0.71, 0.72, 0.72, respectively; all P <0.05). Those correlation coefficients were significantly higher in the liver than in HCC for each phase (P = 0.005, 0.004, <0.001, <0.001, <0.001, respectively). FVFDECT did not differ significantly in all comparisons of scan phases regarding HCC fat or liver fat quantification by one-way ANOVA (P = 0.41, 0.81, respectively).

CONCLUSION

The MMD algorithm quantifying intratumoral fat in DECT images is reproducible across scan phases. However, correlation between FVFDECT and FFMRI was significantly lower for HCC than that for liver parenchyma.

CLINICAL RELEVANCE/APPLICATION

The MMD algorithm might eliminate the need for non-contrast CT scan to measure FVF because of its reproducibility, however, it is needed further technological improvement to quantify HCC fat.

SSK07-03 Non-Invasive MR Index for the Detection of Non-Alcoholic Steatohepatitis (NASH) in Patients with Non-Alcoholic Fatty Liver Disease (NAFLD)

PURPOSE

To evaluate feasibility of MRI to predict NASH and to develop non-invasive MR index for the detection of NASH in patients with NAFLD

METHOD AND MATERIALS

This prospective study was approved by our IRB and the written informed consent was obtained from each patient. 47 patients with NAFLD who were scheduled to undergo or underwent US-guided parenchymal liver biopsy within 6 months were included. Biopsy specimens were graded according to SAF scoring system - semi-quantitative score of Steatosis (0-3), Activity [lobular inflammation (0-2)+ballooning (0-2)], and Fibrosis (0-4) - as NASH group (steatosis score>=1, activity score>=2, any fibrosis score) and non-NASH group. All patients underwent gadoxetic acid-enhanced MRI including MR spectroscopy (MRS), MR elastography (MRE), and T1 mapping. The diagnostic performance of MRS, MRE and T1 mapping for grading steatosis, activity, and fibrosis was evaluated by using ROC curve analysis. Non-invasive MR index, combination of liver signal fat fraction (FF), liver stiffness (LS) value, and T1 relaxation time, was developed for the prediction of SAF score using linear regression analysis. R-squared (R2) was obtained by plotting the predicted value against the observed value. The optimal cut-off value of SAF score differentiating NASH group from non-NASH group was determined using ROC curve analysis. Using the cut-off value, the diagnostic performance of MR index for the detection of NASH was evaluated.

RESULTS

20 NASH patients and 27 non-NASH patients were included. Using MRS, MRE, T1 mapping, the mean AUC for grading steatosis, fibrosis, and activity was 0.870, 0.951, and 0.664, respectively. Non-invasive MR index combining FF, LS value, and T1 relaxation time was -3.819 + 0.037 × FF + 1.4 × LS value + 0.004 × T1 relaxation time. R-squared (R2) was 0.67. Cut-off value of SAF score differentiating NASH group from non-NASH group was 6. Using the cut-off value, MR index provided sensitivity of 84.2% and specificity of 82.1% for detecting NASH in patients with NAFLD.

CONCLUSION

Non-invasive MR index combining FF, LS value, and T1 relaxation time have high diagnostic performance for detecting NASH in patients with NAFLD.

CLINICAL RELEVANCE/APPLICATION

Liver biopsy, a current gold standard for differentiating NASH from simple steatosis, has several drawbacks including invasiveness

Liver biopsy, a current gold standard for differentiating NASH from simple steatosis, has several drawbacks including invasiveness, sampling error, and cost. Non-invasive MR index may help detect NASH in patients with NAFLD.

SSK07-04 Association between Hepatic Magnetic Resonance Elastography-Based Mechanical Properties and Histologic Measures in Adults with Nonalcoholic Fatty Liver Disease without Liver Fibrosis

PURPOSE

To investigate the association between hepatic magnetic resonance elastography (MRE)-based mechanical properties and histology in adults with known or suspected nonalcoholic fatty liver disease (NAFLD) with histology-confirmed absence of liver fibrosis.

METHOD AND MATERIALS

This IRB-approved, HIPAA-compliant, cross-sectional secondary analysis of prospective clinical trials included adults who underwent liver biopsy to assess known or suspected NAFLD and had no liver fibrosis histologically. Subjects were included who had undergone 2D, or both 2D and 3D MRE, and hepatic proton density fat fraction (PDFF) imaging at 3T. Mechanical properties included magnitude of the shear modulus ('shear stiffness') (|G*|), and for 3D MRE, also storage modulus (G'), loss modulus (G"), shear attenuation and damping ratio ($\zeta = G''/2G'$). Histologic features were scored (Nonalcoholic Steatohepatitis Clinical Research Network system). The association between mechanical parameters, and steatosis, inflammation, and ballooning was assessed using Wilcoxon-Mann-Whitney tests or Kruskal-Wallis tests. Spearman's correlation analyses were performed to assess association between mechanical parameters and age, BMI, and PDFF. Adjustment for multiple comparisons was not applied as this was an exploratory study.

RESULTS

89 subjects met the inclusion criteria (52 women; mean age 49 yrs; mean body mass index [BMI] 31 kg/m2), 77 of whom also had 3D MRE. |G*| measured by 2D MRE and G' measured by 3D MRE were significantly higher for patients with inflammation grade >=2 vs. grade <=1 (2.58±0.61 vs. 2.27±0.29 kPa, p=0.033 and 0.42±0.12 vs. 0.36±0.11 kPa, p=0.042, respectively). Hepatic G' and G" by 3D MRE and |G*| by both 2D and 3D MRE increased with age; correlation coefficients ranged from 0.25 to 0.31 (all p<0.03). No 2D or 3D hepatic MRE mechanical parameter had a significant association with BMI, MRI-PDFF, steatosis, or ballooning (p>=0.10).

CONCLUSION

In patients with known or suspected NAFLD but with histology-confirmed absence of liver fibrosis, moderate to severe inflammation is associated with elevated hepatic shear stiffness measured by 2D MRE and loss modulus measured by 3D MRE. In this series, increasing age is associated with higher shear stiffness and hepatic storage and loss moduli.

CLINICAL RELEVANCE/APPLICATION

MRE-measured biomarkers show promise for detecting significant inflammation before the onset of fibrosis in NAFLD.

SSK07-05 Long-Term and Short-Term Repeatabilities of Hepatic Proton Density Fat Fraction Measurements across Field Strengths: Human and Phantom Studies

Wednesday, Nov. 28 11:10AM - 11:20AM Room: S402AB

Participants
Hye Jin Kim, MD, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Bohyun Kim, MD, Suwon, Korea, Republic Of (*Presenter*) Research Grant, Bracco Group
Jimi Huh, MD, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

Jai Keun Kim, MD, PhD, Suwonsi, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To assess the long- and short-term repeatabilities of MR-based proton density fat fraction (PDFF) measurements across MR field strengths in nonalcoholic fatty liver disease (NAFLD) subjects and a phantom.

METHOD AND MATERIALS

A phantom consisted of 10 test tubes containing 3-50% of lard underwent MR-PDFF scans on 1.5T (Signa HDxt; GE) and 3.0T (Discovery 750 W; GE) units within a day and a 14-day interval, in addition to MR spectroscopy. For clinical scan, 20 prospectively-enrolled clinically NAFLD patients underwent the same MR-PDFF scans. All subjects were asked to refrain from consuming excessive fatty meal or alcohol during the recess. A commercially available PDFF pulse sequence (IDEAL IQ, GE) was used for all scans. To estimate PDFF, two radiologists independently drew 1 cm2 circular region of interests on each Couinaud segment. The repeatability of PDFF measurements was assessed by within-subject coefficient of variation (wCV). The correlation of PDFF measurements and field strengths was evaluated.

RESULTS

In the phantom, MRS- and PDFF-measured FF showed excellent correlation in both 1.5T and 3.0T (r2=0.906 and 0.927). PDFF-measured FF across field strengths showed strong correlation (r2=0.996) with mean difference of 1.1% and 95% limits of agreement ranging ± 0.1 on Bland-Altman analysis. Within-day and two-week wCVs were 0.3-0.6% and 1.6% for 1.5T, 0.1-0.3% and 2% for 3.0T, 2.9-5.9% and 4.2-4.7% for across field strengths. In human, the mean ± SD of the BMI and PDFF at 3.0T was 27.5 kg/m2 ± 5.2 and 15.6% ± 11.4 (range, 2.72-42.3%). PDFF-measured FF across field strengths showed strong correlation, with r2=0.995 and 0.996 for the same day, and 0.98 and 0.99 for two weeks interval. Within-day and two-week wCVs were 0.7-0.9% and 4.6% for 1.5T, 1.5-2.2% and 4.6% for 3.0 T, and 3.4-3.7% and 5.2-5.5% for across field strengths. Interobserver agreement for pooled PDFF measurement was excellent with intraclass correlation coefficient reaching 0.99.

CONCLUSION

MR-PDFF measured FF is highly reproducible across field strengths, readers, and 2-week interval. Based on the phantom and clinical scans, FF change in proportion of >5% indicates a true change in a longitudinal follow-up across field strengths.

CLINICAL RELEVANCE/APPLICATION

MR-PDFF scan is a reliable method for the longitudinal follow-up of NAFLD patients regardless of MR field strengths. Interval FF change in proportion of >5% indicates a true change across field strengths.

SSK07-06 Prediction of Hepatic Steatosis Using Sonographic Features

PURPOSE

Eight sonographic imaging features have been proposed to assess hepatic steatosis on conventional ultrasound (CUS). However, there is little guidance on applying these features towards a composite assessment. The purpose of this study is to explore the use of decision rules for assessing hepatic steatosis using sonographic features.

METHOD AND MATERIALS

This is a prospective study of adult patients with known or suspected hepatic steatosis. CUS images were acquired using a standardized protocol (Siemens S3000, 6C1HD transducer). Each patient was included twice in the image bank. Eight radiologists independently graded 8 features on ordinal scales (large hepatic vein blurring, main right portal vein blurring, anterior posterior right portal vein blurring, liver-kidney contrast, posterior beam attenuation, diaphragm definition, focal fat sparing, and liver echotexture) and overall impression of steatosis severity. Seven readers were academic faculty with liver ultrasound expertise, and one was a fourth year resident. Intra-reader agreement was computed using repeat exams. Features with highest agreement were selected as predictors for biopsy-based steatosis (dichotomized into grades 0 and 1 vs. grades 2 and 3) using a Classification and Regression Tree (CART) analysis. The classification accuracy of the decision rule was compared to that of the overall impression in predicting steatosis severity.

RESULTS

40 patients (16 male, 24 female; mean age 55 ± 12 years) were included. The features with the highest reader agreement included in the CART regression were large hepatic vein blurring, liver-kidney contrast, posterior beam attenuation, and focal fat sparing. The CART used only large hepatic vein blurring, and achieved 74% accuracy (59% sensitivity, 86% specificity) for grade 2 or 3 steatosis. The radiologists' overall impression achieved 68% accuracy (83% sensitivity, 57% specificity). There was no significant difference in accuracy.

CONCLUSION

Large hepatic vein blurring may be the sonographic feature most predictive of hepatic steatosis. Accuracy was comparable to that of the radiologists' overall impression, and achieved higher specificity at the cost of lower sensitivity.

CLINICAL RELEVANCE/APPLICATION

Large hepatic vein blurring may be the sonographic feature most predictive of histological hepatic steatosis. If validated in future studies, additional emphasis should be placed on this feature during clinical practice.

SSK07-07 Quantification of Steatosis Using an Ultrasound Generated Hepato-Renal Index (HRI)

Wednesday, Nov. 28 11:30AM - 11:40AM Room: S402AB

Participants
Stephen I. Johnson, MD, Jefferson, LA (*Presenter*) Nothing to Disclose
Edward I. Bluth, MD, New Orleans, LA (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

stephen.johnson@ochsner.org

PURPOSE

Hepatorenal index (HRI) has been shown by Marshall et al (AJR Am J Roentgenol 2012; 199:997-1002) to be an effective, noninvasive ultrasound tool to screen patients for the presence of > 5% hepatic steatosis. The aim of this study was to further refine this HRI tool in order to stratify patients according to their degree of liver steatosis (< 5%, between 5%-20%, and > 20% steatosis).

METHOD AND MATERIALS

We carried out a retrospective review of 174 consecutive patients from 2015-2017 who had abdominal ultrasounds and a subsequent random liver biopsy within a month. The HRI was calculated and compared with the percent steatosis as assessed by histology.

RESULTS

HRI of 1.57 corresponded with > 20% steatosis with a sensitivity of 0.92, specificity of 0.83, negative predictive value of 0.96 and positive predictive value of 0.73. The HRI value of >5% steatosis was updated to 1.41 and corresponded with a sensitivity of 0.94,

specificity of 0.96, negative predictive value of 0.93, and positive predictive value of 0.96.

CONCLUSION

HRI can accurately place patients into categories of less than 5%, between 5%-20%, and greater than 20% steatosis.

CLINICAL RELEVANCE/APPLICATION

HRI is non-invasive, cheap tool which is free of side effects that can be used to accurately follow changes in steatosis over time and determine if therapeutic interventions are being successful and if disease is progressing or regressing.

SSK07-08 Non-Invasive Ultrasonographic Index for the Detection of Non-Alcoholic Steatohepatitis (NASH) in Patients with Non-Alcoholic Fatty Liver Disease (NAFLD)

PURPOSE

1. To evaluate feasibility of US for the prediction of NASH in patients with NAFLD2. To compare diagnostic performance between index using shear wave elastography (SWE) with hepatic/renal echo intensity ratio (H/R ratio) and index using transient elastography (TE, FibroScan®) with controlled attenuation parameter (CAP) for the detection of NASH in patients with NAFLD

METHOD AND MATERIALS

This retrospective study was approved by our IRB and the requirement for informed consent was waived. 55 patients with NAFLD who underwent US-guided parenchymal liver biopsy, SWE with H/R ratio, and TE with CAP were included. Biopsy specimens were reviewed for histologic grading and NAFLD Activity Score (NAS) - the unweighted sum of scores for steatosis (0-3), lobular inflammation (0-3), and hepatocellular ballooning (0-2) - was calculated based on the NASH-CRN criteria. Patients were classified according to the NAS as NASH group (NAS>=5) and non-NASH group (NAS<5). The diagnostic performance of SWE, TE, H/R ratio, and CAP for grading fibrosis and steatosis was evaluated using ROC curve analysis with obtaining the AUC. Using linear regression analysis, indices were developed for the prediction of NAS using SWE with H/R ratio and TE with CAP, respectively. The diagnostic performance was evaluated and compared between two indices using ROC curve analysis.

RESULTS

24 NASH and 31 non-NASH patients were included. The AUC for grading >=G2 and >=G3 steatosis were 0.879 and 0.842 using H/R ratio, and 0.604 and 0.563 using CAP. The AUC for grading >=F1, >=F2, >=F3, and >=F4 fibrosis were 0.653, 0.747, 0.861, and 0.816 using SWE, and 0.742, 0.824, 0.858, and 0.880 using TE. Index using SWE with H/R ratio was $2.374 + 0.091 \times SWE + 0.356 \times H/R$ ratio (Index 1). Index using TE with CAP was $5.251 + 0.035 \times TE - 0.005 \times CAP$ (Index 2). In ROC curve analysis, index 1 showed higher tendency of AUC than index 2 (0.767 vs. 0.655, p=0.13) with corresponding sensitivity of 62.5% and specificity of 80.7%.

CONCLUSION

Index using SWE with H/R ratio have higher diagnostic performance than index using TE with CAP although statistically insignificant.

CLINICAL RELEVANCE/APPLICATION

Liver biopsy, which is a current gold standard for differentiating NASH from simple steatsosis, has several disadvantages including invasiveness, sampling error, and cost. Non-invasive US index using SWE and H/R ratio may help predict NASH in patients with NAFLD.

SSK07-09 Viscosity and Viscoelasticity Measurement in Patients with Nonalcoholic Fatty Liver Disease Using Shear Wave Ultrasound Elastography

Wednesday, Nov. 28 11:50AM - 12:00PM Room: S402AB

Participants
Katsutoshi Sugimoto, MD, PhD, Tokyo, Japan (*Presenter*) Nothing to Disclose
Hirohito Takeuchi, Tokyo, Japan (*Abstract Co-Author*) Nothing to Disclose
Takao Itoi, Tokyo, Japan (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

sugimoto@tokyo-med.ac.jp

PURPOSE

To investigate the usefulness of the shear wave (SW) speed (related to viscoelasticity), dispersion slope (related to viscosity), and attenuation value (related to the degree of steatosis) obtained using a new ultrasound (US) elastography system in patients with histologically confirmed nonalcoholic fatty liver disease (NAFLD).

METHOD AND MATERIALS

A US-based SW imaging system (Aplio i800; Canon Medical Systems) was used to measure three US parameters: SW speed (m/s),

dispersion slope ([m/s]/kHz), and attenuation value (dB/cm/MHz). These parameters were compared against liver histopathologic findings such as fibrosis, ballooning, lobular inflammation, and steatosis as assessed by the NAFLD Activity Score in 24 patients diagnosed with NAFLD.

RESULTS

In univariate analysis, SW speed was significantly correlated with fibrosis (Spearman's rank correlation coefficient: $\rho=0.77$, $P<0.01$) and ballooning ($\rho=0.59$, $P<0.01$). Dispersion slope was significantly correlated with lobular inflammation ($\rho=0.58$, $P<0.01$), ballooning ($\rho=0.53$, $P<0.01$), and fibrosis ($\rho=0.46$, $P=0.02$). Attenuation value was significantly correlated with steatosis ($\rho=0.71$, $P<0.01$). In multivariable analysis with histologic features as independent variables, SW speed was significantly correlated with fibrosis ($P<0.05$), and dispersion slope was significantly correlated with lobular inflammation ($P<0.05$). However, attenuation value was not significantly correlated with steatosis ($P=0.07$).

CONCLUSION

SW speed is more useful than dispersion slope for predicting the degree of fibrosis, and dispersion slope is more useful than SW speed for predicting the degree of necroinflammation.

CLINICAL RELEVANCE/APPLICATION

Dispersion slope, which reflects viscosity, may provide additional pathophysiological insight into NAFLD.

395654582@qq.com

PURPOSE

To evaluate the application of material decomposition technique in spectral CT imaging in the quantitative study of blood flow in patients with liver cirrhosis and patients with healthy liver.

METHOD AND MATERIALS

30 patients with liver cirrhosis diagnosed clinically were enrolled as the study group while 30 abdominal patients whose liver and portal vein enhancement examination were normal as a control group.All patients underwent Spectral CT imaging and iodine-based material decomposition (MD) images were reconstructed. The iodine concentration (IC) was measured in five liver lobes (Caudate, left lateral, left inner, right anterior and right posterior) in both the arterial phase (AP) and portal venous phase (VP) on the iodine-based MD images. The average and total iodine concentrations of the liver were calculated, as well as the arterial iodine fraction (AIF=ICAP/ICVP) and the portal venous iodine concentration (PVIC=ICVP - ICAP). These parameters between the two groups were statistically compared by using independent sample t test.

RESULTS

The iodine concentrations in the five liver lobes in patients with liver cirrhosis were the same in AP ($P>0.05$), but the iodine concentrations of study group in portal venous phase were statistically lower than those of the control group ($P<0.05$). The average IC (6.02±2.12mg/ml) and total IC (33.74±10.84mg/ml) in the liver parenchyma in AP of liver cirrhosis were statistically the same as those in the control group (5.85±1.79 and 33.04±9.28mg/ml) ($P>0.05$); while the average IC (19.42±3.28mg/ml) and the total IC (99.83±16.65mg/ml) in VP of liver cirrhosis were lower than those in the control group (22.82±3.83 and 117.27±19.45mg/ml) ($P<0.05$) (Table 1). The AIF values were the same for the two groups, while the portal venous iodine concentrations in liver cirrhosis were lower than the control group ($P < 0.05$) (Table 2).

CONCLUSION

The material decomposition technology in Spectral CT can be used to assess the change and difference of blood flow between liver cirrhosis and healthy liver.

CLINICAL RELEVANCE/APPLICATION

The material decomposition technology in Spectral CT may be used to provide more evidence for early diagnosis of liver cirrhosis.

SSK08-02 Influence of Radiation Dose on Quantitative Tumor Measurements Using a Dual-Source, Single-Energy CT Acquisition

Wednesday, Nov. 28 10:40AM - 10:50AM Room: S404CD

Guerbet SA; Research Grant, Nemoto Kyorindo Co, Ltd; Speakers Bureau, Bracco Group; Royalties, Wolters Kluwer nv
Daniele Marin, MD, Durham, NC (*Abstract Co-Author*) Research support, Siemens AG

PURPOSE

To determine the effect of different dose levels on quantitative tumour measurements from one dual-source, single-energy CT (DSCT) acquisition.

METHOD AND MATERIALS

A total of 23 patients with 39 metastatic liver lesions were enrolled in this HIPAA-compliant and IRB approved study. Patient underwent a clinically indicated DSCT of the abdomen with reconstruction of seven radiation dose levels (25%, 37.5%, 50%, 63.5%, 75%, 88.5% as well as a 100% corresponding to a diagnostic CT dose level scan [mean CTDIvol 10.4mGy]) by using different combination of projection data of the two tubes from a single DSCT acquisition. CT data were reconstructed using a second-generation iterative reconstruction algorithm. For each dose level, unidimensional measurements of tumor size according to RECIST 1.1 criteria were obtained by four independent and blinded readers using a conventional manual approach, as well as a semi-automated approach using two commercially available lesion segmentation tools (Syngo.Via, Siemens Healthineers and Mint lesion, Mint Medical GmbH). All readers repeated lesion measurements after 4 weeks for measurement of intra-reader variability. The measurements obtained at 100% dose served as the reference standard for each reader.

RESULTS

There was an excellent intra-reader correlation of r2=0.93 (range: 0.93 - 0.94 for all readers) with an intra-reader measurement error of 7.2% 7.9% (range 4.9%-8.6%). For the 25% dose level datasets the inter-reader measurement error was statistically significantly higher compared to the 75% datasets, for both the readers and semi-automatic software algorithms ($p<0.0252$). Of note, the overall intra-reader measurement error (7.2% 7.9%) was significantly higher than the overall measurement error for different dose levels (6.3% 6.3%) ($p=0.001$).

CONCLUSION

Our data suggest that reductions in radiation dose up to 72.5% may not significantly affect manual and semi-automated unidimensional measurements of tumor size. Intra- and inter-reader variability affected unidimensional measurements of tumor size statistically significantly more than a decrease radiation dose.

CLINICAL RELEVANCE/APPLICATION

CT scans with a dose level of 37.5% allow for a high reproducible and accuracy of quantitative tumour measurements, potentially reducing cumulative radiation exposure of oncological staging CTs.

SSK08-05 Virtual Monoenergetic Images from Spectral Detector CT for Visualization of Hypodense Liver Lesions: Contrast Blooming Vice Versa-Proof of Concept in a 3D-Printed Phantom and Evaluation in Patients

PURPOSE

There is a well-known boost of iodine associated-attenuation in low keV virtual monoenergetic images (VMI_low) which is frequently used to improve visualization of lesions and structures that take up contrast media (e.g. hemangiomas, hypervascular metastases or vessels in CT-angiography). This study aimed to evaluate this contrast vice versa: Does improved attenuation of the liver parenchyma allow for improved visualization of little or none-enhancing lesions?

METHOD AND MATERIALS

For the phantom portion a 3D-printed phantom mimicking the shape of a human liver exhibiting a lesion in its center was designed and printed. Both, parenchyma- and lesion-mimic were filled with iodine-solutions of different concentrations exhibiting an attenuation of 80, 100, 120 HU for parenchyma- and 0, 40, 60 HU for lesion-mimics. Further, a total of 75 patients with MRI or follow-up proven cysts and/or hypodense metastases was included. Imaging was performed on a spectral detector CT scanner (SDCT) and VMI of 40-120 keV as well as conventional images (CI) were reconstructed. Regions of interest were placed in lesion and parenchyma (-mimics) on CI and transferred to VMI. Signal- and contrast-to-noise ratio were calculated. Data was statistically assessed using ANOVA with Tukey's posthoc to adjust for multiple comparisons.

RESULTS

In phantoms, S/CNR was significantly higher in VMI_low. A cyst (0HU lesion mimic) in highly attenuating liver parenchyma (120HU) on CI yielded a CNR of 6.4±0.8; using 40keV images, mildly hypodense lesions in poorly attenuating liver parenchyma exhibited a similar CNR (5.8±0.9; $p<=0.05$). The same tendency was observed in patients, again cysts in CI yielded similar values as metastases in VMI_low (4.4±1.2 and 3.9±1.8, respectively, $p<=0.05$).

CONCLUSION

The improved attenuation of the liver outweighs increasing in attenuation of the lesion itself. Hence, VMI_low from SDCT allow for an improved visualization of hypodense focal liver lesions exploiting the concept of contrast blooming vice versa.

CLINICAL RELEVANCE/APPLICATION

Low keV VMI should be considered when screening after focal liver lesions, irrespective of the expected imaging characteristic.

SSK08-06 Quantification of the Liver-Iron Fraction Using Spectral CT Imaging and Material Decomposition Technique: A Vitro Experiment Study

Wednesday, Nov. 28 11:20AM - 11:30AM Room: S404CD

Participants
Tingting Xie JR, MD, Shenzhen, China (*Presenter*) Nothing to Disclose
Guanxun Cheng, Shenzhen, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Our first goal was to build in vitro liver-iron model in order to provide a phantom for iron content quantification in study. The second goal was to evaluate the feasibility and accuracy of using spectral imaging and material decomposition techniques for iron density quantification to provide a basis for the precise iron quantification in clinical use.

METHOD AND MATERIALS

Liver-iron mixture samples were prepared as described. A total of six homogeneous liver-iron mixed samples with a iron content of 0, 3.125, 6.25, 12.5, 25, 50 mg/mL. All samples were scanned on a GE Revolution CT scanner using GSI mode with rapid tube voltage switching between 80-140 kVp, and with tube current 200mA, 320mA, 485mA respectively. After the CT scan reconstructed imaging data were processed with GSI imaging analysis software package for material decomposition and characterization. Iron concentration (on iron-water bases,Unit:mg/mL) was measured. The difference of measured iron concentration(VIC) between 3 groups of tube currents was analyzed by one-way ANOVA. A linear regression was performed to analyze the relationship between the VIC and the actual iron concentration.

RESULTS

(1) We had successfully developed models in vitro for iron content quantification. (2) There was no significant difference in VIC between 3 tube current groups,P=0.999, F=0.001. (3) The model showed good linear relationship between the measured iron concentration and actual iron concentration. And the linear correlation equation was y=2.177x-2.820, R^2 = 0.995, P<0.001, F=3186.883.

CONCLUSION

(1) Spectral imaging and material decomposition techniques were demonstrated to provide accurate and reliable measurement of iron content for liver-iron model, which will contribute to the development of clinical iron content quantification assays. (2) The quantification of the liver-iron fraction was not affected by radiation dose.

CLINICAL RELEVANCE/APPLICATION

This study demonstrated the feasibility of using CT spectral imaging and material decomposition techniques to precisely quantify the iron concentrations. The advantages of this quantitative method are non-invasive, high accuracy, without additional scanning, and the technique can be used to guide the treatment of relieving iron overload in hereditary hemochromatosis and acquired hemochromatosis, and assist the diagnosis of canceration of liver cirrhosis nodules.

SSK08-07 The Influence of Liver Fat Deposition on the Quantification of the Liver-Iron Fraction Using Spectral CT Imaging and Material Decomposition Technique: A Vitro Experiment Study

Wednesday, Nov. 28 11:30AM - 11:40AM Room: S404CD

Participants
Tingting Xie JR, MD, Shenzhen, China (*Presenter*) Nothing to Disclose
Guanxun Cheng, Shenzhen, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Our first goal was to build in vitro liver iron- fat deposition model in order to provide a phantom for iron content quantification in study. The second goal was to evaluate the feasibility and accuracy of using spectral imaging and material decomposition techniques for iron density quantification under the condition of simultaneous fat deposition and iron deposition in the liver.

METHOD AND MATERIALS

Liver-iron-fat mixture samples were prepared as described. A total of 18 samples(3 groups) of homogeneous liver-iron mixed samples with iron concentration gradient of 0, 10, 20, 30, 40, 50 mg/mL were prepared(group A, B and C), group A, B and C added fat with volume percentage of 10%, 30%and 60% respectively. All samples were scanned on a GE Revolution CT scanner using GSI mode with rapid tube voltage switching between 80-140 kVp, tube current 485mA. After the CT scan reconstructed imaging data were processed with GSI imaging analysis software package for material decomposition and characterization. Iron concentration (on iron-fat bases) measured with consistent regions of interest (ROIs) and statistical analysis. A linear regression was performed to analyze the relationship between the measured iron concentration and the actual iron concentration.

RESULTS

(1) We had successfully developed liver iron- fat models in vitro. The designed iron concentration range covered clinical iron content in liver, and the fat volume ratio of 10%, 30% and 60% simulated the mild, moderate and severe fatty liver respectively. (2) The model showed good linear relationship between the measured iron concentration and actual iron concentration. And the linear correlation equation were yA=0.575x-11.222,(R^2= 0.927, P=0.005, F=52.038), yB=0.848x-2.303(R^2 = 0.884, P=0.011, F=31.481), yC=0.788x-9.998(R^2= 0.949, P=0.003, F=76.068).

CONCLUSION

(1) Spectral imaging and material decomposition techniques were demonstrated to provide accurate and reliable measurement of iron content for liver-iron-fat model. (2) Fat affect the results of measured iron concentration.

CLINICAL RELEVANCE/APPLICATION

This study demonstrated the feasibility of using CT spectral imaging and material decomposition techniques to precisely quantify the iron concentrations under the condition of simultaneous fat deposition and iron deposition, and can be used to guide the treatment of relieving iron overload in hereditary hemochromatosis and acquired hemochromatosis.

SSK08-08 Dual Energy CT Iodine Maps for Response Assessment in Colorectal Liver Metastases (CLM) Treated With a Multikinase Inhibitor (MKI) with Anti-Angiogenic Activity

Wednesday, Nov. 28 11:40AM - 11:50AM Room: S404CD

Participants

Maria Antonietta Bali, MD, PhD, Brussel, Belgium (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

udaypatel2@nhs.net

PURPOSE

To assess changes in quantitative CT iodine maps in patients with CLM treated with a MKI with known anti-angiogenic activity and to assess their relationships with treatment outcomes.

METHOD AND MATERIALS

After IRB approval, 28 patients with CLM were prospectively consented and underwent dual energy CT studies on a Siemens SOMATOM CT scanner before and at 8 weeks after treatment. Iodine maps were generated from 3 mm dual energy CT images acquired in the arterial and portovenous phases. In each patient, regions of interest were drawn around a target hepatic metastasis to record the average iodine uptake before and after treatment, as well as the absolute and percentage change in iodine uptake after treatment. Results were compared between responders and non-responders, defined by RECIST 1.1 and clinical criteria. The diagnostic performance of CT iodine uptake for identifying responders was assessed by ROC analysis, and the relationship to overall survival (OS) was evaluated by Kaplan-Meier analysis.

RESULTS

Of the 28 patients, 16 patients were responders and 12 non-responders. Across the entire cohort, a significant decrease in the median averaged iodine uptake after treatment in arterial (17.06 vs. 7.86, p<0.0002) and portovenous phases (20.34 vs. 14.06, p<0.0001) was observed. However, there was no significant difference in the mean absolute or percentage decrease in iodine uptake on arterial (-6 vs -4.5, p=0.82 and -65 vs -38, p=0.22) or portovenous (-8.4 vs -6.1, p=0.10 and -41 vs -28, p=0.17) phase between the two groups. A -33.6% reduction in iodine uptake showed 68.8% sensitivity and 81.8% specificity for identifying responders, but this threshold showed no relationship with OS (36 vs. 29 weeks, p=0.3278).

CONCLUSION

A significant decrease in iodine uptake was observed across the study cohort on arterial and portovenous phase CT after anti-angiogenic therapy. Notwithstanding with small numbers, a significant difference in CT iodine uptake between responders and non-responder was not observed thus the technique cannot be used to inform treatment decisions at this stage.

CLINICAL RELEVANCE/APPLICATION

Dual energy CT iodine maps can not yet be used for response assessment in colorectal liver metastases treated with anti-angiogenic agents.

SSK08-09 How Reliable are CT-Based Measurements of Iodine Concentration? A Comparison of the Minimum Detectable Concentration Difference Among Single-Source and Dual-Source Dual-Energy CT

euler.rad@gmail.com

PURPOSE

To assess the impact of scan- and patient-related factors on the error and the minimum detectable difference in iodine concentration among a wide range of different imaging conditions for second- and third-generation single-source fast kV-switching and dual-source dual-energy CT (DECT).

METHOD AND MATERIALS

Lesions of nine iodine concentrations (0.2 - 4 mgI/mL) were emulated in a 3D-printed phantom of medium and large size. Each combination of concentration and size was scanned in dual-energy mode on four different second- and third-generation single-source (SS) fast-kV switching and dual-source (DS) DECTs. Radiation doses were 7, 10 mGy (medium size) and 10, 13, 16 mGy (large size). Iodine maps were reconstructed with FBP and vendor-specific iterative reconstruction algorithms. ROI measurements of iodine concentration were made from each reconstructed iodine map with an automated script (243,000 total measurements). Absolute error of iodine quantification (E) was calculated. Multivariate regression models determined the influence of CT scanner condition, iodine concentration, phantom size, radiation dose, and reconstruction algorithm on E. Minimum detectable difference in iodine concentration, Dmin, was estimated for each pair of imaging conditions (including inter- and intra-condition comparisons). For a given pair of imaging conditions, Dmin was defined as the minimum difference in iodine concentration in which measured differences corresponded to true differences 95% of the time.

RESULTS

The iodine quantification error E was significantly lower in third-generation compared to second-generation DECT platforms ($P<0.001$). E significantly increased with increasing phantom size and decreasing radiation dose for all CT scanner conditions ($P<0.001$). Iodine concentration only significantly affected E for SS DECT ($P<0.001$). The minimum intra- and interconditional detectable difference in iodine concentration depended on patient- and scan-related factors and ranged from 0.4 mgI/mL to 1.5 mgI/mL

CONCLUSION

Patient- and scan-related factors have a significant impact on the error and minimum detectable difference in iodine concentration within and among second- and third-generation SS fast kV-switching and DS DECT.

CLINICAL RELEVANCE/APPLICATION

To inform radiologists about the impact of patient- and scan-related factors and the high error range of DECT-based iodine quantification when patients are imaged under different conditions.

PURPOSE

To use feature representations based on deep convolutional neural network in differentiating Clear Cell Renal Cell Carcinoma (ccRCC) from Oncocytoma lesions on MRI T2-weighted images.

METHOD AND MATERIALS

94 ccRCCs from 31 patients (12 males, 19 females) and 37 Oncocytoma lesions from 9 patients (6 males, 3 females) were identified from an institutional urologic oncology database. Weighted-T2 MR images taken within 6 months prior to surgery were selected for analysis. Lesions were segmented on every slice. Local square ROIs around each lesion were extracted and resized to 224x224 as neural network inputs. Deep residual network ResNet-101 pre-trained on ImageNet dataset was then used as feature extractor without fine-tuning. Using feature representations from ResNet, the corresponding lesion slices were then classified into either ccRCC or Oncocytoma using Support Vector Machine. Performance was reported based on five-fold cross-validation classification results. Accuracy at the lesion level was calculated based on the majority (> 50%) of correctly predicted class for all the slices in one lesion. If the number of correctly predicted slices is equal to the number of incorrectly predicted slices, then the entire lesion is considered to be incorrectly classified.

RESULTS

Out of a total of 407 slices, our model showed an overall accuracy of 78.62% in detecting Oncocytoma from Clear Cell RCCs. At the lesion level, 80 out of 94 (85%) ccRCC lesions and 23 out of 37 (62%) of oncocytoma lesions were correctly identified. The model showed an overall accuracy of 78.63%.

CONCLUSION

Deep Learning with CNN showed promising diagnostic performance in differentiation of Oncocytoma lesions from Clear Cell RCC.

CLINICAL RELEVANCE/APPLICATION

Our training model can be used as support information in the differential diagnosis between Oncocytoma and Clear Cell.

SSK09-02 Semantic Modeling of Fat Poor Angiomyolipoma (fp-AML) on Multiphase Contrast-Enhanced CTs

Wednesday, Nov. 28 10:40AM - 10:50AM Room: N226

Participants
Yaqin Zhang, MD,PhD, Zhuhai, China (*Presenter*) Nothing to Disclose

Jun Wei, PhD, Ann Arbor, MI (*Abstract Co-Author*) Nothing to Disclose
Hong Shan, PhD,MD, Zhuhai, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

zhyaqin@mail.sysu.edu.cn

PURPOSE

To investigate the efficacy of noninvasive models in which clinical and radiographic descriptors were fused to differentiate the fp-AMLs from clear cell renal cell carcinoma (ccRCCs) in multiphase contrast-enhanced CT images.

METHOD AND MATERIALS

With IRB approval, we retrospectively collected patients at two academic hospitals (A and B) from Jan. 2006 to Dec. 2016 in Guangdong, China. All patients were clinically diagnosed with one suspicious ccRCC on multiphase contrast-enhanced CT acquired at least 30 days before surgical resection. Histopathologic data was served as ground truth. For model selection, we collected 118 cases (13 of 20 fpAMLs diameter <= 4cm and 46 of 98 ccRCCs diameter <= 4cm) at hospital A. An experienced radiologist identified the locations of lesions by examining all available information including the CTs and clinical reports, and provided descriptors of the lesion shapes, gray-level information as well as lesion margins. Twenty-four features including 5 clinical (gender, age, red blood cell in urine, white blood cell in urine, and symptom) and 19 radiographic descriptors were used. LASSO was used for feature selection and fp-AML prediction. To evaluate the efficacy of the developed fp-AML model, an independent set of 63 cases including 15cases (13 diameter <= 4cm) fp-AMLs and 48 (22 diameter <= 4cm) ccRCCs were collected from hospital B. Four additional radiologists independently provided the radiographic descriptors on multiphase CTs as well as the binary diagnostic decision of each lesion for baseline comparison.

RESULTS

On test set, the diagnosis accuracies of four readers were 0.74, 0.73, 0.71 and 0.90 while the models' achieved 0.81, 0.83, 0.87 and 0.92, respectively. Comparing to baselines, the improvements with models were 9.5%,13.7%, 22.5% and 2.2%, respectively. For small lesions (diameter <= 4cm), the readers' accuracies were 0.57, 0.60, 0.57 and 0.89 while the models' were 0.74, 0.71, 0.83 and0.91, correspondingly. The improvements were 29.8%, 18.3%, 45.6% and 2.2%, respectively.

CONCLUSION

Multiple reader study found that the semantic model improved the diagnostic accuracies of fp-AMLs and the bigger improvement were observed for small lesion.

CLINICAL RELEVANCE/APPLICATION

The noninvasive diagnosis of fp-AMLs from ccRCCs is a challenging task in clinical practice. The semantic modeling has the potential to improve the diagnostic accuracy of fp-AMLs.

SSK09-03 Comparison of Computed Tomography (CT), Magnetic Resonance Imaging (MRI), and Contrast-Enhanced Ultrasound (CEUS) in the Evaluation of Unclear Renal Lesions: A 10-Year Single Center Experience

Wednesday, Nov. 28 10:50AM - 11:00AM Room: N226

Participants
Johannes Ruebenthaler, MD, Munich, Germany (*Presenter*) Nothing to Disclose
Dirk-Andre Clevert, MD, Muenchen, Germany (*Abstract Co-Author*) Speaker, Siemens AG; Speaker, Koninklijke Philips NV; Speaker, Bracco Group; Speaker, Samsung Electronics Co, Ltd;

PURPOSE

To compare the sensitivity and specificity of contrast-enhanced ultrasound (CEUS), computed tomography (CT) and magnetic resonance imaging (MRI) in the evaluation of unclear renal lesions to the histopathological outcome.

METHOD AND MATERIALS

A total of 255 patients with a single unclear renal mass with initial imaging studies between 2005 and 2015 were included. Patient ages ranged from 18 to 86 with (mean age 62 years; SD ± 13). CEUS (255 patients), CT (88 out of 255 patients; 34.5%) and MRI (36 out of 255 patients; 14.1%) were used for determining malignancy or benignancy and initial findings were correlated with the histopathological outcome. Out of the 255 renal masses a total of 212 lesions were malignant (83.1%) and 43 were benign (16.9%). Diagnostic accuracy was tested by using histopathology as the gold standard.

RESULTS

CEUS showed a sensitivity of 99.1% (95% confidence interval (CI): 96.7%, 99.9%), a specificity of 80.5% (95% CI: 65.1%, 91.2%), a positive predictive value (PPV) of 96.4% (95% CI: 93.0%, 98.4%) and a negative predictive value (NPV) of 94.3% (95% CI: 80.8%, 99.3%). CT showed a sensitivity of 97.1% (95% CI: 89.9%, 99.6%), a specificity of 47.4% (95% CI: 24.4%, 71.1%), PPV of 87.0% (95% CI: 77.4%, 93.6%) and a NPV of 81.8% (95% CI: 48.2%, 97.7%). MRI showed a sensitivity of 96.4% (95% CI: 81.7%, 99.9%), a specificity of 75.0% (95% CI: 34.9%, 96.8%), a PPV)of 93.1% (95% CI: 77.2%, 99.2%) and a NPV of 85.7% (95% CI: 42.1%, 99.6%). Out of 212 malignant lesions 130 clear cell renal carcinomas, 59 papillary renal cell carcinomas, 7 chromophobe renal cell carcinomas, 4 combined clear cell and papillary renal cell carcinomas and 12 other malignant lesions were diagnosed. Out of 43 benign lesions 10 angiomyolipomas, 3 oncocytomas, 8 benign cysts and 22 other benign lesions were diagnosed. Using CEUS, 10 lesions were falsely identified as malignant or benign: 8 lesions were false positive and 2 lesions false negative. The 8 false-positive lesions included 5 oncocytomas or angiomyolipomas and 3 Bosniak category III cystic lesions.

CONCLUSION

CEUS is an useful method which can be additionally used to clinically differentiate between malignant and benign renal lesions. CEUS shows a comparable sensitivity, specificity, PPV and NPV to CT and MRI.

CLINICAL RELEVANCE/APPLICATION

CEUS can be easily performed during clinical routine for the evaluation of unclear renal lesions as a complementary imaging method.

SSK09-04 Diagnosis of Fuhrman Nuclear Grade in T1a Clear Cell Renal Cell Carcinomas on MRI: Can We

Accurately Differentiate High Grade from Low Grade Disease to Better Guide Management?

nschieda@toh.on.ca

PURPOSE

Multi-parametric (mp) MRI is accurate to diagnose clear cell renal cell carcinoma (cc-RCC). T1a cc-RCC is typically treated radically; however, low-grade tumors may be candidates for active surveillance. Fuhrman nuclear grading (FNG) of cc-RCC with biopsy is not accurate and this study evaluated mp-MRI to differentiate low from high-grade cc-RCC.

METHOD AND MATERIALS

42 consecutive solid <4cm cc-RCC with mp-MRI before nephrectomy between 2013 and 2017 (low-grade=FNG 1 [N=4] or 2 [N=27] and high-grade=FNG 3 [N=11]) were identified. Size, apparent diffusion coefficient (ADC), enhancement wash-in and wash-out (WI/WO) ratios and, chemical-shift signal-intensity index (SI-index) were measured. Subjectively, two blinded radiologists assessed for: 1) intracellular lipid (SI drop on opposed-phase MRI), 2) hemorrhage and 3) homogeneity. Discrepancies were resolved by consensus. Comparisons were performed using logistic regression and Chi-square and accuracy assessed using ROC.

RESULTS

Mean lesion size was 24 ± 7 (13-39) mm with no difference by FNG (p=0.45). 35.5% (11/31) low-grade tumors showed intracellular lipid compared to 9.1% (1/11) high-grade tumors (p=0.009). Agreement was moderate (K=0.65). SI-index was higher in low grade tumors (9.8 ± 34.4 versus 5.2 ± 19.9), p=0.283. Hemorrhage and homogeneity did not differ between groups (p>0.05). Mean ADC was higher in low-grade tumors (0.860 ± 0.142 versus 0.787 ± 0.229 mm2/sec) with significant differences observed for 10th centile ADC (p<0.001). WI index was higher in low-grade tumors for corticomedullary (p=0.019) and nephrographic phase (p=0.027) with no differences in WO. Presence of lipid was specific for diagnosis of low-grade disease (90.9% [58.7-98.8]) with low sensitivity (35.5% [19.2-54.6]). Logistic regression model combining presence of intracellular lipid, SIindex, ADC and WI yielded area under curve=0.79 (CI 0.62-0.96) with better accuracy (p=0.007, improved sensitivity=75.0% but lowered specificity=73.7%) compared to subjective assessment of lipid content alone.

CONCLUSION

Intracellular lipid in T1a clear cell RCC on MRI is highly specific for low-grade disease but with low sensitivity. Combining presence of lipid with ADC, SI-index and enhancement features improved accuracy of diagnosis.

CLINICAL RELEVANCE/APPLICATION

Multi-parametric MRI is accurate to differentiate low-grade and high-grade solid T1a clear cell tumors which may better inform management decisions.

SSK09-05 Radiogenomic Association Study Between PET/MR Imaging Features and Regional Histological and Gene Expression Status of Primary Clear Cell Renal Cell Carcinoma

shengche@med.unc.edu

PURPOSE

To discern potential associations between various imaging features and regionally altered histological and gene expression status of primary clear cell renal cell carcinomas (ccRCC) using a hybrid positron emission tomography/magnetic resonance (PET/MR) system.

METHOD AND MATERIALS

Between 2012 and 2013, eighteen ccRCC patients underwent presurgical PET/MR imaging. Ten histologically-confirmed ccRCC were included for subsequent analysis. Twenty-three regions-of-interest (ROIs) within primary tumors were pre-surgically defined using PET/MR images. Tissue samples of these ROIs were obtained during nephrectomy and sent for histological and microarray analyses.

Four images dataset, including Dixon fat and water images, dynamic contrast enhancement (DCE) from MR imaging and standard uptake value (SUV) from PET, were coregistered, and then radiomic imaging features were extracted from the pre-defined ROIs. Associations between these radiomic features, SUV, and 12 key selected genetic expressions of ccRCC were analyzed using sparse canonical correlation analysis.

RESULTS

Our study highlighted that combined structural and functional information from MRI and PET provides significant moderate to strong correlations between radiomic features and 8 of the selected genetic expressions, including FBP-1, BAP1, VHL, MUC4, PECAM1, PBRM1, TSC1, and MUC1 (P = 0.041). PET provides the highest loadings for the explanations of the radiomic correlations of expressions of PECAM1, while DCE in expressions of FBP-1, VHL, and PBRM1, and Dixon images in expressions of BAP1, MUC4, and TSC1.

CONCLUSION

Our study revealed the associations between PET/MR image features and regional variation of relevant biological features, underscoring the potential utility of PET/MR for discerning regional genetic variability in ccRCC.

CLINICAL RELEVANCE/APPLICATION

PET/MR identifies associations between radiomic features and genetic expressions. Knowledge on radiogenomic associations facilitates non-invasive mapping of tumor heterogeneity and selection of personalized treatments.

SSK09-06 Radiologically-Defined Tumor Necrosis in Clear Cell Renal Cell Carcinoma as a Surrogate of Pathologically-Defined Tumor Necrosis, Staging, and as a Size-Independent Prognostic Biomarker

PURPOSE

Pathologically defined tumor necrosis (PDTN) in clear cell renal cell carcinoma (ccRCC) has been considered as a prognostic factor. We aimed to measure radiologically-defined tumor necrosis (RDTN) of ccRCC and explore its association with PDTN, stage/grade, and with survival outcomes in a multi-institutional cohort.

METHOD AND MATERIALS

183 patients with ccRCC form The Cancer Genome Atlas (TCGA) with available contrast enhanced CT imaging were included in this study. Quantitative imaging methods were used to measure the volume of non-enhancing component of ccRCC (representing necrotic volume) based on the change of attenuation values of each tumor pixel between pre-contrast and postcontrast imaging. The percent of tumor necrosis ((necrotic volume/whole ccRCC volume) x 100) was used as a size-independent variable to represent RDTN. Associations of RDTN with pathological stage/grade were tested using Wilcoxon signed-rank test and with survival outcomes using Kaplan-Meier's curves and Cox regression analyses.

RESULTS

Median RDTN was 8% (interquartile range 3% - 17%) in this cohort. RDTN was higher in ccRCC with PDTN than those without (11% versus 7%; p-value= 0.042). There was no significant association between RDTN and pathological grading (p-value= 0.057). However, RDTN was higher in patients with AJCC pathological stage II, III, and IV in comparison with stage I (11% versus 5%; p-value<0.001). Patients with higher RDTN (>=median) had higher incidence of cancer recurrence after resection (Log-rank test p-value<0.001) and higher incidence of cancer-specific mortality (Log-rank test p-value<0.001). Controlling for age at diagnosis and stage of disease in a multivariable Cox-regresion model, patients with higher RDTN continued to have higher cancer recurrence and worse cancer-specific survival (Odds Ratios= 4.6 and 2.8; p-values= 0.003 and 0.020).

CONCLUSION

RDTN in ccRCC can be a surrogate to pathologically defined TN. Additionally, RDTN is associated with pathological staging and an important independent prognosticator.

CLINICAL RELEVANCE/APPLICATION

Radiologically-defined tumor necrosis in clear cell renal cell carcinoma conveys additional clinically-relevant information regarding tumor stage and prognosis.

SSK09-07 Developing a Sex-Specific Stratification System for Renal Cell Carcinoma Patients Using CT-Based Abdominal Fat and Muscle Quantification and Tumor Molecular Phenotyping

Wednesday, Nov. 28 11:30AM - 11:40AM Room: N226

PURPOSE

Imaging biomarkers of metabolism such as tumor glucose uptake, patient muscle mass, and patient visceral fat have the ability to predict outcomes in cancer patients. Recent evidence has demonstrated sex differences in these metabolic measurements both on the imaging and the molecular levels. We wanted to determine if muscle mass and visceral fat measured by CT and molecular profiling of tumor glycolytic metabolism could be combined to develop a multiparametric sex-specific stratification system for RCC patients.

METHOD AND MATERIALS

This study included 222 patients with clear cell RCC included within The Cancer Genome Atlas (TCGA) and Cancer Imaging Archive (TCIA). The abdominal fat and glycolytic subtyping of patients were performed and used as published previously [PMID: 29558292] and combined with muscle quantification in this study. Abdominal fat was segmented into visceral, subcutaneous, and total fat areas as well as the normalized relative visceral fat area (visceral fat/total fat ratio, or rVFA). Glycolytic gene expression profiling of the tumors using TCGA data was used to metabolically classify the tumors. CT-based muscle mass and density measurements of the psoas muscle at L3 were performed. Biomarker optimization analyses were conducted to identify imaging metric thresholds that maximally stratified the patients based upon overall survival (OS).

RESULTS

The average psoas muscle area measured more in men than women (1171 vs 679.5 mm2) [p<0.0001]. The average psoas muscle density also measured more in men than women (41.1 vs 38.5 HU) [p=0.045]. Increased muscle area (>442 mm2 for women and >784 mm2 for men) was associated with increased OS (men p=0.002, women p=0.001). However, increased psoas density (>48.1 HU) was prognostic only for women; in this cohort, only 1/11 women died compared to the <48.1 HU group that experienced 29/66 deaths [p=0.02]. Combining rVFA, glycolysis and muscle area resulted in the identification of three sex-specific survival groups (Figure 1). Although all three variables contributed to female stratification (p<0.0001), male stratification was driven by glycolysis and muscle area (p=0.001).

CONCLUSION

Abdominal CT measurement of muscle and fat in tandem with molecular features of tumors predicts sex-specific outcomes in RCC patients.

CLINICAL RELEVANCE/APPLICATION

Sex differences in patient and tumor metabolism may provide a new risk-stratification system for patients with clear cell RCC.

annietiger1988@163.com

PURPOSE

Our study aimed to analyze tumor's baseline CT texture features and evaluate the correlation with first-line Sunitinib therapy response in metastatic clear cell renal cell carcinoma patients.

METHOD AND MATERIALS

Jan 2013 to July 2016, 48 metastatic RCC patients who received first line Sunitinib undertook abdominal CT scan before treatment. Forty-two patients were included. Clinical information (age, gender, surgery, MSCKK score and Heng's score, metastasis) and pathological information (tumor diameter, Fuhrmann grade, tumor thrombus) were collected. We collected 30 unenhanced CT images, 30 corticomedullary phase CT images and 36 nephrographic phase CT images from these patients. 2D CT texture parameters were generated from the image with the largest tumor diameter using histogram analysis and spatial gray-level dependence matrices (GLCM and RLM), respectively. Patients were divided into respond group (CR+PR) and non-respond group (SD+PD) according to RECIST criteria. We compared the CT texture feature, clinical and pathological parameters between two groups. We further assess the CT texture parameters with progression-free survival (PFS) using Kaplan-Meier analysis and Cox regression model.

RESULTS

Age, gender, tumor diameter and clinical prognostic scores (MSKCC and Heng's score) had no difference between respond and non

Age, gender, tumor diameter and clinical prognostic scores (MSKCC and Heng's score) had no difference between respond and non-respond group. Gray-level nonuniformity (GLN) from unenhanced and corticomedullary phase CT in respond group was significantly smaller than non-respond group ($p<0.05$). Logistic regression showed that GLN from unenhanced ($p<0.05$, OR 0.98(0.97, 0.99)) and corticomedullary phase CT ($p<0.05$, OR 0.96(0.94, 0.99)) independently associated with therapy response. GLN from unenhanced CT had AUC of 0.76($P<0.05$, sensitivity 84.2%, specificity 63.6%); GLN from corticomedullary phase CT had AUC of 0.77 ($P<0.05$, sensitivity 73.7%, specificity 73.7%). Cox regression model showed that both GLN from unenhanced ($p<0.05$, HR 1.008(1.003,1.013)) and corticomedullary phase CT($p<0.05$, HR 1.012(1.002,1.022)) had significant correlation with PFS.

CONCLUSION

For metastatic patients who received Sunitinib therapy, baseline CT texture parameter Gray-length nonuniformity reflecting tumor heterogeneity correlate with therapy response and PFS.

CLINICAL RELEVANCE/APPLICATION

CT texture parameter reflecting tumor heterogeneity has the potential to predict targeted therapy response before treatment in metastatic clear cell renal cell carcinoma.

SSK09-09 Role of Non-Target Disease and New Lesions as Defined by RECIST 1.1 in Determining Radiological Progression in Renal Cell Carcinoma

PURPOSE

Progression free survival (PFS) based on RECIST 1.1 (R1.1) is still the most accepted primary end point for Phase III trials in renal cell carcinoma. Guidelines to assess tumor response based on changes in target lesions (TG) are quantifiable and established. However, guidelines to assess tumor response based on non-target (NT) or new lesions (NL) are qualitative and subject to inter-observer variation. The purpose of our study was to retrospectively assess the most common criteria for determination of progressive disease (PD) assessed using R1.1 and how these progression events impact PFS.

METHOD AND MATERIALS

We conducted a secondary analysis of a cohort of patients enrolled in a Phase III global multi-center open label trial who were randomized 1:1 to open label anti-VEGFR tyrosine kinase inhibitor (TKI) therapies. All patients had previously progressed after having received prior VEGFR therapy and had measurable disease at screening (SCR). A chest CT, and either a CT or MRI of the abdomen and pelvis were acquired at SCR and every 8 weeks and interpreted at an imaging core laboratory for PD using R1.1. Kaplan-Meier plots, Holm's multiple comparisons and log-rank tests were performed to compare the median PFS for each R1.1 measurement assessment.

RESULTS

We analyzed 395 subjects with a mean age of 60.7 years (SD ± 10.0). The mean number of follow-up visits was 4.9 (SD ± 1.8) with a mean of 6.59 (SD ± 3.70) months enrolled. PD was determined by growth of target (TG) lesions in 126 (32%) subjects (median PFS (mPFS) 5.44 months, IQR 3.87) appearance of a new lesion (NL) in 105 (27%) subjects (mPFS 3.61 months, IQR 3.60), and unequivocal progression of a non-target (NT) lesion in 73(18%) subjects (mPFS 2.79 months, IQR 3.54). The remaining subjects had PD determined by a combination of assessments: 33 (8%) by TG+NT (mPFS 3.54 months, IQR 3.70), 27(7%) by NT +NL (mPFS 3.74 months, IQR 2.48), 23(6%) by TG +NL (mPFS 3.64 months, IQR 5.38), and 8(2%) by TG+NT+NL (mPFS 4.52 months, IQR 4.98).

CONCLUSION

TG disease contributed to PD determination in less than 50% of patients and NT and NL were the most common criteria that defined PD, with a significant decrease in PFS compared to those patients who had PD determine by TG alone.

CLINICAL RELEVANCE/APPLICATION

In R1.1 assessment of metastatic RCC, both NT and NL alone, or in combination, are the dominant contributors to PD and may need updated R1.1 guidelines for NT and NL progression

nschieda@toh.on.ca

PURPOSE

PI-RADS v2 peripheral zone (PZ) observations considered indeterminate on diffusion-weighted imaging (assessment category 3) can be upgraded by 1 when showing early, focal and asymmetric hyper-enhancement on DCE-MRI. It is unclear whether upgraded category 3 PZ observations measuring >15 mm should be scored as category 4 or 5 lesions. This study evaluates DCE-MRI upgraded PI-RADS v2 PZ observations compared to other category 4 and 5 lesions and compares upgraded observations stratified by size when correlated to extra-prostatic extension (EPE), seminal vesicle invasion (SVI) and Gleason score (GS).

METHOD AND MATERIALS

With IRB approval, 230 men with mp-MRI before radical prostatectomy (RP) between 2013 and 2017 and with mp-MRI-RP maps confirming location of PZ dominant tumor foci were evaluated. Two blinded radiologists assigned PI-RADSv2 scores at independent review, then, both radiologists later jointly reviewed observations which were upgraded by abnormal DCE-MRI and discrepancies were resolved by consensus. Size of tumors was measured on axial T2-weighted MRI. Comparisons were performed using ANOVA and Chi-square.

RESULTS

9.1% (21/230) of tumors were upgraded by DCE, with size of upgraded tumors13 ± 5 (6-24) mm. Upgraded tumors had lower EPE (52.4% [11/21]) and SVI (4.8% [1/21]) versus non-upgraded PIRADSv2 score 4 or 5 tumors (EPE 67.5% [141/209], SVI 22.0% [46/209]), p=0.16 and 0.06. 85.7% (18/21) of upgraded tumors had Gleason score (GS)=7 with 14.3% (3/21) GS >7. Assigning PI-RADSv2 score to upgraded lesions based on size, 23.8% (5/21) would be score 5 (size 16-24mm) and the remaining 76.2% (16/21) score 4. All five score 5 upgraded tumors (100% [5/5]) had EPE, 25% (1/5) had SVI and 40% (2/5) had GS >7. In upgraded lesions measuring <15 mm, 31.3% (5/16) had EPE, none had SVI and only one patient had GS >7.

CONCLUSION

Peripheral zone tumors which are upgraded by DCE-MRI are less aggressive compared to non-upgraded score 4 and 5 tumors with lower rates of EPE, SVI and GS>7. In upgraded tumors measuring >15 mm, an assessment category of 5 is appropriate due to higher rates of EPE, SVI and high-risk Gleason score compared to upgraded tumors measuring <15 mm.

CLINICAL RELEVANCE/APPLICATION

DCE-MRI upgraded PZ tumors are less aggressive than non-upgraded score 4 or 5 tumors; however, DCE-MRI upgraded peripheral zone observations measuring >15 mm should be assigned assessment category 5.

SSK10-02 Optimizing MRI-Based Size Thresholds for Prostate Cancer Lesions: Peripheral Zone Cancers are More Predictable than Transition Zone Tumors

Tobias Penzkofer, MD, Berlin, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate if thresholds based on tumor size on MR Imaging can successfully stratify prostate cancers by their aggressiveness separated by their zone of origin. Goal was improve the currently applied PI-RADS 4 vs. 5 differentiation criterion.

METHOD AND MATERIALS

The MRI datasets of 152 patients who underwent 3 T MRI imaging and subsequent systematic and MRI/TRUS-fusion biopsy were re-read in a fully informed setting by three radiologists. All patients hat prostate cancer confirmed on histopathology. All retrospectively identifiable tumors were measured on T2 for lesions originating in the transition zone and on DWI for lesions from the peripheral zone and tabulated against their respective Gleason grade.

RESULTS

151 lesions were measurable in peripheral zone (n=111) and transition zone (n=40) with the following distribution: Gleason 3+3: 36, 3+4: 29, 3+5: 1, 4+3: 36, 4+4: 37, 4+5: 11, 5+5: 1. Looking at different size thresholds, rates of aggressive cancers (defined as Gleason 3+4 and above) in the peripheral zone were 75% (threshold=0.5 cm), 77% (threshold=1.0 cm), 87% (threshold=1.5 cm), 90% (threshold=2 cm) and 100% (threshold=2.5 cm). In the transition zone rates of aggressive cancer were 55% (threshold=0.5 cm), 57% (threshold=1 cm), 55% (threshold=1.5 cm), 57% (threshold=2.0 cm) and 86% (threshold=2.5 cm), 100% were reached at a threshold of 3 cm. Ten lesions were located in the anterior stroma, which were excluded due to small subgroup numbers.

CONCLUSION

Size thresholds can be used to stratify prostate cancer to some extent. Considering peripheral zone and transition zone separately, there was a clearer separation of clinically significant/aggressive tumors in peripheral zone cancers compared to transition zone cancers. Conversely, even low threshold lesions of 0.5 cm and below can harbor clinically significant cancers. Future versions of PI-RADS should therefore consider different cut-offs for peripheral zone and transition zone cancers. Furthermore, additional criteria - other than size - could add value to the differentiation between PIRADS 4 and 5. A clear separation as in BI-RADS 4a-c (2-9%, 10-50%, 50-95%) on the basis of size seems currently unfeasible.

CLINICAL RELEVANCE/APPLICATION

Adopting different size cut-offs for transition zone and peripheral tumors could be warranted. Additional characteristics - other than size - will likely be needed to stratify between PI-RADS 4 and 5 lesions.

SSK10-03 PI-RADS v2 based Characteristics of Missed Prostate Cancer Lesions on 3T Multiparametric-MRI Based on 518 Patients using Whole Mount Histopathology Reference

ambajgiran@ucla.edu

PURPOSE

To determine the characteristics of missed prostate cancer (PCa) lesions on 3TmpMRI using a whole mount histopathology (WMHP) as a standard of reference.

METHOD AND MATERIALS

With IRB approval & HIPAA compliance, the study cohort comprised 518 consecutive men who underwent robotic prostatectomy between Dec 2009 & May 2017. Clinical, 3TmpMRI (T2-weighted imaging, diffusion-weighted imaging (DWI), & dynamic contrast-enhanced (DCE) imaging) & WMHP features were analyzed. A structural report system, based on PI-RADS v2, was used. MRI detected lesions were matched with previously finalized WMHP in a joint session by a genitourinary radiologist and pathologist. MRI lesion detection rate was calculated. After the multidisciplinary sessions, patients without any detected PCa lesion in 3TmpMRI, but with at least one lesion >1 cm on WMHP, were retrospectively reviewed & assigned a PI-RADS v2 score.

RESULTS

In 518 patients with 1085 PCa foci on WMHP, 51.9% (563) lesions were missed & 48.1% (522) detected. Of the 563 missed lesions, 71.4% & 21.7% were graded as GS=3+3 & GS=3+4 respectively, while only 4.4% & 2.5% were graded as GS=4+3 & GS=8-10. The proportion of PCa with GS>7 was significantly lower among missed tumors compared to detected ones(p=0.001). Missed foci were

significantly smaller than detected ones in both overall (0.9 ± 0.7 cm vs. 2.1 ± 0.9 cm) & index (1.5 ± 0.8 cm vs 2.0 ± 0.9cm) lesion subcohorts(p =0.001). Of overall & index missed lesions 34.4% & 71.2% were >1 cm. In 13.7% (71/518) of patients without an MR detected lesion, a total of 151 lesions were detected on WMHP, of which 70(47 %) were >1cm . On retrospective review of these lesions, 42.8% (30), 18.5% (13), 20% (14), 10%(7), 7%(5), were PI-RADS V2 1, 2, 3, 4 & 5 respectively. Evaluation of 27% (19) of these lesions was limited by hemorrhage or susceptibility artifact or geometric distortion. Overall, 5.9% (31/518) of patients with clinically significant (CS) PCa lesions were totally missed in 3TmpMRI.

CONCLUSION

On 3TmpMRI, most missed PCa lesions were small & low grade. Although there were some large & high grade missed lesions on 3TmpMRI, the number of missed patients with CS lesion were small & detection for these patients was excellent.

CLINICAL RELEVANCE/APPLICATION

Number of missed patients with CS lesion were small and detection for these patients was excellent. 3T MRI can be use for every patients with PCa suspicious perior to biopsy and surgery.

SSK10-04 Yield of Concurrent Systemic Biopsy During MRI-Guided Targeted Biopsy According to PI-RADS Version 2 in Patients with Suspicious Prostate Cancer

Wednesday, Nov. 28 11:00AM - 11:10AM Room: N228

Participants
Chuhyun Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Chan Kyo Kim, MD, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

chankyokim@skku.edu

PURPOSE

Few studies have reported the value of concurrent systemic biopsy during MRI-guided targeted biopsy according to PI-RADS version 2 (v2). We aimed to investigate the yield of concurrent systemic biopsy during MRI-guided targeted biopsy based on PI-RADS v2 interpretations in patients with suspicious prostate cancer (PCa).

METHOD AND MATERIALS

285 consecutive patients with suspicious PCa who performed initial (n = 154) or repeated prostate biopsies (n =131) were enrolled in this retrospective study. All patients underwent prebiopsy 3-T multiparametric MRI, and performed MRI-transrectal ultrasound (TRUS) fusion targeted biopsy regarding PI-RADS v2 category 3-5 lesions and concurrent systemic standard biopsy. Detection rates of all PCa and clinically significant cancer (CSC) were evaluated based on the index lesion in each patient. Biopsy-based definition of CSC was Gleason score (GS) >= 3 + 4.

RESULTS

In all 351 target lesions (peripheral zone [PZ] = 215, transition zone [TZ] = 130, and both = 6), distributions of PI-RADS category 3, 4, and 5 lesions were 86, 177 and 88, respectively. Detection rates of all PCa and CSCs were 39.6% (139/351) and 29.6% (104/351), respectively. As each PI-RADS scoring, detection rates of all PCa and CSCs were 7% and 4.7% for category 3, 36.2% and 24.3% for category 4, and 78.4% and 64.8% for category 5. Regarding each PI-RADS category 4 and 5 lesion, CSC detection rates in PZ were 64.7% (33/51) and 92.9% (26/28), while detection rates of insignificant PCa in TZ were 23.1% (3/13) and 28.6% (10/35). In 49 patients (17.2%), systemic biopsy contained the highest GS cancer compared to targeted biopsy: 22 patients with positive targeted and positive systemic biopsy, and 27 patients with negative targeted biopsy and positive systemic biopsy. Of 88 patients with PI-RADS category 5 lesions, 15 (17%) had the highest GS cancer in systemic biopsy: PZ (n = 6), TZ (n = 8) and both (n = 1).

CONCLUSION

When performing a MRI-guided targeted biopsy based on PI-RADS v2, concurrent systemic biopsy cannot be abandoned in patients with suspicious PCa due to potential harboring more aggressive cancer.

CLINICAL RELEVANCE/APPLICATION

Although MRI-guided targeted biopsy regarding PI-RADS v2 category 4 or 5 lesion demonstrates excellent detection rates of all PCa and CSCs, concurrent systemic biopsy should be performed because of potential harboring more aggressive cancer.

SSK10-05 PI-RADS 3/Total Lesion Ratio is Associated with Clinically-Significant Prostate Cancer in Patients with Equivocal Risk Lesions on Multi-Parametric Magnetic Resonance Imaging

Wednesday, Nov. 28 11:10AM - 11:20AM Room: N228

PURPOSE

Prostate imaging reporting and data system (PI-RADS) category 3 (P3) provides an equivocal assessment of prostate cancer. We aimed to investigate multi-parametric magnetic resonance imaging (mpMRI) parameters including the ratio of P3-to-total regions of interest (ROI) that may assist in identifying patients with P3 lesions harboring clinically-significant prostate cancer (csPCa).

METHOD AND MATERIALS

We retrospectively queried our institutional mpMRI-ultrasound fusion (targeted) biopsy database to identify patients without a prior diagnosis of prostate cancer and with at least one P3 lesion on mpMRI who underwent targeted biopsy during Feb 2015-Oct 2017. mpMRI findings were assessed, including prostate and P3 volumes, number of ROIs, and P3-to-total ROIs ratio (P3 lesion volume/total ROIs volumes). Logistic regression and receiver operating characteristics curves with area under the curve (AUC) were used to assess the ability of clinical and mpMRI characteristics to predict csPCa, defined as any Gleason score (GS)>=7 cancer or GS 6 cancer in >2 cores or >50% of any positive core from targeted biopsy of the P3 lesion.

RESULTS

Of 132 men with at least one P3 lesion, 31 (23.4%) had csPCa on the biopsy of P3 lesions. Patients with csPCa in P3 lesions had smaller prostate volumes (p=0.002), lower P3/total ROIs ratios (p=0.002), and higher numbers of total ROIs (p=0.009). Compared with patients who had a P3/total ROIs ratio >0.58, men with ratios <0.58 were more likely to be diagnosed with csPCa in a P3 lesion (53.3% vs 12%, p<0.001). Using a threshold of 0.58, P3/total ROIs ratio was 69% sensitive and 79% specific for csPCa in a P3 lesion. On multivariable analysis, smaller prostate volume (OR 1.04, 95%CI 1.01-1.07, p=0.02) and lower P3/total ROIs ratio (OR 1.04, 95%CI 1.01-1.07, p=0.03) were associated with an increased risk of csPCa in P3 lesions. P3/total ROIs ratio and prostate volume (both AUC 0.70) were superior to prostate-specific antigen (PSA) density (AUC 0.66) for the prediction of csPCa in P3 lesions.

CONCLUSION

P3/total ROIs ratio and prostate volume outperformed PSA density in and were associated with detecting csPCa in P3 lesions. P3/total ROIs ratio could be used to avoid 79% of unnecessary biopsies of a P3 lesion in men with multiple ROIs on mpMRI.

CLINICAL RELEVANCE/APPLICATION

PI-RADS 3/total ROIs ratio might have a potentially significant clinical implication in the setting of equivocal-risk lesions on mpMRI.

PURPOSE

To determine the interobserver agreement of the PI-RADS version 2 lexicon.

METHOD AND MATERIALS

Retrospective IRB approved study. Eight radiologists, with different levels of experience and blinded to clinical data and original multiparametric MRI reports, evaluated a total of 160 lesions, 130 from peripheral zone (PZ) and 30 from transition zone (TZ). On T2w imaging, signs of definite extraprostatic extension or invasive behavior were assessed, for both TZ and PZ lesions. For TZ lesions, the following additional features on T2w imaging were assessed: circumscribed versus obscured margins, encapsulation, heterogeneous versus homogeneous, moderately hypointense and lenticular shape. On DWI and ADC map, the following features were assessed, for both PZ and TZ: focal versus indistinct, marked hyperintensity on high-b-value DWI, and marked hypointensity on ADC map. Finally, on DCE images the readers assigned presence or absence of early enhancement in the lesion/region of the lesion.

RESULTS

Of the five features evaluated on PZ lesions, only definite extraprostatic extension or invasive behavior on T2w had good agreement (AC1= 0.80). All other features (focal versus indistinct on ADC map and DWI, marked hyperintensity on high-b-value DWI, marked hypointensity on ADC map, and presence or not of early enhancement in the lesion/region of the lesion on DCE) had fair agreement (AC1= 0.32 to 0.40). Of the eight features evaluated on TZ lesions, two had good agreement: definite extraprostatic extension or invasive behavior (AC1= 0.77) and moderately/marked hypointensity on T2w (AC1= 0.67). Four features had moderate agreement: encapsulation and lenticular shape on T2w, focal (not indistinct) on ADC map and DWI, and marked hypointensity on ADC map (AC1= 0.45 to 0.60). The four other features had fair agreement: heterogeneous (not homogeneous) and circumscribed (not obscured) margins on T2w, marked hyperintensity on high-b-value DWI, and presence or not of early

enhancement in the lesion/region of the lesion (AC1= 0.30 to 0.38).

CONCLUSION

PI-RADS v2 lexicon ranged from fair to good interobserver agreement. The best agreements were observed for definitive EPE or invasive behavior on T2w on PZ and TZ.

CLINICAL RELEVANCE/APPLICATION

To evaluate the reproducibility of PI-RADS v2 lexicon is essential for clinical use.

SSK10-07 Comparison of Multi and Single Zonal True Positive Index Prostate Cancer Lesions with 3T Multiparametric MRI and Whole Mount Histopathology Correlation in 408 Patients

PURPOSE

To investigate the clinical, 3T multiparametric MRI (3T mpMRI) and histopathologic characteristics of multi and single zone true positive index prostate cancer (PCa) lesions with whole mount histopathology (WMHP) as reference standard.

METHOD AND MATERIALS

In this HIPAA-compliant, IRB-approved study, we evaluated a cohort of 408 men with both 3T mpMRI and WMHP before and after robotic prostatectomy from 12/2009 to 10/2017. A genitourinary (GU) radiologist and GU pathologist matched all WMHP PCa lesions with PI-RADSv2 based detected lesions on 3T mpMRI. The clinical, MRI and WMHP characteristics of true positive index lesions between multi zone (present in both transition (TZ) and peripheral zone (PZ)) and single zone (present in either TZ or PZ) PCa lesions were determined and compared using Chi-square and Mann-Whitney U test in SPSS v24.

RESULTS

Patients' mean age was 62.2±7 years with median PSA of 6.3 (IQR 4.25). 9.3% (38/408) of the lesions were located in both TZ and PZ, 19.4% (79/408) in TZ and 71.3% (291/408) in PZ. Tumor size was slightly but significantly (P=0.002) higher for multi zone lesions (median 2.5cm) compared to TZ lesions (median 2.3cm) and PZ lesions (median 2.1cm). PSA was significantly higher (P= 0.001) in multi zone (7.7 ng/ml) and TZ PCa lesions (7.65 ng/ml) compared to PZ lesions (6 ng/ml). Multi zone lesions had a significantly higher proportion of PI-RADSv2 score 5 (55.3%) compared to TZ lesions (44.3%) and PZ lesions (33.7%) (p<0.001). Other parameters such as PSA density, prostate volume, tumor grading (Gleason score) and staging were similar between single and multi zone lesions.

CONCLUSION

Although multi zone PCa lesions may have more aggressive 3T mpMRI and clinical characteristics, however the grading and staging of the tumors on WMHP are similar to single zone lesions.

CLINICAL RELEVANCE/APPLICATION

Multi zone PCa lesions are associated with more aggressive clinical and MRI features with similar pathologic characteristics compared to single zone PCa lesions.

SSK10-08 Are Qualitative or Quantitative Analysis of DCE the Key to Success in the Grading and Detection of Prostate Cancer?

Wednesday, Nov. 28 11:40AM - 11:50AM Room: N228

Participants
Farid Ziayee, Dusseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Lars Schimmoeller, MD, Dusseldorf, Germany (*Presenter*) Nothing to Disclose
Tim Ullrich, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose

Christian Arsov, MD, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Gerald Antoch, MD, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The primary purpose of this study was to evaluate the performance of (semi-)quantitative analysis of dynamic contrast-enhanced MRI (DCE) in the detection of prostate cancer (PCa) in comparison to qualitative analysis. The secondary purpose of this study was to find out if any of the methods could distinguish clinically significant PCa from insignificant PCa.

METHOD AND MATERIALS

DCE data of 103 consecutive patients with multi-parametric MRI (T2WI, DWI, DCE) and subsequent MRI-(in-bore)-biopsy of the prostate were retrospectively analyzed. Qualitative analysis of DCE (after PIRADS v2 criteria), semiquantitative analysis (curve type after PIRADS v1 criteria) and quantitative (Ktrans, kep after Tofts) analysis of in total 206 lesions (87 cancer positive and 119 benign lesions) were performed. Cancer detection, discrimination of significant cancer, and localization was assessed and compared to histopathologic findings.

RESULTS

Subdivided in peripheral zone (PZ) and transition zone (TZ) Ktrans ($p<0.01$; $p=0.04$) and Kep ($p=0.04$, $p<0.01$) were significantly different between PCa and benign lesions. The PI-RADS v2 overall score could discriminate PCa and benign lesions in both, PZ and TZ ($p<0.01$), whereas PI-RADS single scores of DCE could differentiate PCa better in PZ ($p<0.01$) than in TZ ($p=0.5$). None perfusion parameter could differentiate between insignificant and significant (>=3+4=7) PCa ($p=0.5$-0.8).

CONCLUSION

PI-RADS v2 criteria for DCE discriminate well between benign lesions and PCa in the peripheral zone. Qualitative (curve type) and quantitative parameters (Ktrans, Kep) provide no additional improvement in PCa detection compared to PI-RADS scoring alone. DCE-MRI alone did not allow differentiation between significant and insignificant PCa.

CLINICAL RELEVANCE/APPLICATION

DCE and PI-RADS v2 criteria enable an improvement of PCa detection especially in the peripheral zone, central zone, and anterior stroma; therefore DCE should not be omitted for primary PCA detection. With limitations quantitative analysis can detect PCa, but the additional diagnostic relevance of quantitative parameters is limited. PI-RADS criteria for DCE in transition zone needs to be optimized for PCa detection.

SSK10-09 Is Biopsy Justified in Prostate Patients Assigned to PI-RADS Category 3?

PURPOSE

To systematically analyze patients with PI-RADS-3-lesions (called 'equivocal' according to PI-RADS v2) in multiparametric prostate MRI (mp-MRI) and MR-targeted plus systematic transrectal ultrasound-guided (TRUS-GB) biopsies as reference standard.

METHOD AND MATERIALS

One hundred and twenty consecutive patients assigned to PI-RADS assessment category 3 after mp-MRI (T2WI, DWI, DCE-MRI) at 3T and subsequent targeted MRI/US fusion-guided (FUS-GB) plus systematic 12-core TRUS-GB were retrospectively included in this study. As endpoints prostate cancer (PCa) detection rates, distribution of Gleason scores, location of PCa, and risk stratification by subgroup analyses were defined.

RESULTS

PCa was detected in 13 of 118 patients (detection rate 11%) including five patients with a Gleason score (GS) >=3+4=7 (4.2%). 1.4% of the lesions within the transition zone (3/212) and 9.4% within the peripheral zone (6/64) were positive for PCa. Patients with PCa showed in 54% MRI patterns of peripheral prostatitis combined with diffuse stromal hyperplasia. Prostate volume was significantly lower in PCa patients ($p=0.015$), whereas differences in PSA levels were not statistically significant ($p=0.87$). PSA density was higher in patients with PCa (0.19 vs. 0.12 ng/ml/ml).

CONCLUSION

PCa with a GS >=3+4=7 can be detected in mp-MRI with a high degree of certainty. In patients assigned to PI-RADS category 3 low-grade PCa (GS 3+3=6) can occur, but GS >=4+3=7 PCa is very unlikely. Therefore, primarily follow-up MRI is justified in these patients to avoid overtreatment of clinically insignificant PCa. In patients with a combination of MRI aspects of extensive prostatitis and diffuse stromal hyperplasia, low prostate volume, and/or high PSA density biopsy might be considered.

CLINICAL RELEVANCE/APPLICATION

Patients with PI-RADS 3 lesions can safely be managed by follow-up MRI as "test-of-time" approach without immediate biopsy, especially if lesions are located in the transition zone. This recommendation may apply specifically to patients with low PSA density and without MRI features of peripheral prostatitis combined with diffuse stromal hyperplasia.

PURPOSE

To quantify the time and monetary cost associated with oral contrast administration prior to abdominopelvic CT for patients with non-traumatic abdominal pain in the emergency department (ED). A secondary aim was to assess the cost savings associated with a new institutional policy change for oral contrast administration in this population.

METHOD AND MATERIALS

A HIPAA-complaint, IRB-approved time-driven activity-based costing analysis was performed using both prospective time-studies and retrospective data obtained in a quaternary care center. Retrospective data spanned a 1-year period (1/1/2016-12/31/2016). A process map was generated. Exam volume-related data, labor costs, and material costs were determined and applied to a base-case model. Univariate and multivariate sensitivity analyses were conducted. Multivariate analysis was used to estimate the cost savings associated with a policy change eliminating oral contrast for patients with BMI >=25, no prior abdominal surgery <=30 days, and no inflammatory bowel disease.

RESULTS

The baseline oral contrast utilization rate was 86% (4,541/5,263). The annual base-case cost estimate for oral contrast administration was $155,173. In multivariate analyses, this ranged from $20,034 - $672,469. The model was most sensitive to volume of cases requiring oral contrast and passive ED costs during contrast consumption. The median time cost of oral contrast consumption was 33 minutes (IQR: 23-43 minutes) for barium sulfate suspension and 62 minutes (IQR: 43-81 minutes) for diatrizoate meglumine-sodium. Applying parameters from the new policy change reduced the annual cost by 52% (cost saving: $73,709).

CONCLUSION

Time and monetary costs associated with oral contrast administration prior to abdominopelvic CT in the ED should be balanced with its potential diagnostic benefits to ensure high-quality patient care and healthcare cost stewardship. Our multi-departmental collaborative policy change is estimated to halve hospital costs associated in ED oral contrast administration.

CLINICAL RELEVANCE/APPLICATION

Time and monetary costs associated with oral contrast administration prior to abdominopelvic CT in the ED should be balanced with diagnostic benefits to ensure high-quality patient care and healthcare cost stewardship.

SSK11-02 Testing for Verification Bias in Reported Malignancy Risks for Side-Branch Intraductal Papillary Mucinous Neoplasms: A Simulation Modeling Approach

davis@mgh-ita.org

PURPOSE

To test for the possibility that published malignancy risks for side-branch intraductal papillary mucinous neoplasms (SBIPMN) are overestimates, likely due to verification bias.

METHOD AND MATERIALS

We tested for possible verification bias using simulation modeling techniques. First, in age-defined hypothetical cohorts of one million persons, we projected the frequency of pancreatic ductal adenocarcinoma (PDAC) arising from SBIPMNs over five years using published estimates of their prevalence (4.4%) and rate of malignant transformation (1.9%). Second, we projected the total number of PDAC cases in corresponding cohorts over the same time horizon using national cancer registry data (SEER). For each cohort, we determined if the percentage of all PDAC cases that arose from SBIPMNs (i.e., of SBIPMN-associated PDAC cases) was clinically plausible, invoking an upper limit of 10% to define plausibility, as estimated from the literature. Model assumptions and parameter uncertainty were evaluated in sensitivity analysis.

RESULTS

Across all cohorts, percentages of SBIPMN-associated PDAC greatly exceeded 10%. In the base case (mean age=56 years), 88% of PDAC cases arose from SBIPMNs (874/989). In the oldest cohort evaluated (mean age=75 years), this estimate was 82% (1,549/1,882). In a secondary analysis, we found that if an upper limit threshold of 10% for SBIPMN-associated PDAC was imposed, the model-predicted rate of malignancy for SBIPMN would be <0.21% over a five-year time horizon, substantially lower than most literature-based estimates.

CONCLUSION

Our results suggest that reported malignancy risks associated with SBIPMNs are likely to be overestimates, and imply the presence of verification bias.

CLINICAL RELEVANCE/APPLICATION

Our results highlight the uncertainty surrounding the natural history of SBIPMNs and underscore the importance of each patient's individual circumstance when making decisions regarding follow-up or treatment of SBIPMN.

SSK11-03 Automatic Evaluation of Routine Computed Tomography Scans for Prediction of Osteoporotic Fractures

PURPOSE

Osteoporotic (OP) fractures cause major morbidity and mortality. The clinical importance of fracture risk predictors such as FRAX is well established, and they are integrated into treatment guidelines. However, FRAX is underutilized due to lack of physician time, awareness, and availability of the 18 required inputs. The study's purpose is to establish whether OP fracture risk scores can be produced automatically from routine CTs using an artificial-intelligence based algorithm, and to compare their predictive ability to that of FRAX.

METHOD AND MATERIALS

Members of a healthcare provider aged 50-90, who underwent routine chest or abdomen CTs prior to July 2012 (index date), were divided to train and test sets. An algorithm scored each CT for bone mineral density (BMD) and presence of vertebral compression fractures. Five-year fracture risk scores were assessed as of the index date by: FRAX (module without DXA), CT (based on the algorithm markers and metadata of age and sex), and combined FRAX-CT. Models' discrimination was evaluated using area under the ROC curve (AUC), by comparing the models' outputs to major OP and hip fracture incidence during a 5-years follow-up period (until 2017). Missing FRAX inputs were completed using 10 imputed data sets. Significance was evaluated using 500 bootstrap samples per data set.

RESULTS

A total of 48,227 individuals were analyzed, of these, 5,106 (10.6%) and 1,901 (3.9%) suffered major OP and hip fractures during follow-up, respectively. Missing values occurred in 1.17% of the population. Compression fractures were identified in 7,521 (15.6%) CTs and abnormally low BMD was identified in 8,196 (17.0%). The AUCs of the FRAX, CT and combined models were 68.7%, 70.2% and 71.5% for major OP fractures, and 75.1%, 75.3% and 77.0% for hip fractures, respectively. All AUC differences were significant except those between the FRAX and CT models for hip fractures.

CONCLUSION

Fully automatic screening for OP fracture risk using routinely acquired CT scans achieves discrimination which is at least as good as the well-established FRAX model. If data for all FRAX inputs is available, the CT algorithmic score may be incorporated to further improve its predictive ability.

CLINICAL RELEVANCE/APPLICATION

OP fracture prediction scores can be added automatically to CT reports, and help identify people at high risk for fractures, who are currently missed due to under use of traditional prediction tools.

SSK11-04 Natural Language Processing at Work! Is There a Difference Between LI-RADS Category 3 to Category 5 Progression Assessment Between CT versus MR? A Retrospective Analysis of 1,887 Patients Who Underwent 5,082 Radiologic Exams for HCC Surveillance

Wednesday, Nov. 28 11:00AM - 11:10AM Room: S104A

pojeda@uw.edu

PURPOSE

Using the Liver Imaging Reporting and Data System (LI-RADS), our purpose is to identify the proportion of liver lesions with indeterminate probability of hepatocellular carcinoma (HCC) (LI-RADS 3) which progress to high likelihood of HCC (LI-RADS 5) using a large patient cohort to compare the differences in progression between computed tomography (CT) versus magnetic resonance (MR) imaging.

METHOD AND MATERIALS

This is a retrospective, single-center, longitudinal study of 1,887 patients who underwent a total of 5,082 radiologic examinations for HCC surveillance. Examinations included CT and MR studies identified from 2010-2017 (CT 36.4%, MR 61.6%). The dates of imaging studies, modality type, and associated LI-RADS category assignments were automatically extracted from the original examination reports using natural language processing techniques. We calculated the proportions of lesions initially classified as LI-RADS Category 3 which progressed to LI-RADS Category 5 on both CT and MR.

RESULTS

On MR, a LI-RADS Category 3 lesion was 1.5 times more likely to be upgraded to LI-RADS Category 5 compared to CT (114/379 upgraded on MR vs. 43/217 upgraded on CT, $p<0.01$). While only 20% of CT LI-RADS Category 3 were upgraded to a LI-RADS Category 5, 30% of MR CT LI-RADS Category 3 were upgraded to a CT LI-RADS Category 5.

CONCLUSION

Our data suggests that MR is more likely to upgrade a LI-RADS Category 3 to LI-RADS Category 5 as compared to CT. Improved characterization of lesions definitely representing HCC (LI-RADS Category 5) has the potential to lead to earlier diagnosis and provide lead time for subsequent treatment optimization for these patients.

CLINICAL RELEVANCE/APPLICATION

Using natural language processing, 5,082 CT/MR liver protocol studies were analyzed. MR is more likely to upgrade a LI-RADS Category 3 lesion to Category 5 compared to CT and can provide additional lead time for treatment optimization.

PURPOSE

Knee pain is the most common orthopaedic indication for MRI, and is frequently caused by meniscal tears. Such tears increase in prevalence in the presence of osteoarthritis (OA), with one study showing that, of patients with significant OA, 63% with knee pain and 60% without symptoms have MRI evidence of meniscal tear. If surgery is required in patients with co-existent OA, it should be for joint replacement, which is evaluated with plain X-rays. Therefore, there are a considerable number of patients with significant OA that would not benefit from MRI. We attempt to determine if evaluation of OA via recent X-rays can reduce inappropriate MRI use in patients >55 years of age. Additionally, in our jurisdiction, CT arthrograms are used as surrogate tests for knee internal derangement because of long MRI wait times. Therefore, we attempt to determine if there will be a decrease in knee CT arthrograms as well.

METHOD AND MATERIALS

Our intervention required recent X-rays (within one year) for patients >55 years of age who were scheduled for outpatient MRI of the knee/hip/shoulder. A working group agreed upon red flags (i.e. neoplasm, infection) for which MRI would be indicated regardless. Through review of radiographs on PACS/digital media and use of the validated Kellgren-Lawrence (KL) OA scale, radiologists assessed the degree of OA, and thus the need for advanced imaging. A finding of significant OA (KL >2) without red flags would preclude MRI. Monthly averages of MRI and CT arthrogram requisitions were measured before (33 months) and following our intervention (14 months).

RESULTS

Post-intervention, the average monthly number of MRI requisitions decreased from 61 to 56 ($P = 0.070$) compared with the baseline. If MRI wait time is taken into consideration (9 months), the monthly average decreased to 40. The proportion of protocoled cases that were avoided was 17% (38/227). The average monthly number of knee CT arthrogram requisitions decreased from 21 to 12 ($P = 0.004$) following the intervention.

CONCLUSION

We were able to decrease the number of MRI and knee CT arthrogram exams in patients over 55 years of age with joint pain by implementing an evaluation for OA via recent X-ray imaging.

CLINICAL RELEVANCE/APPLICATION

Recent X-ray evaluation for osteoarthritis can prevent unnecessary MRI and is recommended for patients who are over 55 years of age and have joint pain.

SSK11-06 Second Thoughts: Emergency Clinicians See Value in Secondary Interpretations

Wednesday, Nov. 28 11:20AM - 11:30AM Room: S104A

Awards
Student Travel Stipend Award

dipan.danda@yale.edu

PURPOSE

As technological improvements have lead to increased transportability of imaging, and as facilities have begun to realize the costs, both in terms of liability and time, of offering curbside consults on outside imaging, many large institutions now offer complete secondary read radiology reports and attempt to monetize such efforts. But are clinicians ordering these secondary reads simply as part of their intake process, or is there any real benefit to the emergency physicians and trauma surgeons who obtain these secondary reports? This study seeks to evaluate the benefit of secondary reads, and how clinicians navigate issues regarding payment, reimaging and managing conflicting reports.

METHOD AND MATERIALS

An anonymous electronic survey regarding secondary interpretations and associated issues was circulated to 58 attending emergency physicians and trauma surgeons at Yale-New Haven Hospital. There were 26 responses, representing a 44.8% response rate.

RESULTS

80.8% of respondents requested secondary interpretations either always or most of the time. Over half of respondents cited trust in the house radiologist interpretation over the outside radiologist as the primary reason they requested secondary reads. 92.3% and 84.6% of respondents felt that the ability to obtain second interpretations improves patient care and facilitates disposition, respectively. Furthermore, 88.5% of respondents reported a reduced need to obtain additional imaging due to secondary reads. When presented with conflicting interpretations 65.4% of respondents rely on the in house interpretations while 26.9% consider obtaining further imaging. 96.2% of respondents were uncertain about whether insurance covered secondary reads, but 73.1% would continue to order them regardless.

CONCLUSION

Not only were secondary reads heavily utilized by respondents, but they were felt to influence patient care and aid in disposition,

suggesting that secondary reads have real clinical import. Most felt secondary interpretations reduced the need for more imaging even when presented with conflicting reads, suggesting benefits in resource utilization and minimization of radiation. Finally, most respondents would still request secondary interpretations despite being unaware if insurance covered these interpretations.

CLINICAL RELEVANCE/APPLICATION

This study should be of interest to all radiologists working at institutions which offer or are considering providing secondary reads.

SSK11-07 Emergency Radiology: An Underappreciated Source of Liability Risk

Wednesday, Nov. 28 11:30AM - 11:40AM Room: S104A

Participants
Jeffrey D. Robinson, MD, MBA, Seattle, WA (*Presenter*) Consultant, HealthHelp, LLC; President, Cleareview, Inc;

jeff8rob@uw.edu

PURPOSE

Many studies examine the malpractice risk of radiologists in general, focusing on factors such as the type of error, modality and organ system. However, no publication has focused attention on the patient status as a differentiating factor. This study estimates the relative risk of liability action arising between inpatient, outpatient and emergency department exams.

METHOD AND MATERIALS

90 consecutive malpractice claims referred to a radiology-specific malpractice consulting company were reviewed. The site of service for the exam at issue was identified as Inpatient (IP), Outpatient(OP) or Emergency Department (ED). The Medicare Part B claims file was queried to establish the relative frequency of exams performed in each of these settings for 2016. A chi-squared test was used to compare the distributions of malpractice to Medicare claims. The odds ratio of legal action was calculated using the Medicare data as a proxy for the relative number of exams performed in the US for each patient status.

RESULTS

There were 12 IP, 33 OP and 45 ED malpractice claims. In 2016, Medicare beneficiaries claimed 29,124,475 IP, 78,430,930 OP and 22,356,328 ED exams. The distribution of patient status for malpractice claims differed from the Medicare claims file with a Chi-squared statistic of 67.9 ($p<<0.01$). The odds ratio of a malpractice claim was 4.89 (95%CI 2.58 - 9.24) for ED exams compared to IP, 4.78 (95%CI 3.05 - 7.50) compared to OP exams, and 0.98 (95%CI 0.51 - 1.90) for IP compared to OP exams.

CONCLUSION

This initial examination suggests that Emergency Radiology as it is currently practiced presents an increased risk of a malpractice claim compared to other aspects of the practice of radiology.

CLINICAL RELEVANCE/APPLICATION

Radiology practice groups might wish to consider forming a core radiology section whose members have interest, expertise and/or fellowship training in Emergency Radiology.

SSK11-08 Fully Automated Computer-Aided Detection Implementation in The Emergency Department for Detection of Pulmonary Nodules on CT: Effect on Workflow and Diagnostic Accuracy

Wednesday, Nov. 28 11:40AM - 11:50AM Room: S104A

Participants

Vahid Yaghmai, MD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To assess the feasibility and added value of implementing fully automated computer-aided diagnosis (CAD) for detection of pulmonary nodules on CT angiography studies in emergency setting.

METHOD AND MATERIALS

We retrospectively reviewed a dataset of 48 emergency patients who underwent computed tomography pulmonary angiography (CTPA) for pulmonary embolism (PE) in September 2017. A cardiothoracic radiologist with 6 years experience (RAD1) and a third year radiology resident (RAD2) reviewed the scans separately to detect pulmonary nodules without CAD followed by CAD. CAD detection rate of nodules was also evaluated in the same reading session. CAD nodule detection was fully automated and required no additional processing time by RAD or technologist. The time spent by RAD to evaluate the image sets was measured for each case. Fisher`s exact test and T-test were used to determine the differences between the rate of detection between the readers and the CAD.

RESULTS

CAD significantly increased the rate of RAD1 detection by 27% (2.23 vs. 1.75 nodule/scan, $P<0.05$). CAD significantly increased the rate of RAD2 detection by 34% (2.52 vs. 1.88 nodule/scan, $P<0.05$).

CONCLUSION

Routine utilization of CAD in the emergency setting is feasible and can improve detection rate of pulmonary nodules significantly.

CLINICAL RELEVANCE/APPLICATION

Computer aided detection can be considered as a useful adjunct tool which can optimize pulmonary nodule detection in emergency department CT scans.

PURPOSE

The Protecting Access to Medicare Act of 2014 (PAMA) requires referring physicians to use clinical decision support (CDS) when ordering advancing imaging procedures. We sought to identify opportunities to improve use of radiology order entry CDS.

METHOD AND MATERIALS

All advanced diagnostic imaging orders placed at a 590-bed level II trauma teaching hospital were tracked silently in the CDS: clinicians were prompted to select a study indication from a drop-down menu at the time of order-entry that mapped to AUC categories, but no feedback was given to the ordering clinician. All orders placed in the first 30 days after CDS deployment were mapped to an AUC category. Orders which could not be categorized were reviewed manually to determine if an indication existed.

RESULTS

Of 39,533 advanced diagnostic imaging orders, 23,267 (59%) were not mapped to an indication. Most unmapped orders (16,440/23,267, 71%) used free-text study indications rather than the drop-down menu. Emergency Medicine (3,877/16,440, 24%) and Hematology/Oncology (3,410/16,440, 21%) had the highest free-text entry rates. Exams with the highest free text entry rates were CT Abdomen/Pelvis with IV contrast (1,693/16,440, 10%) and CT Head without IV contrast (1,527/16,440, 9%). Manual review of free-text study indications revealed that 3,132/3,220 (97%) could easily be matched to a single mapped indication in the CDS. The remaining one-third of orders that could not be mapped (6,827/23,267, 29%) reflected issues related to software build and best practice alert configuration.

CONCLUSION

Nearly two-thirds of advanced diagnostic imaging orders placed in the first month CDS was implemented could not be mapped to AUC; this was mainly due to free-text entry of study indication rather than use of drop down menus, although (97%) of free text entries could easily be matched to a single mapped indication in the CDS.

CLINICAL RELEVANCE/APPLICATION

Opportunities for improvement of electronic imaging decision support systems to support CMS PAMA can be identified prior to deployment through piloting of the system in a silent-mode setting.

lbaratto@stanford.edu

PURPOSE

To describe the distribution and range of physiological uptake of 68Ga-RM2 in patients with prostate cancer and to evaluate the spectrum of abnormal uptake using standardized uptake values (SUVs).

METHOD AND MATERIALS

We retrospectively reviewed images of 20 prostate cancer patients who performed either an 68Ga-RM2 PET/CT for primary diagnosis and staging (n=7) or 68Ga-RM2 PET/MRI for a biochemical recurrence (n=13). Two nuclear medicine physicians evaluated images using an AW workstation (GE Healthcare). SUVmax and SUVmean were measured in 24 normal anatomical structures for each patient. 68Ga-RM2 uptake values of each organ was classified as "none" if SUVmean value was less than of the aortic blood pool, "mild" if SUVmean was greater than SUVmean of aortic blood pool, but less than 2.5, "moderate" if SUVmean was between 2.5 and 5 and "intense" if SUVmean was greater than 5. Areas of focal increased 68Ga-RM2 uptake were also collected.

RESULTS

The highest activity was observed in bladder and renal collecting system, related to urinary excretion of radiotracer. The highest physiologic uptake was present in the pancreas (SUVmax 62.38±13.74). Uptake in the kidney cortex, duodenum and esophagus was mostly classified as mild (average SUVmax of 3) and only few times as moderate. Uptake in the in the stomach wall, rectum and adrenal was mostly classified as not significant (average SUVmax of 2.5) and only few times as mild. Brain, adrenals, liver, spleen, bone, gluteal muscle and fat had not significant uptake. Sixteen avid foci of 68Ga-RM2 uptake were detected in 9 patients. Uptake was identified in the prostate bed (n=6), abdominopelvic and mediastinal lymphnodes (n=5 and n=2, respectively), skeleton (n=2) and lungs (n=1).

CONCLUSION

We presented data on patterns of physiological 68Ga-RM2 uptake in normal tissues with the aim of creating an atlas to improve the interpretation accuracy of 68Ga-RM2 PET scan. Our data also confirmed that 68Ga-RM2 is a promising tracer for the assessment of GRPr expression in prostate cancer patients. Further evaluation in a larger cohort are needed to confirm these data.

CLINICAL RELEVANCE/APPLICATION

68Ga-RM2 is a promising radiotracer for prostate cancer imaging. Atlas of 68Ga-RM2 would improve accuracy of imaging interpretation.

SSK12-02 A Fluorescent Glucose Analogue for Selective Imaging of Sodium-Dependent Glucose Transporters in Breast Cancer

richard.agnes@case.edu

PURPOSE

Sodium-dependent glucose transporters (SGLTs) are emerging as biomarkers as well as a potential imaging and therapeutic target in a variety of human malignancies. Recently, we have developed a fluorescent glucose analog with a near infrared fluorophore attached at the carbon-6 position (6FGA) and have reported its cell uptake in cancer cells in vitro. With a goal towards clinical application, we are further characterizing 6FGA for cancer imaging including cell uptake mechanisms, transporter selectivity, and conditions for small animal imaging.

METHOD AND MATERIALS

6FGA was synthesized using click chemistry between 6-azido-glucose and alkyne cyanine 5.5. To assess SGLT-driven cellular uptake, MDA-MB-231 triple-negative breast cancer lines were incubated with 6FGA for 20 minutes in various conditions, including in the presence and absence of SGLT (phlorizin), SGLT2 (dapagliflozin), and GLUT (cytochalasin B) inhibitors as well as in presence and absence of the cotransported sodium ion. 6FGA cellular uptake was examined using confocal microscopy. 6FGA uptake in vivo in murine xenograft tumors that were grown and sectioned to 1 millimeter slices was examined by fluorescence imaging.

RESULTS

Western blots confirmed the expression of SGLT1 and SGLT2. In cell uptake studies, 6FGA accumulation in MDA-MB-231 cells was reduced by SGLT and SGLT2 but not by GLUT inhibitors. Further confirming the SGLT-driven uptake, 6FGA accumulation did not occur when the SGLT co-transported sodium ion was absent from the medium. The uptake in tumor slices was consistent with that in the cell studies in that it increases over time and did not wash out.

CONCLUSION

6FGA is emerging as promising tool for investigating SGLT in cancer cells and tumor tissues. Our preliminary cell uptake studies suggest that 6FGA uptake is mediated through SGLTs. Initial studies with tumor slices suggests feasibility and optimal conditions for in vivo imaging of tumor model in small animals.

CLINICAL RELEVANCE/APPLICATION

6FGA is a model towards designing new tracers for PET imaging to improve detection and treatment for SGLT cancers such as triple negative breast and metastatic prostate.

SSK12-04 Quantitative Magnetic Particle Imaging of Transplanted Ferumoxytol-Labeled Stem Cells

Wednesday, Nov. 28 11:00AM - 11:10AM Room: S504CD

hnejadni@stanford.edu

PURPOSE

To evaluate, if ferumoxytol (Feraheme) can be used for in vivo detection and quantification of stem cell transplants with magnetic particle imaging (MPI).

METHOD AND MATERIALS

Mesenchymal stem cells (MSCs) were labeled with ferumoxytol (Feraheme) or ferucarbotran (Resovist/Vivotrax) and underwent magnetic particle imaging (MPI), magnetic resonance imaging (MRI), prussian blue staining and inductively coupled plasma (ICP) spectrometry. Unlabeled, ferumoxytol, and ferucarbotran-labeled MSCs were implanted in calvarial defects of eight mice and underwent MPI, MRI and histopathology. The iron concentration calculated according to the MPI signal intensity and T2* relaxation times of the three different groups were compared using an analysis of variance (ANOVA) with Bonferroni correction, and a $p<0.05$.

RESULTS

Compared to unlabeled controls, ferumoxytol and ferucarbotran labeled MSC showed significantly increased iron content, MPI signal and MRI signal. The ferumoxytol MPI signal was approximately 4x weaker compared to ferucarbotran at equimolar concentrations ($p=0.0003$) and approximately 1.5 times weaker for labeled cells when using optimized labeling protocols ($p=0.002$). In vivo, the MPI signal of ferumoxytol-labeled MSC decreased significantly between day 1 and day 14 ($p=0.0124$). This was confirmed by histopathology where we observed a decrease in Prussian blue stain of MSCs at the transplant site. The MRI signal of the same transplants did not change significantly during this observation period ($p=0.93$).

CONCLUSION

Ferumoxytol nanoparticles can be used for in vivo detection of stem cell transplants with MPI and provide quantitative information not attainable with MRI.

CLINICAL RELEVANCE/APPLICATION

Clinically applicable ferumoxytol can be detected with MPI, allowing accurate in vivo detection and quantification of labeled stem

cells, which is an important basis for clinical translation of MPI.

SSK12-05 18F-Labeled Magnetic Nanoparticles for the Assessment of Early Anti-angiogenic Therapy Effects in Triple Negative Breast Cancer Xenografts

Wednesday, Nov. 28 11:10AM - 11:20AM Room: S504CD

wangyanshu_1992@sina.com

PURPOSE

To investigate the positron emission tomography/magnetic resonance imaging (PET/MRI) dual-modality imaging probe 18F-RGD-PAA-USPIO for the in vivo monitoring of avß3-integrin expression as biomarker of anti-angiogenic therapy effects in breast cancer xenografts model.

METHOD AND MATERIALS

A multimodal imaging agents 18F-RGD-PAA-USPIO nanoparticles was synthesized and tested in vitro and in vivo.Mice bearing MDA-MB-231 subcutaneous tumors were treated with bevacizumab or placebo(n=10/group,intraperitoneal injections of bevacizumab or a volume-equivalent placebo solution at the dose of 10 mg/kg every other day for 4 times). Tumor volumes were assessed with caliper measurements everyday.The animals were imaged with 18F-RGD-PAA-USPIO,the target-to-background ratio (TBR, VOImaxtumor/VOImeanmuscle,ΔTBR=TBRday7-TBRday0) and ΔT2 value(ΔT2=T2pre-contrast-T2post-contrast,ΔΔT2=ΔT2day7-ΔT2day0) were served as semiquantitative measure to determine the effect of bevacizumab.Imaging results were validated by ex vivo multiparametric immunohistochemistry with regard to microvascular density (CD31) and proliferation(Ki-67).

RESULTS

18F-RGD-PAA-USPIO did not cause cellular toxicity in MDA-MB-231 cell lines.Both small-animal PET and T2-weighted MRI show integrin specific delivery of 18F-RGD-PAA-USPIO. No intergroup difference in tumor volume development between day 0 and day 7 was observed (p=0.118).18F-RGD-PAA-USPIO binding was significantly reduced after bevacizumab compared with the control group shown both in PET/CT (ΔTBR,-0.65 ± 0.43 vs 0.66 ± 1.04,p=0.032) and MRI imaging (ΔΔT2,9.56 ± 4.14 vs 4.92 ± 6.10,p<0.01).Correspondingly,immunohistochemistry revealed a significantly lower microvascular density (CD31,15.19 ± 7.58 vs 42.90 ± 16.81,p<0.01), tumor cell proliferation (Ki-67,420.60 ± 113.67 vs 702.30 ± 119.62,p<0.01) in the therapy compared with the control group.

CONCLUSION

18F-RGD-PAA-USPIO can be use to monitor and evaluate the therapeutic effects of anti-angiogenesis agents on breast cancer model.

CLINICAL RELEVANCE/APPLICATION

(to dealing with PET/MRI) the multimodal imaging agents, 18F-RGD-PAA-USPIO,which are capable of simultaneously providing both PET and MRI information, can expand the applicability of PET/MRI dual modality imaging system.

SSK12-07 Fractional Excretion and Biodistribution of the Manganese-Based MRI Contrast Agent Mn-PyC3A in Rats

Wednesday, Nov. 28 11:30AM - 11:40AM Room: S504CD

Participants
Eric Gale, Charlestown, MA (*Abstract Co-Author*) Co-founder, Reveal Pharmaceuticals; Stockholder, Reveal Pharmaceuticals
Ian Ramsay, BS, Charlestown, MA (*Abstract Co-Author*) Nothing to Disclose
Peter D. Caravan, PhD, Charlestown, MA (*Presenter*) Research Grant, Pfizer Inc;

For information about this presentation, contact:

caravan@mgh.harvard.edu

PURPOSE

To determine the fractional excretion and biodistribution of manganese at 1 day and 7 days following injection of the manganese-based MRI contrast agent Mn-PyC3A in rats.

METHOD AND MATERIALS

All experiments were performed in accordance with the National Institutes of Health's Guide for the Care and Use of Laboratory Animals, 8th Edition, and were approved by the institutional animal care and use committee of Massachusetts General Hospital. [52Mn]Mn-PyC3A was prepared from an aliquot of a 0.5 M solution of Mn-PyC3A that was mixed with 3 mCi of 52MnCl2 (beta+, t1/2 = 5.56 d) at pH to 3.0. After stirring for 30 min, the pH was adjusted to 8.0 with N-methyl-D-glucamine and returned to the bulk 0.5 M solution. [52Mn]Mn-PyC3A (2.0 mmol/kg, 100 - 300 µCi) was administered via tail vein to Wistar Rats. Rats, equal numbers of males and females, were housed in metabolic cages and euthanized after 1 d (N=10) or 7 d (N=8), and the organs were harvested and 52Mn quantified by gamma counter. The fractional excretion into urine and feces was also determined.

RESULTS

One day after [52Mn]Mn-PyC3A injection, 0.36±0.11 percent of the injected dose (%ID) remains in the rat and this drops to 0.052±0.042% after seven days. These values are an order of magnitude lower than reported Gd-retention following injection of gadolinium based contrast agents (GBCAs) (Tweedle, Invest. Radiol 1995;30(6):372-380). [52Mn]Mn-PyC3A is eliminated

84.9±4.9% into the urine and 15.1±4.9% into the feces. Mass balance indicated that 97.5±3.9 %ID was recovered from the excreta, tissues, and GI contents 1 d after injection.

CONCLUSION

Mn-PyC3A is >99.6% eliminated from rats one day after, and >99.9% eliminated seven days after intravenous injection. Mn-PyC3A shows extremely low levels of metal retention after administration.

CLINICAL RELEVANCE/APPLICATION

Mn-PyC3A has been proposed as a Gd-free alternative for contrast enhanced MRI. Before clinical translation, it is important to establish whether there is manganese ion accumulation. These studies indicate that Mn-PyC3A is rapidly and efficiently eliminated from the body and prompt further development of this new contrast agent.

SSK12-08 A pH-sensitive Manganese Core Nanoparticle as the Tumor Targeting MR Contrast Agent: Comparison with Gd-DTPA in a Mouse Model

Wednesday, Nov. 28 11:40AM - 11:50AM Room: S504CD

Participants
Jiali Li, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose
Zhen Li, MD, PhD, Wuhan, China (*Presenter*) Nothing to Disclose
Daoyu Hu, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose
Yaqi Shen, PhD, MD, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

A novel manganese core nanoparticle designed as pH-sensitive MR contrast agent (L-EGCG-Mn), confirmed the tumor targeting properties in a mouse model. In vitro and in vivo MR properties were compared with Gd-DTPA.

METHOD AND MATERIALS

This study was approved by the local Animal Ethics Committee. The physicochemical properties of L-EGCG-Mn were characterized by dynamic light scattering, transmission electron microscopy(TEM), and near infrared fluorescence small animal living imaging. A serial of different concentration of L-EGCG-Mn dispersed in phosphate buffered saline(PBS) with different pH (pH=7.4, 6.8, 5.5) and Gd-DTPA solutions were evaluated at a 3 T MRI scanner, and the relaxivities (r1 and r2) were obtained for comparison in vitro-analysis. A total of eight Hepatoma-22 cells implanted mice (5 for L-EGCG-Mn;3 for Gd-DTPA) were scanned at a 3.0 T MRI with an animal coil. MR images of pre- and 30min, 1h, 2h, 4h after injection of L-EGCG-Mn and Gd-DTPA were acquired. The signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of tumor were calculated.

RESULTS

The particle size of L-EGCG-Mn was 277.4±5.5 nm and the zeta potential of it was -13.56±1.91mV, the negative zeta potential indicating a good biocompatibility. TEM images confirmed that L-EGCG-Mn incubated in pH=5.5 PBS expanded faster than that in pH=6.8 PBS. And the r1(r2) relaxivity of L-EGCG-Mn increased from 1.8(10.1) to 6.4(22.9) $mM^{-1} \cdot s^{-1}$ when the pH values decreased from 7.4 to 5.5, which was higher than Gd-DTPA (r1=4.7, r2=5.4 $mM^{-1} \cdot s^{-1}$). In H22 model mice, L-EGCG-Mn had significantly higher average CNR and SNR compared with Gd-DTPA for all acquired time point ($P < 0.05$ for all).

CONCLUSION

L-EGCG-Mn had promising pH sensitivity and superior enhancement properties, compared with Gd-DTPA in H22 model mice and vitro relaxivity analysis.

CLINICAL RELEVANCE/APPLICATION

L-EGCG-Mn with tumor-microenvironment changeable relaxivity may be an alternative to Gd-DTPA and overcome controversy regarding gadolinium-associated toxicity and retention in the clinical.

SSK12-09 First-Pass CMR Perfusion Imaging with a Novel Manganese Chelate Contrast Agent in Myocardial infarction: Comparison with Gd-DTPA

Wednesday, Nov. 28 11:50AM - 12:00PM Room: S504CD

PURPOSE

To evaluate the feasibility of novel Mn2+ chelate to quantify myocardial perfusion in myocardial infarction (MI), by comparison with Gd-based First-pass perfusion MRI.

METHOD AND MATERIALS

We designed and synthesized an aza-semi-crown pentadentate chelator that formed manganese (Mn2+) complexes as a novel MRI contrast agent. MI was induced in 6 rabbits by permanent occlusion of left circumflex coronary artery. After 7days post-surgery, cine MRI, T1WI, T2WI, first-pass perfusion MRI were performed on a 3.0T clinical MRI scanner (Achieva, Philips, Andover, MA) with a clinical 8-channel knee coil. Dynamic signal changes on first-pass perfusion MRI was acquired using segmented turbo-FLASH sequence with 80 dynamic acquisitions. Three contiguous short-axis images was obtained after intravenous injection of gadolium (Gd-DTPA, Magnevist, Berlin, Germany) at 0.15 mmol/kg and Mn2+ chelate successively. A 120-minute washout period proceeded

between administration of contrast agents to ensure independent enhancement pattern. Short-axis cine images were analyzed for assessment of left ventricular (LV) volumes, ejection fractions (EF), first-perfusion images for slope, max signal intensity, time to peak, time to 50% max with dedicated software (Cmr42,Circle Cardiovascular Imaging Inc.,Calgary, Canada). The correlation between methods was evaluated with two-variable linear regression analysis, with Pearson correlation.

RESULTS

All rabbits survived after MRI scanning without significant differences in heart rate, LV end-diastolic volume, end-systolic volume and EF between baseline and after injection of Gd or Mn ($p>0.05$). First-pass perfusion MRI identified infarcted myocardial segments when compared with normal myocardial segments. When compared with normal myocardial segments, the slope, max signal intensity of infarcted myocardial segments decreased significantly, time to peak and time to 50% max extended (all $p<0.05$). All the perfusion parameters of infarcted and normal myocardial segments correlated well between Gd-based and Mn-based perfusion imaging (all $p<0.05$, $r=0.43-0.72$).

CONCLUSION

Our novel Mn2+ Chelate contrast agent is safe and reliable to visualize myocardial perfusion in myocardial infarction.

CLINICAL RELEVANCE/APPLICATION

Although still in the preclinical stage, the novel Mn2+ Chelate contrast agent may be useful for assessment of myocardial perfusion in myocardial infarction.

SSK13-01 Lower Leg Muscle Activation during Walking and Running: Quantitative Muscle-specific Assessment of Microvascular Perfusion with Intravoxel Incoherent Motion (IVIM) MR Imaging

Participants
Pia M. Jungmann, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose
Christian W. Pfirrmann, MD, MBA, Forch, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Christian Federau, Basel, Switzerland (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Little is known about muscle activation patterns during walking and running. Blood flow to skeletal muscles depends on the metabolic activity. Aim of this study was to non-invasively assess specific muscle activation of the lower limb after walking and running by using Intravoxel Incoherent Motion (IVIM) perfusion MRI.

METHOD AND MATERIALS

3T MR IVIM diffusion-weighted images of the lower extremities of 8 healthy female volunteers (mean age 27.5±5.7 years) were acquired at rest and immediately after walking and running, respectively. For IVIM measurements, a transverse monopolar pulsed gradient fat suppressed spin echo (SE) EPI sequence was used (9 b-values from 0 to 1000s/mm2, 3 orthogonal directions). In addition, anatomical transverse T1-weighted turbo SE images were acquired at rest. Entire muscles of the pelvis, thigh and lower leg were segmented. IVIM perfusion parameters f, D* and fD* and the diffusion coefficient D were obtained after standard two-steps fitting of the IVIM bi-exponential signal equation. Descriptive statistics, paired t-tests, multiple regression models and Pearson's correlations were used for statistical analyses.

RESULTS

Mean heart rates were 63±3min-1 at rest, 113±14min-1 during walking and 166±14min-1 during jogging. Microvascular blood-flow related fD* correlated significantly with heartrate while walking and running, respectively ($P<0.05$). Mean fD* of all muscles was significantly higher after running (2.18±0.98*10-3mm2/s, $P<0.001$) and after walking (1.99±0.80*10-3mm2/s, $P<0.001$) compared to rest (1.65±0.83*10-3mm2/s). Perfusion increase was gradual and most pronounced for the lower leg muscles (fD* increase of 60.8% after walking, 137.3% after running compared to rest, $P<0.001$) and for the feet muscles (78.4% and 181.4%, $P<0.001$) (Figure). Abductor muscles showed a higher microvascular perfusion than adductor muscles; quadriceps muscles showed a higher perfusion than hamstrings ($P<0.05$).

CONCLUSION

Non-invasive IVIM MRI is able to quantitatively measure local microvascular muscle perfusion in order to detect muscle activation patterns after walking and running.

CLINICAL RELEVANCE/APPLICATION

IVIM is a promising modality to non-invasively assess muscle physiology. It may potentially be of use to monitor changes in physiological microvascular muscle perfusion after training and to detect pathological muscle recruitment patterns.

SSK13-02 Evaluation of Role of Diffusion Weighted Imaging (DWI), Apparent Diffusion Coefficient (ADC) and Chemical Shift Imaging (CSI) in Distinguishing Benign versus Malignant Vertebral Body Lesions with Histopathological Correlation

PURPOSE

To evaluate the role of qualitative DWI, qualitative CSI: quantitative DWI(ADC values) and quantitative CSI(Signal Intensity Ratio - SIR values) in the differentiation of benign and malignant vertebral lesions.

METHOD AND MATERIALS

44 patients of all age group of both sexes showing presence of vertebral fractures on MRI were included in study. We used the biopsy results or results of clinical and radiologic follow up for at least 6 months, as the gold standard to classify the vertebral fractures as benign or malignant. The presence of high SI of vertebral fractures on DWI were considered as diffusion restricting. ADC values acquired, by placing ROI in ADC maps over the areas within the vertebral fractures that were showing abnormal signal intensities on T1, T2 weighted and STIR. The SI of vertebral fractures were compared in in-phase and out-of-phase image and loss of signal on out-of-phase image was evaluated. Quantitative analysis was done by calculating SIR values of opposed-phase to in-phase, by placing ROI over the areas within the vertebral fractures on the in-phase images and corresponding areas on the out-of-phase images(that were of abnormal SI on T1, T2 weighted and STIR sequences). SIR = SI opposed-phase / SI in-phase.

RESULTS

Qualitative DWI resulted in sensitivity of 92.9%, specificity of 20%, PPV of 35.14%, NPV of 85.71% and accuracy of 43.2%. The mean ADCs for the benign (1.37 ± 0.22) compression fracture group were significantly higher than the malignant (0.94 ± 0.17) group, and ADC cutoff value of 1.085 resulted in sensitivity of 85.7%, specificity of 83.3%, PPV of 70.59%, NPV of 92.59% and accuracy of 84.1%. Qualitative CSI resulted in sensitivity of 92.9%, specificity of 53.3%, PPV of 48.15%, NPV of 94.12% and accuracy of 65.9%. The mean SIRs for the benign (0.67 ± 29) compression fracture group were significantly lower than SIR values for the malignant (1.12 ± 0.15) group and SIR cutoff value to be 0.97 was identified with sensitivity of 92.9%, specificity of 90%, PPV of 81.25%, NPV of 96.43% and accuracy of 90.9%.

CONCLUSION

Quantifying the loss of signal on out-of-phase imaging and quantifying diffusion on ADC maps, can be used in differentiation between benign and malignant vertebral compression fractures.

CLINICAL RELEVANCE/APPLICATION

Quantitative DWI and quantitative chemical shift imaging can differentiate between benign and malignant vertebral fractures and is recommended as part of a MR study.

SSK13-03 Asymmetric Muscle Recruitment of the Back during Exercise in Patients with Scoliosis Demonstrated with Intravoxel Incoherent Motion (IVIM) MR Perfusion Imaging: Preliminary Results

Wednesday, Nov. 28 10:50AM - 11:00AM Room: N229

Participants
Christian Federau, Basel, Switzerland (*Presenter*) Nothing to Disclose
Daniela Kroismayr, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Linda Dyer, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Mazda Farshad, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Christian W. Pfirrmann, MD, MBA, Forch, Switzerland (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

It is thought that patients with scoliosis overuse the back muscle in the convexity of their scoliosis, which might worsen their condition. Because muscle activity increases local blood flow, muscle recruitment can be mapped using MR perfusion imaging. The purpose of this work was to study the muscular recruitment of back muscle during Roman chair exercise in patients with scoliosis using Intravoxel Incoherent Motion (IVIM), an imaging technique which extracts local and quantitative perfusion information from a diffusion weighted MRI sequence, without the need for an injection of a contrast agent.

METHOD AND MATERIALS

4 patients (3/1 f/m,20±4y) with scoliosis (Cobb angle 28±2°, range [25-30°]) were scanned at 3T first after observing a period of rest of 20 min, and then immediately after performing a symmetric back muscle exercise on a Roman chair, holding a 4kg dumbbell with both hands in the middle of the thorax, until exhaustion (72±2s). The IVIM diffusion-weighted sequence consisted of a spin-echo with echo planar readout and monopolar pulsed gradients with 16 b-values ranging from 0-900s/mm2. The IVIM bi-exponential signal equation model was fitted using a C++ implementation of a standard two steps algorithms. A region of interest was drawn in the paraspinal muscles at the level of the convexity of the scoliosis on both sides. Statistical significance was assessed using paired Student t-test.

RESULTS

At rest, microvascular blood-flow related IVIM fD* was found larger in the paraspinal muscles on the side of convexity (5.8±1.1x10-3mm2/s) compared to the concavity (4.3±1.5x10-3mm2/s), but the difference was not significantly (p=0.11). After Roman chair muscle exercise, fD* increased significantly in the paraspinal muscles (p=0.001), and fD* was significantly larger in the paraspinal muscles on the side of convexity (7.7±0.8x10-3mm2/s) compared to the concavity (5.3±1.0x10-3mm2/s,p=0.001).

CONCLUSION

The preliminary data of this study demonstrates an asymmetric microvascular muscle perfusion pattern in the muscle of the back after exercise in patient with scoliosis.

CLINICAL RELEVANCE/APPLICATION

This study helps clarifying muscular recruitment of back muscle during exercise in patients with scoliosis, and could help to improve current physiotherapeutic and surgical treatment approaches.

SSK13-04 Diffusion Weighted Imaging of Musculoskeletal Infections: Quantitative ADC Analysis of Lower Extremity Superficial and Deep Infections

PURPOSE

This study investigates the value of diffusion weighted imaging (DWI) and apparent diffusion coefficient (ADC) in the differential diagnosis of musculoskeletal infections and determines the region of interest (ROI) values for cellulitis, soft tissue abscess, osteitis, osteomyelitis and intraosseous abscesses in the lower extremity.

METHOD AND MATERIALS

The MRIs of sixty-two patients with musculoskeletal inflammation and/or infection were retrospectively evaluated through measurement of ROIs on DWI and ADC at the site of disease. Imaging was conducted between 2014 and 2017 with inclusion criteria of: adults 18-100 years, no metal in the field of view, extremity MRI scans with DWI imaging, and established reference standards of biopsy, surgery, and follow-up results. Patient cases were placed into six categories of infection: soft tissue edema, soft tissue cellulitis, soft tissue abscess, osteitis, osteomyelitis, and osteomyelitis with abscess. Diagnosis was based on a combination of pathology reports and clinical correlation (lab values, patient care notes, treatment regimen, time to resolution of symptoms). ROIs were measured by three readers trained by an experience musculoskeletal radiologist at the region of interest with minimum area of 1cm2. Statistical analysis of data was performed to measure inter-reader agreement with ICC and significance of ROI measurements on ADC with ANOVA to test for differences between the six categories of infection. The Bonferroni adjustment was applied to adjust the p value for multiple comparisons.

RESULTS

The mean ADC value of osteitis is 1.58 compared to 1.41 for osteomyelitis and 0.78 for intraosseous abscess with statistically significant difference ($p < 0.02$). Similarly, mean ADC value of soft tissue cellulitis is 1.70 and soft tissue abscess is 0.73 with statistically significant difference ($p < 0.001$). Intra-reader agreement was excellent with ICC of 0.93 and 0.96 between the three readers.

CONCLUSION

DWI and ROI measurements on ADC can reliably distinguish between osteitis, osteomyelitis and intraosseous abscess, as well as soft tissue abscess and soft tissue cellulitis.

CLINICAL RELEVANCE/APPLICATION

DWI and ADC measurements can distinguish between musculoskeletal infections and are recommended as part of the MRI studies and evaluation of these conditions.

SSK13-05 Diffusion MRI of Human Patellar Tendon: Initial Experience

PURPOSE

The patellar tendon (PT) is essential for knee extension. Patellar tendinopathy causes persistent anterior knee pain and occurs in ~14% of recreational athletes. Despite the high prevalence, no consensus treatment exists. PT microstructure and microcirculation play crucial roles in the progression of tendinopathy and tendon repair. Diffusion tensor imaging (DTI) and intravoxel incoherent motion (IVIM) imaging can assess the microstructure and microcirculation characteristics of biological tissue. However, the application of conventional diffusion MRI protocols to PT is challenged by short T2/T2* values (~2ms) and the long TE (~60ms) requirement. In this study, a stimulated-echo based short TE (~15ms) diffusion protocol (ste-RS-EPI), originally developed for Achilles tendon, was applied to PT of healthy subjects. After validation, this technique can be readily adopted to assess treatment response in patellar tendinopathy.

METHOD AND MATERIALS

Six healthy subjects were recruited for this IRB approved study on a Siemens Prisma 3T magnet. Stimulated-echo diffusion

preparation with readout-segmented EPI (ste-RS-EPI) was adopted. To further boost tendon MR signal, magic angle effect was exploited by positioning PT ~55 degrees w.r.t. B0 direction. PT fractional anisotropy (FA), radial diffusivity (RD), axial diffusivity (AD), and mean diffusivity (MD) maps were generated with DTI Studio. PT diffusion coefficient (D), pseudo-diffusion coefficient (D*), and perfusion fraction (fp) were calculated using standard bi-exponential fit to the IVIM signal. The product of D* and fp was used as an indicator of intra-tendinous blood flow.

RESULTS

Ste-RS-EPI images achieved high signal and good image quality for the PT. The measured DTI and IVIM parameters (diffusivities in units of ×10-3 mm2/s) in the PT were: AD (1.54±0.09), RD (1.01±0.06), MD (1.19±0.07), FA (0.29±0.02), fp (4.6±1.2%), and D*×fp (36.6±6.9).

CONCLUSION

This preliminary study demonstrated the feasibility of the ste-RS-EPI DTI and IVIM protocols to assess patellar tendon microstructure and microcirculation. The estimated DTI and IVIM parameters in control subjects may serve as a baseline for subsequent studies on patients with clinical and subclinical patellar tendinopathy.

CLINICAL RELEVANCE/APPLICATION

The ste-RS-EPI DTI and IVIM techniques may be used for evaluation of tendinopathy and to quantitatively assess pathophysiological changes that occur as a result from various treatments.

SSK13-06 Diffusion Tensor Imaging With Quantitative Evaluation of Sciatic Nerve within the Pelvis in Patients with Non-Contributory Lumbar Spine Magnetic Resonance Imaging in Radiculopathy: Preliminary Results

PURPOSE

Diffusion tensor imaging with quantitative evaluation of sciatic nerve within the pelvis in Patients with non-contributory lumbar spine magnetic resonance imaging in radiculopathy: preliminary results.

METHOD AND MATERIALS

This prospective institutional review board-approved study included 32 consecutive patients (11 males and 21 females; mean age of 41.2, range 19-52 years) studied between October 2016 and February 2018. The study population included 32 patients suffering from sciatica pain with negative lumbar MRI. All patients underwent DTI sequence of the pelvis (TR/TE 5800/97 ms; b=1000; slice thickness 3,5 mm; directions=20) by using a 1.5T scanner (Siemens Aera). DTI data were postprocessed on a dedicated offline workstation by two radiologists (25 and 11 years of experience, respectively) blinded to clinical data. Each radiologist placed two ROI on the nerve roots at three different levels within the pelvis on both side, and the mean value was used for further analysis. Clinical findings served as standard of reference. Diagnostic accuracy values of the FA numbers by using receiver operator curves (ROC) and relative area under the curve (AUC) were calculated. Inter-observer and intra-observer agreement were calculated with k-statistics. Continuous and categorical variables were evaluated by using t test and x2 or Fisher exact test, as appropriate. A value of $p<0.05$ was considered statistically significant

RESULTS

The lumbar nerve roots were visualized and FA values were calculated in all subjects. The FA values were significantly different between suffering nerve roots (178± 48; range 146-285) and spared side (296± 52; range 221-412) with a p value <0.001. The ROC curve analysis revealed an AUC of 0.816 (95% confidence interval: 0.682-0.874). By using a FA of 220 as cutoff to identify suffering nerve roots, the sensitivity, specificity, PPV and NPV and accuracy of DTI sequences were and 81.8, 95.4, 90.0, 91.3 and 90.9%, respectively. The interobserver and intraobsever agreement were near perfect (k=0.83 and k=0.81, respectively)

CONCLUSION

DTI can quantitatively demonstrate the presence of suffering sciatic nerve roots within the pelvis.

CLINICAL RELEVANCE/APPLICATION

DTI can quantitatively evaluate compressed nerve roots of sciatic nerve in patients with negative lumbar MRI. This sequences could be used to guide the identification of nerve compression site within the pelvis by means of a tailored MR study

SSK13-07 Comparison of Proton Density Fat Fraction, Simultaneous R2*, and Diffusion Weighted Image for Assessment of Focal Vertebral Bone Marrow Lesions

Wednesday, Nov. 28 11:30AM - 11:40AM Room: N229

Participants
Seong Woo Jeon, MD, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Kyu-Sung Kwack, MD, PhD, Suwon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Sunghoon Park, MD, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate proton density fat fraction (PDFF), R2* and apparent diffusion coefficient (ADC) estimation for assessing focal vertebral bone marrow lesions.

METHOD AND MATERIALS

We retrospectively reviewed 182 spine MRIs performed in 119 patients with focal vertebral bone marrow lesions from November 2016 to February 2018. The lesions were divided into bone metastases and focal benign vertebral bone marrow lesions. The protocol consisted of routine clinical sequences followed by IDEAL-IQ and diffusion-weighted (DW) magnetic resonance (MR) imaging with 1.5T MR unit (Signa HDxt, GE Healthcare, Waukesha, WI). PDFF and R2* were performed using a quantitative chemical shift-based water-fat separation method known as IDEAL-IQ with a multi-echo gradient echo sequence. ADC (b = 0 and 800 s/mm2) was calculated with a monoexponential fitting of the DW image data. PDFF, R2*, and ADC were compared using the Mann-Whitney U test. Receiver operating characteristic (ROC) curve analysis was performed to assess the diagnostic performances for differentiating metastasis from benign vertebral bone marrow lesions.

RESULTS

In the comparison of diagnostic performance among parameters, the PDFF (AUC = 0.960; 95% confidence interval [CI], 0.921, 0.984) showed a significantly larger AUC as compared to the R2* (AUC = 0.667; 95 % CI, 0.593 - 0.735) and ADC (AUC = 0.754; 95 % CI, 0.685 - 0.815) value. The optimal cut-off value of fat fraction for predicting focal malignant vertebral bone marrow lesions was 9.0 %; at this threshold, sensitivity was 97.30 % and specificity was 91.55 %. All the PDFF, R2*, and ADC values sequences were in almost perfect agreement (r values > 0.8)

CONCLUSION

Our study shows that PDFF measurement can enable in differentiating focal vertebral bone marrow lesions, and may be more useful than DW MR imaging.

CLINICAL RELEVANCE/APPLICATION

PDFF can be the excellent diagnostic performance in differentiating focal vertebral bone marrow lesions and this examination recommend in the evaluation of suspected bone metastases.

SSK13-08 Quantitative Analysis with 3T Multiparametric MR imaging: Differentiation between Benign and Malignant Soft Tissue Tumors

whjee12@gmail.com

PURPOSE

To determine the reliability and accuracy of 3T multiparametric magnetic resonance (MR) imaging in the differentiation between benign and malignant soft tissue tumors.

METHOD AND MATERIALS

This retrospective study was approved by the institutional review board and informed consent was waived. Sixty-eight patients with pathologically confirmed soft tissue tumors (35 benign and 33 malignant) who underwent 3T standard MR imaging, intravoxel incoherent motion (IVIM) diffusion-weighted MR imaging (DWI), and dynamic contrast-enhanced (DCE) MR imaging were enrolled with exclusion of lipoma and well-differentiated liposarcoma. IVIM parameters (true diffusion coefficient, D; pseudodiffusion coefficient, D*; perfusion fraction, f), apparent diffusion coefficient (ADC), and DCE parameters (transfer constant, Ktrans; rate constant, Kep; extravascular extracellular volume fraction, Ve; initial area under time-signal intensity curve, iAUC) were calculated by Syngovia software. All parameters were compared using Student's t test and multivariate logistic regression analysis. The receiver operating characteristic (ROC) curve with areas under the curve (AUC) was obtained.

RESULTS

ADC and D were significantly lower in malignant tumors than benign tumors (1181.6±484.7 vs 1472.3±349.1 μm^2/sec; 1152.2±505.0 vs 1414.9±373.8 μm^2/sec; P<.05, respectively). Ktran, Kep, Ve, and iAUC were significantly different between malignant tumors and benign tumors (211.3±158.2 vs 92.4±67.0 10^3/min; 775.9±528.9 vs 311.5±230.4 10^3/min; 31.7±17.3 vs 43.9±28.2 %; 23.3±14.6 vs 11.8±9.0 %, P<.05, respectively). The best discriminative parameters for prediction of malignant tumors versus benign tumors were ADC (odds ratio [OR]: 0.991, P=.046), Kep (OR: 1.004, P=.003) and iAUC (OR: 1.064, P=.048). The AUCs of ADC alone, ADC combined with Kep, and ADC combined Kep and iAUC were 0.738, 0.816, and 0.848, respectively.

CONCLUSION

ADC, Kep, and iAUC may be reliable and accurate parameters for the differentiation between benign and malignant soft tissue tumors at 3T multipamametic MR imaging.

CLINICAL RELEVANCE/APPLICATION

Multiparametric MR imaging is reliable and accurate in the differentiation between benign and malignant soft tissue tumors.

SSK13-09 Fat Suppression for Ultrashort Echo Time (UTE) Imaging Using Single Point Dixon Method

h4jang@ucsd.edu

PURPOSE

Use of fat saturation (FS) pulses with UTE sequences can improve short T2 contrast but reduce short T2 signal, and two point Dixon (2p-Dixon) method can misestimate fat due to short T2* decay. We propose single point Dixon (1p-Dixon) method to suppress fat for high contrast UTE imaging of short T2 tissues.

METHOD AND MATERIALS

1p-Dixon technique directly decomposes fat and water from complex MR signals after correcting phase errors due to field inhomogeneity (Ma. JMRI 2008). The proposed method utilizes dual echo 3D UTE imaging, where UTE is followed by the 2nd TE (TE2), chosen flexibly. Fat is estimated by applying 1p-Dixon to the non-UTE image at TE2, and used to suppress fat in the UTE image. In-vivo experiments were performed in 3T (GE-MR750) with two healthy volunteers (left knee of male aged 36 and left ankle of male aged 26). Parameters for knee imaging were as follows: flip angle=15degree, TE1/TE2/TR=32μs/2.7ms/20ms, voxel size=0.6x0.6x3mm scan time=3min50sec. Parameters for ankle imaging were set same as above except: TE2 =2.9ms, voxel size=0.5x0.5x3mm scan time=5min30sec.

RESULTS

Since 2p-Dixon does not consider signal decay between UTE and TE2, the short T2* decay is misinterpreted as a contribution of fat signal partially nulling water signal. Therefore, in the knee imaging fat signal in tendon and bone was misestimated by 2p-Dixon method, while the 1p-Dixon method was not affected by the short T2* signal decay. Compared with FS, 1p-Dixon based approach showed strong signal intensity in the patellar and Achilles tendon with less spatial variation in the fat suppressed UTE images, while the UTE images with FS pulse exhibited lower intensity in the tendons with gradually varying signal. The pattern of signal variation in the UTE images with FS was very similar to the water images at TE2 where most of short T2 (especially bound water) signal already decayed, which implies broad-spectrum short T2 components were partially affected by the FS pulse.

CONCLUSION

We demonstrated feasibility of 1p-Dixon based fat suppression in UTE imaging, which has the advantage of flexible echo spacing and accurate fat estimation over 2p-Dixon. Moreover, the proposed method preserves short T2 (especially bound water) signal significantly better than FS method.

CLINICAL RELEVANCE/APPLICATION

The proposed method has potential to aid with various types of morphological and quantitative UTE imaging, such as T2* mapping or UTE-MT modeling.

PURPOSE

Anti-Programmed Death 1 (anti-PD1) antibody triggers new patterns of response and progression in patients with Hodgkin lymphoma (HL). We aimed to evaluate the incremental value of interim 18F-FDG PET/CT over CT scans in patients treated by anti-PD1.

METHOD AND MATERIALS

We retrospectively analyzed patients treated by anti-PD1 from 2013 to 2017. Concomitant 18F-FDG PET/CT and CT scans were acquired at baseline and upon treatment. A pair of radiologists classified blindly and independently patients as immune-responding or immune-refractory based on the first evaluation, using the International Harmonisation Project Cheson 2014 criteria and the Lymphoma Response to Immunomodulatory therapy Criteria (LYRIC) (2016 revised criteria).

RESULTS

Forty-four consecutive HL patients were included. Forty-four interim 18F-FDG PET/CT and CT scans were acquired at a median time of 3.7 months after anti-PD1 initiation. Radiologists classified patients as immune-responding or immune-refractory on both 18F-FDG PET/CT and CT-scan in 55.7% and 35.2% of cases, respectively. Radiologists experienced a significant incremental value of 18F-FDG PET/CT in 8.0% (95%CI: 3.3%-15.7%) of patients, whom were reclassified as immune-refractory (2.3%) or immune-responding (5.7%). Additionally, 18.2% (95%CI: 10.8%-27.8%) of patients were reclassified from PR on CT-scan to CR on PET.

CONCLUSION

CT-scan alone can reliably be used for response assessment in patients with HL treated with anti-PD1: radiologists correctly classified patients as immune-responding or immune-refractory in 92% of cases. However, interim 18F-FDG PET/CT showed clear incremental value to reclassify immune-responding patients from partial response to complete response, which is crucial for risk-adapted strategies.

CLINICAL RELEVANCE/APPLICATION

Interim 18F-FDG-PET/CT in HL patients treated with anti-PD1 supplied incremental value over CT-scan by reclassifying patients to immune-responding or complete response. This concept is crucial for risk-adapted therapeutic strategy.

SSK14-02 Impact of FDG-PET/CT on the Staging, Management and Outcomes of Patients with Presumed Limited Stage Hodgkin's Lymphoma and Aggressive Non-Hodgkin's Lymphoma

PURPOSE

To determine the impact of positron-emission tomography/ computed tomography (PET/CT) on the staging, management and outcomes of patients with apparent limited-stage (LS) Hodgkin's lymphoma (HL) or aggressive non-Hodgkin's lymphoma (aNHL) being treated with curative intent.

METHOD AND MATERIALS

This single arm, prospective multicenter registry included patients with apparent LS HL or aNHL based on clinical data and CT, or with equivocal CT findings for advanced stage, being considered for curative-intent therapy. Pre-PET/CT treatment plan was compared to actual treatment received. Outcomes at 1 year post first line therapy included survival and second-line therapy initiation. These were compared to a historical control pool staged with CT alone. Administrative data sources were used to obtain and control for baseline characteristics using propensity score matching and regression adjustment. Outcomes were assessed using adjusted Cox proportional hazards regression and propensity score matching.

RESULTS

PET/CT upstaged 58/330 (17.6%) patients with HL and 92/520 (17.7%) patients with aNHL. Change in planned mode of therapy was seen in 119/266 (44.7%) patients with HL and 131/334 (39.2%) with aNHL ($p<0.00001$ for both). There was a lower 1-year mortality for aNHL patients with LS on PET compared to those with LS on CT (for propensity score matched cohort: HR, 0.34; 95% CI: 0.15, 0.74; $p=0.0072$). For patients with HL, no significant difference was found in survival or second-line therapy initiation at 1 year.

CONCLUSION

PET/CT upstaged >17% of patients with presumed LS aggressive lymphoma to advanced stage and planned management was altered in a significant proportion of patients. Patients with confirmed LS aNHL after PET/CT treated with curative intent had significantly better survival compared to the cohort of LS determined by CT.

CLINICAL RELEVANCE/APPLICATION

1. PET has a significant impact on the management of patients with HL and aNHL. 2. Patients with presumed limited stage aNHL on PET/CT treated with curative intent had a significantly better survival at one year compared to patients with presumed limited stage as determined by CT. 3. These results support the recent recommendation of the International Conference on Malignant Lymphoma in Lugano for the utilization of PET in the staging of patients with aggressive lymphoma.

SSK14-03 Altered Liver FDG Uptake in Lymphoma Patients with Chemotherapy Associated Hepatic Steatosis on PET/CT

Wednesday, Nov. 28 10:50AM - 11:00AM Room: S505AB

moyw@sysucc.org.cn

PURPOSE

To evaluate the prevalence of hepatic steatosis in lymphoma patients after chemotherapy; to reveal whether lymphoma patient with chemotherapy associated hepatic steatosis (CAHS) will change liver FDG uptake on PET/CT, compared to their baseline and to further study the relation between liver FDG uptake and severity of fatty liver.

METHOD AND MATERIALS

88 of 1647 lymphoma patients had been diagnosed fatty liver during or after chemotherapy from December 1, 2014, to June 30, 2017. 176 FDG PET/CT scans of the 88 lymphoma patients were reviewed retrospectively. These 88 lymphoma patients all had a normal liver before chemotherapy and then got hepatic steatosis after chemotherapy. Each patient had performed two PET/CT scans: baseline and post-chemotherapy. Paired t test was used to compare BMI, blood glucose (BG), liver SUVmax (SUVmax-l), liver average SUV (SUVave-l), liver SULmax (SULmax-l), aorta SUVmax (SUVmax-a), aorta average SUV (SUVave-a) and aorta SULmax (SULmax-a) between baseline and post-chemotherapy. CAHS was divided into three groups: mild-grade, moderate-grade, and severe-grade. The relationship within or between groups was assessed.

RESULTS

The prevalence of CAHS in lymphoma patients of our hospital was about 88/1647 (5.3%). After chemotherapy, 28 of 88 (31.8%) patients had increased liver SUVs, whereas 60 of 88 (68.2%) patients showed decreased liver SUVs. There were significant differences of mean liver SUVs between baseline and CAHS (baseline versus CAHS; SUVmax-l, 2.84±0.57 vs 2.57±0.64, P<0.00; SUVave-l, 2.17±0.43 vs 1.95±0.51, P=0.001; SULmax-l, 2.24±0.40 vs 2.0±0.41, P<0.001). BG had a slight decrease after chemotherapy (baseline versus CAHS, 5.5±1.2 vs 5.2±1.0, P=0.01). No difference was identified when the mean aorta SUVs and BMI for baseline were compared with those for CAHS (P>0.05). The patients with severe-grade of CAHS had significant lower liver SUV values, compared to those with mild-grade (P<0.05). And BMI showed no difference among the three groups of CAHS.

CONCLUSION

Increase of liver FDG uptake coexists with decrease. The severer the fatty liver is, the more likely the liver FDG uptake declines. The altered liver SUV due to CAHS might affect the response assessment and prognostic evaluation for lymphoma patients.

CLINICAL RELEVANCE/APPLICATION

(dealing with 18F-FDG PET/CT)'18F-FDG PET/CT is a powerful imaging technique and has become the standard for staging and response assessment of FDG-avid lymphomas'.

SSK14-04 Is Dual-Time Point 18F-FDG PET/CT Valuable for Differentiating Goitrous Hashimoto's Thyroiditis from Primary Thyroid Lymphoma?

Wednesday, Nov. 28 11:00AM - 11:10AM Room: S505AB

metnakada@yahoo.co.jp

PURPOSE

Goitrous Hashimoto's thyroiditis (HT) occasionally shows diffusely increased F-18 fluorodeoxyglucose (FDG) uptake in the thyroid that it mimics primary thyroid lymphoma (PTL) on FDG-PET/CT i,ages. The aim of the study was to determine whether delayed imaging of FDG-PET/CT was valuable in differentiating PTL from HT.

METHOD AND MATERIALS

53 patients with HT, who were suspected of PTL due to enlarging goiter, underwent dual-time-point (60 ± 5min and 120± 10min after FDG injection) PET/CT scan using FDG combined with neck ultrasound (US) and US-guided core needle biopsy. Specimen of core needle biopsy was subjected to immunohistochemical staining (CD20,CD3,CD79a,Ki-67, etc.) along with H-E staining. Re-arrangement of igH was also analyzed by PCR. In addition to visual assessment based on 5-point scale from The Lugano classification, the maximum standardized uptake value for the thyroid at the early image (SUV-E) and that at the delayed image (SUV-D) for the thyroid were determined. In addition, SUV increment (ΔSUV) was calculated by subtracting SUV-E from SUV-D. Those parameters were compared between patients with PTL and those with HT.

RESULTS

Pathological diagnosis was PTL in 36 (MALT lymphoma 31, DLBCL 5) and was HT in 17. 11 patients with PTL was excluded from analysis because they had either nodular FDG uptake in the thyroid or abnormal uptake in extrathyroidal area. The remaining 25 patients with PTL and all patients with HT showed diffusely increased thyroid FDG uptake on both the early and the delayed PET/CT images. There was no statistically significant difference between PTL and HT in 5-PS (early 4.4 vs. 4.2. delayed 4.1 vs. 4.0) as well as SUV-E and SUV-D (9.02 vs. 7.51, 8.28 vs. 6.54). 7 of 25 patients (28%) with PTL had plus values of ΔSUV while none but one (6%) with HT had plus value of ΔSUV. When plus value of ΔSUV was considered as a sign for PTL, PPV, NPV, and accuracy for PTL was 88%. 47%, and 55%, respectively.

CONCLUSION

Neither visual nor semi-quantitative analysis of dual tome-point FDG-PET/CT was helpful in differentiation HT from PTL among enlarging goiter. Needle biopsy may be the best strategy in differential diagnosis of HT with enlarging goiter.

CLINICAL RELEVANCE/APPLICATION

Addition of delayed imaging does not improve diagnostic performance of FDG-PET/CT in diffusely increased thyroidal uptake in enlarging goiter.

SSK14-05 Utility of Integrated 18F-FDG PET/MRI for Response Assessment of Isolated Limp Perfusion in Patients with Soft-Tissue Sarcomas

PURPOSE

To evaluate the diagnostic potential of simultaneously obtained PET- and MR-datasets for therapy response assessment of isolated limp perfusion with TNF-alpha and melphalan (TM-ILP) in patients with soft-tissue sarcomas.

METHOD AND MATERIALS

A total of 32 patients with histopathological confirmation of a soft-tissue sarcoma were prospectively enrolled for an integrated 18F-FDG PET/MRI examination before (1st scan) and after (2nd scan) neoadjuvant TM-ILP. In each examination morphological (tumor size) and metabolic (SUVmax, SUVpeak) parameters of the tumors were determined. Two readers analysed the datasets and assessed treatment response based on RECIST 1.1 and PERCIST criteria. Results from subsequent tumor resection served as reference standard and therapy response was determined based on the tumour regression grading scale of Salzer-Kuntschik.

RESULTS

Based on the reference standard, a total of 25 patients were classified as partial responder (PR) and 7 patients as stable disease (SD). Calculated mean values of the maximum tumor diameter, SUVmax and SUVpeak in patients with stable disease amounted to 62.4 ± 42.4mm, 11.1 ± 7.9 and 9.1 ± 6.2 before and 59.5 ± 50.3mm, 8.4 ± 5.3 and 6.7 ± 5.1 after treatment. The respective values in the responder group were 78.1± 65.6mm, 11.9 ± 7.4 and 9.6 ± 6.1, before and 71.1 ± 65.9mm, 5.1 ± 3.1 and 3.9 ± 2.4 after treatment. Based on RECIST criteria, 25 patients were classified as SD and 6 patients as PR, whereas 1 patient showed progressive disease (PD). PERCIST criteria categorized 11 patients as SD, 20 patients as PR and one patient as PD. In accordance with PERCIST, a significantly higher number of patients (n = 23, 71.9%) could be correctly categorized as SD/PR, when compared to RECIST (n = 9, 28.1%; $p < 0.005$).

CONCLUSION

Our results demonstrate the significant discrepancy in morphological and metabolic response and underline the diagnostic superiority of 18F-FDG PET data over MRI for response assessment of neoadjuvant ILP in sarcoma patients.

CLINICAL RELEVANCE/APPLICATION

18F-FDG PET/MRI might enable more accurate therapy response assessment of isolated limp perfusion in patients with soft-tissue sarcomas when compared to MRI alone.

SSK14-06 Evaluation of 18F-FDG-PET/CT for Response Assessment in Patients with Advanced Melanoma Treated with Immune Checkpoint Inhibitors

PURPOSE

Treatment with immune checkpoint inhibitors (ICI) have improved outcomes for patients with advanced melanoma. The aim of this retrospective study was to characterize the findings on 18F-FDG PET/CT that predict response in these patients.

METHOD AND MATERIALS

Ninety-seven patients with advanced melanoma treated with ICI were identified, with 70 having baseline (PET0) and interim 18F-FDG PET/CT studies (PET1, median 84 and range 19 to 181 days after cycle 1). Of these, 34 were treated with ipilimumab alone (N=17) or combined with nivolumab (N=17, analyzed together as the ipi cohort) and 36 with pembrolizumab (pembro cohort) alone. AutoPERCIST software was used to determine the SULpeak and SUVmax of the hottest lesion on each scan. Clinical assessment at the last office visit determined responders (R- partial response, stable, or no disease) and nonresponders (NR- progression) at a median 9.5 (range 0 to 61) months after PET1 for the ipi cohort and 5.5 months (range 0 to 20) for the pembro cohort. Repeated measures analysis of variance (SigmaPlot 12.5, Systat Software, Inc.) determined differences between PET0 and PET1 metrics among response categories by cohort. The Mann-Whitney rank sum test assessed for differences in the % change in each metric between response categories.

RESULTS

Thirteen R and 21 NR were identified in the ipi cohort and 26 R and 10 NR in the pembro cohort. Within the ipi R cohort, SULpeak (PET0 6.8±5.1, PET1 1.2±2.4, p=0.002) and SUVmax (PET0 9.9±7.0, PET1 2.0±4.3, p=0.002), were significantly different. The PET1 SULpeak (13±12, p=0.007) and SUVmax (19±19, p=0.006) of the NR was also significantly different from the R PET1 values. For the pembro NR cohort, SULpeak (PET0 6.2±5.3, PET1 10±8.7, p=0.017) and SUVmax (PET0 9.5±9.1, PET1 14±12, p=0.033) were significantly different, and the pembro R PET1 SULpeak (2.0±3.6, p<0.001) and SUVmax (3.4±6.0, p<0.001) were also significantly different from NR PET1 values. The % change in all metrics was significantly different between R and NR in both treatment cohorts.

CONCLUSION

Changes in the SULpeak and SUVmax of the hottest lesion on interim 18F-FDG PET/CT studies may be useful in predicting responders to ICI.

CLINICAL RELEVANCE/APPLICATION

Higher SULpeak and SUVmax values and lower % decrease in these parameters on interim 18F-FDG PET/CT scans during ICI treatment are predictors of poor treatment response.

SSK14-07 Is 18F-FDG PET/MR Including DWI an Alternative to Sentinel Lymph Node Biopsy in Initial N-Staging in Patients with Malignant Melanoma?

Wednesday, Nov. 28 11:30AM - 11:40AM Room: S505AB

Participants
Benedikt M. Schaarschmidt, MD, Essen, Germany (*Presenter*) Stockholder, Bayer AG; Stockholder, General Electric Company; Stockholder, Siemens AG; Stockholder, Teva Pharmaceutical Industries Ltd
Johannes Grueneisen, Essen, Germany (*Abstract Co-Author*) Nothing to Disclose

Gerald Antoch, MD, Duesseldorf, Germany (*Abstract Co-Author*) Nothing to Disclose
Thorsten D. Poeppel, Essen, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To compare 18F-fluordesoxyglucose positron emission tomography / computed tomography (18F-FDG PET/CT), 18F-FDG PET / magnetic resonance (18F-FDG PET/MR) as well as 18F-FDG PET/MR and diffusion weighted imaging (DWI) with sentinel lymph node biopsy (SLNB) in initial lymph node staging in patients with malignant melanoma.

METHOD AND MATERIALS

In this retrospective study, 52 patients with malignant melanoma (female: n=30, male: n=22, mean age 50.5y) that underwent 18F-FDG PET/CT and consecutive 18F-FDG PET/MRI including DWI prior to lymphoscintigraphy with single photon emission computed tomography / CT (SPECT/CT) and consecutive SLNB were included. By two readers, the status of the sentinel lymph nodes detected by SPECT/CT (benign/malignant) was assessed on 18F-FDG PET/CT, 18F-FDG PET/MR as well as 18F-FDG PET/MR and DWI images. In all modalities, increased tracer uptake in comparison to the background was considered as a sign of malignancy. In PET/MR, morphological criteria were considered as additional signs of malignancy. In 18F-FDG PET/MR and DWI, all of the aforementioned criteria and diffusion restriction were considered as signs of malignancy. Discrepancies were resolved in a consensus reading. Histopathologic results served as a reference standard to calculate sensitivity, specificity as well as positive (PPV) and negative predictive values (NPV).

RESULTS

In all patients, a total of 87 sentinel lymph nodes were detected by lymphoscintigraphy and SPECT/CT. According to histopathology, lymph nodes were metastatic. We found a sensitivity, specificity, PPV and NPV of 17.7%, 95.6%, 50.0% and 82.3% for PET/CT and of 23.5%, 96.9%, 66.7% and 82.3% for PET/MR. Additional DWI was available in 56 lymph nodes and led to two additional false positive findings, thus decreasing specificity of PET/MR and DWI.

CONCLUSION

Due to its low sensitivity and specificity, 18F-FDG PET/MR cannot be considered an alternative to SLNB in initial N-Staging in patients with malignant melanoma even if additional DWI is performed.

CLINICAL RELEVANCE/APPLICATION

18F-FDG PET/MR is inferior to SLNB in N-Staging in patients with malignant melanoma. Therefore, neither 18F-FDG PET/MR nor 18F-FDG PET/MR and DWI will be able to replace SLNB in clinical routine.

SSK14-08 Prognostic Value of 18F-FDG PET/CT in Intralesional Interleukin-2 Therapy for Cutaneous Metastatic Melanoma

Wednesday, Nov. 28 11:40AM - 11:50AM Room: S505AB

Participants
Rick Wray, MD, Sacramento, CA (*Presenter*) Nothing to Disclose
Jason Kao, BS, Sacramento, CA (*Abstract Co-Author*) Nothing to Disclose
Sarah Bateni, MD, Sacramento, CA (*Abstract Co-Author*) Nothing to Disclose
Emanuel Maverakis, MD, Sacramento, CA (*Abstract Co-Author*) Nothing to Disclose
Amanda Kirane, MD, Sacramento, CA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Intralesional interleukin-2 (IL-2) therapy is an effective treatment for cutaneous metastatic melanoma even in cases refractory to multiple treatment modalities. 18F-FDG PET/CT is a valuable tool for diagnosis, staging and surveillance of melanoma, but its role in therapy assessment is unclear given the strong local inflammatory response in injected sites. This study investigates the prognostic value of 18F-FDG PET/CT for assessment of intralesional IL-2 in cutaneous metastatic melanoma.

METHOD AND MATERIALS

13 patients (10M/3F, 23 - 96 years) with Stage IIIC/IV cutaneous metastatic melanoma or stage IIB disease not amenable to surgical intervention had a total of 31 PET/CT scans performed at baseline, interim and completion time points while receiving variable injections of intralesional IL-2 (range, 1 - 20; mean 7.8) at variable doses (range 5 - 22 million units; mode 7) . PET/CT scans were evaluated using maximum SUV (SUV max) and a 5 point scale (5PS): 1, no uptake; 2, uptake <= mediastinum; 3, uptake > mediastinum <= liver; 4, uptake moderately < liver; 5, uptake markedly > than liver. The 5PS was dichotomized to

negative (score 1, 2, and 3) or positive (score 4 and 5). The Kaplan-Meier (KM) method with log-rank test and Cox-regression analysis were performed.

RESULTS

Of the 31 scans, 17 were positive and 14 were negative. SUV max range, 1.3 -20.6 g/ml. Follow-up range, 8 - 51 months (median 15). Baseline scans with higher SUV max had a significantly lower PFS with hazard ratio (HR) of 1.55 (95% CI 1.001-1.33, p=0.048). KM curves demonstrated a trend of improved OS with lower SUVmax at baseline (p=0.11). Positive scans at completion trended toward lower OS with HR of 2.74, (p=0.48). The progression-free survival (PFS) was worse for positive groups at completion, HR of 12.12 (95%CI 1.22-120.49, p=0.03), with significant separation in KM curves (Log-rank, p=0.008).

CONCLUSION

18F-FDG PET/CT SUV max at baseline and qualitative therapy assessment at completion time points during intralesional IL-2 can predict PFS and show potential to predict OS, with larger sample size, in patients with cutaneous metastatic melanoma.

CLINICAL RELEVANCE/APPLICATION

A baseline PET/CT prior to intralesional IL-2 adds prognostic value. Additionally, using a qualitative therapy assessment method such as the 5PS increases the prognostic value of 18F-FDG PET/CT for therapy response in intralesional IL-2 treatment for cutaneous metastatic melanoma.

SSK14-09 Opportunistic Screening of FDG-PET/CT Reveals Undiagnosed Low Bone Mass in Patients Being Evaluated for Oncology Purposes

PURPOSE

To assess the prevalence of undetected low bone mineral density (BMD) in a cohort of patients undergoing PET/CT with opportunistic quantitative computed tomography (QCT).

METHOD AND MATERIALS

A retrospective survey was conducted to identify PET/CT studies obtained between Oct/2015 and Jan/2016 in a Biograph 64 scanner (Siemens). CT images were processed with the QCT Pro software (Mindways). A calibration CT scan was obtained in the same PET/CT scanner using the asynchronous Model 4 QCT Phantom. Two radiologists and a trained research technician performed the analyses of trabecular BMD at vertebral bodies L1 and L2. The American College of Radiology (ACR) criteria was used for diagnosing low BMD. Total BMD of femoral necks were measured on DXA-equivalent images (CTXA) of the hips and used to generate FRAX-scores for calculating absolute fracture risks. We obtained clinical data from institutional medical records. Requirement for signed informed consent was waived by the IRB.

RESULTS

Sixty-nine studies were identified, two studies excluded due to severe scoliosis and one excluded due to Schmörl node affecting the analysis. The final cohort comprised 66 subjects (20F/46M, mean age: 53.8, SD: 12.1). Mean coefficient of variation (CV) for trabecular BMD in L1-2 between the 3 readers was 1.2%. Distribution of subjects according to ACR category is shown in Table 1. Thirty-two percent (21/66) of subjects showed low lumbar spine BMD on QCT. Twenty-four percent (5/21) of subjects with low BMD on QCT had a prior DXA scan, all of which showing low BMD. None of the subjects with normal BMD on QCT had a prior DXA scan. Femoral neck BMD was assessed with CTXA in 20 of 66 subjects by one radiologist and the research technician. Mean CV between the readers was 6.1%. Fifteen percent (3/20) of the subjects had at least a 3% risk of hip fracture within 10 years. Only 33.3% (1/3) of these subjects had a prior diagnosis of low BMD.

CONCLUSION

Low BMD was an under recognized condition in our sample. Future analysis will correlate metabolic activity (FDGuptake) with bone mass.

CLINICAL RELEVANCE/APPLICATION

PET/CT provides a unique opportunity to screen patients for occult low BMD by leveraging the quantitative capabilities of CT. Identification of subjects at risk for future osteoporotic fractures may not only improve outcomes, but also decrease downstream costs.

PURPOSE

Endovascular thrombectomy (EVT) is supported by Level IA evidence for middle cerebral artery (MCA) M1 occlusion stroke, yet more distal occlusions lead to challenges in decision making. In stroke patients with large vessel MCA occlusion, distance to thrombus (DT) can be measured from the carotid T. We determined the value of DT in the context of established clinical and imaging parameters.

METHOD AND MATERIALS

We selected patients with isolated MCA occlusions (M1-M3) and follow-up-confirmed stroke. Two independent, blinded readers evaluated imaging. DT was measured as the distance from the carotid T to the proximal end of the thrombus on coronal CT angiography images. Established clinical and imaging parameters were assessed. Linear and ordinal regression analyses were performed to identify independent associations.

RESULTS

The study population of 162 patients had a median DT of 14.0 mm (interquartile range: 8.0-24.0mm). Dichotomizing the study population by median DT, patients with DT<=14.0 mm showed significantly higher median admission National Institutes of Health Stroke Scale scores (14 vs 9, p<0.001; NIHSS), no significant difference in median final infarction volumes (31 mL vs. 23 mL, p=0.224), but worse median modified Rankin Scale (mRS) scores at discharge (4 vs 3, p=0.004) and 90 days (5 vs 2, p=0.037). Patients with shorter DT had worse median non-contrast Alberta Stroke Program Early CT Scores (8 vs 9, p<0.001; NCCT-ASPECTS) and more frequently underwent EVT. When adjusted for age, sex, admission NIHSS, NCCT-ASPECTS, thrombolysis, EVT and DT, linear regression analyses revealed only significant associations of admission NIHSS (b=0.229, p=0.006) and NCCT-ASPECTS (b=-0.357, p<0.001) with final infarction volumes. In similarly adjusted ordinal regression analyses on clinical outcomes, only admission NIHSS was an independent predictor of discharge mRS (b=0.144, p<0.001) and 90-day mRS (b=0.137, p=0.004).

CONCLUSION

In this comprehensive analysis on the value of DT in acute stroke, DT was outperformed by existing imaging parameters for morphologic outcome prediction and had no independent predictive value for clinical outcomes.

CLINICAL RELEVANCE/APPLICATION

In stroke imaging, DT is a quantifiable occlusion parameter yet carries no independent predictive value. However, DT could be used to standardize selection for randomized EVT trials on M2 occlusions.

SSK15-02 MRI or CT Before Recanalization in Acute Ischemic Stroke: Impact on Clinical Workflow: Results from the THRACE Randomized Controlled Trial

PURPOSE

To compare clinical workflow and functional outcome in acute ischemic stroke patients screened by Magnetic Resonance Imaging (MRI) or Computed Tomography (CT).

METHOD AND MATERIALS

Data were analyzed from THRACE, a multicenter, randomized, controlled trial that evaluated the efficacy of mechanical thrombectomy in addition to intravenous tissue-plasminogene activator (IV-tPA) in patients with acute ischemic stroke and proximal occlusion. Recruiting centers were free to use their routine MRI or CT stroke protocol before randomization. Brain imaging was performed within 4h of stroke onset. Workflow times were obtained from the trial database and extracted from Digital Imaging and Communications in Medicine (DICOM) metadata. All patients or their legal representative provided written informed consent.

RESULTS

403 patients were included: 300 based on MRI and 103 on CT. Median baseline National Institutes of Health Stroke Scale score was 18 in both groups. Time interval (median, interquartile range) from stroke onset to imaging was similar (MRI: 114 min (89-139); CT: 108 min (88-140); P = .23). MRI scan duration was overall longer (MRI: 13 min (10-16); CT/CT angiography: 9 min (7-12); P < .001), irrespective of the imaging protocol (without perfusion-weighted imaging [MRI: 12 min (10-15); CT: 7 min (2-11); P < .001] or with perfusion-weighted imaging [MRI: 16 min (15-19); CT: 10 min (8-13); P < .001]. Time from stroke onset to IV-tPA (MRI: 150 min (121-179); CT: 150 min (123-180); P = .31) and onset to entry in angiography suite (MRI: 200 min (170-250); CT: 213 min (180-246); P = .57) did not differ between groups. In the endovascular treatment arm, imaging modality of inclusion was not associated with unfavorable outcome (modified Rankin Score scale > 2) in multivariate analysis (MRI: odds ratio 0.72; 95% confidence interval: 0.33 - 1.54; P = .40).

CONCLUSION

In the THRACE trial, use of MRI at the acute phase of ischemic stroke did not delay treatment nor was associated with poorer functional outcome than CT after endovascular treatment.

CLINICAL RELEVANCE/APPLICATION

Efficient workflow allows to use MRI as a screening tool for stroke patients, without delay to treatment nor negative impact on clinical outcome.

SSK15-03 Focal Thinning in Remote Cortical Layers via Degeneration of Connecting Fibers Correlates with Clinical Outcome in Lacunar Infarct Patients

PURPOSE

Ischemic infarcts have been observed to exert structural effects distant from the acute lesion itself, in remote, connected cortex. We aimed to extend this knowledge by exploring with in-vivo T1-relaxation 3T-MRI, surface-based cortical thickness analysis and tractography if (i) in patients with chronic lacunar infarct, involving the corticospinal tract, the cortical layers of the connected primary motor cortex are differently affected, and if (ii) these differences correlate with clinical symptomatology.

METHOD AND MATERIALS

Our cohort included patients (n=20) with history of chronic lacunar infarct, involving the posterior limb of the internal capsule or the corona radiata, with residual motor deficit, and healthy controls (n=15). T1-component probability maps, dividing the cortex into 5 laminar Gaussian-classes (noted L1-L5) were calculated, and tractography with lacunar infarcts as the seed areas to reconstruct the corticospinal tracts (CSTs) were performed.

RESULTS

Results demonstrated focal cortical thinning in the connected primary motor cortex (M1) and specifically only in its deepest L5-class compared to the non-affected mirrored cortex (P<0.001 and P=0.0001, respectively). There was loss of microstructural integrity of the affected CST connecting the lacunar infarct to the M1 with significantly increased mean diffusivity (MD) and decreased fractional anisotropy (FA) compared to the non-affected hemisphere (P=0.002 and P=0.0002, respectively). Increased MD and decreased FA were associated with focal thinning in M1 and in its deepest L5-class in the affected compared to the non-affected hemisphere (MD: P=0.07 and P=0.05, respectively; FA: P=0.02 and P=0.005, respectively). No significant difference was found between the laminar thickness pattern of the bilateral M1 or the microstructural integrity of the bilateral CSTs for the healthy subjects. Clinical scores were significantly correlated with microstructural damage of the CST and with thinning of both M1 and its deepest L5-class (P<0.05).

CONCLUSION

Our results support the concept of secondary neurodegeneration of Betz cells in layer V of connected M1, following a lacunar infarct affecting the CST, with a novel finding that the majority of the cortical thinning occurs in the deepest cortex.

CLINICAL RELEVANCE/APPLICATION

The severity of clinical symptoms is significantly correlated with the microstructural damage of the CST and with the connected M1 atrophy pattern.

SSK15-04 Clinical Decision Support Based on Automated Non-Contrast CT Density Measurements in Patients with Acute Ischemic Stroke

PURPOSE

To examine the clinical value of automated non-contrast CT (NCCT) density measurements in Alberta Stroke Program Early CT Score (ASPECTS) regions to support decision making in acute ischemic stroke.

METHOD AND MATERIALS

From a cohort of 1644 consecutive patients admitted for suspected stroke, we included patients with follow-up-confirmed middle cerebral artery infarction and available NCCT and CT perfusion (CTP) data. ASPECTS region density was assessed using automated software (Figure 1A). Relative Hounsfield units (rHU) were defined as the ratio of ipsilesional by contralesional region density. Extent of ischemic core was measured on CTP maps. Regression coefficients from a linear regression analysis on the association of regional rHU and infarction core volume were used as weighting factors to calculate a composite rHU score of all regions. Receiver operating characteristics (ROC) analyses were performed to test this score's discriminative value regarding time from symptom onset (TFSO) <=4.5h, current CTP trial selection criteria, and subacute stroke complications on follow-up imaging.

RESULTS

In total 121 patients were included. The composite rHU score resulted in significant classification of patients with TFSO<=4.5h (area under the curve [AUC]=0.721, p=0.018). Moreover, the score was able to classify patients who meet CTP selection criteria of ischemic core size <70mL and target mismatch >1.8 (AUC=0.759, p<0.001). The score discriminated between patients with and without subsequent space-occupying edema development (AUC=0.771, p<0.001). ROC curves are shown in Figure 1B. The score could not classify patients by occurrence of hemorrhagic infarction or parenchymal hematoma (both p>0.05).

CONCLUSION

The composite rHU score on NCCT allowed significant classification of patients with thrombolysis-eligible symptom onset times and current CTP imaging criteria for extended time window thrombectomy selection. The score also identified patients with subsequent space-occupying edema development.

CLINICAL RELEVANCE/APPLICATION

Automated NCCT density measurements have the potential to act as observer-independent imaging biomarkers that could support decision making in patients with unknown TFSO or in centers in which CTP is not available.

SSK15-05 Does IV-tPA Induce Thrombus Migration? A Retrospective Study Comparing Bridging Therapy and Thrombectomy Alone

Wednesday, Nov. 28 11:10AM - 11:20AM Room: E350

clara.cohen.cc@gmail.com

PURPOSE

Thrombus migration (ThrMi) before mechanical thrombectomy (MT) is an epiphenomenon in acute ischemic stroke (AIS) treatment with few available data. The aim of this study is to evaluate ThrMi prior to MT in a bridging protocol (tPA-MT group) and stand-alone MT (MT group).

METHOD AND MATERIALS

205 consecutive AIS patients treated by MT (tPA and no tPA) were retrospectively analyzed. Distance between vessel origin and beginning of the thrombus on MRI (3D time of flight and/or contrast enhanced magnetic resonance angiography sequences) and digital-substracted-angiography (DSA) were measured in millimeters using a curve tool and the same anatomical parameters. DSA pixels were converted in millimeters by measuring 3 large vessels diameters in MRI and determining the ratio from pixels to millimeters.

RESULTS

129 patients were included in tPA-MT group, with ThrMi in 36.4%, and 76 patients in MT group, with ThrMi in 6.6% ($p<0.0001$). In tPA-MT group, 27 (20.9%) patients had a moderate migration between 5-10 millimeters, 11 (8.5%) patients had a distal migration of more than 10 millimeters or to another segment and 9 (7%) presented recanalization defined by spontaneous TICI score>=2B. In MT group, 69 (90.8%) patients had no ThrMi, moderate ThrMi in 6.6%, thrombus' extension in 2.6%; no patient presented distal migration or recanalization. The two groups had the same clinical prognosis (bleeding event at 48hours, NIHSS at discharge, mRS and death at 3 months). Number of device passes to reach thrombectomy was 1.40 (±1.39) in tPA-MT group, 1.63 (±1.09) in MT group, $p=0.061$.

CONCLUSION

IV thrombolysis seems to promote thrombus migration, present in 36.4% of patients in tPA-MT group compared to 6.6% of patients in MT group. This study adds more data concerning IV thrombolysis effects on AIS treatment when MT is also involved.

CLINICAL RELEVANCE/APPLICATION

(dealing with acute ischemic stroke) 'Before performing mechanical thrombectomy, the possibility of a thrombus migration favored by prior thrombolysis is an important data for neurointerventionalists.'

SSK15-06 Public Health and Cost Consequences of Treatment Delays in Endovascular Thrombectomy for Stroke Based on HERMES Collaboration Data

PURPOSE

The benefit that endovascular thrombectomy (EVT) offers to stroke patients with large vessel occlusions is highly time-dependent. Our aim was to determine the lifetime quality of life and cost consequences of delaying EVT administration for patients, the healthcare system, and the society.

METHOD AND MATERIALS

A Markov model estimated lifetime quality-adjusted life years (QALY) of EVT-treated patients and associated costs based on stroke onset to arterial puncture time (model structure in Figure 1). The analysis was performed from a United States perspective with two cost frameworks: 1) healthcare costs and 2) societal costs, which include productivity losses and costs of informal care given by family members. Input parameters were based on best available evidence (Table 1), including patient data from the 7-trial HERMES collaboration (ESCAPE, EXTEND-IA, MR CLEAN, REVASCAT, SWIFT PRIME, PISTE, THRACE; Figure 2). In addition to diminished functional outcomes with later EVT, the model also projects that a proportion of patients becomes EVT-ineligible over

time. The lead analysis was conducted for stroke onset at 65 years. Probabilistic sensitivity analysis was performed.

RESULTS

Lifetime QALYs decreased for every hour of time delay until arterial puncture (Figure 3A). Within the first 6 hours of onset, every hour of delay resulted in an average loss of 0.69 QALYs. The healthcare and societal costs of each QALY yielded by EVT increased for every hour of time delay (Figure 3B). Within the first 6 hours of onset, every hour of delay increased the cost of QALYs yielded by EVT by $5,310/QALY in healthcare costs and by $7,914/QALY in societal costs. Within the first 3 hours of onset, a treatment delay of 2 hours - the amount typically associated with drip-and-ship compared to mothership care delivery - would result in an average loss of 1.7 QALYs per patient. In addition, this delay would result in an extra of about $10,000/QALY gained incurred by the healthcare system and $15,000/QALY gained incurred by the society.

CONCLUSION

Every hour of treatment delay in EVT for stroke reduces a patient's QALYs by almost three-quarters of a year and substantially increases healthcare and societal costs per QALY.

CLINICAL RELEVANCE/APPLICATION

Investments in healthcare policies and procedures to improve the efficiency of pre-hospital triage and in-hospital workflow for earlier treatment of stroke patients are likely highly cost-saving.

SSK15-07 Association Between Wall Characteristics of Atherosclerotic Middle Cerebral Artery with High-Resolution Magnetic Resonance Imaging and Infarction Pattern

Wednesday, Nov. 28 11:30AM - 11:40AM Room: E350

markweal_image@163.com

PURPOSE

To study the characteristics of atherosclerotic middle cerebral vascular wall by using 3.0 T high-resolution magnetic resonance imaging (HRMRI), explore the association between the characteristics of vascular wall and cerebral infarction, and predict the mechanism of infarction.

METHOD AND MATERIALS

Thirty-two patients with atherosclerotic patients were retrospectively enrolled and intracranial artery HRMRI was peformed. HRMRI protocol included a 3D T1 weighted technique known as inversion-recovery (IR) prepared SPACE. The plaque morphology, distribution, enhancement, stenosis degree and reconstruction index (positive reconstruction) of the middle cerebral artery were analyzed. Characteristics of acute infarct on diffusion weighted imaging (DWI) were categorized according to the number (single or multiple infarcts)and the pattern of cerebral infarcts(cortical,border zone, or perforating artery territory infarcts). The relationship between wall characteristics and infarction patterns was evaluated.

RESULTS

In the Thirty-two patients with acute infarction, twenty-one patients had multiple acute cerebral infarcts and eleven showed single acute cerebral infarcts. Border zone infarcts were the most common (16, 76.2%) among multiple acute infarcts. Eleven single infarcts were subcortical deep penetrating artery infarcts (11,100%). Thirty(93.8%) plaque were eccentric. Seven plaques (63.6%) in penetrating artery infarcts were located at the upper wall among single acute infarcts. Twelve plaques(75.0%) in border zone infarcts were located at the ventral wall among multiple acute infarcts. There was no significant difference in clinical data and laboratory examination of patients with single and multiple infarcts($P>0.05$). The percentage of plaques located on the ventral wall, plaques with strong enhancement, pattern of PR reconstruction and degree of stenosis of the lumen in the multiple infarction were all significantly higher than those in the single infarction ($P<0.05$).

CONCLUSION

The strong enhancement plaque is associated with its vulnerability in the patients with intracranial MCA atherosclerosis. PR or obvious lumen stenosis were associated with artery to artery embolism. HR MRI provides insights into intracranial atherosclerosis, and predicting infarction patterns.

CLINICAL RELEVANCE/APPLICATION

HRMRI can provide insights into intracranial atherosclerosis, and predict infarction patterns.

SSK15-08 Deep Learning Based Quantitative Diagnosis of Ischemic Stroke on CT

pchang077@gmail.com

PURPOSE

To evaluate a deep learning based tool for quantitative and objective CT diagnosis of acute ischemia, benchmarked on a large population with CT/MR correlation.

METHOD AND MATERIALS

After IRB approval, all patients with suspected ischemia in a five-year interval (January 2013 to 2018) receiving a non-contrast head CT followed by MR within 48 hours were identified. For each patient, DWI was co-registered to CT after brain extraction. For all MR exams, regions of reduced diffusion were segmented by a custom deep learning algorithm and confirmed through visual inspection. A hybrid 3D/2D object localization network based on the faster R-CNN architecture was implemented using a feature pyramid backbone (Figure 1A-D). A region proposal network identified potential regions of infarct, and a separate head network quantified the primary CT findings of acute ischemia: gray-matter hypoattenuation and mass effect (Figure 1E-F). Network outputs are represented on a normalized scale from 0 to 1 based on finding severity. After training, population statistics for hypoattenuation and mass effect were used to create a nomogram of stroke risk.

RESULTS

A total of 4,382 patients with short-interval CT/MR were identified, 831 of which had DWI-confirmed ischemia, yielding 326,394 images across 8,764 exams for analysis. As quantified by the neural network, degree of hypoattenuation (0.68 vs. 0.21; $p < 0.001$) and mass effect (0.59 vs. 0.11; $p < 0.001$) was more severe in patients with ischemia vs. controls. A nomogram based on deep learning quantification of these findings predicted ischemia with AUC, accuracy, sensitivity, specificity, PPV and NPV of 0.823, 0.815, 0.729, 0.835, 0.508 and 0.929 respectively. By varying the thresholds for diagnosis, algorithm sensitivity/PPV for ischemia detection ranged between 0.91/0.14 to 0.33/0.89.

CONCLUSION

A deep learning tool is presented for completely objective assessment of hypoattenuation and mass effect in the setting of acute ischemia. A deep learning based nomogram of stroke risk as a function of these two variables yields a powerful and flexible tool for ischemia detection. Arguably, prediction errors from this entirely objective approach may primarily be attributed to limitations in CT technology.

CLINICAL RELEVANCE/APPLICATION

A deep learning enabled nomogram of stroke risk based on quantitative image findings yields a powerful and flexible tool for completely objective diagnosis of acute ischemia on CT.

SSK15-09 The Significant Difference of Plaque Characteristics in Middle Cerebral Artery between Ischemic Stroke Patients with Positive and Negative Penumbra Area: A Study of Intracranial Vessel Wall Imaging

Wednesday, Nov. 28 11:50AM - 12:00PM Room: E350

tjliusong0128@163.com

PURPOSE

The purpose of this study was to investigate the difference of plaque characteristics in middle cerebral artery assessed by High-resolution Vessel Wall Imaging (HRVWI) between patients with positive and negative penumbra area , and to identify the risk factors affected penumbra volumes.

METHOD AND MATERIALS

Sixty-seven patients (44 males; age, 59.33 ± 10.57 years) with severe stenosis in the unilateral middle cerebral artery were enrolled. Patients were assigned to two groups: Positive Penumbra (PP group) and Negative Penumbra (NP group). MRI data were collected on a 3T Siemens MAGNETOM Trio Tim, including High-Resolution T1-SPACE, and DSC-PWI. The plaque characteristics in MCA was measured in the T1-SPACE, and all the cross-sectional image slices of a stenotic MCA on T1-SPACE were analyzed, and plaque characteristics was calculated as follows: outer vessel wall area (OWA) , lumen area (LA) and wall area (WA). Other extended parameters include normalized wall index (NWI), arterial remodeling , plaque length, configuration and enhanced behavior. The Mismatch volume was acquired using the RApid processing of PerfusIon and Diffusion (RAPID) software. Independent sample t test, Kruskal-Wallis H test and Chi-square test was performed in the difference of plaque characteristics in PP group and NP group. The relationship between the plaque characteristics and penumbra volume was calculated with Spearman's correlation or Kruskal-Wallis H test.

RESULTS

The results showed that eccentric plaques were observed 10 (37.04%) in PP group and 32 (80.00%) in NP group, which means significant difference was found between two groups ($\chi 2=12.72$, $p<0.001$). There were no significant difference between two groups in WA ($p=0.761$), NWI ($p=0.572$), expansive remodeling ($p=0.427$), diffused plaque distribution ($p=0.370$) and enhancement ($p=0.262$). Patients with diffused plaque length had larger penumbra volume comparing with the focal one in PP group ($Z=-2.754$, $p=0.005$).

CONCLUSION

Plaque with eccentric distribution in MCA is a remarkable sign to predict the presence of penumbra. Based on the patients with positive penumbra, plaque with diffused plaque length hint the larger penumbra volume, which could be rescued by timely treatment.

CLINICAL RELEVANCE/APPLICATION

Plaque with eccentric distribution in MCA can predict the presence of penumbra area, and plaque with diffused length hint the larger penumbra volume, which could be rescued by timely treatment.

SSK16-01 Functional Segmentation of Resting-State Brain Networks by Using Mutual Connectivity Analysis with Non-Metric Community Detection Methods

Participants
Adora M. D'Souza, MSc, Rochester, NY (*Abstract Co-Author*) Nothing to Disclose
Anas Z. Abidin, MS, Rochester, NY (*Presenter*) Nothing to Disclose
Axel Wismueller, MD, PhD, Rochester, NY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To explore functional network identification using Mutual Connectivity Analysis (MCA) on resting-state functional MRI (rsfMRI) using non-metric community detection (CD) methods.

METHOD AND MATERIALS

We present the MCA computational framework to construct an affinity matrix characterizing mutual nonlinear predictability between each pair of voxel time-series in rsfMRI. The goal of MCA is to establish the degree of dynamic coupling between two time-series based on their ability to locally predict each other. Here, generalized radial basis function neural networks are used as non-linear time-series predictors. To recover their community structure, the resulting affinity matrices are subject to non-metric clustering using different CD approaches, namely the Louvain Method (LM), Agglomerative Clustering (AC) and Topographic Mapping of Proximity (TMP). We test our method on rsfMRI (1.5T, TR=0.5s, TE=40ms, 512 acquisitions) of four subjects, in which images from a finger tapping motor stimulation task were acquired as well. After pre-processing with motion correction and time-series detrending, recovered networks were compared with the localization aid from the motor stimulation task by computing the Dice Coefficient (DC) and the Area Under receiver operator characteristic Curve (AUC) in order to quantitatively evaluate the agreement between actual and recovered motor cortex network segmentations.

RESULTS

All three non-metric CD methods were able to recover bilateral motor cortices and the supplementary motor area with DC values of 0.57 (LM), 0.50 (AC), and 0.60 (TMP), respectively. High segmentation quality was confirmed by AUC values of 0.79 (LM), 0.86 (AC) and 0.85 (TMP), where statistically significant differences between the CD methods in their ability to perform functional motor cortex segmentation were not observed at a $p<0.05$ level.

CONCLUSION

Our results suggest that affinity matrices obtained using the model-free non-linear MCA approach can capture valuable information regarding the underlying brain network functional connectivity structure from rsfMRI data. Using this information, non-metric CD techniques can successfully perform functional segmentation of connected brain regions.

CLINICAL RELEVANCE/APPLICATION

Functional connectivity network identification at a rsfMRI voxel scale resolution using MCA can contribute to developing imaging biomarkers for diagnosis and therapy management of neurologic diseases.

SSK16-02 Functional Connectivity Measured By Functional Resting State MRI in Glioma Patients: Association with WHO Grade and Clinical Parameters

PURPOSE

Gliomas diffusely infiltrate the brain. We hypothesized that this could lead to disturbances in functional connectivity. We developed an individual measure for altered functional connectivity and aimed to establish association of this novel marker with aggressiveness of the tumor as indicated by WHO grade and IDH mutation status as well as clinical parameters, specifically neurocognitive performance and overall survival.

METHOD AND MATERIALS

34 patients with de-novo gliomas were prospectively included and resting state functional MRI (rsfMRI) data as well as 3D anatomical reference data were obtained at 3 Tesla. Neurocognition was tested using the Montreal Cognitive Assessment test. We developed a standardized score to evaluate the abnormality of functional connectivity by comparing each patient's data to data obtained from 1000 healthy individuals. Abnormality was quantified at each voxel of the brain, resulting in an individual measure for abnormality (abnormality score, AS). Statistical analysis was conducted adjusting for tumor volume, age and signal-to-noise ratio of the rsfMRI data.

RESULTS

13 patients were diagnosed with WHO grade II tumors, 6 with WHO grade III and 15 with WHO grade IV. 17 patients had IDH1/2-mutations. We found that AS is significantly associated with WHO grade: patients with grade III and IV displayed higher AI than patients with grade II ($p<0.01$), with the strongest association seen in the non-lesional hemisphere ($p=0.0294$). Additionally, AS was significantly increased in patients with IDH-wildtype gliomas, again with strongest effects in the non-lesional hemisphere ($p=0.013$). Neurocognitive performance and AI was significantly correlated, this was most pronounced in the lesional hemisphere. 6 patients died within the follow-up period. We observed a trend towards association of overall survival with AI.

CONCLUSION

AS is a novel method to investigate functional connectivity on an individual basis. Especially in the non-lesional hemisphere, AI is significantly associated with WHO grade and IDH mutation status and correlates significantly with neurocognitive performance. Individual AS maps show the potential of this technique to gain information beyond conventional structural MRI.

CLINICAL RELEVANCE/APPLICATION

AI can detect widespread disturbances in functional connectivity which reach beyond the tumor visible on conventional MRI. AI might therefore be used to assess disease burden in glioma patients.

SSK16-03 Tumor-Induced Functional Reorganization of Language and Voxel-Based Morphometry of the Cortex: A Possible Window on Stemcells-Driven Plasticity

PURPOSE

Cortical thickening has been related to the process of learning in humans. fMRI has previously shown functional plasticity in patients with brain tumors. In this study, we retrospectively investigated the correlation between cortical morphometry and fMRI language activation in the non-dominant hemisphere of right-handed patients who have left brain tumors invading the Broca's area. Our aim was to test if tumor-induced language reorganization displayed a corresponding cortical thickening

METHOD AND MATERIALS

Patients with the following criteria were included: right handed, left tumor invading Broca's area, available fMRI, no previous irradiation, no surgery-related artifacts. The patients were divided in 2 groups by language dominance, assessed by hemispheric and Broca's laterality index. In a second analysis, we divided the patients with atypical language dominance by the results of intra-operative direct cortical stimulation of the inferior frontal gyrus. Structural data was analyzed to measure cortical thickness (or volume) with the FSL-VBM (Voxel-Based Morphometry) tool and compared between the groups

RESULTS

26 patients were included (13 left dominant, 13 atypical language dominant). VBM demonstrated a significant thickening of the right Broca's area analogue in patients with atypical language ($p<0.05$). The patients with neurosurgically-proven reorganization showed increased volume of the right hippocampal gray matter ($p<0.05$) and cortical gray matter in SMA and right insula ($p<0.05$)

CONCLUSION

Increased right-side Broca's area activation showed a corresponding cortical thickening. In the adult brain, structural plasticity is driven by the stem-cell located in the periventricular zone and the hippocampal perigranular zone (PGZ). The increased PGZ volume in patients with language reorganization to the right side may suggest that the compensatory increase in fMRI activation and the increased volume of the right language-related cortical structures is mediated by stem cells originating in the PGZ

CLINICAL RELEVANCE/APPLICATION

Our results address the mechanism of tumor-induced language reorganization, which may partly compensate the language deficits, by displaying cortical thickening of the right language areas and PGZ

SSK16-04 Cerebral Perfusion is Altered by Real-Time fMRI Neurofeedback-Directed Self-Regulation of the Primary Auditory Cortex

PURPOSE

To determine the effects of real-time functional magnetic resonance imaging neurofeedback training (fMRI-NFT) of the primary auditory cortex (A1) on quantified cerebral perfusion (i.e., cerebral blood flow, CBF).

METHOD AND MATERIALS

18 healthy volunteers with hearing loss <40dB underwent 5 experimental sessions conducted using a 3T MRI. The first session started with a baseline measure of resting CBF using a 3D pseudo-continuous arterial spin labeling sequence. Next, fMRI-NFT was carried out by first implementing a single run of a simple auditory task with blocks of white noise stimulation with no auditory stimulation. Then, 2 runs of neurofeedback were completed where subjects were asked to relax and lower the displayed A1 activity in the presence of continuous white noise. The second, third, and fourth sessions only contained fMRI-NFT. On the fifth session, a final measure of CBF followed fMRI-NFT. A control group consisting of 8 subjects performed the same procedures except sham neurofeedback was yoked from the experimental group. The average deactivation in the target ROI was extracted from each fMRI-NFT run as a representative measure of A1 self-regulation performance. CBF maps were created from the raw ASL data using proton density maps and a single-compartment perfusion model. The CBF maps were registered to a reference space. Permutation testing compared the changes in CBF between groups on a voxel-wise basis using 1,000,000 permutations. The permutation test results were cluster-corrected for multiple comparisons.

RESULTS

A repeated-measures ANOVA revealed significant main effects of group ($p = 0.029$) and training ($p = 0.0175$) on A1 self-regulation performance. Those subjects most successful reportedly adopted mindfulness tasks associated with directed attention. The permutation analysis identified several regions with greater increased CBF in the experimental group including the left temporal lobe, bilateral parietal lobe, and bilateral frontal gyrus.

CONCLUSION

For the first time, changes in resting CBF have been observed following fMRI-NFT. CBF is coupled with metabolic activity and, thus, fMRI-NFT is likely altering resting metabolic rates which could be important in the treatment neurologic disorders such as chronic tinnitus.

CLINICAL RELEVANCE/APPLICATION

Our study indicates that fMRI neurofeedback may provide an innovative approach to augment resting metabolic activity which can be altered in neurologic disorders.

SSK16-05 Investigation of Functional Networks Changes Using Degree Centrality in Heavy Smokers

Wednesday, Nov. 28 11:10AM - 11:20AM Room: E351

PURPOSE

To investigate the value of degree centrality (DC), a novel resting-state fMRI parameter, in voxel-wise whole-brain functional networks analysis in heavy smokers and mild smokers as compared with that in non-smokers.

METHOD AND MATERIALS

20 heavy smokers, 12 mild smokers, and 70 non-smokers served as normal controls were recruited,aged 20 to 55 years old, with an average (36.8±2.5) years old. Their cognitive functions were evaluated by the fagerstrom test for nicotine dependence(FTND)and other clinical scales. The resting-state BOLD-fMRI datawere acquired and preprocessed. Analysis of DC map changes between the two smoking groups and the control group were performed by two sample t test. (threshold at $P<0.05$).

RESULTS

Compared with the control group, heavy smokers showed significantly reduced DC value in cerebrum, frontal lobe, pons, left posterior cingulate and left brainstem, increased DC value was observed in fusiform gyrus and temporal lobe. In mild smokers,

significantly reduced DC value was found in right superior occipital gyrus, left superior temporal gyrus and right angular gyrus.

CONCLUSION

Changes of DC value occurred in some region of brain in the two smoking groups when compared with the control group. It was indicated that DC, as a novel resting-state fMRI parameter in the voxel-wise whole-brain functional networks, might be an appealing alternative approach for further study on pathologic and neuropsychological states of heavy smokers.

CLINICAL RELEVANCE/APPLICATION

Changes of DC value occurred in some region of brain in the two smoking groups when compared with the control group. It was indicated that DC, as a novel resting-state fMRI parameter in the voxel-wise whole-brain functional networks, might be an appealing alternative approach for further study on pathologic and neuropsychological states of heavy smokers.

SSK16-06 Identification of Eloquent Cortex for Presurgical Planning Using Independent Component Analysis of Resting-State fMRI

Wednesday, Nov. 28 11:20AM - 11:30AM Room: E351

Participants
Gaurang V. Shah, MD, Ann Arbor, MI (*Presenter*) Nothing to Disclose
Scott Peltier, Ann Arbor, MI (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

In this study, presurgical patients with brain tumors were imaged. Task activation and resting-state ICA maps for motor and language networks were generated for all subjects and compared for spatial overlap.

METHOD AND MATERIALS

Subjects: 28 subjects undergoing presurgical planning were included in this study (18M/10F; 53 (±15) years old; heterogeneous pathologies, grade IV glioblastoma most common).MRI Acquisition: Task and resting-state fMRI scans were collected using a 3T Philips Ingenia MR scanner. Resting-state EPI parameters: TR/TE/FA = 2s/28ms/90, 64x64 matrix, 3.75x3.75x3.5 mm, 39 slices, 300 timepoints. Resting-state data were collected with eyes closed on all subjects. A single finger-tapping motor task and a verb generation task were acquired for functional activation localization in the motor and language networks, respectively.Data analysis: Motor and language task activation maps were generated using DynaSuite Neuro software (InVivo Diagnostic Imaging), thresholded at 0.05 significance. Resting-state network maps were generated using FastICA. For each subject, the ICA maps with highest spatial correlation with the task activation map were selected as winning network, with secondary components also inspected.Spatial overlap of the activation maps with the resting state networks was calculated. The Dice coefficient of spatial similarity was also calculated.

RESULTS

Testing state maps show good definition of the motor network, in agreement with the task activation maps; the second ICA component in some subjects added additional motor network information.The calculated motor task activation overlap with the resting state network was high across all subjects (0.73±0.14), but the Dice coefficient was low (0.29±0.14), indicating the resting-state networks contain the majority of task activation, but also extend farther spatially. The resting-state language ICA network has a high spatial overlap with the verb task activation (0.83±0.17).

CONCLUSION

Th resulting resting-state maps compared well to task activation maps, with high percent of spatial overlap, without requiring an external task, with both motor and language networks identified from a single resting-state scan.

CLINICAL RELEVANCE/APPLICATION

This work examines identification of eloquent cortex using network identification in resting-state fMRI, which may complement and extend current clinical practice of using task fMRI.

SSK16-07 fMRI Guided Personalization of Cortical Parcellation Maps

acarbu@boun.edu.tr

PURPOSE

To personalize the 3D cortical parcellation of T1w MRI volumes to increase intra-parcel functional homogeneity by means of co-registered fMRI guidance.

METHOD AND MATERIALS

Inspired by the Demons Algorithm (Med. Image Anal., 2(3), pp 243-260,1998), we propose an iterative 3D deformation of the cortical parcellation map of a given subject, constrained to the cortex, to maximize the pairwise intra-parcel correlation coefficients (CCs) of fMRI BOLD signals (B). The co-registered T1w MRI, fMRI and (148 parcel, P) Destrieux cortical parcellation map are the inputs. The iterations are driven by a vector-field, F(rij), normal to boundary (rij) of Pi and Pj, and zero elsewhere. F is computed according to a local cost that takes into account the change in intra-parcel functional homogeneity and parcel volume change (ΔV). The former uses the CCs between the local signal, B(rij), and the parcel representative signals (Bi, Bj) defined as the in-parcel B that is closest to the left principal singular vector of the matrix composed of parcel's B's. The latter is added with a

multiplicative factor λ. We used FreeSurfer and FSL for all co-registration and parcellation steps. We tested the algorithm on 5 normal subjects for λ=0 and 0.25, by measuring the mean of pairwise CCs between in-parcel B's and the mean B per parcel, before and after the algorithm, for each subject. Statistical significance is assessed with paired t-test of CCs per parcel per subject and mean values over subjects is reported. The mean of subject-wise minimum and maximum parcel volumes (Vmin, Vmax) are reported together with the percentage of parcels with ΔV>20%.

RESULTS

The initial mean intra-parcel CC of 0.43±0.04 was increased to 0.52±0.04 (0.51±0.04) with mean p-value 1.21e-5 (4.50e-5) for λ=0 (0.25). The mean [Vmin/Vmax] (mm3) was changed from [282.8/15747.1] to [592.7/10467.9] ([582.5/11136.8]) with 64% (57%) of parcels having ΔV>20% for λ=0 (0.25).

CONCLUSION

The proposed functionally homogeneizing personalization of cortical parcellations showed a statistically significant improvement in intra-parcel correlations accompanied by a decrease in parcel volume variation. Volume constraint with λ=0.25 does not affect the final intra-parcel CCs while limiting the volume change.

CLINICAL RELEVANCE/APPLICATION

fMRI guided personalization of 3D cortical parcellation maps significantly improves intra-parcel functional homogeneity, and can potentially improve brain network models.

SSK16-08 Sex Differences in Resting-State Cerebral Activity Alterations in Internet Gaming Disorder

Wednesday, Nov. 28 11:40AM - 11:50AM Room: E351

Participants
Yawen Sun, Shanghai, China (*Presenter*) Nothing to Disclose

cjs1119@hotmail.com

PURPOSE

Although evidence has shown that the prevalence rates of Internet gaming disorder (IGD) differ between males and females, no study has examined whether such sex differences extend to brain function. This study aimed to explore the sex differences in resting-state cerebral activity alterations in IGD.

METHOD AND MATERIALS

Thirty male participants with IGD (IGDm), 23 female participants with IGD (IGDf), and 30 male and 22 female age-matched healthy controls (HC) underwent resting-state functional MRI. Maps of the amplitude of low-frequency fluctuation (ALFF) and functional connectivity (FC) were constructed. A two-factor ANCOVA model was constructed using SPM8, with sex (Male, Female) and diagnosis (IGD, HC) as the between-subject factors. When interaction effects occurred, post hoc pair-wise comparisons were performed using two-sample t-tests within the interaction masks. We used the Barratt Impulsiveness Scale-11 (BIS-11) to assess the behavioural inhibition function of the IGD participants. The correlations of the psychological scores with the ALFF and FC values were assessed using partial correlation analyses.

RESULTS

The ALFF values in the orbital part of left superior frontal gyrus (SFG) significantly decreased specifically in IGDm, which were negatively correlated with BIS-11 scores. IGDm also demonstrated lower connectivity between the orbital part of the left SFG and the posterior cingulate cortex, the right angular gyrus, and the right dorsolateral prefrontal cortex than HCm. Furthermore, IGDm had lower seed connectivity between the orbital part of the left SFG and the PCC than ICDf.

CONCLUSION

Our findings suggest that sex-specific regional- and network-level alterations exist in IGD, and the altered ALFF values in the SFG represent a clinically relevant biomarker for the behavioural inhibition function of IGDm.

CLINICAL RELEVANCE/APPLICATION

These neuroimaging findings can provide a comprehensive understanding of the neural basis of the sex-specific alterations in IGD.

bnumra@gmail.com

PURPOSE

Iterative decomposition of water and fat with echo symmetry and least-square estimation (IDEAL) imaging has shown potential in assessment of degenerative changes in muscle. The purpose of this research was to evaluate changes in vastus medialis (VM) and semimembranosus (SM) .

METHOD AND MATERIALS

Eighty-one individuals were enrolled for measurement of water and fat IDEAL values in SM and VM. All of whom were divided into Group A consisting of 33 participants with no knee related symptoms, and Group B with 48 participants who had degenerative changes in their knees. IDEAL values of water and fat along with the area of the respective muscle were measured. Each measurement was taken in two different axial sections, the first was measured in the level of the superior border of the patella and second, in the level immediately after the superior border of patella. Independent T test was used to analyse the means of the IDEAL values (p value <0.05)

RESULTS

The IDEAL values for water and fat in VM and SM were greater in Group B with superiority in fat. Means of fat in VM of Group A was 121.56±41.92 and of Group B was 195.92±78.73. Likewise, means of fat in SM of Group A and B were 140.48±43.66 and 222.92±79.7, respectively. The area of VM in Group A and B appeared to have a significant difference rather than SM. Both VM and SM showed significant differences in fat of Group B. (p value=0.00)

CONCLUSION

Water and fat IDEAL values were found to be higher in degeneration group for both muscles with obvious increment in fat. Significant change in the area of VM was observed in degeneration group.

CLINICAL RELEVANCE/APPLICATION

IDEAL can be considered as a useful quantitative method for evaluation of fatty degeneration with severity in knee osteoarthritis.

SSK17-02 Manganese Dioxide-Based Nanoparticles for MR Imaging and Photothermal Anti-Cancer Therapy

PURPOSE

Facile synthesis a manganese dioxide (MnO2)-based MRI contrast agent and in vivo evaluation of its photothermal breast cancer therapy.

METHOD AND MATERIALS

Bovine serum albumin (BSA)-MnO2-melanin-like-polymernanoparticle (BMD NP) was obtained via KMnO4-initiated in situ dopamine-polymerization induced self-assembly in the presence of BSA, and its size and r1 relaxivity were carefully measured. Mice injected with 4T1 breast cancer for MR imaging were randomly assigned into two groups; BMD NP and control group (DTPA-Gd). Images were acquired before injection and at 30, 60, 90, and 120 min post injection and then signal-to-noise ratio (SNRpost/SNRpre) at the tumor ring were quantitatively calculated. Mice bearing same tumors were randomized into the following four groups; BMD NP with/without photothermal therapy, PBS with/without photothermal therapy as control groups. The tumor sizes were measured and calculated every other day. All animal studies were performed in accordance with the guidelines established by the Institute for Experimental Animals of Zhejiang University.

RESULTS

BMD NP with a diameter of 60 nm and a high r1 relaxivity of 38.14 mM-1 s-1, which was incredibly 9 times higher than those of clinically used (Gd-DTPA). In vivo an obviously SNRpost/SNRpre at the tumor margin showed 1.57 times that of DTPA-Gd at 1h post injection, which provided detailed imaging features for precise diagnosis differentiation. The mice group treated both nanoparticle and irradiation exhibited excellent therapeutic efficacy in comparison the other three groups. The mice injected with BMD NP and irradiated by laser showed complete ablation without recurrence in 20 days, and the tumor-free period up to 60 days.

CONCLUSION

The BMD NP having excellent MRI contrasting capability and PTT efficacy plus its facile synthesis was a very promising theranostic agent for MRI-mediated photothermal anti-cancer therapy.

CLINICAL RELEVANCE/APPLICATION

The BMD NP exhibits MRI contrasting capability and photothermal anti-cancer therapy efficacy, which creates a novel theranostic methodology in evaluation and therapy of breast cancer.

SSK17-03 T1 Mapping for Myocardial Iron Overload in Thalassemia Major (TM) Patients: Time to Replace T2*

Wednesday, Nov. 28 10:50AM - 11:00AM Room: E353B

kazi.aamish@gmail.com

CONCLUSION

T1 is possibly a better biomarker than T2, WB T2* and BB T2* to assess cardiac iron load at 3T.

Background

T2* at 1.5T is a clinically accepted biomarker for assessing cardiac siderosis. Cardiac T2* quantification at 3T is challenging due to increased artifacts & T2* shortening. Studies have shown that there is a linear relationship of T1 & T2 to T2* at 1.5 T & 3T indicating that T1 & T2 are potential alternative biomarkers. However, studies haven't explored the efficiency of these biomarkers in categorizing the severity of cardiac siderosis. In this study, we have explored the performance of T1,T2,white blood (WB) T2* & black blood (BB) T2* in categorizing in-vivo cardiac iron content at 3T.

Evaluation

Myocardial T1,T2, WB T2* & BB T2* maps of 103 patients with TM (age 20.5 ± 13.5 years, 46 females),obtained at 3T MRI scanner (Ingenia,Philips,Netherlands),were retrospectively analysed.The quantitative imaging protocol included ECG gated single breath-hold Modified Look-Locker Inversion recovery sequence for native T1,Double Inversion Recovery (DIR) prepared multi-echo gradient echo BB T2*, DIR prepared GraSE for T2 & multi-echo gradient echo WB T2*.The values were measured by manually selecting ROIs on cardiac septum in a single mid ventricular short axis slice. Patients were categorized based on severity of cardiac siderosis as per WB T2* equivalent values at 1.5T as follows: Normal: > 20 ms, Mild:12 ms - 20 ms, Moderate: 8 ms - 12 ms & Severe: < 8 ms. Tukey test results for significant difference in mean values for Normal, Mild, Moderate & Severe patient groups was performed for each of the four sequences. A p-value of 0.01 was set as significant.

Discussion

Results indicate T1 to be the best biomarker among T1,T2,WB T2* & BB T2* in categorizing the severity of cardiac siderosis at 3T. Studies have shown that there is a linear relationship between T1, T2, WB T2* & BB T2* at 1.5T & 3T. This study shows that T1,T2,WB T2* and BB T2* linearly correlate with each other, confirming that T1 & T2 are potential alternative biomarkers to T2* on 3T. It demonstrates the effectiveness of each of these biomarkers in categorizing the disease severity, of which T1 shows better sensitivity than the others.

SSK17-04 Accurate Bound Water T1 Measurement Using 3D adiabatic Inversion Recovery Ultrashort Echo Time (3D IR-UTE) Imaging with Complete Suppression of Pore Water in Cortical Bone Accurate T1 Measurement of Bound Water in Cortical Bone Using 3D Adiabatic I

PURPOSE

To accurately measure the bound water T1 of cortical bone ex vivo and in vivo using 3D IR-UTE imaging on a clinical 3T scanner.

METHOD AND MATERIALS

Six human tibia bone specimens (43 to 91 years) and the tibial mid-shaft of five male volunteers (26 to 73 years) were studied. A 3D adiabatic IR-UTE sequence with different TRs and inversion times (TI) was used to accurately calculate the nulling point of pore water in cortical bone at each TR. For the specimens 6 TRs (150, 200, 250, 300, 400, 500ms) were chosen with 7 TIs at each TR to cover the likely nulling points of pore water. For the volunteer study f4 TRs (150, 200, 300, 400ms) were chosen with 5 TIs at each TR. Each IR-UTE acquisition was performed with dual echoes (TE=32μs/2.5ms), flip angle=20°, FOV=8-10cm, slice thickness=4-6mm, reconstruction matrix=128×128, number of slices=10. The equation S=S0[1+(Q-1)×e^(-TI/T1)-Q×e^(-TI/T1)]/(1-Q×cosθ×e^(-TI/T1)) was used to calculate the nulling point of pore water. The specimens and volunteers were then scanned at different TRs using the IR-UTE with the calculated TI for nulling point at each TR. The bound water T1 of cortical bone was calculated from the different TR/TI combinations. The experiments were performed on a 3T MRI system using a 30ml solenoid coil and a 1.5 inch surface coil respectively.

RESULTS

The calculated TIs for nulling were 60.2±3.4ms, 76.3±3.3ms, 91.1±3.5ms, 104.3±3.4ms, 128.5±5.0ms and 148.7±6.5ms for TRs from 150 to 500ms in the specimen group. The mean bound water T1 of the bone specimens was 104.5±6.7ms. For the volunteers the nulling point TIs were 64.2±8.8ms, 81±10.3ms, 121.2±25.2ms and 148.8±28.1ms for TRs from 150 to 400ms respectively. The mean bound water T1 of the volunteer tibias was 98±8.8ms. The figure shows pure bound water and nulled pore water images with excellent inversion recovery fitting (for the pore water nulling time) and bound water T1 fitting in a specimen and a volunteer.

CONCLUSION

Our technique allows accurate determination of bound water T1 by completely nulling pore water signals in cortical bone and the use of variable TR/TI combinations. Measurement of bound water T1 without contamination from pore water has not previously been possible.

CLINICAL RELEVANCE/APPLICATION

Accurate measurement of bound water T1 provides a new biomarker for the assessment of cortical bone integrity and may assist with water fraction mapping and MT modeling in the study of bone diseases such as osteoporosis.

SSK17-05 MRI "Pharmacokinetics" of Gd Deposition: Quantitative Analysis of Serial Monthly Administration of Triple? Dose Gadopentetate Dimeglumine in 26 Multiple Sclerosis Patients Involving 13 Consecutive Monthly Triple-Doses

PURPOSE

Studies on gadolinium (Gd) deposition and retention in the brain are limited by the lack of systematic administration of Gd inherent to most retrospective studies. Our purpose was to examine subjects who had been enrolled in a prospective trial for monitoring response to MS treatment (Wolansky L et. al. ACTRIMS 2006, Chicago) and received consecutive monthly triple-doses of gadopentetate dimeglumine.

METHOD AND MATERIALS

The cohort consisted of 26 patients who received 13 consecutive monthly triple doses (0.3 mmol/kg) of gadopentetate dimeglumine. 'Plain-T1' MR images were obtained at each monthly visit and studied for potential deposition from the prior month's Gd administration. Subjects were imaged with T1-weighted, proton-density (PD) and T2-weighted MRI at 14 time points (M1, M2 to M14). Gd deposition and retention were studied by evaluating intensity changes over time in the dentate nucleus, pulvinar, putamen, pallidum, caudate and corpus callosum. For each patient, these were manually segmented on the PD and T2 images at M14 and automatically registered to the T1 image at M14 as were the 13 preceding T1 images. Intensities in the sub-cortical structures on the bias-corrected, registered T1 images were then normalized to the mean intensity of the CC using the segmented structures as a mask. Longitudinal trends in Gd deposition and retention over time were evaluated using a Walds Wolfowitz runs test on the median of the normalized intensities over all patients. We also examined the intensity of the corpus callosum normalized

with respect to cerebrospinal fluid (CSF).

RESULTS

The dentate nucleus, caudate and pallidum showed an increasing trend ($p < 0.05$) in normalized intensity with respect to the corpus callosum over the 14 months (0.0055/month, 0.0022/month and 0.0023/month) indicating Gd deposition and retention in these structures with time. Intensity changes in the corpus callosum relative to CSF were not significant.

CONCLUSION

These findings demonstrate the rate of Gd deposition and retention in the brain after triple-dose administration of gadopentetate dimeglumine, monthly, for over a year.

CLINICAL RELEVANCE/APPLICATION

Though not linked with symptoms, Gd deposition in the brain has caused safety concerns. This pharmacokinetic study provides further scientific insight into the rate of MRI detectable deposition.

SSK17-06 The Effect of DCE-MRI Scanning Parameters on Parenchymal Enhancement of the Breast

PURPOSE

Background parenchymal enhancement (BPE) on breast DCE-MRI is increasingly used in cancer diagnosis, prognosis, and risk assessment. However, BPE, in particular quantitative measures, may be dependent on scanner and protocol, complicating pooling of results across studies. The purpose of this retrospective study was to explore the effect of differences in MRI protocol on parenchymal enhancement of the breast.

METHOD AND MATERIALS

We focused on contralateral parenchymal enhancement (CPE, Radiology 276.3(2015):675-685): CPE is the mean of the top-10% relative late enhancement in the parenchyma without lesions and has been associated with long-term survival. We performed simulations and tested these in four patient cohorts: the effect of flip angle (FA) and repetition time (TR) on CPE was simulated (Haacke, MRM 58.3(2007):463-472), and the effect of voxel size and slice thickness (resulting in differences in partial volume effect) was assessed by subsampling 50 scans from two databases (1.5T and 3T). Verification in clinical cohorts was done by comparing CPE distributions in four MRI cohorts: - cohort 1: 415 early breast cancer patients, 1.5T, FA=20°, TR=8.1ms, voxelsize=1.35x1.35x1.35mm - cohort 2: 100 advanced breast cancer patients, 1.5T, FA=20°, TR=8.1ms, voxelsize=1.21x1.21x1.69mm - cohort 3: 77 advanced breast cancer patients, 3T, FA=10°, TR=4.4ms, voxelsize=1.1x1.1x1.2mm - cohort 4: 150 women without breast cancer, 3T, FA=10°, TR=3.8ms, voxelsize=0.9x0.9x0.9mm

RESULTS

Analysis 1: Larger FA led to higher CPE, e.g. FA=15° at 1.5T yields CPE of 0.47 versus 0.23 at FA=5°. This was comparable at 3T. The opposite was observed for TR: larger TR yielded lower CPE. Analysis 2: Larger voxel size led to a decrease in CPE. Analysis 3: the distributions of CPE were not significantly different between the four cohorts (P=.496, KruskalWallis test) independent of scanner differences. Although FA and TR varied between datasets, the ratio between FA and TR was comparable.

CONCLUSION

We simulated the effect of MRI-protocol parameters on contralateral parenchymal enhancement in breast DCE-MRI. Although effects were present, implications for different cohorts appear to be limited when the ratio between flip angle and repetition time is comparable. This was confirmed by MRI scans of four different cohorts.

CLINICAL RELEVANCE/APPLICATION

Differences in MRI-protocol parameters should be taken into account when pooling parenchymal enhancement across studies.

SSK17-07 Acceleration of MR Imaging of Spine Using Compressed-SENSE: A Comparison with Existing Standard of Care Clinical Acquisition Methods

PURPOSE

To objectively evaluate the impact of Compressed-SENSE (CSENSE), a novel acquisition technique that combines compressed sensing with parallel imaging (or SENSE), on acquisition time and image quality in MR imaging of the spine.

METHOD AND MATERIALS

Current standard of care clinical axial T1 and T2-weighted acquisitions of the cervical and lumbo-sacral spine were modified to obtain higher acceleration with CSENSE (CSENSE factor 1.3999). Twenty-six patients were scanned both, with and without CSENSE, on a 3.0 T wide-bore MRI (Ingenia, Philips Healthcare). The images were anonymised and shared with three specialist MRI radiologists blinded to the acquisition type. Both sets of images were rated on a scale of 1 to 5 for image quality and delineation of specific structures including vertebral bodies, lateral recess, neural foramina, facet joints, cauda equina, nerve roots, spinal cord and paraspinal muscles. Disc abnormalities, foraminal stenosis, nerve root compression and facet joint degeneration were also rated. Dicom metadata was analysed to assess scan time acceleration (ratio of original time to CSENSE time).

RESULTS

Interrater agreement on image quality was compared between the Normal and CSENSE scans via a multivariate non-parametric Hotelling's T2 test. There was no statistically significant difference between Normal and CSENSE scans in the 12 measures evaluated by each radiologist (alpha < 0.001 level). Further, the mean percentage observed agreement between Normal and CSENSE scans for all three measures across the radiologists was 93%. The average time acceleration achieved using CSENSE on axial T1 was 1.41 and on axial T2 was 1.36 and the average time saved was 58 seconds (29%) and 50 seconds (26%) respectively.

CONCLUSION

There is no difference in image quality between current standard of care and CSENSE-based T1 and T2 axial MRI scans of the spine. Compressed-SENSE in the spine can reliably replace current axial T1 and T2 acquisitions without loss in image quality and with significant reduction in scan time.

CLINICAL RELEVANCE/APPLICATION

The potential for CSENSE to accelerate MRI acquisition without hampering image quality will increase patient throughput and patient compliance in MR scanning.

SSK17-08 Daily Qualitative and Quantitative Assessment of Magnetic Resonance Fingerprinting Using the American College of Radiology and Alzheimer's Disease Neuroimaging Initiative Phantoms

PURPOSE

Repeatability tests for robust T1/T2 measurements obtained from Magnetic Resonance Fingerprinting (MRF) based on inversion recovery requires approximately 5 hours. The goal of this study was to enable a 10-minute quality assurance protocol for MRF that could be employed on a daily basis prior to clinical studies. This involved investigating qualitative and quantitative measures of data consistency between multiple MRF scans and vendor/manufacturer supplied targets, demonstrated on in vitro Quality Assurance (QA) phantoms

RESULTS

MR signal intensity images for the ACR phantom from the SE and MRF acquisitions indicated similarity in contrast and resolution. The grid features indicated distortion due to gradient warps. The MRF implementation passed the positioning accuracy, ghosting and low contrast detectability as per the ACR guidelines. It failed tests with respect to resolution, slice thickness, geometric accuracy and signal uniformity. Relaxometric maps for the ADNI phantom from vendor supplied standard scans and MRF showed spatial correspondence. ROI analysis indicated variation of values within each ROI to be less than 13.5% whereas the variations in the repeats for each ROI was negligible. This indicated that the precision of measurements (T1) over repeats and spatial distribution of ROI were consistent. The accuracy of the measurements in the ROI varied as indicated significantly (<30% for T2, < 10% for T1) while the corresponding measures over repeats were consistent (< 1%). However, it must be noted that the ADNI phantom is primarily utilized for T1 measurements rather than T2. The MRF scans also involve variations due to the gridding reconstruction (such as the kernel size) of non-Cartesian k-space data. This is expected to impact the resolution, slice thickness and geometry accuracy tests. Incorporation of field maps into reconstruction may mitigate challenges with respect to signal uniformity, specifically in the context of spiral readouts and off-resonance challenges.

CONCLUSION

We have demonstrated a twelve minute QA protocol that could be used on a daily basis to enable measures of repeatability, accuracy and precision. We have utilized a VFA based T1- and FSE based T2-mapping schemes to enable shorter QA acquisition times. Prospective longitudinal data being currently pursued would enable insights into systemic errors and/or robustness of

implementation; thus providing higher confidence in MRF based studies at multiple sites. This is expected to aid in harmonization of MRF data between multiple sites and centers.

METHODS

An MRF implementation with 979 time points, 89 shot variable density spiral with 732 points was implemented on a GE 1.5T scanner. Spin Echo (SE) based structural imaging of the American College of Radiology (ACR) phantom was utilized for qualitative assessment with TR/TE = 500/20ms; 11 slices, 5mm slice thickness, in plane resolution of 1mm x 1mm. For comparison, MRF derived synthetic signal intensity data from the relaxation parameters was utilized. These were compared by two trained medical physicists with experience greater than five years. A 3D Fast Spoiled Gradient Recalled Echo Variable Flip Angle (2o, 5 o, 10 o, 20 o and 30 o) based T1 mapping with TR/TE = 6/1.4ms, 20 slices, 5mm slice thickness; and Fast Spin Echo based T2 mapping with eight echoes with TR/minimumTE = 1000/10ms with an echo spacing of 10.3ms, 20 slices, 5mm slice thickness were performed on the Alzheimer's Disease Neuroimaging Initiative (ADNI) Magphan EMR051 phantom (The Phantom Laboratory, NY) to obtain T1/T2 measurements. These were then compared to corresponding values determined by dictionary matched MRF scans that were repeated 5 times as part of test-retest experiments. Regions-of-interest (ROI) were drawn on specific spheres in the ADNI phantom to assess accuracy and precision of measurements. MATLAB (The Mathworks Inc., MA) based regression analysis was performed on conventionally obtained signal intensity images to determine T1/T2 maps. The total protocol time including the MRF scans was under twelve minutes.

SSK17-09 Simultaneous Measurement of T1, T2* and Fat Fraction for the Assessment of Non-Alcoholic Fatty Liver Disease

Wednesday, Nov. 28 11:50AM - 12:00PM Room: E353B

Participants
Nicholas Rubert, PhD, Chicago, IL (*Presenter*) Nothing to Disclose
Jie Deng, PhD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

This study assessed the feasibility of measuring T1 and T2* in the livers of patients exhibiting steatosis using a breath-hold dual flip-angle 3D GRE Dixon sequence.

METHOD AND MATERIALS

Imaging was performed on a 1.5T scanner. The proposed sequence consisted of two consecutive acquisitions of a 6-echo 3D GRE sequence with flip angle of 5° then 15°. From the acquisition at 5°, fat fraction (FF) and T2* were estimated at each voxel with a regularized fat-water separation algorithm. T1 of fat and water components of a voxel were then estimated in a separate step. In this step, a non-linear least squares fit of the signals at both flip angles to an equation incorporating sequence TR and fat and water T1 was performed with FF and T2* fixed. Three experiments were used to verify the performance of the algorithm: 1) A non-fat phantom containing nine vials each with different T1 and T2* values, was imaged with an inversion recovery (IR) and the proposed method. Mean T1 in an ROI within each vial was compared between the IR and proposed method. 2) Two healthy volunteers were imaged with the proposed method three times in rapid succession. Mean FF, T2*, and T1 within large ROI's in the livers of the volunteers were compared between acquisitions. 3) Patients with hepatic fat infiltration were imaged with the proposed technique. Mean FF, T2*, and T1 within large ROI's in the livers of the patients were examined.

RESULTS

For the phantom experiments T1 in each of the 9 vials ranged from 353 to 1751 ms according to the IR method. Agreement with T1 by the proposed method was within 10% for all vials. For the repeatability study on healthy volunteers measurements of FF, T2*, and T1 all exhibited coefficient of variations of <6%. Among volunteers and patients, T1 was found to be uncorrelated with FF with R2 < .01 and weakly correlated with T2* with R2 of 0.47. FF in patients ranged from 3.2% to 34.2%, T1 from 342 to 956 ms, and T2* from 17 to 50 ms.

CONCLUSION

The proposed method demonstrates close agreement with IR measurements of T1 in a phantom and highly repeatable measurements among volunteers. T1 was found to yield independent information from either FF or T2* estimated in a routine Dixon imaging sequence.

CLINICAL RELEVANCE/APPLICATION

Liver T1 can be accurately estimated from a single breath-hold GRE MRI sequence when steatosis is present. T1 measurements may be useful for evaluation of inflammation and fibrosis in patients with NASH.

cruzbastida@wisc.edu

PURPOSE

CT number accuracy at low dose levels has been found to be strongly biased. It was demonstrated that the stochastic noise associated with photon detection is the root cause of inaccurate CT number. The purpose of this work is to investigate the impact of three different denoising strategies to alleviate CT number inaccuracy in FBP-based CT: image domain denoising, sinogram domain denoising and raw counts domain denoising.

METHOD AND MATERIALS

Data acquisition was performed in a benchtop CT system, which included a CdTe-based photon counting detector. A Catphan phantom, containing inserts of known composition, was scanned at 60 kV and two different CTDIw levels: 1.5 and 15 mGy. The acquired data was reconstructed using FBP with ramp filter. Locally adapted denoising diffusion filter was applied to the lowest dose data set, in image, sinogram and raw counts domain. The contrast of Teflon and LDPE inserts was measured in averaged images across repetitions. FBP reconstruction of the average raw counts at the highest dose was considered as reference.

RESULTS

Experimental results from in this study corroborate that CT number estimates are inaccurate at low dose levels. As a consequence, the contrast of inserts relative to the background is overestimated. Particularly, the contrast of the analyzed inserts is doubled in the lowest dose scans. After adapted denoising, only the strategy to perform denoise in the raw counts domain was successful in restoring the reference contrast values.

CONCLUSION

Results in this study suggest that locally adaptive denoising is an adequate methodology to preserve the quantitative accuracy of low dose CT when performed in the pre-log projection domain.

CLINICAL RELEVANCE/APPLICATION

Healthy tissue and disease characterization often rely on both absolute CT number and relative contrast, for example: liver and pancreatic steatosis, acute cerebral venous sinus thrombosis, etc. Dose reduction efforts in CT must be guided by both imaging performance and quantitative capabilities.

SSK18-02 Task-Based Image Quality Assessment of X-ray CT Using Convolutional Neural Networks

Wednesday, Nov. 28 10:40AM - 10:50AM Room: E353C

Participants
Felix K. Kopp, Munich, Germany (*Abstract Co-Author*) Nothing to Disclose

Peter B. Noel, PhD, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study is the task-based image quality assessment of X-ray computed tomography.

METHOD AND MATERIALS

A phantom with contrast targets similar to lesions in a contrast enhanced liver (acrylic spheres, varying diameters, +30 HU) was repeatedly scanned with a computed tomography scanner. A board certified radiologist rated image patches containing the contrast targets with a confidence rating for the presence of the signal. Labeled image data were used to build several anthropomorphic model observers to predict the performance of the human observer: A neural network based on softmax regression (SR-MO) and a convolutional neural network (CNN-MO). Results were compared to a more traditional model observer, the channelized Hotelling observer (with Gabor channels and internal channel noise (CHOi)). The performance of the different model observers and the human observer were evaluated with a receiver operating characteristic curve analysis. The machine learning based model observers were trained with two different strategies: A) building a separate model for each lesion size; B) building one model that was applied to lesions of all sizes.

RESULTS

Machine learning based model observers as well as the CHOI and the human observer were highly correlated at each lesion size and dose level. With strategy A, Pearson's product-moment correlation coefficients r were 0.961 (95% confidence interval (CI): 0.863-0.989) for SR-MO and 0.974 (95% CI: 0.907-0.993) for CNN-MO. Mean absolute percentage differences (MAPD) between the model observer and the human observer were 1.1% for SR-MO and 1.0% for CNN-MO. With strategy B, r was 0.956 (95% CI: 0.845-0.988) for SR and 0.958 (95% CI: 0.854-0.989) for CNN. For CHOi, r was 0.971 (95% CI: 0.897-0.992). MAPD were 2.0% for SR-MO and 1.5% for CNN-MO. For the CHOi the MAPD was 1.9%.

CONCLUSION

Machine learning based model observers can accurately predict the performance of a human observer for all lesion sizes and dose levels in the evaluated signal detection task.

CLINICAL RELEVANCE/APPLICATION

Model observers are widely used in research regarding the development and optimization of medical imaging devices. Our results show that machine learning based model observers can accurately predict the performance of a human observer in a signal detection task for CT.

SSK18-03 DestreakNet: A Deep Convolutional Neural Network to Reduce Metal Streak Artifacts in CT Images

ge-wang@ieee.org

PURPOSE

To design and train a deep convolutional neural network to reduce metal artifacts in CT images.

METHOD AND MATERIALS

Our network structure (DestreakNet) consists of two parallel streams, each with 20 residual units. In each residual unit, there are two convolution layers with batch normalization (BN) and rectified linear unit (ReLU) activation. The network is trained on the residual error between the input and output of the unit. The outputs of both streams are merged in the network's feature space, and then passed through nine more convolution layers to yield a final output. A mean squared error (MSE) and a perceptual loss function were both investigated for network optimization. All training, testing, and validation datasets were generated using CatSim, an industrial-grade CT simulator. Real data from the Visible Human Project were used to create voxelized phantoms of pelvic and spinal regions with and without metal implants. For initial correction, CT images were reconstructed using the state-of-the-art NMAR algorithm. The reconstructed images without metal were the ground truth and target of the network. From full-size images, approximately 150,000 patches of size 56x56 were extracted for training. Patches from the NMAR images were input to one network stream and patches from uncorrected CT images were input to the other to harness complimentary features simultaneously.

RESULTS

To validate the network performance, hip and spine images withheld from training were used. In a hip case, the image quality metrics including structural similarity index (SSIM) and peak signal-to-noise ratio (PSNR) were calculated for all images in reference to the artifact-free truth. The SSIM and PSNR were 0.2382 and 9.1830, respectively, for the initial uncorrected reconstruction image, 0.7014 and 18.8975 for the NMAR-corrected image, 0.8636 and 23.8582 for DestreakNet with MSE loss, and 0.8264 and 22.1685 for DestreakNet with perceptual loss.

CONCLUSION

Our network substantially reduced metal streak artifacts that remained in the CT image after initial correction by the NMAR algorithm.

CLINICAL RELEVANCE/APPLICATION

Our proposed data-driven metal artifact reduction method may provide sufficient image quality in radiation therapy planning, which requires accurate tumor characterization near implants for precise dose delivery.

SSK18-04 Patient-Specific Local Noise Power Spectrum Measurement via a Deep-Learning Generative Adversarial Network

Wednesday, Nov. 28 11:00AM - 11:10AM Room: E353C

PURPOSE

With the increased use of low-dose CT techniques which are characterized for its highly shift-variant noise properties, the measurement of the noise power spectrum (NPS) has become challenging and time consuming since current solutions require multiple scans of a given clinical scenario. In this work, a deep-learning generative adversarial network (GAN) was developed to address this challenge and provide a fast and accurate way to measure patient-specific local NPS.

METHOD AND MATERIALS

GANs were utilized to learn a mapping from white noise input to output CT noise realizations with correct CT noise correlations from a single local uniform ROI. To achieve this, a two-stage training strategy was implemented. In the pre-training stage, repeated scans of a quality assurance phantom were performed to extract 1600 (64x64) local MBIR noise-only images used as labels to train the network. This network characterized the noise magnitude and correlation in labels and was able to generate 64x64 noise-only images with similar characteristics as the input. For the next stage, a single scan of an anthropomorphic phantom was used for fine-tuning, while repeated scans were used for validation. First, a 101x101 ROI was extracted from a single MBIR image, detrended, and augmented to obtain 128 (64x64) training labels and fine-tune the pre-trained GANs. To validate the GAN-generated noise images, their NPS was compared to the NPS from the physical ensemble of repeated scans in terms of overall RMSE, noise magnitude, and mean frequency across 30 trials. This patient-specific approach was applied to clinical data reconstructed with MBIR (same patient at two doses) to assess the estimated NPS in terms of noise magnitude and coarseness.

RESULTS

The overall RMSE between the GAN-generated NPS and the physical NPS was 0.83 HU2mm2. The mean percent discrepancy for their noise magnitude and mean frequency were 4.51% and 3.62%, respectively. The runtime for the fine-tuning stage was <100s and 1s to generate 250 noise images.

CONCLUSION

It was demonstrated that GANs can characterize CT noise in terms of magnitude and coarseness and generate multiple noise realizations with comparable characteristics from a single noise realization.

CLINICAL RELEVANCE/APPLICATION

A fast and accurate way to estimate patient-specific local NPS was provided and can be easily adapted to any given CT system. This is an essential step towards patient-specific image quality assessment.

SSK18-05 Multi-Kernel Synthesis for CT Images Using a Deep Convolutional Neural Network

Wednesday, Nov. 28 11:10AM - 11:20AM Room: E353C

Awards
Trainee Research Prize - Fellow

For information about this presentation, contact:

Missert.Andrew@mayo.edu

PURPOSE

To produce a single synthetic image that combines the best qualities of images reconstructed with different kernels using a deep convolutional neural network (CNN).

METHOD AND MATERIALS

A CNN was trained from scratch to synthesize multiple input images, each produced with a different reconstruction kernel, into a single output image that exhibits improved image qualities (in terms of high sharpness and low noise levels) compared to each input individually. The CNN architecture was based on the ResNet design, and consisted of repeated blocks of residual units with a total of 32 convolutional layers. The CNN inputs consisted of three images produced by soft (B10), medium-sharp (B45), and sharp (B70) kernels that were stacked in the channel dimension. The CNN output was treated as a perturbation that was added to the sharp-kernel input, which reduced the required training time. The network was trained using supervised learning with both full-dose and simulated quarter-dose abdominal CT images. The simulated quarter-dose images obtained from different kernels were used as the

network input, and the corresponding full-dose images reconstructed with a sharp kernel were used as the ground truth to evaluate a mean-squared-error loss function. The network was trained on 500,000 example images of various sizes that were cropped from ten abdominal CT exams. After training, the performance was evaluated by comparing input and output images using a reserved set of full-dose abdominal, chest, and phantom CT scans that were not used in the network training.

RESULTS

The synthetic images improved the signal-to-noise ratio by 338% compared to the sharp kernel images, without observable blurring of sharp edges. No perceptible artificial texture was introduced that detracted from the natural appearance of the synthetic image. The algorithm was robust enough to be applied to multiple tissue types, including the bones, lungs, and liver.

CONCLUSION

An artificial neural network can be used to combine images from multiple reconstruction kernels into a single synthetic image that exhibits both low noise and a high degree of sharpness.

CLINICAL RELEVANCE/APPLICATION

CT Images from different reconstruction kernels can be merged using a neural network into a single image with superior qualities that can be used for reading multiple tissue types simultaneously.

SSK18-06 Correlation Between 2D Channelized Hoteling Observer in a Uniform Water Background and Human Observers in a Patient Liver Background for Low-Contrast Lesion Detection and Localization in CT

Wednesday, Nov. 28 11:20AM - 11:30AM Room: E353C

Participants
Hao Gong, PhD, Rochester,, MN (*Presenter*) Nothing to Disclose
Lifeng Yu, PhD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose

Cynthia H. McCollough, PhD, Rochester, MN (*Abstract Co-Author*) Research Grant, Siemens AG

For information about this presentation, contact:

Gong.Hao@mayo.edu

PURPOSE

To investigate the correlation between 2D channelized Hoteling observer (CHO) performance in a uniform water background (with single-slice viewing mode) and human observer (HO) performance in a patient liver background (with multi-slice scrolling viewing mode) for a low-contrast liver lesion detection and localization task when lesion location is uncertain.

METHOD AND MATERIALS

Seven routine dose abdominal patient scans (mean CTDIvol 12.6 mGy) were retrospectively collected. Patient scans at half and quarter of routine dose were simulated using a projection-based noise insertion tool. An abdomen-sized water phantom was repeatedly scanned (n = 10) on the same scanner. Lesion models generated from real metastatic liver lesions (size 7, 9 and 11 mm, and contrast 15, 20, and 25 HU) were inserted into both phantom and patient images using a projection-based method. CT images were created using filtered-back-projection (FBP) and iterative reconstruction (IR). Region-of-interests (ROIs) around lesions were extracted to generate trials for CHO and HO studies. Centers of the ROIs were shifted to randomly distribute lesion locations in the ROIs. A 2D CHO with 12 Gabor channels was applied to phantom images. Two subspecialized radiologists (10 and 25 years of experience) performed HO studies on patient images. For each trial, they localized lesions by scrolling through multiple slices. The performance of CHO and HO was compared across 12 experimental conditions with varying dose, lesion characteristics, and reconstruction types. Area under the receiver operating characteristic (ROC) curve and localization ROC curve were used as figure of merits for CHO and HO performance.

RESULTS

2D CHO performance in phantom images correlated well with HO performance in patient liver images (Pearson correlation coefficients 0.960 ($p = 0.0023$) and 0.984 ($p = 0.0004$) for detection and localization, respectively) for all conditions . No statistically significant difference was observed in Bland-Altman agreement analysis.

CONCLUSION

It is possible to use a simple single-slice viewing CHO and uniform water phantom to assess performance for realistic CT detection and localization tasks in patient liver backgrounds.

CLINICAL RELEVANCE/APPLICATION

Single-slice 2D CHO with Gabor channels provides a convenient tool to evaluate diagnostic performance and optimize abdominal CT scanning protocols.

SSK18-07 Can Deep Learning Unseat Iterative Reconstruction for Low-Dose CT?

Wednesday, Nov. 28 11:30AM - 11:40AM Room: E353C

wangg6@rpi.edu

PURPOSE

Although widely applied in clinical practice, studies have reported that iterative reconstruction (IR) alters image appearance, and can adversely affect low contrast lesions. The purpose of this project is to systematically compare commercial/clinical iterative reconstructions by major vendors with FBP-reconstruction-based deep learning (FBP-DL) reconstruction for low-dose chest and abdomen CT exams.

METHOD AND MATERIALS

Our study included 80 low-dose chest and abdomen CT exams from three major CT vendors (de-identified). We created a neural network including 4 convolutional and 4 deconvolutional layers, each of the layers contains 32 filters except for the last layer with only 1 filter. For preserving image features, former feature-maps were reused at latter layers by three conveying-paths. The rectified linear unit was used for each layer. The network was optimized in the Wasserstein generative adversarial network framework with an additional perceptual loss. 128K normal- and low-dose FBP image patches from the MGH dataset were used in training our network. Image quality metrics including peak signal-to-noise ratio (PSNR) and structural similarity index (SSIM) were calculated for all the images in reference to the normal-dose FBP images. Also, a blinded reader study was designed to evaluate the image quality. Then, the Wilcoxon signed-rank test was used to compare FBP-DL with commercially available state-of-the-art IR techniques.

RESULTS

FBP-DL achieves a significantly better image quality and performance than commercially available IR images evaluated by PSNR and SSIM for all the selected vendors. Also, the reader study demonstrated that FBP-DL images had superior visibility of small and subtle structures with lower noise and less severe artifacts as compared to the IR counterparts. In addition to that, deep learning is computationally more efficient than IR.

CONCLUSION

The deep learning method has a great potential to outperform the commercial/clinical iterative reconstruction for low-dose CT. An integrated deep learning workflow from raw data to final images/radiomics is under active development.

CLINICAL RELEVANCE/APPLICATION

Emerging deep learning-based CT methods may provide a superior diagnostic performance in routine clinical applications.

SSK18-08 Reference-Based Image-Detail and Noise Texture Metrics for CT Image Quality Assessment

Wednesday, Nov. 28 11:40AM - 11:50AM Room: E353C

Participants
Sathish Ramani, Niskayuna, NY (*Abstract Co-Author*) Employee, General Electric Company
Lin Fu, PhD, Niskayuan, NY (*Abstract Co-Author*) Employee, General Electric Company
Bruno De Man, PhD, Niskayuna, NY (*Presenter*) Employee, General Electric Company

PURPOSE

Task-based image quality metrics are the gold-standard in evaluating and comparing the performance of imaging algorithms. Nevertheless, algorithm designers still benefit from lower-level more direct metrics reflecting the actual image presentation. Traditional noise and spatial resolution metrics are coming short for non-linear iterative reconstruction approaches. This work proposes quantitative metrics for separately assessing object-detail, artifact-level and noise texture based on a gold-standard reference.

METHOD AND MATERIALS

A phantom constructed from a freshly-cut turkey was scanned 117 times at 120 kV and 200 mA. FBP images were reconstructed and averaged over the scans to obtain a noise-free reference image Z, from which a noisy sinogram S was simulated. Model-Based Image Reconstruction (MBIR) images at varying regularization strengths, ß, were reconstructed from S. For an MBIR-image M, the object-detail metric was computed as a normalized covariance between M and Z. Artifact metric was computed as the normalized energy of the difference between M and its geometric-projection along Z. Histogram and spectral density shapes of the residue R=M-Z, were used to assess noise texture.

RESULTS

With increasing ß, noise decreased in M at the expense of loss of image features: the object-detail metric monotonically decreased correspondingly. Artifact metric exhibited a minimum and increased either way due to high noise at low ß or loss of image features at high ß. Histogram of R evolved from being broad with long tails (high noise at low ß) to being narrow (nearly no noise at high ß). The spectral density of R evolved from exhibiting high-frequency behavior (high noise at low ß) to being predominantly low-frequency in nature (noise with long spatial correlation at low ß).

CONCLUSION

The proposed metrics captured expected behavior of MBIR at varying strengths indicating their validity. These metrics can be helpful in judging preservation of image features and evaluation of artifact-level and noise texture for CT algorithm development and tuning.

CLINICAL RELEVANCE/APPLICATION

CT iterative reconstruction was introduced a decade ago and is continuing to be improved. The proposed image quality evaluation methods are useful for algorithm designers to achieve the best possible tuning of CT algorithms before clinical deployment.

SSK18-09 Task Based Image Quality in Virtual Monoenergetic Images Across 3 Generations of Scanner Models

yakun.zhang@duke.edu

PURPOSE

To use task-based metrics to assess the impact of patient size, beam spectra separation, and radiation exposure on image quality for virtual monoenergetic images (VMIs) across three scanner platforms.

METHOD AND MATERIALS

This study used a commercially available phantom with iodine, soft tissue and calcium inserts (Gammex Multi Energy CT phantom). The phantom was configured with additional fat rings simulating five different sizes (20, 30, 35, 40, and 50 cm diameter). All scans used radiation exposures of 4, 8, 16, and 24 mGy, and were repeated on three DECT platforms from one manufacturer (Siemens Force, Flash and Edge). VMIs were reconstructed at 50, 70 keV and 150 keV. Noise and image texture in terms of average frequency of the noise power spectra (Favg) and the contrast-dependent spatial resolution in terms of the 50% amplitude of the iodine-task transfer function (F50) were calculated. A task-specific detectability index (d') was calculated for iodine inserts using a 5 mm Gaussian circular disk as the task.

RESULTS

The Favg and F50 decreased with increasing phantom size. For 100/150Sn kV on Force scanner, Favg was 0.31, 0.30, 0.27, and 0.25 mm^{-1} for the 20, 30, 35, 40 cm sizes; F50 was 0.43, 0.43, 0.37, 0.32 mm^{-1}, respectively. For the same phantom size, the Favg appeared to be insensitive to changes in acquisition spectra separations, but F50 increased with increasing spectra separation. Different keVs did not affect either Favg or F50, but affected the noise magnitude and contrast, and thus the detectability index. d' for the 15 mg/ml iodine insert had an average of 23% increase for all sizes and kV combinations when keV decreased from 70 to 50. At 70 keV, the larger spectra separation (80/150Sn kV) led to an increase in d' compared to less spectra separation (100/150Sn kV) at round 10% for the 20 and 30 cm phantoms, but only 3% higher d' for the 35 and 40 cm phantoms. For a fixed keV, image contrast, Favg, and F50 were relatively insensitive to changes in radiation exposure for sizes below 40cm.

CONCLUSION

The system behaved non-linearly for different phantom sizes and spectra separation. Task based metrics was able to capture the characteristics of the VMIs. Highest detectability was achieved with larger spectra separation and for smaller sizes.

CLINICAL RELEVANCE/APPLICATION

Highest iodine detectability for the VMIs was achieved with larger spectra separation and for smaller sizes.

SSK19-01 The Safety and Efficacy of Interstitial 125I Seeds Implantation Brachytherapy for Metastatic Epidural Spinal Cord Compression

Participants
Chaojie Li, MD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the safety and efficacy of 125I seeds interstitial implantation for metastatic epidural spinal cord compression (MESCC) and the life quality of the patients.

METHOD AND MATERIALS

From April 2009 to May 2015, 28 patients who met the inclusion criteria were retrospectively reviewed. The number of 125I seeds implanted ranged from 7 to 62 with specific activity of 0.5 to 0.8 mCi. The post-plan showed that the tumor matched peripheral dose (MPD) were 80-140 Gy. Follow-up ranged from 1 to 32 months with a median of 18 months. Visual analogue scale (VAS), karnofsky performance scale (KPS) and motor performance were measured before and after treatment.

RESULTS

All patients tolerated seed implantation well. All patients were obviously alleviated pain. VAS scores of patients decreased from 4.89±1.52 before treatment to 1.61±1.20 after treatment, and KPS scores increased from 73.93±12.27 to 86.76±10.90, both differences were statistically significant($P<0.05$). The 1-, 2-, 3- year local control rates were 77%, 34%, and 14%, respectively, with a median of 19 months (7-32 months). The 1-, 2-, 3- year survival rates were 81%, 54%, and 14%, respectively, with a median of 25 months. 7(100%) nonwalking patients regained motor ability. No myelopathies or other neurologic sequelae were encountered.

CONCLUSION

Interstitial 125I seeds implantation brachytherapy was a promising local therapy and an alternative and palliative way to treat MESCC.

CLINICAL RELEVANCE/APPLICATION

To investigate the safety and efficacy of 125I seeds interstitial implantation for metastatic epidural spinal cord compression (MESCC) and the life quality of the patients.

SSK19-02 Cancer-Related Anxiety Following Definitive Treatment of Localized Prostate Cancer: A Population-Based Cohort Study

Wednesday, Nov. 28 10:40AM - 10:50AM Room: S504AB

Awards
Student Travel Stipend Award

Ronald Chen, MD, Chapel Hill, NC (*Abstract Co-Author*) Consultant, Accuray Incorporated

PURPOSE

Psychological distress following localized prostate cancer treatment is not well-understood. We assessed cancer-specific anxiety post-treatment and factors associated with increase in anxiety level.

METHOD AND MATERIALS

Population-based prospective cohort of newly diagnosed localized prostate cancer patients were enrolled from 1/2011 to 6/2013. A

total of 838 patients who received definitive treatment with radical prostatectomy (RP) or radiotherapy (RT) were analyzed. Patients with recurrence after treatment were excluded. Cancer-related anxiety one year post-treatment was assessed using the validated Memorial Anxiety Scale for Prostate Cancer (MAX-PC) questionnaire, which consists of 3 subscales: recurrence anxiety, PSA anxiety, and prostate cancer anxiety. Multivariable linear regression assessed factors associated with anxiety.

RESULTS

Median age was 64 and 74% were White. In this cohort, 53%, 25%, 11%, and 11% of patients received RP, conventional RT, stereotactic body RT, and brachytherapy, respectively. Multivariable analysis showed that White men had lower recurrence anxiety, PSA anxiety, and prostate cancer anxiety than non-White men (all $p<0.001$), while older men had less PSA anxiety and prostate cancer anxiety compared to younger men ($p=0.002$ and $p=0.001$, respectively). Patients with high risk prostate cancer had increased recurrence anxiety than those with low risk disease ($p=0.04$). Compared to men receiving RP, those receiving brachytherapy and conventional RT had borderline significant increase in recurrence anxiety and PSA anxiety, respectively (both $p=0.05$). Frequency of post-treatment PSA testing and last PSA value were not associated with level of anxiety.

CONCLUSION

White men and older patients overall had less cancer-related anxiety, while high risk patients had increased recurrence anxiety.

CLINICAL RELEVANCE/APPLICATION

Better understanding of factors associated with prostate cancer-related anxiety may aid in counseling patients to improve psychological well-being after definitive treatment.

SSK19-03 Evaluation of Prognostic Factors of Bone Metastasis Treated By Radiotherapy: A Single-Institution Experience

Toshifumi Gabata, MD, PhD, Kanazawa, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

We investigated the prognostic factors of bone metastases treated by radiotherapy and evaluated the efficacy of prognostic scoring systems in our institution.

METHOD AND MATERIALS

Between April 2011 and December 2016, 288 patients were evaluated (median age, 64 years). The median follow-up period was 11months. The common primary lesion was lung cancer (22%), liver cancer (12%) and prostate cancer (10%). We investigated the overall survival (OS) for all patients using Kaplan-Meier Method and the verification of prognostic prediction using Katagiri score and number of risk factor method (NRF). Katagiri score is scoring system using 6 factors; primary site, metastasis other than bone, poor PS, previous chemotherapy, multiple bone metastasis and abnormality of laboratory data. On the other hand, NRF uses only 3 factors; non-breast cancer, metastases other than bone, and KPS =2). Also, we analyzed factors (gender, age, primary lesion, PS, multiple bone metastases, previous chemotherapy, metastasis other than bone) by a multivariate analysis using the Cox proportional hazards model.

RESULTS

The OS rate for all patients was 42% at 1 year and median survival time was 9 months. In Katagiri score, 190 patients could be scored. The OS rate after 1 year was 79% for low risk (score0-3) and 51% for intermediate risk (score4-6). The OS rates for high risk (score7-10) after 6 months and 1 year were 43% and 19%, respectively. In NRF, all patients could be scored. Patients with a prognostic score of =3, the survival rate was 37% at 6 months, and only 18% at 1 year. Both Katagiri score and NRF, the significant differences are recognized between each all three groups. A multivariate analysis showed the significant prognostic factors for PS, primary lesion, previous chemotherapy, metastasis other than bone. Our results don't contradict the factors of previous studies.

CONCLUSION

We could investigate significant prognostic factors in our institution and show the validity of the prognostic scoring system previously reported.

CLINICAL RELEVANCE/APPLICATION

We could investigate the significant prognostic factors for radiotherapy of bone metastases and show the validity of the prognostic scoring systems (Katagiri score and number of risk factor method).

PURPOSE

To demonstrate Kaposi Sarcoma (KS) lesion imaging by planar and SPECT/CT of cutaneous and subcutaneous KS-associated lesions using 99mTc-tilmanocept (TCT). Such imaging may augment current clinical and biopsies evaluation of KS patients.

METHOD AND MATERIALS

In previous work, we confirmed that Tumor-associated Macrophages (TAMs) and KS cells express the macrophage mannose receptor (CD206), which is the receptor target for TCT. Here we present the first results from a Phase I open-label, dose escalation clinical study of TCT imaging in KS patients. Four subjects with biopsy confirmed cutaneous KS lesions (3 HIV+) were administrated 100 µg of tilmanocept radiolabeled with 5 mCi of 99mTc by intravenous injection (IV) followed by planar and SPECT/CT imaging of areas of interest. Images were acquired at 60 to 75 and 150 to 210 minutes post-injection and were visually cross-examined for uptake in cutaneous and presumably subcutaneous lesions.

RESULTS

IV injection of TCT was well-tolerated. No drug-related adverse events were observed. Uptake on SPECT/CT images was observed in cutaneous lesions of the feet and lower legs as well as suspected subcutaneous lesions of the same regions. All SPECT/CT images were compared to the photographs of KS lesions and other targeted areas of the body taken prior TCT administration. Overall, SPECT/CT imaging revealed highly specific TCT localization in the KS-affected area. Some of the results showed presumptive TCT localization in lymphatic vessels along legs.

CONCLUSION

Results suggest that TCT is a valuable immunodiagnostic agent for imaging of cutaneous and presumably subcutaneous KS lesions. The results shows that this method would improve the accuracy of disease staging in KS patients. TCT imaging may also contribute to monitoring the efficacy of KS therapies.

CLINICAL RELEVANCE/APPLICATION

This is a first attempt of merging TCT imaging data of cutaneous and presumably subcutaneous sites of KS-associated lesions in HIV subjects diagnosed with KS-lesions tissues biopsy results obtained from pathology labs and external medical evaluation of the lesions. Currently, TCT is a first highly specific immunodiagnostic agent, which was proven to support KS evaluation without drug-related adverse events.

PURPOSE

For select patients with stage IV soft tissue sarcoma of the extremity (STSE), definitive surgery to the primary site (SP) is a treatment option as per NCCN and other modalities, such as radiotherapy (R), chemotherapy (C), and metastasectomy (M) can be added to the treatment regimen. We sought to compare the oncologic outcomes of such patients treated with SP in the National Cancer Data Base (NCDB).

METHOD AND MATERIALS

In the NCDB, patients with stage IV STSE who received SP from 2004-2014 with complete treatment records were identified. Survival distributions were estimated using the Kaplan-Meier method and compared using log-rank tests. Covariates were compared using chi-squared tests or ANOVA.

RESULTS

1,291 patients met entry criteria. 5-yr overall survival (OS5) was best for patients treated with metastasectomy (SP+M+/-C+/-R) at 31.4% compared to 20.7% for those treated with other non-surgical adjuvant therapies (SP+C, SP+R, SP+C+R) and 16.2% following SP alone (p<0.0001). Patients with adipocytic tumors had the best OS5 at 29.4% with a median OS of 2.4 years (p=0.0003). On multivariable analysis (MVA), higher Charlson-Deyo score trended with inferior OS (HR 1.20 [95% CI: 0.99-1.45], p=0.07). Patients with well-differentiated tumors had better OS (HR 0.40 [95% CI: 0.17-0.93], p=0.033). 17% of patients had lymph node sampling and this was associated with improved OS (HR 0.75 [95% CI: 0.59-0.94], p=0.014) on MVA. In addition, 27.4% of patients had positive surgical margins, and this was associated with worse OS (HR 1.56 [95% CI: 1.29-1.88], p<0.001). Tumors greater than 10-15cm (HR 1.69 [95% CI: (1.26-2.27) p<0.001) and tumors >15cm (HR 2.04 [95% CI: (1.53-2.73) p<0.001) were predictive for worse OS compared to tumors less than 5cm.

CONCLUSION

In this analysis of a national cancer database, negative surgical margins and lymph node dissection were both associated with prolonged overall survival in patients with stage IV STSE undergoing resection of the primary sarcoma. Metastasectomy was also associated with longer survival is this group. These hypothesis generating data warrant further study.

CLINICAL RELEVANCE/APPLICATION

Surgeons should consider lymph node dissections and re-resections for positive margins in patients with stage IV STSE undergoing resection of the primary sarcoma as both associated with prolonged overall survival. Metastasectomy was also associated with longer survival is this group.

SSK19-08 Radiomic Models of Pathological Markers of Sarcoma, Including Grade and Translocation Status

PURPOSE

Soft tissue sarcomas (STS) are traditionally classified by tumor grade, and recently more complex pathologic markers such as translocation status have become of interest. Radiographic correlates may help determine tumor grade and detect targetable mutations, and radiomic features have been correlated to pathologic markers in other tumor types. We examined associations between radiomic features extracted from magnetic resonance images (MRI) of sarcoma with tumor grade and translocation status.

METHOD AND MATERIALS

A retrospective analysis of 199 patients (age>14 years) with histology-confirmed STS was performed. 30 radiomic features (histogram, Haralick, neighborhood difference, and zone size features) were extracted from T1-weighted contrast-enhanced MRI in the tumor volume. FNCLCC grade and translocation status were determined by expert pathologist review. Associations between patients who were grade 1+2 vs 3 and patients with translocation vs no translocation with radiomic features were investigated using univariate logistic regression. P-values were adjusted for multiple comparisons via permutation-based stepdown (A=0.05 for each feature).

RESULTS

101 patients (51%) had grade three STS, and 52 patients (26%) had known translocation. Patients with translocated tumors were younger (42 vs 56 years, p<0.001) with lower grade tumors (p<0.001). Before adjustment, 4 variables were associated with translocation status and 14 radiomic variables were associated with tumor grade. After adjustment, no features were significantly associated with translocation status but 3 features retained significant association with tumor grade (variance, odds ratio [OR]: 0.6, p=0.045; dissimilarity, OR: 0.6, p=0.002; and contrast OR: 0.6, p=0.035).

CONCLUSION

These results suggest translocation-driven STS occur more frequently in younger individuals and are associated with lower grade tumors. Radiomic features examined were not associated with translocation status but were significantly associated with FNCLCC tumor grading of STS. The results suggest radiomic-pathologic models might provide value for patient management in sarcoma in the future.

CLINICAL RELEVANCE/APPLICATION

Radiomic analysis of conventional imaging modalities may elucidate noninvasive sarcoma biomarkers that complement current classification systems.

SSK19-09 A Radiomics Model for Preoperative Metastasis Prediction for Soft-Tissue Sarcomas

Wednesday, Nov. 28 11:50AM - 12:00PM Room: S504AB

PURPOSE

To develop and validate a radiomics model based on multimodality images (PET, CT, T1-weighted and T2-weighted MRI) for the early evaluation of the metastasis risk in patients with soft-tissue sarcomas (STSs).

METHOD AND MATERIALS

In this retrospective study, a total of 51 patients with histologically confirmed STSs and clinically followed up for the metastasis were enrolled. Among the 51 patients, 35 were selected randomly as the primary cohort to build the prediction model, while the remaining 16 patients were used to test the prediction power of model. A total of 474 radiomics features were extracted from the single modality image for each patient. Feature selection was performed in 3 steps using Mann-Whitney U test, intra-class Spearman Rank Correlation test and Least absolute shrinkage and selection operator (LASSO) regression. Radiomics signature was developed based on each single modality images or their combinations. Delong test was used to detect the difference levels between the different radiomics signatures. The performance was assessed in discrimination of area under the curve (AUC) and clinical utility using 4-fold cross-validation.

RESULTS

The AUC for radiomics signatures in the primary cohort based on CT, T1-weighted MRI, T2-weighted MRI and PET individually was 0.71, 0.70, 0.80 and 0.73, respectively. In contrast, the AUC for the validation cohort based on CT, T1-weighted MRI, T2-weighted MRI and PET individually was 0.75, 0.82, 0.83 and 0.73, respectively. The combination of the radiomics signatures from CT, T2-weighted MRI and PET images improved AUC, with the optimal performance reached AUC of 0.87 for the training cohort, as well as 0.88 for the validation cohort. Besides, P<0.05 from Delong test showed significant differences between the combination of CT, MRI and PET and others. In addition, decision curve analysis confirmed the clinical usefulness of the multimodality model.

CONCLUSION

A radiomics model, based on CT, T2-weighted MRI and PET images improves the accuracy for the early evaluation of the metastasis risk in patients with STSs.

CLINICAL RELEVANCE/APPLICATION

The non-invasive radiomics model combining CT, T2-weighted MRI and PET images could be used to predict metastasis risk in patients with STSs.

PURPOSE

To prospectively determine and compare therapy response and safety of microwave (MWA) ablation and radiofrequency ablation (RFA) of hepatocellular carcinoma (HCC) in a randomized trial.

METHOD AND MATERIALS

In this prospective study 50 patients (39 males/11 females; mean 64 years; range 42-82; SD 9.98) underwent CT-guided thermal ablation: 25 received RFA and 25 MWA. Using MRI the location of the HCC and changes in size, volume, necrotic area, diffusion and ADC value in the malignant tissue were evaluated. First MRI control took place before treatment with thermal ablation. The follow-up contained MRI controls 24 hours after ablation and then within 12 months in 3-month intervals.

RESULTS

50 HCC lesions with a mean diameter of 2.05 cm (range 0.62-5 cm: MWA 2.22 cm, RFA 1.84 cm) were treated with thermal ablation. The mean volume 24 hours after ablation was 49.2 cm3: 69.9 cm3 for MWA and 28.3 cm3 for RFA. Complete ablation was recorded in 94.0% (47/50): 100% (18/18) in the MWA group and 88.0% (22/25) in the RFA group. Local recurrence rate wihtin one year for both groups was 6.0% (3/50) and local recurrences were only documented in the RFA group. The recurrence rate for new malignant formations occurred at the control MRI 6 months after the ablation. 12.0% (6/50) of the patients underwent thermal ablation before taking part in this trial, 14% (7/50) again recieved a treatment with thermal ablation in other segments of the liver while being part of this trial. The mortality rate for this trial amounted to 8% (4/50): 4% (1/25) for the MWA group and 12% (3/25) for the RFA group. The survival rate after one year for both groups ws 92%: 96% for the MWA group and 88% for the RFA group. Major complications were not noticed.

CONCLUSION

The first data of the MIRA trial document no significant differences in mortality or complication rates between RFA and MWA. The study shows that thermal treatment with MWA generates greater ablation volumes. 1-year follow-up of the MWA group shows a lower rate of local recurrences and the 1-year survival rate is a little higher.

CLINICAL RELEVANCE/APPLICATION

MWA provdes greater ablation volume versus RFA with a lower rate of local recurrences.

SSK20-02 MR-Guided High Intensity Focused Ultrasound (MRgFUS) For the Treatment of Oligometastatic Prostate Cancer Bone Metastasis: Can Sound Waves Downstage Cancer Spread?

PURPOSE

With improvements in diagnostic modalities such as functional imaging, oligometastatic prostate cancer is being diagnosed with greater frequency than ever before. Our aim was to determine MRgFUS ability to downstage patients with oligometastatic bone disease with single session of non-invasive metastasis-directed therapy.

METHOD AND MATERIALS

The study was designed with intention-to-treat metastatic bone lesions. Patients were enrolled if they had accessible bone metastasis and could safely undergo MRgFUS (InSightec, Israel). Baseline measurable characteristics included dynamic contrast enhanced MRI study (Gd-BOPTA, Bracco; GE 750 3T magnet) with semiquantitative perfusion analysis, PSA level (ng/ml) and choline PET (SUV). Measurable variables were obtained at treatment time, 3 months, 12 months, 24 and 36 months follow-up.

RESULTS

23 patients fulfilled the inclusion criteria and safely underwent MRgFUS procedure of metastatic bone ablations. Lesions were located in the pelvis (13), scapula (4) and long bones (6). At baseline all lesions showed a significant DCE perfusion (highly vascular) with mean perfusion reduction of 88% at 3 months follow-up (CI: 100-50; $p<0.001$) stable at subsequent follow-up scans. Similarly PSA levels decreased from a mean baseline of 19 (ng/ml) to 7.1, 2.9, 2.1 and 1.9, at 3-12-24 and 36 months respectively. SUV values showed similar trend with reduction from baseline (mean 8.9 to 3.0, 2.3, 1.7 and 1.3: $p<0.001$). In all patients single MRgFUS session was appropriate without any major or minor adverse events reported.

CONCLUSION

MRgFUS is a totally non-invasive procedure that can obtain nearly complete bone ablation in patients with oligometastatic prostate disease. The technique features a radiation-free approach that can be of incremental value in long-survivor subset on oncological patients, significantly reducing risk of toxic effects.

CLINICAL RELEVANCE/APPLICATION

MRgFUS could be routinely introduced as a treatment option for oligometastatic bone disease non responding to conventional treatment.

SSK20-03 Modified ABLATE-Score (mABLATE): A Specific Nephrometric Score to Predict Complications and Relapses in Percutaneous Cryoablation of Renal Lesions

PURPOSE

RENAL ed mRENAL scores have been validated on predicting adverse events and relapses in percutaneous treatments of renal lesions. However these scores remain of surgical origin. The aim of this work is to obtain a specific score (mABLATE) to quantify the risk of complications and relapses in percutaneous kidney ablation procedures

METHOD AND MATERIALS

Taking inspiration from the paper 'AJR 2014;202:894-903' with some changes based on our practical experience, a score was built trying to take into account the real difficulties faced in percutaneous treatment of renal lesions(Fig.1) .The mABLATE was retrospectively assessed on 60 cryoablations to evaluate its predictive value for complications (all procedures) and relapses (malign histology). Logistic regression was used to predict complication incidence;Cox regression was used for relapses;ROC analysis was used to evaluate the accuracy of the three different scores

RESULTS

Among 60 renal lesions treated with cryoablation technique we experienced 3 bleedings with anemia(5%), 2 of them treated with angiographic embolization(3%). Among 51 lesions with malignant histology (MH) we experienced 7 relapeses(13.7%) between 2 and 17 months from treatment,with a mean FU of 19,3 months. Mean MH RENAL score: 7.2pts. Mean relapsed RENAL score: 7.71pts. Mean MH mRENAL score: 7.26. Mean relapsed mRENAL score: 8pts. Mean MH mABLATE score: 4.98. Mean relapsed mABLATE score: 8.07pts. The Cox regression analysis for Renal ($p=0.35$) and mRENAL ($p=0.29$) showed a lack of predictive value for relapses.On the contrary the mABLATE score was found to be an independent predictor of relapses(HR 1,56; $p=0,001$).The predictive accuracy based on the ROC analysis of the mABLATE showed an AUC of 89.1%(vs 61,5% for mRENAL and 58,8% for RENAL).In the logistic regression analysis none of the three scores showed statistic significance in predicting complications($p>0.05$),likely due to the small number of adverse events

CONCLUSION

The mABLATE score showed to be a better predictor of relapses than RENAL and mRENAL. All three scores showed a lack of statistic significance in predicting complications likely conditioned by the small number of complications occurred in our population.

CLINICAL RELEVANCE/APPLICATION

At the moment surgical (RENAL) or surgical modified (mRENAL) scores are used to quantify risks in percutaneous kidney ablations; a specific score (mABLATE) better performs in this task.

SSK20-04 Image-Guided Radiofrequency Hyperthermia-Enhanced Local Chemotherapy of Hepatic Tumors: The Underlying Molecular Mechanisms

PURPOSE

To investigate the treatment effects and mechanisms of image-guided radiofrequency hyperthermia (RHF)-enhanced interventional chemotherapy of hepatic tumors.

METHOD AND MATERIALS

This study included two portions: (1) in-vitro experiments with VX2 tumor cell lines for establishing 'proof-of-principle' of the innovative concept; and (2) in-vivo experiment using rabbit models with orthotopic hepatic VX2 tumors to validate the feasibility of the new interventional technique. VX2 cell lines and animals were randomly assigned to four treatment groups (n=6/group): (i) combination therapy with 5-μM Doxorubicin plus RFH; (ii) Doxorubicin-only; (iii) RFH-only; and (iv) saline. Viability and doxorubicin uptake and distribution, as well as proliferation rate of VX2 cells, were evaluated using flow cytometer, fluorescence microscopy, and MTS assay, while potential molecular mechanism via the heat shock protein (HSP70) pathway was investigated using western blot and immunohistochemistry.

RESULTS

Of in-vitro experiments, microscopy showed an increased doxorubicin concentration in tumor cells, which correlated to significantly higher HSP70 expression in combination therapy (1.28±0.13), compared to other control treatments (0.15± 0.03, 0.64± 0.13, 0.83± 0.10, $p<0.05$). Of in-vivo experiments, immunohistochemistry staining demonstrated a significant increase of HSP 70-positive signaling (1.47±0.13) in combination therapy, compared to the control treatments, as verified in western blot analysis as well (0.16±0.04, 0.51±0.13, 0.74± 0.11, $p<0.01$). In addition, a significant increase of tumor apoptosis and necrosis was found in combination therapy in comparison to other controls with Ki-67 and TUNEL staining ($p < .001$).

CONCLUSION

Image-guided interventional RFH-enhanced local chemotherapy can effectively eradicate hepatic tumors, via the molecular mechanisms of activating HSP70 pathway, as well as enhancing the doxorubicin penetration and tumor apoptosis, which thus inhibits tumor growth and prevents tumor metastasis efficiently. This technical development may open the new avenues for effective treatment of malignancies, not only in the liver but also in other solid organs through the integration of image-guided interventional oncology, RF technology, and direct intratumoral therapies.

CLINICAL RELEVANCE/APPLICATION

An underlying way and its mechanisms to enhanced doxorubicin effects in tumor margin after RFA.

SSK20-05 Early Assessment of Post-Radiofrequency Ablation with CT Perfusion Imaging in Rabbit VX2 Liver Tumor

Wednesday, Nov. 28 11:10AM - 11:20AM Room: E353A

Participants
Li Qian, MD, Wuhan, China (*Presenter*) Nothing to Disclose
Ping Han, MD, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose

lipb37@163.com

PURPOSE

To evaluate the diagnostic potential of CT perfusion, and assess the characteristics of the quantitative parameters for discriminating the residual/recurrent tumors from the benign periablational enhancement (BPE) after radiofrequency ablation (RFA) in the rabbits liver VX2 tumor models, with pathological results as the standard.

METHOD AND MATERIALS

This protocol was approved by the Institutional Animal Care and Use Committee at our institution. Twenty-eight VX2 tumor were

This protocol was approved by the Institutional Animal Care and Use Committee at our institution. Twenty-eight VX2 tumor were implanted into the livers of 28 rabbits by the laparotomy method, then were treated with RFA while confirmed the existence of tumors by enhanced CT. On days 1, 3, 7, 14 after RFA, seven animals were randomly chosen for CT perfusion. Pathology exam was performed immediately after the completion of post-RFA CT perfusion. The perfusion parameters were observed both in BPE and residual/recurrent tumors, including blood flow (BF), blood volume (BV), time to peak (TTP), permeability (P), hepatic arterial perfusion (ALP), portal vein perfusion (PVP) and hepatic perfusion index (HPI), along with the profile of time-density curves (TDCs) and pseudo-color images of parameters, and compared with the pathology results.

RESULTS

26/28 rabbits successfully underwent CT perfusion while 6/26 lesions were confirmed to be residual/recurrent tumors. The TDCs of BPE were mainly speed-up curves(15/26), whereas were speed-up-speed-down (3/6) and speed-up-platforms (2/6) types in residual/recurrent tumors. The PVP values of BPE were significantly higher than residual/recurrent tumors in all the different time groups, and the HPI values were significantly lower in BPE than in residual/recurrent tumors ($P < 0.01$). These characteristics of CT perfusion parameters were consistent with the pathological changes.

CONCLUSION

The TDCs and PVP and HPI parameters have the potential to indicate BPE and residual/recurrent tumors effectively in the early postoperative RFA treatment. Thus it can be seen that CT perfusion has more advantages, with greater efficacy in monitoring therapeutic effect response early after RFA treatment.

CLINICAL RELEVANCE/APPLICATION

To evaluate the diagnostic potential of CTP as an appropriate and timely postoperative radiographic evaluation in monitoring RFA efficacy

SSK20-06 TACE plus RFA versus Surgical Resection for Single 3 to 5 Cm HCC: Propensity Score Matching Analysis

PURPOSE

To compare long-term therapeutic outcome for single nodular 3-5 cm HCC between transcatheter arterial chemoembolization with radiofrequency ablation (TACE+RFA) and surgical resection (SR).

METHOD AND MATERIALS

139 patients treated with SR and 60 patients treated with TACE+RFA were enrolled. Long term therapeutic outcomes including local tumor progression (LTP), intrahepatic distant recurrence (IDR), disease-free survival (DFS), and overall survival (OS) rates were evaluated between two groups before and after propensity-score matching. Major complications and length of hospital stay were also investigated.

RESULTS

1-, 3-, and 5-year LTP rates were 1.8%, 3.9%, and 8.1% in TACE+RFA and 4.3%, 8.1%, and 9.3% in SR, respectively ($P = .444$). 1-, 3-, and 5-year IDR rates were 6.7%, 31.7%, and 41.6% in TACE+RFA and 14.4%, 38.0%, and 51.3% in SR, respectively ($P = .188$). 1-, 3-, and 5-year DFS rates were 88.1%, 65.3%, and 49.0% in TACE+RFA and 84.2%, 58.2%, and 46.5% in SR, respectively ($P = .446$). 1-, 3-, and 5-year OS rates were 95.0%, 73.5%, and 54.0% in TACE+RFA and 97.1%, 87.4%, and 75.0% in SR, respectively ($P = .055$). After matching ($n = 52$), there was no difference in therapeutic outcomes between groups ($P = .349$, $P = .127$, $P = .253$, $P = .878$, respectively). SR showed higher complication rates and significant longer hospital stay than TACE+RFA ($P = .015$ and $P < .001$).

CONCLUSION

TACE+RFA may be a feasible treatment for single 3-5 cm HCC with comparable therapeutic outcomes with SR and more efficiency in terms of hospital stay.

CLINICAL RELEVANCE/APPLICATION

Before and after matching, there were no significant differences in long-term therapeutic outcomes between TACE plus RFA and SR groups. Therefore, TACE plus RFA may be an alternative treatment for single 3-5 cm HCCs with an expectation of similar outcomes.

SSK20-07 Outcomes of Thermal Ablation versus Surgery for Hepatocellular Carcinoma

Wednesday, Nov. 28 11:30AM - 11:40AM Room: E353A

johannes.uhlig@med.uni-goettingen.de

PURPOSE

To compare outcomes of radiofrequency ablation (RFA) and cryoablation (CRA) versus surgical resection for hepatocellular cancer (HCC).

METHOD AND MATERIALS

The National Cancer Database was analyzed for HCC diagnosed from 2004-2015. Patients treated with thermal ablation, comprising RFA and CRA, or surgical wedge/segmental resection were included. Exclusion criteria were radiotherapy, age <18, and unknown survival status. Patients were 1:1 propensity score matched to account for confounders. In the matched cohort, duration of hospital stay, 30d unplanned hospital readmission, 30d/90d survival and 3-month postoperative overall survival were compared.

RESULTS

The study included 17,091 patients; 10,092 received RFA (59%), 243 CRA (1.4%) and 6,756 surgery (39.6%). Caucasian race, Medicare insurance, higher income, higher comorbidity indices, lower tumor stage, and treatment at academic centers were associated with an increased likelihood of thermal ablation. The matched cohort comprised 6,212 patients, 3,106 treated with thermal ablation and 3,106 with surgery, and demonstrated a balanced distribution of confounders. In the matched cohort, postoperative outcomes were superior for thermal ablation: hospital stay was short (mean 2.5d vs. 67d, p<0.001) and unplanned readmission low (2.9% vs. 4.9%, p=0.006). Mortality (30d/ 90d) was lower for thermal ablation (0% vs. 3.8%; 0% vs. 7.5%; each p<0.001). Three-month postoperative survival was superior for thermal ablation versus surgery (HR=0.75, 95% CI: 0.61-0.91, p=0.003). No significant difference was evident comparing postoperative outcomes of RFA to CRA (mean hospital stay 2.5d vs. 2.3d, p=0.96; unplanned hospital readmission rate 2.6% vs. 2.7%, p=1; 3 month postoperative survival HR= 1.41, 95% CI: 0.58 - 3.5, p=0.466).

CONCLUSION

Thermal ablation provides superior short-term outcomes to surgical resection of HCC with shorter hospital stay, lower unplanned readmission rates, and superior 3-month postoperative survival. Prospective randomized trials contrasting both modalities are warranted to assess whether this advantage translates into comparable long-term survival.

CLINICAL RELEVANCE/APPLICATION

For treatment of HCC, thermal ablation provides superior short-term outcomes compared to surgical resection, including shorter hospital stay, fewer readmissions and improved 3-month overall survival.

SSK20-08 Combined Local Thermal Ablation and Chemoembolization in Irresectable or Recurrent Intrahepatic Cholangiocarcinoma, Impact on Local Tumor Control and Overall Survival

Wednesday, Nov. 28 11:40AM - 11:50AM Room: E353A

PURPOSE

To retrospectively evaluate the combined role of local thermal ablation and transarterial-chemoembolization in cases of irresectable or recurrent intrahepatic choloangiocarcinoma.

METHOD AND MATERIALS

Retrospective analysis for 30 patients with CCC from Januar 2007 till December 2017, in which 11 males (36.7 %) and 19 (63.3 %) females with mean age 59.2 years (25-86) with either irresectable (20/30, 66.66%) or recurrent lesions (10/30, 33.33%) managed by at least three sessions of TACE (3-26, mean 9) with local thermal ablation for overall 65 lesions with mean size 21 mm (10-74) with either laser (4/65, 6.2%), radiofrequency (8/65, 12.3%) or microwave (53/65, 81.5%) devices, with mean ablation time (8 minutes /1-27 min.) and mean Watt 640 (45-2095) at mean treatment duration 17.5 months (2-88 months). Follow up using CEMRI to evaluate local tumor control based on modified Response Evaluation Criteria for Solid Tumors (mRECIST) and the survival was evaluated using Kaplan-Meier method.

RESULTS

The mean survival was 33.4 months (CI: 22.7-44.2). The initial local tumor response following 3 TACE was 10% stable (SD), 80% partial response (PR), 10 % progressive (LR) and 0% complete remission (CR). The final effect was 13.3% SD, 16.7% PR, 63.3% LR and 6.7% CR. Local lesion response following thermal ablation was either complete resolution of the targeted lesion in 39/65 lesions (60%) or incomplete response at 26/65 (40%). Two patients (2/30 = 6.6%) developed local non-life threating complications following thermal ablation.Significant correlation has been found between the size of the targeted lesion and the response with better results at diameter ranging from 10-50 mm. However no significant correlation was found between the device type or the amount of watt used and the ablation outcome.

CONCLUSION

Combined targeted local liver therapy has a potentiality to provide a therapeutic option for irresectable or recurrent cholangiocarcinoma and may affect the overall patients' survival as well with better local results for smaller ablated lesions.

CLINICAL RELEVANCE/APPLICATION

Combined TACE and local Ablation therapy of irresectable or recurrent CCC provide the potentiality for local tumor control and improvement of survival rates.

SSK20-09 MRI-Guided High Intensity Focused Ultrasound in the Treatment of Osteoid Osteoma: Long-Term Outcomes

Wednesday, Nov. 28 11:50AM - 12:00PM Room: E353A

Awards
Student Travel Stipend Award

Andrea Leonardi, MD , Roma, Italy (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate clinical and radiological long-term outcomes after non-invasive radiation-free ablation of osteoid osteoma with MRI-guided high intensity focused ultrasound (MRgFUS).

METHOD AND MATERIALS

50 patients with clinical and radiological diagnosis of osteoid osteoma eligible for MRgFUS and anaesthesia, were enrolled in this dual-centre prospective observational study. Osteoid osteomas with vertebral location were excluded as considered inaccessible. MrgFUS was performed using InSightec ExAblate 2100 system. Safety, clinical effectiveness and durability of treatment were evaluated in terms of rate of complications, Visual Analogue Scale (VAS) pain score reduction and stability of results over time, respectively. Tumour control (nidus ablation) at dynamic contrast enhanced MR imaging (Discovery 750, GE; Gd-BOPTA, Bracco) was considered as secondary outcome. All patients underwent a minimum follow-up period of 5 years.

RESULTS

Out of 55 subjects screened for recruitment, 50 were eligible to treatment and underwent to MRgFUS. A complete and durable response was achieved in 80% of cases at 5-years follow-up. Median VAS pain score dropped from 8 (IQR 7-9) to 0 at 1-week, and at all subsequent follow-up check points (1 month, 1 and 5 years). Also scores evaluating interference of pain with sleep, physical and daily activities showed similar improvement after treatment. Among subjects with partial response (20%), 5 received a second treatment (3 with CT-guided Radiofrequency Ablation, 2 with MRgFUS), and 5 did not need any other treatment. All re-treated patients achieved 0 VAS score. Overall, 87% of patients after MRgFUS treatment reached and maintained a stable 0 VAS score during follow-up. At 5-year MRI osteoid osteoma showed no vascularization in 36/47 patients (77%) treated with MRgFUS alone.

CONCLUSION

MRgFUS is a safe, effective and durable option in the treatment of non-spinal osteoid osteoma.

CLINICAL RELEVANCE/APPLICATION

This technique provides relevant advantages in the treatment of this impairing disease affecting mostly young population: no ionizing radiation, no incisions or needles, and, so far, no complications. Our results demonstrate the clinical and radiological long-term resolution of MRgFUS which should be the first-line treatment option for accessible osteoid osteoma.

SSM01-01 Cryoablation as a Primary Treatment of Low-Risk Breast Cancers: An Interim Update of the Ice 3 Trial

Wednesday, Nov. 28 3:00PM - 3:10PM Room: E351

Participants
Kenneth R. Tomkovich, MD, Freehold, NJ (*Presenter*) Consultant, Scion Medical Technologies, LLC;

For information about this presentation, contact:

ktomkovich@princetonradiology.com

PURPOSE

The Ice 3 Trial is the first of its kind large scale multi center trial in the world to assess image guided cryoablation as a primary treatment for breast cancer without surgical lumpectomy. We report updated interim results and important imaging findings.

METHOD AND MATERIALS

This HIPPA compliant and IRB approved trial seeks enrollment of between 150 and 200 patients for cryoablation of low risk carcinoma of the breast. The study is limited to female patients ages 60 and over with biopsy proven primary, unifocal cancer. Cancers must measure 1.5cm or less with tumor prognostic panels that are ER+/PR+ or ER+/PR-and HER 2-. All patients underwent ultrasound guided cryoablation using the IceSense 3 system (IceCure Medical). Following local anesthesia, patients underwent a freeze, thaw, freeze cycle of cryoablation with the goal of a visible ice ball producing at least a 10mm margin of ice around the tumor. Patients will be followed for recurrence with mammography at 6 and 12 months and then annually for 5 years. Additional imaging with MRI or Ultrasound may be utilized as needed but is not a requirement. All patients have the option of post cryoablation chemotherapy, hormone therapy and or radiation therapy as clinically indicated. Patients will not undergo surgical lumpectomy following cryoablation.

RESULTS

A total of 157 patients have been treated with since enrollment began in October 2014 at 17 participating centers across the United States. Patients ranged from 60-90 years of age. Tumor sizes ranged from 3 to 15mm. No serious adverse events were reported. There has been 100% procedural success. All patients have had at least 6 months follow up. 78 patients have had at least 24 months follow up. 24 patients have had at least 36 months follow up. There has been no recurrence in 156/157 patients with at least 6 months follow up (99.4% success rate). Common imaging findings include fat necrosis, scarring and a mammographic "halo" effect.

CONCLUSION

Cryoablation of the breast is safe and well tolerated with a 100% initial procedural success rate. The overall clinical success rate for 157 patients with at least 6 months follow up is 99.4%. Long term results are also promising.

CLINICAL RELEVANCE/APPLICATION

Interim results suggest that cryoablation is a safe and effective primary treatment for women with small low risk breast cancers as an alternative to surgical lumpectomy.

SSM01-02 Do Eligibility Criteria for Ductal Carcinoma in Situ (DCIS) Active Surveillance Trials Identify Patients at Low Risk for Upgrade to Invasive Carcinoma?

Wednesday, Nov. 28 3:10PM - 3:20PM Room: E351

Participants
Manisha Bahl, MD,MPH, Boston, MA (*Presenter*) Nothing to Disclose
Tawakalitu Oseni, Boston, MA (*Abstract Co-Author*) Nothing to Disclose

mbahl1@mgh.harvard.edu

PURPOSE

Due to concerns regarding overtreatment of ductal carcinoma in situ (DCIS), randomized controlled trials are currently underway in the United States and Europe to determine the safety and efficacy of active surveillance versus usual care for women with DCIS. The purpose of this study is to determine upgrade rates of DCIS at core needle biopsy to invasive carcinoma at surgical excision among women who meet eligibility criteria for three active surveillance trials.

METHOD AND MATERIALS

In this IRB-approved and HIPAA-compliant study, a retrospective review was performed of consecutive female patients diagnosed with DCIS at vacuum-assisted core needle biopsy from 2007 to 2016. Medical records were reviewed for mode of presentation, imaging findings, core biopsy pathology results, and surgical outcomes. DCIS cases were classified based on eligibility criteria for the COMET, LORD, and LORIS Trials. Of note, eligibility for the LORIS Trial also requires real-time central pathology review with features not routinely reported and thus not captured in this retrospective study.

RESULTS

Over a ten-year period, 1378 patients were diagnosed with unilateral DCIS at core biopsy and 12 were diagnosed with bilateral DCIS, for a total of 1390 patients (mean age 57, range 27-89) with 1402 cases of DCIS. 79.8% (n=1119) were detected on screening mammography. 17.3% of cases (n=243) were low nuclear grade, 47.2% (n=662) were intermediate nuclear grade, 26.2% (n=368) were high nuclear grade, and 9.2% (n=129) were unreported. The overall upgrade rate to invasive disease was 19.1% (268/1402). 485 were eligible for the COMET Trial, 163 for the LORD Trial, and 489 for the LORIS Trial. The rates of upgrade to invasive carcinoma were 12.2% (59/485), 7.4% (12/163), and 12.5% (61/489) for the COMET, LORD, and LORIS Trials, respectively. Of the 69 cases that upgraded to invasive carcinoma, 31.9% (n=22) upgraded to microinvasive disease (less than or equal to 1 mm) and 91.3% (n=63) were node-negative.

CONCLUSION

The upgrade rates for women with DCIS who meet eligibility criteria for active surveillance trials range from 7.4 to 12.5%. Of the upgraded cases, nearly one-third were microinvasive disease and more than 90% were node-negative.

CLINICAL RELEVANCE/APPLICATION

The risk of missing occult invasive carcinoma in women eligible for active surveillance trials ranges from 7.4 to 12.5%, and the majority of these cancers have favorable biologic profiles.

SSM01-03 Role of Vacuum Assisted Excision (VAE) in Managing Ductal Atypia Such as Flat Epithelial Atypia (FEA) and Atypical Intraductal Epithelial Proliferation (AIDP)

Wednesday, Nov. 28 3:20PM - 3:30PM Room: E351

Participants
Nisha Sharma, MBChB, Leeds, United Kingdom (*Presenter*) Nothing to Disclose
Isobel Haigh, Leeds, United Kingdom (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

nisha.sharma2@nhs.net

PURPOSE

It is recognised that surgical excision for B3 lesions is considered over treatment and vacuum excision (VAE) is playing a role in managing these lesions.. In Europe and USA ductal atypia is still treated with surgical excision. In the UK ductal atypia is managed with vacuum excision rather than surgical excision.

METHOD AND MATERIALS

Retrospective audit performed from a prospective database of all B3 lesions identified through the Breast Screening Programme. All cases of pure ductal atypia, including AIDP and FEA were identified from April 2009 to March 2016. The mode of biopsy and upgrade rate were recorded and follow up data obtained until March 2018.

RESULTS

268990 women were screened from April 2009 to March 2016, of which 12434 were recalled to assessment (4.6%). 5582 biopsies were performed of which 688 were B3 lesions (12.3%). Ductal atypias (FEA and AIDP) (excluding papilloma and radial scars with ductal atypias) accounted for 39.8% of the biopsies. 69% (190/274) were managed with vacuum assisted excsion (VAE) and annual mammographic follow-up or routine screening surveillance. 3% (7/190) developed a cancer during surveillance period, of which 4 were in the same quadrant. 13% (35/274) were upgraded to malignancy following VAE and were treated with therapeutic surgery. 2 developed further cancer on surveillance in the same breast. 8% (21/274) had a vacuum excision and a surgical biopsy due to radiological or pathological concern and 14/21 was benign and 7/21 upgraded to malignancy. One case developed cancer in the contralateral breast on cancer follow up. 8% (22/274) had a surgical diagnostic biopsy instead of vacuum excision and 13/22 were benign and 9/22 were upgraded to malignancy. 2% (6/274) did not go on to have either vacuum excision or surgery due to co-morbidities. 2 developed cancer on surveillance. 12/274 (4%) developed malignancy during surveillance period of which 8/274 were in the same breast.

CONCLUSION

Our study shows that managing ductal atypia with vacuum assisted excision (VAE) is a safe alternative to surgical excision as a primary intervention but multidisciplinary review is important to determine if further surgery is required. Vacuum excision allowed 13% of our women to have a therapeutic surgery as preoperative diagnosis of malignancy was made and 69% avoided surgery altogether.

CLINICAL RELEVANCE/APPLICATION

Vacuum assisted excision is a safe alternative to surgical biopsy in managing ductal atypias

SSM01-04 Papillary Breast Lesions Without Atypia Diagnosed by Core Biopsy: Should They Be Surgically Excised?

Wednesday, Nov. 28 3:30PM - 3:40PM Room: E351

Participants
Sarah Dhundass, MD, Saint Cloud, France (*Presenter*) Nothing to Disclose
Pascal Cherel, Saint Cloud, France (*Abstract Co-Author*) Nothing to Disclose
Adriana Langer, MD, Saint Cloud, France (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the upgrade rate of benign papilloma without atypia diagnosed after core needle biopsy (CNB) or Vacuum assisted biopsy (VAB) in order to determine whether they should require surgical excision or not.

METHOD AND MATERIALS

Histological results of 15615 biopsy procedures were reviewed from January 2001 to December 2014 in our institution. Sampling methods included large gauge VAB by ultrasonographic (US) or stereotaxic guidance and US guided 14G CNB. A total of 179 papillary lesions without atypia that were diagnosed in 159 women were included: 121 had surgical excision following initial detection and 58 underwent imaging surveillance. Initial histological results were compared to the histological results after surgery or to the follow up findings. Statistical analysis was performed to evaluate the association of clinical and radiological variables with the upgrade rate to malignancy.

RESULTS

After exclusion of patients lost to follow up, 158 lesions have been analyzed. 90 were diagnosed by VAB and 68 by CNB. Surgical excision revealed 7 malignant lesions (6 DCIS and 1 carcinoma). The upgrade rate to malignancy was 4.4%. Among the 42 followed up patients, two necessitated secondary surgery, one of them corresponded to a malignant lesion (45 months after biopsy). The median follow-up period was 30 months (6-93). The upgrade rate was statistically higher in the group diagnosed with CNB 8.9% vs 1.1% in the VAB group ($p=0.042$). Age, history of cancer, size of the lesion, ultrasound and mammographic findings including BIRADS category were not associated with underestimation of malignancy ($p>0.05$).

CONCLUSION

Papilloma without atypia detected with VAB could not require surgery (upgrade rate 1.1%) if the excision is complete but should be radiologically followed up at least 5 years to screen for potential biopsy site changes. Papilloma without atypia diagnosed with CNB require surgical excision as the risk of coexisting carcinoma is significantly higher (8.9% in our study)

CLINICAL RELEVANCE/APPLICATION

Papilloma without atypia diagnosed with vacuum assisted biopsy can be radiologically followed up given the low rate of underestimation.

SSM01-05 Follow-Up Outcomes of BI-RADS Category 3 Solid Nodules Identified on Screening and Diagnostic Breast Ultrasound

Wednesday, Nov. 28 3:40PM - 3:50PM Room: E351

Awards
Student Travel Stipend Award

Participants
Joanna Marie D. Choa, MD, Taguig, Philippines (*Presenter*) Nothing to Disclose
Anna Lyn C. Egwolf, MD, Taguig, Philippines (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

choa.jmd@gmail.com

PURPOSE

Our study aims to determine significant difference in BI-RADS category from initial imaging to its subsequent follow-up and the minimum length of time that the BI-RADS category will change for solid nodules. Our study also wants to assess the characteristics and growth pattern of BI-RADS category 3 solid nodules.

METHOD AND MATERIALS

We did a retrospective cohort study reviewing patient reports across a 10-year follow-up period. All solid nodules with at least 2 follow-up ultrasound imaging within a minimum of 22 months were included. Patients were segregated into 2 groups by age: one group below 40 years old and another group age 40 years old and above. Mammogram results were not viewed. Patients with known carcinoma and those with other lesions having a higher BI-RADS assessment in either breast were excluded. Nodule size, characteristics, and BI-RADS score for each follow-up were obtained. We employed ANOVA for repeated measures for statistical analysis.

RESULTS

A total of 511 nodules (5.1% of identified solid nodules) were included and showed no significant difference in BI-RADS scores over the course of 2 follow-ups, regardless of age. Significant change was identified at the sixth and seventh follow-ups with downgrading of BI-RADS scores to 2. Significant changes in size between the second and third follow-up and comparing the first with the third follow-up were appreciated in patients 40 years old and above. Patients in this study were also found out to have an average interval between follow-up imaging of 14.39 months. The minimum length of time for a BI-RADS category 3 solid nodule to become category 4 on follow-up was approximately 1 year (354 days). Only 1 out of the total 511 nodules turned out malignant, 44 months after initial imaging.

CONCLUSION

There is no significant change between BI-RADS scores of solid nodules regardless of age within a 2-year follow-up period. The minimum time for change in BI-RADS from 3 to 4 is about 1 year. Low patient compliance to BI-RADS category 3 follow-up guidelines should be taken into consideration in formulating institutional protocols in the management of these solid nodules.

CLINICAL RELEVANCE/APPLICATION

Patient compliance to follow-up recommendations of BI-RADS category 3 solid nodules is very low, hence can be re-classified as category 2 and follow an annual schedule of follow-up imaging. Only 1 out of 511 nodules turned out malignant after 44 months (~0.2%, low turn-out rate).

SSM01-06 Comparison of Upright Digital Breast Tomosynthesis-Guided Vacuum-Assisted Biopsy with Conventional Prone Stereotactic Vacuum-Assisted Biopsy

Wednesday, Nov. 28 3:50PM - 4:00PM Room: E351

Participants

mbahl1@mgh.harvard.edu

PURPOSE

Breast imaging practices are rapidly transitioning from digital 2D mammography (DM) to digital breast tomosynthesis (DBT), but there is limited research on the clinical performance of DBT-guided vacuum-assisted breast biopsy (VABB). The purpose of this study was to compare the performance of upright DBT VABB to that of conventional prone stereotactic (PS) VABB.

METHOD AND MATERIALS

In this IRB-approved and HIPAA-compliant study, a retrospective review was performed of consecutive patients who underwent PS VABB from August 2014 to December 2015 (PS VABB group) and DBT VABB from February 2016 to June 2017 (DBT VABB group). Tissue sampling methods and materials (9-gauge needles) were the same for PS VABB and DBT VABB. Student's *t*-tests and chi-square tests were used to compare the following variables between the PS VABB and DBT VABB groups: sampling success, procedure times, exposures, lesion types, histologic results, and complications.

RESULTS

Over a 17-month period before the introduction of DBT VABB, 444 PS VABBs in 410 patients (mean age 57, range 32-84) were performed (PS VABB group). Over a 17-month period after complete integration of DBT VABB, 709 DBT VABBs in 682 patients (mean age 58, range 23-90) were performed (DBT VABB group). Technical success was achieved for more lesions with DBT VABB than PS VABB (98.4% [698/709] vs 93.2% [414/444], $p<0.001$). Mean procedure time was shorter with DBT VABB (12 vs 28 minutes, $p<0.001$), and significantly fewer exposures were acquired with DBT VABB (3 vs 11, $p<0.001$). A higher percentage of lesions biopsied with DBT VABB were non-calcified lesions (eg, architectural distortion, asymmetry, and mass) (29.5% [206/698] with DBT VABB vs 3.1% [13/414] with PS VABB, $p<0.001$). There were no differences in the distribution of histologic results (benign, high-risk, or malignant) ($p=0.94$). No major complications were observed in either group. Two patients in the DBT VABB group (2/682, 0.3%) experienced self-limited vasovagal symptoms.

CONCLUSION

DBT VABB has higher technical success than PS VABB and can be performed in less than half the time and with less than one third of the radiation. In addition, more distortions and asymmetries are amenable to biopsy with DBT VABB.

CLINICAL RELEVANCE/APPLICATION

Clinical performance of DBT VABB is superior to PS VABB. DBT VABB can replace PS VABB for routine use in patients with suspicious findings identified on DBT alone and on conventional DM.

PURPOSE

There is insufficient large-scale evidence supporting screening mammography in women <40 years with risk factors. This study compares risk-based screening of women ages 30-39 versus women age 40-49 with no known risk factors, using screening mammography performance metrics from the National Mammography Database (NMD).

METHOD AND MATERIALS

This HIPAA compliant and IRB approved study analyzed data from 150 mammography facilities in 31 states in the NMD. The NMD collects clinical practice data including self-reported patient demographics, clinical findings, screening mammography interpretation and biopsy results. Patients were stratified by 5-year age intervals and specific risk factors for breast cancer: family history of breast cancer (any first degree relative regardless of age), personal history of breast cancer and breast density of heterogeneously or extremely dense (C or D). Prior mammograms were identified by patient date of birth and facility-assigned identification number. Four performance metrics for screening mammography were calculated for each age and risk group: recall rate, cancer detection rate, and positive predictive values for biopsy recommended (PPV2) and biopsy performed (PPV3).

RESULTS

5,772,730 screening mammograms were performed between January 2008 and December 2015 in 2,647,315 women. Overall, mean cancer detection rate was 3.7 per 1000 (95% CI: 3.65-3.75), recall rate was 9.8% (9.8-9.8%), PPV2 was 20.1% (19.9-20.4%), and PPV3 was 28.2% (27.0-28.5%). Overall, women age 30-34 and 35-39 had similar cancer detection rates, recall rates and PPVs, with the presence of the three evaluated risk factors associated with significantly higher cancer detection rates. Moreover, compared to a population currently recommended for screening mammography in the USA (age 40-44 with no known risk factors), incidence screening (at least one prior screening examination) of women ages 30-39 with tthe three evauated risk factors has similar cancer detection rates and recall rates.

CONCLUSION

Women ages 30-39 with 3 specific risk factors should benefit by starting screening at age 30 instead of the age 40 start recommended for average-risk women.

CLINICAL RELEVANCE/APPLICATION

Women

SSM02-03 A Deep-Learning Breast Cancer Risk Prediction Network: Trained on the Population-based Swedish CSAW Data

PURPOSE

Almost half of breast cancer diagnoses among women attending mammographic screening are interval cancers or large screen-detected cancers. To enable more effective individualized screening, accurate risk prediction is paramount. In this study, we examine how our trained deep learning network compares with mammographic density in risk prediction based on negative screening mammograms.

METHOD AND MATERIALS

The Swedish cohort of screen-age women (CSAW) contains over 500,000 women linked to the cancer registry and to an image database. Our deep learning network was trained on negative mammograms from incident cases from one uptake area 2008 to 2011. The test set consisted of cases from 2013 and 2014. In each set, we included a random sample of concurrent non-overlapping controls. The input was each negative mammogram downscaled as well as full-resolution central crops, age at mammography and selected DICOM parameters. The prediction output is called deep learning risk score (DLR). For comparison, mammographic density was calculated using the validated LIBRA software. Logistic regression models were fitted to examine odds ratios.

RESULTS

The training set consisted of 3167 negative mammograms from women with subsequent breast cancer and 125,683 mammograms from healthy women. The test set consisted of negative mammograms from 752 screening rounds of 326 women with subsequent breast cancer and 6728 rounds of 2065 healthy women. AUC was higher for DLR (0.63; 95%CI: 0.61 to 0.66) than for density (0.57; 95%CI: 0.54 to 0.60) and for age-adjusted density (0.58; 95%CI: 0.56 to 0.61). The proportion of cases were 10.1% in the top quintile and 2.5% in the bottom quintile of DLR. The top-to-bottom quintile odds ratio was 4.37 (95%CI: 3.01 to 6.45) and 1.69 (95%CI: 1.23 to 2.32) for DLR and age-adjusted density respectively.

CONCLUSION

We have demonstrated that it is possible to train a deep learning network on negative screening mammograms from subsequent breast cancer cases, and produce risk predictions with reasonable accuracy and ability to identify women at elevated risk.

CLINICAL RELEVANCE/APPLICATION

After external validation, our network may be used in individualizing breast cancer screening.

SSM02-04 Potential Role of Convolutional Neural Network based Algorithms in Patient Selection for DCIS Observation Trials

PURPOSE

Minimizing over-diagnoses and treatment of Ductal Carcinoma in Situ (DCIS) has led to clinical trials of observing patients with DCIS instead of surgery. Despite careful selection for 'low risk' DCIS patients, there is evidence of occult invasive cancers in a significant number of these patients. We investigated the feasibility of utilizing convolutional neural networks (CNN) for predicting patients with pure DCIS versus DCIS with invasion using mammographic images.

METHOD AND MATERIALS

An IRB-approved retrospective study was performed. 246 unique images from 123 patients were used for our CNN algorithm. 164 images in 82 patients diagnosed with DCIS by stereotactic-guided biopsy of calcifications without any upgrade at the time of surgical excision (pure DCIS group). 82 images in 41 patients with mammographic calcifications yielding occult invasive carcinoma as the final upgraded diagnosis on surgery (occult invasive group). Two standard mammographic magnification views (CC and ML/LM) of the calcifications were used for analysis. Calcifications were segmented using an open source software platform 3D Slicer and resized to fit a 128x128 pixel bounding box. A 15 hidden layer topology based on residual convolutions was used to implement the

neural network. A class balanced holdout set with 40 patients was used for testing. 5-fold cross validation was utilized with cases randomly separated into a training set [80%] and validation set [20%].

RESULTS

The CNN algorithm for predicting patients with pure DCIS achieved an overall validation accuracy of 74.6% (95%CI, ± 5) with area under the ROC curve of 0.71 (95% CI, ±0.04), specificity of 49.4% (95% CI, ± 6%) and sensitivity of 91.6% (95% CI, ± 5%).

CONCLUSION

It's feasible to apply a CNN to distinguish pure DCIS from DCIS with invasion using mammographic images. A larger dataset will likely improve our prediction model and could potentially be useful in appropriate patient selection for observation trials.

CLINICAL RELEVANCE/APPLICATION

Convolutional neural networks have demonstrated strong performance in various image classification tasks and may potentially be used in appropriate patient selection for DCIS observation trials.

SSM02-05 The Effect of Screening Modality and Race on BI-RADS Breast Density in a Large Urban Screening Cohort

PURPOSE

Increased breast density is an independent breast cancer risk factor and also limits the sensitivity and specificity of mammography. We investigated the effect of screening mammography modality and race on BI-RADS breast density assessments, accounting for age and body-mass index (BMI).

METHOD AND MATERIALS

We retrospectively analyzed data from 24,740 individual women (45% White, 55% Black) who underwent screening from September 2010 through February 2017 at our institution. 15,147 women (55%) had repeated screening studies (N = 60,774 studies). Over this time period, three screening modalities were used: digital mammography alone (DM; N = 8,936); digital breast tomosynthesis (DBT) with DM (DM/DBT, N = 30,786); and synthetic 2D with DBT (s2D/DBT, N = 21,052). BI-RADS density classifications ranging from lower (fatty or scattered) to higher (heterogeneous or extremely dense) density were extracted from screening reports. Random-effects ordered logistic regression (panel variable: individual woman) was performed to estimate the odds of being assigned to higher BI-RADS density by each modality, adjusted for race, age, BMI and radiologist. The interaction of modality and race on density was tested in the model, and analyses were stratified by race.

RESULTS

Women screened with DBT had significantly lower odds of high density compared to those screened with DM alone (DM/DBT vs. DM: OR = 0.62, $p < .0001$; s2D/DBT vs. DM: OR = 0.48, $p < .0001$). Lower odds of high density were also observed in s2D/DBT compared to DM/DBT (OR = 0.76, $p < .0001$). There was a significant interaction of modality and race on breast density ($p = .0003$). All differences by modality maintained statistical significance in analyses stratified by race, with lower ORs for black (DM/DBT vs. DM: OR = 0.61; s2D/DBT vs DM: OR = 0.40; s2D/DBT vs. DM/DBT: OR = 0.67) than for white women (DM/DBT vs. DM: OR = 0.65; s2D/DBT vs. DM: OR = 0.58; s2D/DBT vs. DM/DBT: OR = 0.89).

CONCLUSION

Screening mammography modality has a significant effect on BI-RADS density assessment with an overall trend of assigning lower density with DBT and s2D/DBT screening versus DM alone. Furthermore, this effect seems to be more prominent in black than in white women.

CLINICAL RELEVANCE/APPLICATION

Our findings have direct implications for personalized screening since breast density assignments, which often drive recommendations for supplemental screening, may vary greatly by modality and race.

PURPOSE

Segmentation of the left ventricle myocardium of the heart is important to obtain information regarding myocardial wall thickening and functional analysis data. In this study, we performed deep learning analysis for the automated segmentation of the left ventricle of the heart in cardiac computed tomography (CT) data.

METHOD AND MATERIALS

To develop a fully automated deep learning algorithm using sementic segmentation methods based on fully convolution network, 50 subjects with coronary artery diseases were used as training set, and the approach is evaluated using a data set of 1000 subjects with coronary artery diseases present whole 3D volume images of the LV. Reference standard manual segmentation data generated by experienced cardiac radiologists. Cross validation was performed using randomly selected 5% cases from the training set. The comparison of quantitative measurement data between the manual and automatic segmentations was performed using dice similarity coefficient.

RESULTS

Overall, automated segmentation data were comparable to manual segmentation data. We obtained mean 88.3% (min 78.1% and max 96.5%) of dice similarity coefficient in whole LV myocardium. The sensitivity and specificity of automated segmentation in each segment (1-16 segments) were high (range: 85.5 - 99.9).

CONCLUSION

Using a large data set, we presented a deep learning based automatic segmentation of the left ventricle of the heart, and the results was comparable to manual segmentation data with high dice index.

CLINICAL RELEVANCE/APPLICATION

Automated LV segmentation can reduce time to obtain information regarding myocardial wall thickening and LV function, and might improve the reproducibility of clinical assessment.

SSM03-02 Microcirculation Dysfunction in Patients with End-Stage Renal Disease Undergoing Dialysis: Associated with Heart Failure in the Follow-Up

PURPOSE

The dialysis treatment was used widely in the ESRD patients, but myocardial ischemia and the cardiovascular disease were the major cause of death in chronic kidney disease (CKD) patients. Our study aimed to quantitative evaluation of myocardial microcirculation dysfunction by rest CMR perfusion imaging in patients with ESRD undergoing dialysis, and to understand of the association between perfusion parameters and heart failure.

METHOD AND MATERIALS

In total, 67 ESRD patients with preserved EF (EF>=50%) and 22 healthy subjects underwent rest first-pass perfusion. The LV regional myocardial perfusion parameters were analyzed by a commercial soft included upslope, time to maximum signal intensity (TTM) and max signal intensity (Max SI). Continuous variables were compared using one-way analysis of variance (ANOVA). The association between perfusion parameters and the composite of CHF was assessed by Cox proportional hazards regression.

RESULTS

For the analysis, the Max SI of basal, mid- and apical segments were reduced in ESRD patients with preserved EF compared with normal controls (all $P < 0.05$). In contrast to the patients with preserved EF, the patients with impaired EF had lower upslope and longer TTM in the basal segment. Over a mean follow-up period of 12.5 months, 24 subjects developed heart failure. The TTM of Basal-, mid-, and apical- segments were inversely associated with risk of heart failure (per unit increment, HR:1.052, 95% CI: 1.010-1.095, HR:1.086, 95% CI: 1.033-1.143, and HR:1.084, 95% CI: 1.024-1.146, respectively) after multivariable adjustment by gender, age, BMI, dialysis time, hypertension, and diabetes.

CONCLUSION

In summary, the first-pass perfusion CMR parameters can early detect the regional myocardial microcirculation dysfunction in ESRD patients undergoing dialysis. The myocardial dysfunction can predictor the progression of heart failure.

CLINICAL RELEVANCE/APPLICATION

(dealing with first-pass perfusion CMR)CMR perfusion imaging with vasodilator can detect myocardial microcirculation dysfunction in ESRD patients undergoing dialysis.

SSM03-03 Differences in Cardiac MR-based Assessment of Myocardial 2D Strain between Subjects with Prediabetes, Diabetes, and Normal Controls in the General Population

PURPOSE

In the setting of diabetes mellitus, diabetic cardiomyopathy is associated with limited event-free survival but difficult to detect. However, cardiac MR based assessment of subtle alterations of left ventricular function using 2D cardiac strain analysis may represent an early marker of disease development. Thus, we determined differences in left ventricular strain between subjects with prediabetes, diabetes, and healthy controls in a sample from the general population.

METHOD AND MATERIALS

Subjects without prior history of stroke, coronary or peripheral artery disease were enrolled in a case-controlled study and underwent 3T whole body MRI. In all patients without history of hypertension, LGE and normal ejection fraction, radial, longitudinal and circumferential strain was measured on Cine SSFP imaging (TR: 29.97ms, TE: 1.46ms, ST: 8mm) using a semiautomatic segmentation algorithm (CVI42, Circle, Canada). Differences in strain rates were derived in multivariate linear regression analysis adjusting for age, gender, BMI, blood pressure, and smoking, HDL, LDL and TG.

RESULTS

Radial and circumferential strain analysis was performed in in total 347 subjects, of which 41 (11.8%) suffered from diabetes, 92 (26.5%) from pre-diabetes and 214 (61.7%) controls. Mean HbA1c of diabetic subjects was 6.5±1mmol/mol Hb. Pre-diabetic subjects showed a significantly higher systolic global and endocardial radial strain compared to controls (p=0.036 and p=0.011 respectively), whereas diabetic subjects didn't show any significant difference (p=1.00 and p=0.811). Similarly we detected significant lower systolic global and endocardial circumferential strain values in pre-diabetic subjects (p=0.044 and p=0.009), whereas diabetic subjects didn't show a significant difference (p=1.00 and p=0.580). Regarding diastolic radial and circumferential strain we didn't find any significant difference.

CONCLUSION

In our cohort of well-treated diabetic subjects we didn't find any changes in strain values whereas pre-diabetic subjects showed early changes. Therefore early and consequent treatment of diabetes seems to be cardioprotective.

CLINICAL RELEVANCE/APPLICATION

MR based Strain Imaging is able to detect early changes in cardic function in patients with prediabetes. As these changes are not seen in well treated diabetic patients consideration should be given to early antidiabetic therapy.

PURPOSE

In 25 % of patients with ischemic stroke, no etiologic factor can be identified. Asymptomatic paroxysmal atrial fibrillation (AF) is often suspected to be the cause of these cryptogenic strokes (CS). AF is frequently associated with left atrial (LA) structural and functional alterations. Accordingly, the aim of this study was to examine LA deformation in patients with CS using cardiovascular magnetic resonance myocardial feature tracking (CMR-FT).

METHOD AND MATERIALS

29 patients with the diagnosis of CS underwent CMR imaging. Based on the initial cranial computed tomography (cCT), the patient group was divided into patients with previous ischemic lesions (recurrent CS) and patients without (first-time CS). LA deformation was analyzed based on CMR-FT of standard cine 4- and 2-chamber views including LA reservoir function (peak total strain [s], peak positive SR [SRs]), LA conduit function (passive strain [e], peak early negative SR [SRe]) and LA booster pump function (active strain [a], late peak negative SR [SRa]). Moreover, the "time to s" and "time to SRs" were calculated and expressed as a percentage of the entire cardiac cycle.

RESULTS

Previous ischemic lesions were detected in 5 of 29 patients (17%). LA conduit strain was lower in patients with recurrent CS as compared to first-time CS (6.4 ± 1.1 % vs. 10.3 ± 3.3 %, respectively, p=0.005). Furthermore, "time to s" and "time to SRs" were prolonged in patients with recurrent CS (47 ± 6 % vs. 57 ± 8%, p=0.007; and 19 ± 5% vs. 30 ± 7%, p=0.001, respectively). In multivariable regression models "time to s" and "time to SR" were independently associated with the presence of previous ischemic lesions (ß=0.41, p=0.006 and ß=0.51, p=0.015, respectively) after adjustment for traditional risk factors (age, gender, arterial hypertension, vascular disease and diabetes).

CONCLUSION

Prolonged time to peak LA reservoir strain and SR is associated with the presence of previous ischemic lesions in patients with CS. These findings propose advanced LA impairment as a distinct feature of CS which may be associated with unrecognized paroxysmal AF. Future research is warranted to confirm these findings alongside their prognostic implications in larger prospective clinical trials.

CLINICAL RELEVANCE/APPLICATION

Advanced LA impairment detected by cardiac magnetic resonance imaging may improve management of patients with or prior to CS.

SSM03-05 Machine Learning for Automated Image Quality Control and Segmentation of Large-Scale CMR Population Studies

Wednesday, Nov. 28 3:40PM - 3:50PM Room: S102CD

PURPOSE

UK Biobank is a large-scale prospective cohort study that follows the health of 500,000 subjects across the UK. Of all the subjects, 100,000 will undergo imaging scans including brain, heart and body scans. We propose a machine learning-based and automated pipeline for cardiac MR (CMR) image quality control and segmentation on this large-scale dataset.

METHOD AND MATERIALS

CMR images were obtained from the UK Biobank under Application Number *****. Short-axis and long-axis cine images were acquired using a Siemens 1.5T scanner with the balanced steady state free precession (bSSFP) sequence. For image quality control, hybrid random forests were trained to detect landmarks on long-axis images, specifically the apex and mitral valve, which were then compared to the space encompassed by short-axis image stacks for identifying incomplete heart coverage. For image segmentation, fully convolutional networks were trained to segment the left ventricle (LV) and right ventricle (RV) on short-axis images and the left atrium (LA) and right atrium (RA) on long-axis images. The segmentation accuracy was evaluated using the Dice metric and mean contour distance error.

RESULTS

The pipeline took ~1 second for image quality control and ~10 seconds for short-axis and long-axis image segmentation. Cases

with heart coverage deemed incomplete by visual examination were automatically identified with 88% sensitivity and 99% specificity on a random test set of 3,000 subjects. Regarding segmentation accuracy, the average Dice metric is 0.94 for LV cavity, 0.88 for LV myocardium, 0.90 for RV cavity, 0.93 for LA cavity (2-chamber view), 0.95 for LA cavity (4-chamber view) and 0.96 for RA cavity (4-chamber view), evaluated on a test set of 600 subjects. The average mean contour distance error is smaller than the in-plane pixel resolution of 1.8mm.

CONCLUSION

We have proposed a machine learning-based pipeline for CMR image quality control and segmentation, which is automated, fast and accurate.

CLINICAL RELEVANCE/APPLICATION

The pipeline will facilitate the analysis of large-scale CMR population studies such as the UK Biobank and enable automated extraction of clinically relevant phenotypes including the ventricular volumes and mass. Future work could evaluate its potential to add quantitative image-derived phenotypes as part of routine clinical practice.

SSM03-06 Cardiac Adaptation of Left Ventricular Volume and Mass during a Multistage Marathon Over 4486 Km

florian.sagmeister@uniklinik-ulm.de

PURPOSE

Long-term side effects of intense physical training and long-distance running has led to increasing concerns especially among athletes. However, the consequences on long-term endurance training on cardiac structure and function are not yet fully understood. The purpose of this study was to evaluate the effect of running a transcontinental, multistage ultramarathon of 4486km on 64 consecutive days on the heart.

METHOD AND MATERIALS

20 ultra-endurance athletes with a mean (standard deviation) age of 47.9 (10.4) years received a cardio MRI-scan at three time points (baseline, at ~2000km, ~3500km) during the multistage ultramarathon. Cardiovascular magnetic resonance (CMR) was performed on a portable 1.5 Tesla MRI unit (Magnetom Avanto™mobile MRI) which was installed on a specially hired truck. Left ventricular mass (LVM), end-diastolic volume (EDV), end-systolic volume (ESV) and myocardial strain was calculated from SSFP-cine gradient echo sequences using the commercially available software (Heart Deformation Analysis, HDA, Siemens, Erlangen, Germany). Cardiac MRI-parameters were indexed for body surface area (BSA). Ten runners were serially examined in follow-up scans eight months after the race.

RESULTS

Athletes ran at a mean running speed of 8.2 ± 1.2 km/h during the ultramarathon. Left ventricular mass increased significantly ($p<0.001$) over the course of the race while no significant changes were observed in end-diastolic volume, end-systolic volume as well as global radial, circumferential and longitudinal left ventricular strain. Results of follow-up scans showed a significant reduction in LVMi ($p=0.004$), left ventricular EDVi ($p=0.015$) and right ventricular EDVi ($p=0.045$). We did not observe any significant differences regarding myocardial strain during follow-up.

CONCLUSION

The observed structural cardiac alterations during a multistage ultra-endurance marathon indicates a physiological response to excessive cardiac volume load. The reduction in end-diastolic volumes during follow-up corresponds to the reduced endurance exercise volume within eight months after the multistage ultramarathon.

CLINICAL RELEVANCE/APPLICATION

Extreme long-distance running leads to physiological cardiac adaptations without any detectable adverse cardiovascular remodeling in non-contrast enhanced cardiovascular magnetic resonance imaging.

SSM04-01 Radiographic Features of Pulmonary Veins Morphology from Chest CT Predicts Risk of Post-Ablation Atrial Fibrillation

Wednesday, Nov. 28 3:00PM - 3:10PM Room: S103AB

PURPOSE

Atrial fibrillation (AF) is the most common sustained arrhythmia, affecting 1-2% of the population. Although endovascular pulmonary vein isolation (PVI) may temporarily reduce symptoms in patients failing medical management, recurrence rates are high and identifying patients likely to have successful outcomes remains elusive. Pulmonary vein morphology and left atrial size have been previously identified as radiographic markers for AF, but have not been assessed for PVI outcome. We explore pulmonary vein and left atrial morphometry as a means of predicting response to PVI.

METHOD AND MATERIALS

A retrospective review of PVI procedures from 2014-2016 excluding prior PVI or valve surgery revealed 314 cases. 154 had pre-PVI CT imaging and clinician-assessed PVI outcome recorded in the EMR at follow-up, with 50 cases diagnosed with recurrent AF within 3 months to 1 year. 50 non-recurrent cases were randomly selected to produce a balanced dataset for analysis (n = 100). Radiographic features were obtained characterizing left atrium size, pulmonary vein morphology, and angle of vein entry into the left atrium using Syngo.Via (©Siemens Healthcare). The 5 most distinguishing features were selected by Wilcoxon rank-sum and used to train a support vector machine classifier in a 3-fold cross-validation setting. Ability to predict recurrence was assessed by area under the receiver operating characteristic curve (AUC) among all patients and the predictive ability including clinical features was investigated similarly.

RESULTS

Distinguishing radiographic features include angle between right pulmonary veins ($p = 0.063$) and angle of left inferior pulmonary vein entry into the left atrium ($p = 0.060$). Radiographic features effectively predicted recurrence of AF within 1 year of PVI (AUC = 0.65 ± 0.03) and inclusion of clinical features further improved performance (AUC = 0.77 ± 0.02). Distinguishing clinical features include age ($p < 0.001$), BMI ($p = 0.005$), left ventricular ejection fraction ($p = 0.014$), history of hypertension ($p = 0.016$), NYHA class of I or greater ($p = 0.016$), and use of apixaban ($p = 0.016$).

CONCLUSION

Pulmonary vein morphology in CT successfully predicts recurrence of AF after endovascular treatment.

CLINICAL RELEVANCE/APPLICATION

The ability to identify patients likely to have recurrent AF based on CT morphometric features may provide a pre-treatment indicator of response and anatomic features that may be targeted.

SSM04-02 Relationship Between Chronicity of Atrial Fibrillation and Left Atrial Remodeling Determined with Cardiac Magnetic Resonance Imaging in Patients with Atrial Fibrillation: Significance of Regional Left Atrial Late Gadolinium Enhancement

Wednesday, Nov. 28 3:10PM - 3:20PM Room: S103AB

Participants
Dong Kyu Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Hwan Seok Yong, MD, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

Yu-Whan Oh, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Sung Ho Hwang, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Left atrial (LA) remodeling is associated with progression of atrial fibrillation (AF). Cardiac magnetic resonance (CMR) imaging can assess the LA remodeling with LA volume (LAV) and LA late gadolinium enhancement (LA-LGE). The distribution of LA-LGE by LAV is largely unknown. This study aimed to determine the relationship of LA-LGE distribution with LAV and progression of AF.

METHOD AND MATERIALS

195 patients (mean age: 55.7 ± 10.7 years, 82.6% men) underwent LGE-CMR examinations before ablation of paroxysmal AF (PAF, n = 121) or persistent AF (PeAF, n = 74). The LAV and LA-LGE were assessed by three-dimension reconstruction of LGE-CMR images. In each of all 9 preselected LA regions, the presence of LA-LGE was evaluated. Additionally, the incidences (in %) of LA-LGE were calculated in every LA region.

RESULTS

Of all the preselected LA regions, the anterior wall and left inferior pulmonary vein (LIPV) region showed a significantly different incidence of LA-LGE ($p < 0.05$, respectively) depending on the LAV. In all 195 patients, the incidences of LA-LGE in the anterior wall and LIPV region were 15.4% and 15.9%. The patients with PeAF showed significantly higher LA-LGE incidence in the anterior wall (31.1% vs. 5.8%, $p < 0.001$) and LIPV region (29.7% vs. 7.4%, $p < 0.001$) than did those with PAF. After adjusting for LAV, the odd ratios for PeAF of the LA-LGE in anterior wall and LIPV region were 3.8 (95% CI = 1.40-10.41, $p = 0.009$) and 3.7 (95% CI = 1.46-9.75, $p = 0.006$), respectively.

CONCLUSION

In evaluation of LA remodeling using CMR imaging, the regional LA-LGE in anterior wall and LIPV region of LA may be associated with the presence of PeAF.

CLINICAL RELEVANCE/APPLICATION

Cardiac MRI can describe the LA remodeling related to the chronicity of AF. Furthermore, the LA remodling determined with cardiac MRI may help understanding the AF mechanism.

SSM04-03 Determination of Conducting Channels from LGE CMR in Patients with Myocardial Infarction-Direct Comparison with Electroanatomic Mapping for Ventricular Tachycardia Ablation

Wednesday, Nov. 28 3:20PM - 3:30PM Room: S103AB

avy.cutie@gmail.com

PURPOSE

LGE CMR is an excellent tool to evaluate scar in patients after myocardial infarction (MI). Electroanatomic mapping (EAM) is traditionally used to locate areas in scar tissue giving rise to ventricular tachycardia (VT) and guide ablation. However, new software using pixel signal intensity (PSI) algorithms has made it possible to locate conducting channels (CC) in scar tissue which form VT substrate using LGE CMR. We compared LGE derived CC with EAM findings in patients with VT post MI.

METHOD AND MATERIALS

We evaluated retrospectively 28 patients with previous MI and VT who underwent CMR prior to EAM and VT ablation. Short axis LGE CMR were evaluated using ADAS-VT (Galgo Medical SL, Barcelona) to identify CC within myocardial layers. A PSI-based algorithm was applied to characterize the LGE area as scar core or border zone, using 60% and 40% of the maximum LGE intensity as thresholds. CC were identified topologically by finding border zone coursing through scar core, representing corridors of viable tissue. CC on LGE-CMR were co-registered with EAM on Carto system. This data was evaluated according to AHA 17 segment model for targeted sites of VT ablation on a per patient and per channel basis

RESULTS

In 28 patients, 232 potential VT sites were identified on EAM-CMR merge, of which 129(55%) were targeted for ablation.138 sites of CC were identified. On a per patient basis, 4 CMR analyses were in total agreement with EAM, 24 had partial agreement. 87(67.4 %) CC sites matched sites of ablation, 50(21%) CC sites were detected only on CMR. 53(23%) scar sites had neither CC on CMR nor ablation on EAM. 42(32.5%) sites of ablation on EAM did not show CC on LGE CMR. CC were also correlated with sites having late(64%), fractionated(65%) potentials, critical isthmus, entry points (60%), pacing sites(60%) and induced VT(48%). LGE CMR PSI-based analysis showed sensitivity of 67.4%(95%CI 58.6%-75.4%), specificity of 52%, positive predictive value of 64%(95%CI 58 % - 69.6%) and negative predicting value of 56% and overall diagnostic accuracy of 60% in identifying sites of EAM sites of ablation.

CONCLUSION

LGE CMR PSI-based analysis has good sensitivity and positive predictive value in identifying sites of VT on EAM.

CLINICAL RELEVANCE/APPLICATION

Target sites for VT ablations can predicted by LGE-CMR to aid preprocedural planning, potentially reducing the need for extensive EAM and additional CC on CMR can also identify cause of recurrent VT

SSM04-04 Comparison of Cardiac Venous Anomalies in Complete and Congenitally Corrected Transposition of

the Great Arteries: Implications for Cardiac Resynchronization Therapy

Wednesday, Nov. 28 3:30PM - 3:40PM Room: S103AB

hugo.vidalalberdi@uhn.ca

PURPOSE

Cardiac resynchronization therapy (CRT) can help improve cardiac function of progressively failing subaortic morphologic right ventricles in both complete (c-TGA) and congenitally corrected (cc-TGA) transposition of the great arteries, but requires transvenous access to the subaortic morphologic right ventricle. We aim to compare the prevalence of cardiac venous anomalies and accessibility for CRT in c-TGA and cc-TGA using cardiac gated computed tomography angiography (CTA).

METHOD AND MATERIALS

With institutional review board approval, all CTA studies performed between 2007-2018 in patients with c-TGA and cc-TGA were retrospectively reviewed. CTAs were evaluated for cardiac venous anomalies and whether both subaortic and subpulmonic ventricles could be accessed via the subpulmonic atrium and coronary sinus. Statistical analysis included independent samples t-test for continuous variables and Fisher's exact test for categorical variables.

RESULTS

121 patients were included [mean age 36 years (range 18-69 yrs), 75 males (62%)] including 70 patients with c-TGA (44 atrial switch, 13 arterial switch, 13 Rastelli) and 51 with cc-TGA (48 no surgery, 3 double switch). Cardiac venous anomalies were more frequent in cc-TGA (30% vs. 6%; $p<0.001$). Accessibility was significantly higher in cc-TGA compared to c-TGA (86% vs 60%; $p<0.002$). Accesibility was lower among c-TGA patients who had undergone atrial switch compared to those with arterial switch or Rastelli procedures (39% vs. 96%, $p<0.001$). Accesibility was also significantly lower among cc-TGA patients who had undergone double switch compared to those who had not (33% vs. 89%, $p=0.048$).

CONCLUSION

Cardiac CTA identifies cardiac venous anomalies that impact eligibility for CRT. CRT eligibility is significantly lower among both c-TGA patients who have undergone atrial switch procedure and cc-TGA patients who have undergone double switch procedure compared to patients who have not.

CLINICAL RELEVANCE/APPLICATION

Cardiac-gated CTA is essential prior to CRT due to high prevalence of cardiac venous anomalies that may render the patient ineligible due to lack of access.

SSM04-05 Anatomical Shape Differences of Left Atrium on CT Predicts Post-Ablation Recurrence of Atrial Fibrillation

Wednesday, Nov. 28 3:40PM - 3:50PM Room: S103AB

thomas.atta-fosu@case.edu

PURPOSE

Approximately 30% of Atrial Fibrillation (AF) patients who undergo endovascular ablation experience recurring symptoms within the first year after ablation. Patients with long-standing AF demonstrate changes in left atrial morphology and the atrial appendage and pulmonary veins are known regions of interest in ablation, although the impact of morphology on ablation outcome remains unclear. In this study we employed image analysis and machine learning approaches to investigate whether the morphology of the left atrium (LA) was predictive of recurrence in patients undergoing ablation for AF.

METHOD AND MATERIALS

Pre-operative chest CT scans of 68 patients who underwent surgical ablation were acquired between July 2015 and November 2016, of which 31 had AF episodes between 3 and 12 months after ablation. LA masks were created for each patient using an in-house segmentation toolbox and verified by a cardiologist. All patient LA were registered to a common atlas defined by the LA with median volume. Sites of interest (SOI) was then defined for each patient as the regions on the atrial surface with significant difference between recurrent (AF+) and non-recurrent (AF-) patients using a t-test based comparison of the registered atrial. First order statistics of the Gaussian curvature of the surface within the SOI and deformation from atlas to patient LA were extracted,

and a 5-fold cross-validation scheme across 100 runs was conducted to evaluate performance of the features in distinguishing between AF+ and AF- patients using area under the receiver operating characteristic curve (AUC).

RESULTS

The identified regions of maximum shape variation consisted of sites around the atrial appendage and pulmonary veins. Employing feature maps from these regions to classify recurrence performed better (AUC=0.69±0.049) than features from the remaining atrial sites (AUC=0.58±0.58). Combining the feature maps with clinical features (Age, Height, BMI and Weight) produced an AUC of 0.77±0.09, while Using Clinical variables alone produced AUC of 0.66±0.11

CONCLUSION

We identified shape differences between AF+ and AF- patients as well as a set of features relating to local curvature within regions differing different between the two populations that was correlated with likelihood of recurrence.

CLINICAL RELEVANCE/APPLICATION

A systematic process for identifying patients at increased risk for post-ablation recurrence may lead to improved management.

SSM04-06 Detects Myocardial Dyssynchrony of Isolated Left Ventricular Noncompaction Patients with Preserved Ejection Fraction Using Cardiac Magnetic Resonance Feature Tracking

Wednesday, Nov. 28 3:50PM - 4:00PM Room: S103AB

Xrongdoctor@163.com

PURPOSE

Left ventricular non-compaction (LVNC) is a rare congenital cardiomyopathy, with or without LV dysfunction, and it may be asymptomatic or it may lead to severe HF, sudden death. The aim of our study is to early evaluate the myocardial dyssynchrony in isolated LVNC children with preserved EF by using cardiac magnetic resonance (CMR), and to explore the correlate factors of progress of LVNC.

METHOD AND MATERIALS

we investigated 17 isolated LVNC patients with preserved LVEF (EF>=50%), and 23 age- and gender-matched controls. The feature tracking parameters including peak strain (PS), peak displacement (PD) and strain rate in radial, circumferential, and longitudinal directions were measurement in all subjects.

RESULTS

In all patients, 14 patients were left ventricular apical (73.7%), two patients were left ventricular septum (10.5%), one patient were global left ventricular noncompaction (5.3%). The PS and PD in radial, circumferential, and longitudinal directions decreased significantly in the LVNC patients with preserved EF compared with the normal controls (all $p<0.001$), Furthermore, the PS in three directions were associated with the EF ($r=0.43$; $r=-0.41$; $r=-0.54$); and PS in three directions were also significant correlates with age ($r=-0.47$; $r=0.46$; and $r=0.47$).

CONCLUSION

CMR feature tracking can be used for the detection of early myocardial deformation in the isolated LVNC children who are subclinical left ventricular dysfunctions, and early clinical intervention might be important for the decrease of LVEF function and myocardial deformation.

CLINICAL RELEVANCE/APPLICATION

(dealing with MRI feature tracking) CMR feature tracking can detect early myocardial deformation in the isolated LVNC children with subclinical dysfunctions.

PURPOSE

To develop a new interventional oncologic technique, namely 'image-guided intratumoral radiofrequency hyperthermia (RFH)-enhanced local HSV-TK/GCV-mediated suicide gene therapy of lung cancers' and investigate its associated bio-molecular mechanisms.

METHOD AND MATERIALS

Human lung cancer cells (A549) transduced with Luciferase/mCherry/lentivirus for in-vitro confirmation, and 24 nude rats with the same orthotopic lung cancers for in-vivo validation were divided into four study groups with different treatments of (i) combination therapy with intratumoral HSV-TK/GCV gene therapy followed by RFH at 41-42 °C for 30 minutes; (ii) HSV-TK/GCV gene therapy alone;(iii) RFH alone; (iv) PBS as a control. In in-vitro experiments, bioluminescence assay, confocal microscopy and flow cytometry were used to determine the viability and apoptosis of cells, while in the in-vivo experiments molecular optical/x-ray imaging was used to evaluate the changes of bioluminescent signals among different groups over 2 weeks. To investigate the potential mechanisms of apoptosis, IHC staining and WB were used for detecting the expression of Bcl-2/Bax, and Caspase-3. To determine mechanisms of immune-response, IHC and WB were used to exam the expression of HSP-70, IL-2 and CD94.

RESULTS

Of in-vitro experiments, compared with gene therapy alone, RFH alone or PBS, combination therapy induced the lowest cell viability ($P<0.01$), the highest cell apoptosis ($P<0.001$), and a significant decrease of relative bioluminescence signal ($P<0.01$). Of in-vivo experiments, optical imaging detected a significantly decreased bioluminescence signal of the tumor with combination therapy ($P<0.05$). Regarding to the mechanisms, both WB analysis and IHC staining displayed the significantly decreased expression of Bcl-2, as well as increased expression of Bax, Caspase-3, HSP-70, IL-2 and CD94 in cancer tissues of combination therapy, compare to other control treatments.

CONCLUSION

This study validated the feasibility of image-guided interventional RFH-enhanced direct suicide gene therapy of orthotopic lung cancers, which is activated through the mechanisms of augmenting Bax/Bcl-2/caspase-3-depended apoptosis and the HSP-70/IL-2 depended immune regulation pathway.

CLINICAL RELEVANCE/APPLICATION

This alternative technique may open new avenues for effective treatment of lung cancers via integrating image-guided interventional oncology, RF technology, and direct gene therapy.

SSM05-02 Impact of Availability of PET-CT Imaging on Diagnostic Accuracy and Biopsy Safety of CT-Guided Percutaneous Needle Biopsy (PNB) of Suspected Lung Cancer

kstefanidis@nhs.net

PURPOSE

To determine whether the availability of PET-CT improves diagnostic yield and safety in lung cancer PNB.

METHOD AND MATERIALS

PNB diagnostic rates over 3yrs for 3 thoracic radiologists (6-17yr practice) were retrospectively reviewed. Radiologists review PET-CT, if available, prior to PNB, to target the maximum activity tissue (PET-CT-MA). The availability of PET-CT pre or post PNB was recorded, and whether PNB was ultimately taken from the PET-CT-MA (whether PET-CT pre- or post PNB). The number of needle passes, complications and biopsy results were recorded. The influence of lesion morphology on results was assessed.

RESULTS

353 PNBs were performed in 350 patients (median lesion size 30mm, 7-120mm). 178 PNB (50.4%) had PET-CT pre-PNB, in 102 (28.9%) cases PET-CT was post-PNB. In 73 (20.7%) PET-CT was never performed.Overall PNB success was 83.9% (95.8% malignant). 88.8% of 178 PNB with PET-CT pre-PNB were diagnostic, versus 78.9% of 175 PNB without PET-CT upfront ($p<0.01$ Fisher exact test).Correct targeting to PET-CT-MA was present in 87.1% of 278 cases with PET-CT. 88.8% of 242 PNB targeting the PET-CT-MA were successful, but only 52.8% of 36 PNB not targeting PET-CT-MA ($p<0.0001$). PET-CT pre-PNB had higher rates of PET-CT-MA targeting compared to PET-CT post PNB (91.0% v 80.0%, $p=0.01$).More patients with PET-CT pre-PNB (n=162) and correct localization had diagnostic PNB than patients with PET-CT pre-PNB (n=16) but incorrect localization (90.1% v 75%). Similarly, more patients with no PET-CT pre-PNB (n=80) but ultimately correct localization had successful PNB compared to patients with no PET-CT pre-PNB (n=20) and ultimately incorrect localization (86.3% v 35%, $p<=0.0001$).Patients with a PET-CT pre-PNB underwent fewer PNB passes (mean 2.6 v 3.1, $p<0.0001$ Mann Whitney U). Serious complications were less common in PET-CT pre-PNB group (4.5% v 10.9%, $p<0.05$). Pre-PNB PET-CT performance improvement applied to all 3 radiologists and was greatest for masses and infiltrative abnormalities.

CONCLUSION

PNB localisation to the PET-CT-MA is associated with higher diagnostic biopsy rates and appears to account for improved performance, less needle passes and complications when available pre-biopsy.

CLINICAL RELEVANCE/APPLICATION

Prospective studies are required to confirm the results that suggest PET-CT should be available prior to biopsy particularly for larger masses or infiltrative lesions.

PURPOSE

The goal of this study was to assess the diagnostic yield and safety profile of US-guided biopsy in the diagnosis of thoracic lesions, including lesions located in the chest wall, mediastinal and lung parenchyma.

METHOD AND MATERIALS

A total of 147 US-guided percutaneous needle biopsies of thoracic lesions performed in 146 consecutive patients (66±7y,83M,63F)

were analyzed, including lesions originating from the lung (67/147), chest wall (54/147), mediastinum (14/147) and pleura (12/147), obtained with FNA and/or CNB (FNA/CNB). Lesions varied in size from 1.5cm to 16cm. The overall diagnostic yield and complication rate of US-guided biopsy as well as the influence of lesion location and size, biopsy technique (FNA or CNB) and number of specimens on diagnostic yield and complication were calculate. Fisher's exact test, Chi-square test and logistic regression were used for statistical analysis. Results with $p<0.05$ were considered to be statistically significant and yield was summarized as proportion with 95% CI.

RESULTS

The overall diagnostic yield of US-guided needle biopsy was 88%. Biopsy of lesions located in the chest wall were diagnostic in 91% of cases, compared to 88% for lung lesions and 75% for pleural lesions and 93% for mediastinal lesions, although this was not statistically significant ($p = 0.45$). The diagnostic yield of FNA was similar to that of CNB (89% and 86% respectively) and the number of specimens obtained for either FNA or CNB did not affect yield ($p = 0.10$). Complications occurred in 4/147(3%) cases, including pneumothorax in two and mild hemoptysis in one patient. In all cases patients were treated conservatively with no cases requiring intervention. Complications were not statistically associated with any of the covariates analyzed.

CONCLUSION

US-guided biopsy has high yield for the diagnosis of thoracic lesions, including lesions located in the mediastinum and lung parenchyma. Tissue diagnosis sufficient to direct specific management is often obtained. The safety profile of US-guided thoracic biopsy is excellent with very low complication rates.

CLINICAL RELEVANCE/APPLICATION

Imaging-guided percutaneous biopsy is a safe minimally invasive technique used for the diagnosis of thoracic lesions and usually considered the initial modality to obtain tissue diagnosis.

SSM05-04 Artificial Intelligence Based Aortic Diameter Quantification on Routine Unenhanced Chest CT

PURPOSE

To validate a supervised machine learning algorithm to quantify thoracic aortic diameters on non-ECG synchronized, non-contrast material enhanced chest CT.

METHOD AND MATERIALS

A novel deep learning based radiology assistant was applied to a training dataset of manually annotated chest CTs. Aortic measurements were made by a single observer off of volumetric datasets utilizing double-oblique short axis measurements at 7 levels, as defined by the American Heart Association (sinuses of Valsalva, sino-tubular junction, mid ascending aorta, proximal aortic arch, mid aortic arch, proximal descending thoracic aorta, mid descending aorta). A deep convolutional image-to-image learning model was used to learn the mapping between the input CT volume and the ground truth aorta mask. The algorithm was then applied to a test set of 72 cases, and aortic diameters between manual measurements and the machine learning algorithm were compared.

RESULTS

The overall correlation between manual and machine learning measurements was r=0.86. The best correlation between manual and machine learning measurements was in the mid descending aorta (r=0.875). The model predictions resulted in an area under the curve of 0.877 when applying a threshold of 38 mm to detect an abnormally enlarged mid ascending aorta, with peak performance of the model set at cutoff 39 mm (indicating a small bias in the model) and resulting in sensitivity and specificity of 77% and 89%, respectively.

CONCLUSION

A machine learning algorithm may be able to automatically provide reliable quantitative measures of thoracic aortic diameters and flag abnormal values.

CLINICAL RELEVANCE/APPLICATION

Automated aortic measurements could enrich radiology reports for epidemiologic studies, save time for the interpreting clinician, and ensure that abnormally dilated aortas are not missed.

SSM05-05 Volume-Helical-Shuttle Mode with Low Contrast Dose and Low Tube Voltage in CT Pulmonary Angiography for Critically Ill Patients

PURPOSE

To explore the value of using volume-helical-shuttle (VHS) mode with low contrast dose and low kVp in CT pulmonary artery (CTPA) imaging for critically ill patients.

METHOD AND MATERIALS

38 critically ill patients for CTPA were in the study group (Group A), and other 38 cases of conventional CTPA served as the control group (Group B). Group A used the VHS mode: tube voltage 80kVp, smart mA, noise index (NI) 25HU, pitch 1.375:1, rotation speed 0.5s for 4 passes with scan started 6s after the contrast injection. Contrast dose of 25mL (350mgI/ml) at 4mL/s flow rate was used. Images were reconstructed using 60%ASiR and the best images were selected from the 4 passes for analysis. Group B used tube voltage 120kVp, smart mA for NI of 12HU, pitch 1.375:1, rotating speed 0.8s and contrast dose of 60ml, and images were reconstructed with 40%ASiR. The CT values and SD values of vessels and the vertical spinal muscles were measured to calculate SNR and CNR for vessels. Artifacts near superior vena cava was graded with 5 being the worst. The attenuation difference between the right inferior pulmonary artery and right inferior pulmonary vein was calculated. Two experienced physicians also evaluated image quality double blindly using a 5-point scoring system. Measurements in both groups were statistically compared.

RESULTS

The total radiation dose in VHS mode (Group A) was the same as the conventional CTPA ($P>0.05$), but the contrast dose in Group A was reduced by 58% compared with Group B. The target vessel CT and SD values in Group A were both higher than group B ($P<0.05$), resulting in similar SNR and CNR values in both groups ($P>0.05$), except that the CNR values of MPA and RPA in group B were higher ($P<0.05$); There was no difference in the subjective score of image quality between the two groups ($P>0.05$). However, Group A was better in both the attenuation difference and superior vena cava artifacts ($P<0.05$).

CONCLUSION

CTPA using VHS mode at low kVp works for critically ill patients who were unable to cooperate. Compared with the conventional CTPA, the proposed method provides more satisfactory image results with the same total radiation dose and 58% contrast dose reduction.

CLINICAL RELEVANCE/APPLICATION

For critically ill patients, this method can reduce contrast dose, make multi-phase diagnosis, overcome difficulties that patients cannot cooperate well and ensure the success rate of examination.

SSM05-06 Real-Time Patient Specific Scan Initiation for Pulmonary Embolism CTA: Impact on Image Quality

fides.schwartz@duke.edu

PURPOSE

Real-time modulation of scan initiation based on patient specific hemodynamics may allow for optimal timing of contrast enhancement in the pulmonary arteries in evaluation of pulmonary embolism (PE), reducing the number of non-diagnostic scans. The purpose of this study is to assess image quality for PE chest CTA using a modulated scan initiation delay based on patient specific hemodynamics.

METHOD AND MATERIALS

This was a HIPAA compliant, IRB approved quality improvement project. Fluoroscopic administration of contrast was used for all PE chest CTA exams. A new modulated scan initiation delay software was evaluated in 30 patients (cohort 1) scanned on a dual-source 192 detector CT (Siemens FORCE, Forchheim, Germany) from 01/2018-04/2018. 30 patients (cohort 2, matched to cohort 1 for BMI and age) with exams performed using a fixed scan initiation delay of 5 seconds (sec) were identified from 10/2016-12/2017. Subjective image quality was graded on a 4-point Likert-scale (1=excellent, 2=good, 3=fair and 4=inadequate). Objective image quality was determined by measuring the Hounsfield (HU) values in the main pulmonary artery, the bilateral lower lobe segmental and subsegmental arteries (150 arterial segments/cohort). HU values and standard deviations were compared for both cohorts.

RESULTS

Average patient age was 54.5 vs 54.3 years for cohorts 1 and 2 respectively. Average BMI was 32.9 kg/m2 for both cohorts. There was a statistically significant difference in scan initiation delay of 11±3.6 sec (range 7.8 to 27.8 sec) for cohort 1 vs the set delay of 5 sec for cohort 2 ($P<0.01$). Subjective image quality for cohort 1 was graded as excellent or good in 22 patients, fair in 5 and inadequate in 3 patients; for cohort 2 it was graded as excellent or good in 20 patients, fair in 4 and inadequate in 6 patients. Average HU values were higher for cohort 1 vs cohort 2 in segmental (382 vs 349 HU right/387 vs 359 HU left) and subsegmental arteries (371 vs 327 HU right/382 vs 330 HU left). A total of 20/150 segments in cohort 1 and 31/150 segments in cohort 2 were non-diagnostic (HU<250; 7.4% reduction).

CONCLUSION

Real time, patient specific modulated scan initiation delay achieved higher image quality than a set delay for PE chest CTA.

CLINICAL RELEVANCE/APPLICATION

A real-time patient specific scan initiation can improve subjective image quality for PE chest CTA exams and reduce the total number of non-diagnostic pulmonary artery segments.

PURPOSE

IgG4-related disease (RD) is an immune-mediated fibro-inflammatory disease that can affect the respiratory system. The goal of this study is to investigate the association between thoracic imaging manifestations of IgG4-RD, IgG4 antibody levels and pulmonary symptoms.

METHOD AND MATERIALS

In this IRB-approved retrospective study, 62 patients with a pathology-proven diagnosis of IgG4-RD and thoracic CT imaging were identified. Images were reviewed by two thoracic radiologists. IgG4 antibody levels, pulmonary symptoms and patient demographics were collected. Wilcoxon rank-sum test was used to assess for differences of the mean IgG4 levels between patients with and without thoracic imaging manifestations of disease. Fischer's exact test was performed to assess for independent association between IgG4 levels and the presence of imaging findings. Spearman correlation analysis was used to assess the correlation between the number of imaging findings and IgG4 levels. Univariate logistic regression analysis was performed to assess for independent contribution of IgG4 levels and pulmonary symptoms in predicting the presence of imaging manifestation on CT.

RESULTS

Of the 62 patients enrolled, 36 patients (58%) had imaging findings attributable to IgG4-RD. Patients with imaging findings had significantly higher IgG4 antibody levels (897±218 mg/dL vs. 87±17 mg/dL in those without imaging findings) ($p<0.01$). Airway involvement was a common imaging finding, present in 19/36 (52.8%) patients. Patients with bronchial wall thickening ($p<0.01$), mosaic lung attenuation ($p=0.01$), and saber sheath trachea ($p=0.03$) had significantly higher serum IgG4 levels compared to those without airway involvement. IgG4 levels and pulmonary symptoms were independent predictors of presence of thoracic imaging manifestations on regression analysis ($p=0.02$ and 0.01 respectively). Overall, there was a positive correlation between the number of thoracic manifestations on CT and serum IgG4 levels ($r=0.60$, $P<0.01$).

CONCLUSION

Airway involvement is a common manifestation of IgG4-RD. High IgG4 levels and pulmonary symptoms are independently associated with presence of findings on chest CT in patients with IgG4-RD.

CLINICAL RELEVANCE/APPLICATION

Elevated IgG4 antibody levels and the presence of pulmonary symptoms should prompt thoracic imaging to identify lung involvement and direct management decisions in patients with IgG4-RD.

SSM06-02 Chest CT Analysis for Prediction of Treatment Response in Organizing Pneumonia: A 20-year Retrospective Cohort Study

PURPOSE

To investigate the CT imaging features associated with poor clinical outcome after steroid treatment (Tx) in patients diagnosed with organizing pneumonia (OP).

METHOD AND MATERIALS

The study retrospectively enrolled 166 patients (M:F=55:111; mean age, 57.2; mean FVC, 65.9; mean DLco, 58.5) with the pathologically proven OP, which included 131 cases of cryptogenic OP (COP) and 35 cases of connective tissue disease-related OP (CTD). Baseline chest CTs prior to Tx were semi-quantitatively analyzed by two thoracic radiologists in consensus. Lesion extent (consolidation, GGO, reticulation, and total), dominant lesion pattern, dominant distribution, and presence of bronchiectasis (BE), lymph nodes, pleural or pericardial effusions, and reverse halo were evaluated. Uni- and multivariate logistic regression analyses were performed to identify variables associated with poor clinical outcomes including failure to achieve complete response (non-CR) and relapse after Tx.

RESULTS

CR was achieved in 40 (24%) patients and relapse was detected in 53 (31%) patients. While BE was detected in 30% of patients with CR, 65% of patients with non-CR were found to have BE on baseline chest CT. Average extent of consolidation for CR and non-CR group was 14.1% and 15.2%, respectively. Presence of BE (hazard ratio (HR), 4.38) and extent of consolidation greater than 10% of the lung (con>10%) (HR, 2.46) were significantly associated with higher non-CR rate (all, $p < 0.01$). CTD-OP was also found to have higher non-CR rate (HR, 4.19) than COP. On multivariate logistic regression analysis adjusted for age and sex, BE, con>10%, and CTD-OP all remained as significant predictors. For the prediction of relapse, significant associations were found with con>10% (HR, 2.86), total extent > 25% (HR, 2.77), and CTD-OP (HR, 6.79). After adjusted for age and sex, con>10 % and CTD-OP were found be significant predictors of relapse.

CONCLUSION

In patients diagnosed with OP, patients with BE and greater extent of consolidation on baseline chest CT were less likely to achieve CR, and the latter was also associated with higher rate of relapse after treatment. Additionally, CTD-OP was found to have worse treatment outcome than COP.

CLINICAL RELEVANCE/APPLICATION

Patients with underlying CTD, bronchiectasis, and greater extent of consolidation at the time of diagnosis were found to have worse treatment outcome in OP, and therefore should be monitored with extra vigilance.

SSM06-03 Identification of CT Patterns for Disease Progression in CTs of Patients with Idiopathic Pulmonary Fibrosis - An Unsupervised Machine-Learning Approach

PURPOSE

To identify CT patterns which can be used as markers of disease progression in patients with idiopathic pulmonary fibrosis (IPF) using an unsupervised machine-learning approach.

METHOD AND MATERIALS

695 CT scans from 106 IPF patients (1-4 per patient) were investigated in the study. All CT studies were automatically segmented into into super-voxels and gray-level co-occurrence features at the centroid positions were extracted. Twenty clusters of these super-voxels proved to be stable across the population in the feature space. The volume of each cluster relative to the entire lung was used as the signature of a lung. To identify prognostic markers in these signatures, we trained a random-forest classifier to predict for any pair of scans for one patient (scans A and B) if A was acquired prior to B or vice versa (overall 230 pairs). The classifier determined which features were most informative regarding the classification. To determine whether the signature was predictive and stable, a four-fold cross-validation was performed on the data set. The classifier was trained on 3/4 of the patients, and predicted an A/B sequence on the remaining 1/4 of these patients. To study the distribution of predictive information in the lung, we split the volume into upper-, middle-, and lower third, and performed the evaluation for each of them individually.

RESULTS

The random forest identified four distinct clusters as predictive for the temporal course. In the four-fold cross-validation experiment, using all lung data, the classifier correctly determined the sequence of scans for 80.35% of the cases. Using only cluster information in one of three parts of the lung reduces the accuracy, but reveals that the middle segment results in highest accuracy (76.52%) compared to upper (73.04%) and lower (72.61%) segments. Three clusters where among the top four most predictive clusters in all folds, and one cluster was in the top four for three of four folds.

CONCLUSION

The described approach identified four patterns that were markers of disease progression in lung CT data of IPF patients. The information contributed by individual clusters differs depending on their location in the lung.

CLINICAL RELEVANCE/APPLICATION

Data-driven identification of imaging markers enables the exploitation of complex patterns for the detection and quantification of progression.

SSM06-04 Interstitial Lung Abnormalities in Stage IV Non-Small Cell Lung Cancer Patients: A Validation Study for the Association with Poor Clinical Outcome

PURPOSE

The presence of interstitial lung abnormalities (ILA) at diagnosis of stage IV non-small cell lung cancer (NSCLC) patients have previously shown to be associated with shorter survival. The present study aimed to validate the association in a larger cohort of treatment-naïve stage IV NSCLC patients.

METHOD AND MATERIALS

This study included 484 patients (205 males and 279 females, median age: 62) with stage IV NSCLC. ILA was scored on the baseline chest CT scans at diagnosis prior to therapy using 3-point scale (0=no ILA, 1=equivocal for ILA, 2=ILA) using a sequential reading method by 3 readers as published previously. Clinical characteristics and overall survival (OS) were compared in patients with ILA (score 2) vs. those without ILA (score 0 or 1).

RESULTS

ILA was present (score 2) on baseline CT in 19 of the 484 patients (3.9%, 95%CI: 2.4 - 6.1 %). Patients with baseline ILA were older (median age: 69 vs. 62 years, Wilcoxon p=0.0008) and were more commonly male (68.4% (13/19) vs. 41.3% (192/465); Fisher p=0.03) compared to those without ILA. Other variables including race, smoking history, and histology were not significantly associated with baseline ILA. Patients with baseline ILA had significantly shorter overall survival compared to those without (median OS: 9.95 months [95%CI: 5.88-15.5] vs. 16.95 months [95%CI: 14.65-18.7]; Log-rank p=0.0002). In multivariable analyses, baseline ILA remained significant as a marker for shorter overall survival (HR=2.09; Cox p=0.004), after adjusting for age (>70 years using the 75th percentile; HR=1.48; Cox p=0.001), male gender (HR= 1.22; Cox p=0.055) and smoking (never vs. current/former smoker; HR=0.79; Cox p=0.051).

CONCLUSION

The presence of ILA at diagnosis of stage IV NSCLC was significantly associated with shorter survival, validating ILA as an independent marker for poor outcome.

CLINICAL RELEVANCE/APPLICATION

Recognition of ILA on chest CT at diagnosis of stage IV NSCLC is important, because ILA can serve as a marker for shorter survival and may contribute to patient monitoring and management.

SSM06-05 Juxta-Pleural and Acutely-Folded Bronchi: Differential CT Findings of IPF without Evidence Honeycombing From NSIP

PURPOSE

To evaluate juxta-pleural and acutely-folded bronchi for the differentiation of IPF patients without honeycombing from idiopathic NSIP.

METHOD AND MATERIALS

The derivation cohort consisted of 80 consecutive patients (41 IPF and 39 NSIP; 17 probable, 10 indeterminate, 53 non-IPF CT patterns) who met following criteria in a single hospital: (a) multidisciplinary diagnosis of IPF or idiopathic NSIP with surgical biopsy from 2005 to 2017, (b) diagnostic thin-section chest CT, and (c) lack of honeycombing in case of IPF. For validation, 22 patients (14 IPF and 8 NSIP; 4 probable, 11 indeterminate, 7 non-IPF CT patterns) with the same condition were included from another institution. Two radiologists for derivation cohort independently assessed the presence of juxta-pleural and acutely-folded bronchi on axial, coronal, sagittal minimum intensity projection (MinIP) images (20mm overlap, 5mm increment; MEDIP software, MEDICALIP Co., Ltd. Seoul, South Korea). Juxta-pleural bronchus was defined as bronchiectasis attached perpendicular to the pleura 1.5cm or longer in length. Acutely-folded bronchus was defined if a single bronchus folded abruptly over 90 degrees and if bronchus branched at an angle of 135 degrees or larger. Logistic regression analysis was used to identify the association of the MinIP findings with IPF. For validation, we assessed the diagnostic accuracy and interobserver agreement of 4 radiologists blinded to any clinical information using a proportion of correct diagnosis of IPF and NSIP and ROC curve before and after reviewing MinIP images.

RESULTS

Non-juxta-pleural and juxta-pleural acutely-folded bronchi (OR, 3.5 95%CI, 1.37-8.66; p=.008 and OR, 6.22, 95%CI, 1.62-23.84; p=.008, respectively), and co-existence of non-juxta-pleural acutely-folded bronchus and juxta-pleural bronchus in same patient (OR, 5.67, 95%CI, 2.03-15.85; p=.001) were significant imaging features for IPF. After reviewing MinIP images, the readers' area under the curve mildly improved from 0.496-0.808 to 0.554-0.808 with increased proportion of correct diagnosis from 40.9-54.5% to 50.0-77.3%. Mean interobserver kappa values for juxta-pleural and acutely-folded bronchi were 0.373 and 0.475.

CONCLUSION

Juxta-pleural and acutely-folded bronchi were differential CT findings for IPF without honeycombing.

CLINICAL RELEVANCE/APPLICATION

Analysis of bronchial trajectory using MinIP images could increase an imaging confidence of IPF without honeycombing.

SSM06-06 Fibrotic Lung Disease on CT Predicts Adverse Outcomes in Patients Undergoing Transcatheter Aortic Valve Replacement

clin97@jhmi.edu

PURPOSE

To evaluate the relationship between CT findings of diffuse lung disease (fibrosis and emphysema) and outcomes in patients who underwent transcatheter aortic valve replacement (TAVR).

METHOD AND MATERIALS

Retrospective review of pre-operative CT scans obtained from 507 patients who underwent TAVR during 2012-2017. Lung images were divided into ten contiguous axial sections spaced equally apart. The extent of fibrotic lung disease - characterized by reticular abnormality and/or honeycombing - was graded by a thoracic radiologist using a five-point scale based on the percent of lung parenchyma involved. A similar approach was used to grade the extent of emphysema. Scores from all the axial slices for each patient were summed to determine fibrosis and emphysema scores. Demographic and clinical data, including pulmonary function tests, were extracted from institutional data submitted to the national Transcatheter Valve Therapy (TVT) Registry. Outcome analyses were performed according to the Kaplan-Meier method using a combined endpoint of death and readmission as the primary outcome.

RESULTS

Complete clinical parameters and outcome data were available in 335 patients. Fibrosis was present in 91 out of 507 (18%) patients with fibrosis scores ranging from 1-34. Emphysema was seen in 33 out of 507 (6.5%) patients. Fibrosis scores between patients with and without chronic lung disease - defined according to TVT registry as FEV1 below 60% - were not statistically different (p=0.59). The presence of fibrotic lung disease on CT was significantly associated with the primary outcome (HR 1.62; 95% CI

1.09-2.40; p=0.016) after adjustment for pre-specified covariates (including FEV1, smoking status, age, and LVEF). Emphysema scores were not associated with the primary outcome. FEV1 was also an independent predictor of worse outcome (HR 0.99; 95% CI 0.984-0.998; p<0.01).

CONCLUSION

The presence of fibrotic lung disease on pre-TAVR CT scans was a significant predictor of adverse events, independent of known risk factors for mortality. Radiologists should be aware that these pulmonary findings could help identify patients who are at higher risk among those referred for TAVR.

CLINICAL RELEVANCE/APPLICATION

Visual assessment of reticular abnormality and honeycombing on pre-operative CT scans can predict adverse events in patients undergoing transcatheter aortic valve replacement.

PURPOSE

CECT is the gold standard for the detection and grading of hepatic and splenic injuries in BAT. Due to the high incidence of low energy trauma with negative CECT findings and the high doses of iodinated contrast used, contrast enhanced ultrasound(CEUS) is an alternative tool in the detection of solid organ injuries in the emergency setting. This study was done to assess the agreement between the grades of hepatic and splenic injuries assigned on CEUS and CECT

METHOD AND MATERIALS

In this ethically approved study consecutive hemodynamically stable patients with BAT with CECT showing solid abdominal organ injuries were recruited. These patients underwent CEUS by a radiologist who was blinded to the findings of CECT. The injuries were graded on both modalities using the American Association for the Surgery of Trauma (AAST) scales. The agreement between the grading of injuries on CECT and CEUS was analysed through kappa statistics. The injuries were further classified as high grade (AAST grades IV & above) and low grade (AAST grades I to III) and agreement between the grading on CECT and CEUS was compared

RESULTS

Among the 105 patients included as a part of a larger study, there were 66 hepatic and 43 splenic injuries detected on CECT. CEUS identified 63 out of the 66 liver injuries and these 63 injuries were graded and compared with CECT. There was significant agreement between their grading on CECT and CEUS with a kappa value of 0.95 (>0.75 is significant). On combining the grades as low grade and high grade injuries, there was significant agreement on both modalities with a kappa value of 1.00. Similarly, 40 splenic injuries were detected on CEUS out of the 43 detected on CECT and these were graded on both the modalities and compared. There was significant agreement between the grading with a kappa value of 0.87. On combining the grades as low grade and high grade injuries there was significant agreement between the grading of splenic injuries on both modalities with a kappa value of 0.91

CONCLUSION

CEUS is accurate in grading of hepatic and splenic injuries in case of blunt traumatic solid abdominal organ injuries

CLINICAL RELEVANCE/APPLICATION

CEUS can provide a radiation free alternative for accurately grading hepatic and splenic injuries and can suggest further management.

PURPOSE

The role of imaging has become more important for preoperative assessment of traumatic penetrating injuries (PIs). This study aims to evaluate the overall diagnostic accuracy of preoperative MCDT in abdominal and pelvic PIs.

METHOD AND MATERIALS

We used our hospital's trauma registry to retrospectively identify patients with penetrating abdominal and pelvic injuries from 1/1/2006 to12/31/2016. Only patients who had a 64-MDCT scan at presentation and subsequently underwent laparotomy or laparoscopy were included in our study cohort. Each finding noted on MDCT was rated using a 5-point scale to indicate certainty of injury, with a score of 0 being definitive. Using surgical findings as the gold standard, the accuracy of radiology reports was analyzed in 2 ways. A kappa statistic was calculated to evaluate each pair of values for absolute agreement, and ratings for all organ systems were analyzed using a repeated measures ANOVA to determine if radiology and OR findings were similar enough to be clinically meaningful.

RESULTS

Of the 194 trauma patients identified from the trauma registry, 42 met our inclusion criteria - 14 of which sustained GSW, 25 sustained stab wounds, and 3 were miscellaneous penetrating injuries. Our cohort consisted of 38 males and 4 females with a median age of 29 years and a median injury severity score (ISS) of 15.6. For this study, 15 different organ groups were categorized and analysed. Of those organ groups, absolute agreement between MDCT and surgical findings was found only for liver, spleen, peritoneal space and retroperitoneum (kappa values ranging from 0.2 to 0.5). Additionally, the ANOVA revealed an interaction between finding type and organ system ($F(1, 33) = 7.4$, $p < 0.001$). The most clinically significant discrepancies between MDCT and OR findings were for gallbladder (GB), bowel and mesenteric, and diaphragmatic injuries (DI). In particular, MDCT imaging showed a slight tendency towards false negatives for GB, mesenteric and DI.

CONCLUSION

The detection of clinically significant injuries to solid organs in trauma patients with penetrating abdominal and pelvic injuries on 64-MDCT is adequate. However, detection of injury to the remaining organ groups on MDCT - especially the GI tract, mesentery, and diaphragm - remains a challenge.

CLINICAL RELEVANCE/APPLICATION

The accurate preoperative detection of bowel, mesenteric and diaphragmatic injuries on preoperative MDCT remains a challenge.

Charles-Andre Cuenod, Paris, France (*Abstract Co-Author*) Research collaboration, Guerbet SA Speaker, Guerbet SA

PURPOSE

To evaluate accuracy of individual or associations of CT and clinical signs To determine signs that are implied in missed diagnosis on first CT

METHOD AND MATERIALS

This retrospective case-control study included 30 cases with surgically confirmed bowel and/or mesentery requiering surgical repair and 52 consecutive controls with blunt abdominal or chest trauma and no surgically important bowel and/or mesenteric injury. CT findings were screened by two radiologists: a 10-year-experimented in abdominal imaging radiologistand a second-year resident blinded to the patients' outcome. Clinical outcomes were analysed by consulting the medical file. Sensitivity and specificity were calculated for each sign and a kappa coefficient were used to establish the interobserver variability.

RESULTS

The CT signs with best positive likelihood ratio were extra luminal air, bowel wall defect and thickening, decreased bowel wall enhancement and mesenteric vessels abnormalities. The specificity of clinical seat belt sign associated with anterior abdominal wall injury on CT was 98%. The sensitivity of free intraperitoneal fluid was 100% and its density was higher in cases. More than 50% of patients with missed diagnosis on first CT had a visceral injury associated. Diagnosis of mesenteric and/or bowel injury depends on

the experience of the radiologist (kappa = 0,6).

CONCLUSION

CT scan is accurate for the diagnosis of bowel and/or mesenteric injuries in blunt abdominal trauma depending on the experience of the radiologist. The association of clinical seat belt sign and anterior abdominal wall injury on CT is highly specific.

CLINICAL RELEVANCE/APPLICATION

The radiologist should know the relevant signs and have a stratified strategy for the diagnosis. Therefore we propose an algorithm for the diagnosis.

SSM07-04 Radiation Dose versus Injury Yield: A Study of CT Imaging Findings in Stabbing Related Injuries at an Urban Level 1 Trauma Center

Wednesday, Nov. 28 3:30PM - 3:40PM Room: S404AB

Participants
Oliver Duxbury, MBBCh,FRCR, London, United Kingdom (*Presenter*) Nothing to Disclose
Gurinder Nandra, FRCR,MBChB, London, United Kingdom (*Abstract Co-Author*) Nothing to Disclose
Ioannis Vlahos, MRCP,FRCR, London, United Kingdom (*Abstract Co-Author*) Research Consultant, Siemens AG Research Consultant, General Electric Company

PURPOSE

Clinical uncertainty over stab injury severity results in extensive CT use based solely on anatomic location often without consideration of injury depth or other clinical parameters. The study aim was to determine whether the diagnostic yield of emergency department (ED) requests justifies the CT radiation dose exposure.

METHOD AND MATERIALS

All ED CT examinations performed for stabbing in 2017 at an Urban Level 1 Trauma Center were retrospectively assessed. CT coverage/protocol phases were determined by ED referral based on injury anatomic location. CT evaluation (Definition,Siemens Medical Solutions,Forchheim,DE) was performed with autoKVp selection (80-140kVp, filtered back projection). Parameters recorded included: age, body parts imaged, phases per scan, identifiable site injuries and depth, organ injuries, presence of active bleeding and patient management. Effective radiation dose was calculated.

RESULTS

A total of 175 patients were scanned for 179 stabbing related injuries (median age 25, 87% male). A mean 1.6 phases of CT were performed per patient (range 1-3), imaging a mean 3.9 body part-phases/patient. Mean dose was 11.8mSv (1.5-43.9). A total of 79 organ injuries were identified in 61/179 patient episodes, imaged at a cost of 26.7mSv/organ injury. The injury site was identifiable in 95% of cases, but was limited to the subcutaneous layer in 38% and the muscular layer in 66% of patients. No injuries were fatal. 106/179 (59%) of studies had more than one phase, but only 17% of all patients demonstrated active bleeding, and only one third of these required surgery or interventional radiology. Excluding 15 patients with clinically overt injuries (knife in situ, evisceration, needing chest drain prior to CT), only 22% of 164 patients had CT detected injuries necessitating treatment. The dose in patients without injuries was only slightly lower than patients with treatable injuries(11.3mSv v. 13.1mSv, $p<0.05$, Mann-Whitney U).

CONCLUSION

Most stab injuries are superficial, or not necessitating treatment. A high radiation dose burden in young patients without significant injury dictates better CT use criteria are required to limit imaging to the minority with significant injuries.

CLINICAL RELEVANCE/APPLICATION

The high radiation dose in young patients dictates better clinical criteria are needed to limit CT in stabbing injuries to the patient minority likelier to have injuries requiring further management.

ddreizin@umm.edu

PURPOSE

The diagnostic performance of intravenous contrast extravasation on computed tomography for prediction of angiopositivity after pelvic ring disruption has not been previously assessed using meta-analysis, despite ongoing controversy and widely variable results

in the literature. We performed a meta-analysis to determine pooled accuracy of CE, and to assess the influence of CT scanner generation and multiphasic protocols.

METHOD AND MATERIALS

We conducted a systematic literature search to answer the following: 'What is the diagnostic accuracy of intravenous contrast extravasation (CE) at admission trauma CT for predicting angiopositivity and need for angioembolization in patients who have sustained blunt pelvic ring disruptions?'. MEDLINE, Embase, and Cochrane databases were queried using a combination of text words and MeSH terms. Of 206 potentially eligible studies, 23 studies that met criteria were assessed for methodologic quality using the QUADAS-2 tool. Sensitivity and specificity were synthesized using bivariate mixed-effects logistic regression. Heterogeneity was assessed using the I2 statistic. Publication bias was examined using Deeks' test. Subgroup analyses were conducted to explore the heterogeneity based on the use of 64-section CT, multiphasic versus single phase protocols, study sample size, and prevalence of arterial bleeding on angiography.

RESULTS

23 included studies provided 3855 patients for meta-analysis. There was no evidence of publication bias (p=0.62) Pooled sensitivity and specificity were 80% (95% CI: 66-90%, I2 = 92.65%) and 93% (CI: 90-96, I2 = 89.34%), respectively, with substantial heterogeneity. Subgroup analysis showed pooled sens and spec of 94% and 89% for 64-section CT compared to 69% and 95% with older generation scanners. With multiphasic protocols, CE had pooled sensitivity and specificity of 95% and 92%, compared to 74% and 94% with single phase protocols. Studies with lower disease prevalence and larger sample size also had better diagnostic performance.

CONCLUSION

Multiphasic protocols and improved scanner quality result in substantial gains in sensitivity of CE, potentially at the expense of specificity.

CLINICAL RELEVANCE/APPLICATION

Little further improvement in sensitivity can be expected beyond 64MDCT. Increased conspicuity of small foci of self-limiting CE could potentially reduce specificity for angioembolization need.

SSM07-06 Whole Body CT Using Biphasic Injection Protocol with Adaptive Statistical Iterative Reconstruction-V (Asir-V) in Multi-Trauma Patients: Impact on Dose Reduction and Image Quality

Wednesday, Nov. 28 3:50PM - 4:00PM Room: S404AB

mokadem83@yahoo.com

PURPOSE

To evaluate potential dose savings and image quality after implementing adaptive statistical iterative reconstruction-V (ASiR-V) algorism on a revised protocol for whole-body computed tomography (WBCT) for multi-trauma patients and compare it to conventional protocols.

METHOD AND MATERIALS

One hundred multi-trauma patients were scanned using a 256-multidetector CT system (GE Healthcare Revolution system). They were randomized into two groups using two different scanning protocols. Group (A) (n=50, age 32.48±8.09) underwent conventional protocol including unenhanced WBCT scan, then contrast-enhanced arterial-phase of the thorax and abdomen followed by a portal and delayed scan of the abdomen and pelvis. Group (B) (n=50, age 35.94±13.57) underwent biphasic injection protocol including unenhanced WBCT scan, followed by a one-step acquisition of the thorax, abdomen, and pelvis following a biphasic injection, the examination was ended by delayed phase for the abdomen and pelvis. All examination were done under 50 % ASiR-V. Image count, radiation dose, total acquisition time, mediastinal artifacts were compared. Two radiologists independently graded image quality from 1 to 5. In addition, contrast enhancement was measured in the pulmonary artery, aorta, inferior vena cava, portal vein, liver, spleen, and kidneys.

RESULTS

The mean (±SD) dose length product value for group (A) was 2202.3 ± 271.8 mGy*cm and higher when compared to group (B) ($p < 0.001$) which was 1485.8 ± 489.2 mGy*cm. Protocol B gave a dose reduction of 32.5% and 7.7 % acquisition time reduction. The Houndsfield unit values of the aorta, liver and spleen were significantly higher in group (A) while both kidneys values were higher in group (B). There was no statistically significant difference between the image quality scores for both groups however, group (A) scored higher grades (4.62±0.56 & 4.56±0.67).

CONCLUSION

Implementing ASiR-V algorism on biphasic injection WBCT protocol reduced radiation dose significantly with maintenance of diagnostic accuracy and image quality.

CLINICAL RELEVANCE/APPLICATION

Whole body computed tomography (WBCT) is an important diagnostic tool for initial clinical trauma management. Dose reduction with maintenance of image quality is still a concerning subject for emergency radiologists.

PURPOSE

To identify baseline imaging and biochemical factors that would determine prognosis, tumor response to treatment and overall survival in patients with HCC.

METHOD AND MATERIALS

This retrospective, IRB approve HIPAA compliant study included 220 HCC patients between March 2005 and November 2016. Diagnosis was confirmed either pathologically (n=105) or by typical imaging criteria (n = 115). All patients had baseline liver MRI before treatment. Baseline tumor variables were measured including tumor volume, volumetric ADC, and viable tumor volume. Baseline Child score, BCLC criteria, laboratory data, comorbidities and etiology of the liver disease were recorded. Patients were followed until death, or until December 2017. Cox regression models were utilized to identify the impact of clinical and imaging variables on patient survival. Additive value of imaging variables to the BCLC criteria and clinical variables was quantified. Classification and Regression Trees (CART) analysis was performed to predict patient overall survival based on the final model with independent predictive variables.

RESULTS

Among baseline variables BCLC criteria, tumor type (infiltrative vs well vs ill-defined tumors on MRI), tumor volume and viable tumor volume had significant impact on overall patient survival. Adding imaging variables to BCLC significantly increased the accuracy of overall patient survival prediction by 6% (p<=0.001); the number of treatments did not alter the predictive ability of the imaging variables. However, including liver transplantation status in the model with BCLC and imaging criteria significantly improved the accuracy of overall survival prediction by 7% (p<= 0.001), Figure 1. CART analysis showed that patients who received liver transplant had the highest survival. In patients who did not receive liver transplant, those with viable tumor volume <=800 ml3 had higher survival compared to those who had viable tumor volume >800 ml3, Figure 2.

CONCLUSION

In a relatively large sample size of HCC patients we were able to show that in patients who do not receive transplant, viable tumor volume and tumor type were the most important criteria in predicting survival.

CLINICAL RELEVANCE/APPLICATION

Baseline features in HCC patients stratified patients into those who would benefit from management with improved overall survival and those who would not.

PURPOSE

Radiological categorization of liver nodules is standardized by the AASLD and LIRADS criteria. However, a significant proportion of nodules in cirrhotic livers remains classified as indeterminate. We aimed to improve categorization of indeterminate nodules recognized at CT, in patients at high risk of hepatocellular carcinoma (HCC) through machine-learning.

METHOD AND MATERIALS

We analyzed retrospectively and consecutively 106 pts with indeterminate liver nodules reaching predefined quality criteria: (i) biopsy-proven, (ii) follow-up at our institution, (iii) triphasic CT-scan (non contrast-enhanced 'NCP', arterial 'AP' and portal 'PVP' phases). The volume of HCC was contoured on CT-scans gathered from 2010 and 2015. Model building used Random Forest algorithm and 1.160 quantitative imaging features extracted from NCP, AP, PVP, deltaNCP-AP, deltaAP-PVP, and delta NCP-PVP, respectively. The performance of prediction model was evaluated by the area under the receiver operating characteristic curve (AUC) and ten-fold cross-validation. The Synthetic Minority Over-sampling Technique (SMOTE) was employed to alleviate the sample imbalance problem.

RESULTS

The proportion of HCC in indeterminate liver nodules biopsied was 81%: 86 pts in HCC group and 20 pts in non-HCC group. The model based on DeltaAP-PVP features achieved the highest AUC=0.85. As a comparison, model built on NCP, AP, PVP, DeltaAP-PVP, Delta DeltaNCP-PVP imaging features reached AUCs of 0.73, 0.73, 0.78, 0.71, and 0.72. The 5 most important features were features characterizing lesion contours and homogeneity (DWT1, Gabor, GLCM homogeneity, Laws and RSRE). Non-HCC nodules were composed of dysplastic (n=8), regenerative nodules (n=5), steatohepatitis (n=4), and others (n=3).

CONCLUSION

This study is a proof of concept that quantitative CT interpretation can categorize indeterminate nodules of cirrhotic patients as HCC or non-HCC, with a great precision. We demonstrated that the optimal imaging features characterized the change in lesion contours and homogeneity and allow to differenciate HCC from non HCC.

CLINICAL RELEVANCE/APPLICATION

Noninvasive categorization of indeterminate nodules in cirrhotic patients is feasible. Virtual biopsies using artificial intelligence will improve patients' management for earlier diagnosis of HCC.

SSM08-03 Exploring the Uncharted Realm of Laboratory Radiology: Quantification and Landmark-Based Normalization of Liver Volume

Wednesday, Nov. 28 3:20PM - 3:30PM Room: S502AB

Participants
Therese Lincke, Basel, Switzerland (*Presenter*) Nothing to Disclose
Guillaume J. Chabin, MS, Princeton, NJ (*Abstract Co-Author*) Employee, Siemens AG
Sasa Grbic, Princeton, NJ (*Abstract Co-Author*) Employee, Siemens AG
Dorin Comaniciu, PhD, Princeton, NJ (*Abstract Co-Author*) Employee, Siemens AG
Daniel Boll, Basel, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Bram Stieltjes, MD,PhD, Basel, Switzerland (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To become meaningful in a clinical context, quantitative imaging-based values, in this case liver volumes, may need to be normalized to reveal their relevance. Here, we evaluate variability of liver volumes and assess methods for normalization using automatically detected osseous and soft tissue body landmarks.

METHOD AND MATERIALS

4578 CT-datasets of 1812 woman and 2766 men were consecutively included. Liver volumes and body landmarks were fully automatically detected using Multi-scale Deep-Reinforcement Learning for 3D body markers detection and Adversarial Deep

Image2Image for 3D liver segmentation. The landmark detection library includes 17 landmarks e.g. th6, liver top and right lung top. Distances between landmark pairs were extracted and Pearson correlation was calculated for landmark-distances/liver volumes. As a measure of normalization effect, the quartile coefficient of dispersion before and after normalization was calculated.

RESULTS

A large spread of liver volumes was found (mean f:1496.4±486.1ml, m:1746.0±571.2ml, total 1647.2±552.7ml). Of all extracted landmark pairs, a high correlation was found between the distance vertebral body th6-l5 and l1-l5 (m/f: r=0.83/0.87) and liver volume. The high correlation between liver volume normalized by the th6-l5 distance and liver volume itself confirms that the normalization step preserves the information (r=0.97/0.95). In parallel, a 68% drop of the quartile coefficient of dispersion using this landmark pair illustrates the highest reduction of the variability within the normalized volume among all available landmarks

CONCLUSION

The large variance of non-normalized liver volumes illustrates the limited potential of liver volume as a measure of disease. The distance between th6 and l5 is a valid candidate for normalization since the thus normalized volume shows little loss of information while reducing substantially the variability

CLINICAL RELEVANCE/APPLICATION

Automatically derived imaging-based reference values, very much comparable to current laboratory medicine, may be helpful to classify an organ as normal or pathological. In future research, the pathological value of thus extracted normalized volumes will be further elucidated.

SSM08-04 Comparison of Magnetic Resonance Elastography and Ultrasound Shear Wave Elastography for Long-Term Monitoring of Direct Antiviral HCV-Treatment

PURPOSE

Direct antiviral treatment of chronic hepatitis C virus (HCV) induced liver fibrosis is associated with viscoelastic tissue changes. The purpose of this prospective study is to non-invasively monitor treatment-related liver elasticity changes in HCV-patients over a period of 15 months using magnetic resonance elastography (MRE) and shear wave elastography (SWE).

METHOD AND MATERIALS

In this prospective study a total of 54 MRE/SWE examinations of the liver was performed in 15 patients with chronic HCV infection and biopsy proven liver fibrosis. Patients were treated daily over 3 months with direct-acting antivirals (Daclatasvir/Sofosbuvir). MRE/SWE and laboratory results were obtained at baseline and during a follow-up period after therapy at 3, 6 and 15 months. The results were compared to a healthy control group (CTR, n=7). Multifrequency MRE (1.5 T scanner, Siemens) with tomoelastography postprocessing was performed at 4 frequencies from 30 to 60 Hz. SWE (Aplio500, Canon Medical Systems) based on an ultrasonic burst captured by a 5 MHz convex broadband transducer was employed. Shear wave speed (SWS), reflecting tissue stiffness, was obtained from both MRE and SWE and compared to each other.

RESULTS

Mean time point to reach undetectable viral RNA was 22±13 days. Analysis of repeated measurements of MRE and SWE showed a significant decrease in liver SWS at 6 months (1.56±0.27 m/s; 1.62±0.36 m/s; $p<0.01$) compared to baseline (1.67±0.33 m/s; 2.09±0.68 m/s), being stable at 15 months (1.55±0.26 m/s; 1.63±0.34 m/s; $p<0.05$). Compared to CTR (MRE, 1.36 m/s; SWE, 1.48±0.23 m/s), the patient group showed higher values at baseline and after 3 months (patients vs. CTR: baseline, $p<0.01$; 3 months, $p<0.05$). SWS values from MRE and SWE were highly correlated ($r=0.8$; $p<0.000.1$).

CONCLUSION

Changes in liver stiffness after viral clearance were related to reduction in the inflammatory response. Both, MRE and SWE are sensitive in detecting early changes in hepatic stiffness after direct antiviral treatment.

CLINICAL RELEVANCE/APPLICATION

Mechanical properties obtained from both techniques could be used as non-invasive biomarker for novel antiviral HCV-treatment.

SSM08-05 Individuals with NAFLD Show Stronger Improvements in Liver Function and Insulin Sensitivity Than Individuals without NAFLD upon Dietary Weight Loss

PURPOSE

Non-alcoholic fatty liver disease (NAFLD) is a driver of insulin resistance and metabolic diseases. The presence or absence of NAFLD in obesity may in part explain the phenomena of metabolically healthy vs. unhealthy obesity. Here, we tested whether individuals with NAFLD at baseline show stronger metabolic improvements upon dietary weight loss with regard to liver function and insulin sensitivity than individuals without NAFLD.

METHOD AND MATERIALS

We used data of the HELENA-Trial, an RCT among 143 non-smokers with BMIs between 25 and 40 kg/m2 at baseline (50 % female). The participants underwent a three-month dietary intervention that induced moderate weight loss (5.0±4.3% on average). MRI-derived liver fat content before and after the intervention was evaluated on a post-processing software (OsiriX, Pixmeo SARL, Bernex, Switzerland) manually using the proton density fat fraction map, based on mean counts from three identical regions of interest. Liver fat values >5.56 % were classified as NAFLD.

RESULTS

Overall, 52.4% of the study participants had NAFLD at baseline; 73.3% of those with NAFLD and 47.1 % of those without NAFLD were obese (BMI values >30 kg/m2). Mean age was 50.0±8.1 years among participants with NAFLD, and 50.1±8.1 years among participants without NAFLD. The prevalence of NAFLD was higher among men (61.1%) then women (43.6%). Diet-induced weight loss was similar in both groups (NAFLD: -5.0±0.6%, No NAFLD: -5.3±0.5%), while the relative decrease in liver fat was significantly greater in the NAFLD group (-50.1±5.7% vs. -11.9±4.2%). Relative decreases in liver function tests (GGT, ALT, AST) and HOMA-IR were also significantly stronger in the NAFLD group. Other metabolic parameters (blood lipids, adipokines, CRP) showed no significant differences between the groups.

CONCLUSION

Our data suggest that individuals with NAFLD show stronger improvements of liver function and insulin sensitivity with moderate diet-induced weight loss than individuals without NAFLD.

CLINICAL RELEVANCE/APPLICATION

With increasing incidence of obesity also NAFLD is increasing. NAFLD is an important entity as it can progress in NASH and advanced liver disease and therefore intervention to stop development of NAFLD and NASH is crucial.

SSM08-06 Association Between 3D Radiomic Features and Size of Hepatic Metastasis in Breast Cancer

Wednesday, Nov. 28 3:50PM - 4:00PM Room: S502AB

Participants
Yuri Velichko, PhD, Chicago, IL (*Presenter*) Nothing to Disclose
Amirhossein Mozafarykhamseh, MD, Chicago, IL (*Abstract Co-Author*) Grant, Siemens AG
Tugce Agirlar Trabzonlu, MD, Chicago, IL (*Abstract Co-Author*) Grant, Siemens AG
Zhuoli Zhang, MD,PhD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
Vahid Yaghmai, MD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the effect of the size of the hepatic metastasis in patients with breast cancer on 3D radiomic imaging features.

METHOD AND MATERIALS

This HIPAA compliant retrospective study was IRB approved. CT scans of 81 liver metastases from 54 patients with breast cancer were evaluated. To exclude imaging variability, the same CT scanner and imaging protocol were used. 3D radiomic features from the histogram and gray level co-occurrence matrix (GLCM) categories were calculated for the normal liver and hepatic metastasis. The effect of size (tumor volume) was evaluated by using linear mixed-effects regression models with variable slopes and intercepts. The tumor size and the treatment period were considered as independent variables. If the slope of the regression was significantly ($P < 0.05$) different between the normal liver and hepatic metastasis, then the effect of the size was considered to be significant.

RESULTS

3D radiomic features from GLCM demonstrate tumor-size dependence. In particular, Homogeneity (log model, $P < 0.001$), Energy

(power model, P < 0.03), Contrast (power model, P < 0.001), Correlation (log model, P < 0.001), Entropy (log model, P < 0.024) and Dissimilarity (power model, P < 0.001) show statistically significant size dependence.

CONCLUSION

Radiomic imaging features from the major texture feature category demonstrate statistically significant size dependence in breast cancer hepatic metastasis. This finding demonstrates the complex behavior of imaging features and the need to include feature specific properties into radiomic models.

CLINICAL RELEVANCE/APPLICATION

Radiomic features of breast cancer hepatic metastasis may be affected by tumor size. Caution should be exercised when directly comparing radiomic features of different size tumors.

PURPOSE

To evaluate the correlation between tumor differentiation or stage of gallbladder cancer (GBC) and the apparent diffusion coefficient (ADC), as well as to assess whether ADC value can predict long-term disease-free survival (DFS) after surgery.

METHOD AND MATERIALS

This retrospective study was approved by the Institutional Review Board and the requirement for informed consent was waived. Between March 2008 and June 2016, 79 patients who underwent magnetic resonance (MR) imaging with diffusion-weighted image and subsequent surgery for GBC were included in this study. Correlations between quantitative ADC values, and tumor differentiation or stage based on the American Joint Committee on Cancer (AJCC) were assessed using Spearman's correlation analysis. Prognostic factors for DFS were identified with multivariate Cox regression analysis using imaging and clinical characteristics.

RESULTS

All patients were classified as having well- (n = 18), moderately- (n = 35), or poorly-differentiated GBCs (n = 26). The ADC value of GBCs was significantly correlated with tumor differentiation and AJCC stage ($p < 0.001$ and $p < 0.001$, respectively). Sixty nine patients were followed up for 2.0-92.4 months (median, 23.5 months). On multivariate analysis, the significant prognostic factor for DFS was not tumor differentiation or AJCC stage, but a binary tumor ADC value (hazard ratio, 4.29, $p = 0.009$).

CONCLUSION

The ADC value of GBCs was significantly correlated with tumor differentiation as well as AJCC stage. In addition, it predicted long-term outcomes after surgery in patients with GBC.

CLINICAL RELEVANCE/APPLICATION

Tumor recurrence after curative surgical resection in patients with GBC could be predicted by using ADC values on diffusion-weighted images preoperatively.

SSM09-02 Is the MR Contrast Agent Gadoxetate Disodium Suitable for CT Cholangiography?

Wednesday, Nov. 28 3:10PM - 3:20PM Room: S503AB

PURPOSE

Gadoxetate disodium (Eovist®), a Gadolinium-based contrast agent, is primarily used in MR, with an FDA approved dose limit of 0.1 mL/kg. The purpose of this work is to determine whether low doses of gadoxetate disodium can be visualized for CT cholangiography using a phantom setup.

METHOD AND MATERIALS

Vials containing four concentrations of gadoxetate disodium (9.6, 4.8, 3.4, and 1.9mgGd/ml) were placed in a 35x26cm2 water phantom and imaged on two CT scanners: Siemens Somatom Flash and Force (Siemens Healthcare, Erlangen, Germany). These concentrations correspond to the dose limit for a 200, 100, 70, 40kg patient, respectively. Single-energy (SE) scans were acquired at 70, 80, 90, 100, 120, and 140kVp. Dual-energy (DE) scans were acquired at 90/150Sn (Force) and 100/150 (Flash) for two dose levels (13 and 23 mGy). Virtual monoenergetic images at 50keV were created (Mono+, Siemens). The mean intensity and standard deviation for each concentration of gadoxetate disodium and the water background were extracted from each image set. To determine whether the signal provided by gadoxetate disodium was sufficient for clinical imaging, the contrast, noise, and contrast-to-noise ratio (CNR) were compared to measurements acquired from 12 clinical CT cholangiography exams performed with iodine-containing iodipamide meglumine.

RESULTS

From the retrospective clinical cohort, mean contrast (± standard deviation) of 239±107HU and CNR of 12.8±4.2 were found in the bile duct relative to the liver. Comparing these metrics to the gadoxetate disodium samples, the highest concentration (9.6mgGd/ml) surpassed these thresholds at all energy levels. The 4.8mgGd/ml had sufficient CNR in the Force, but not in the Flash. The 3.4mgGd/ml had clinically relevant CNR at low kV of SE (<100kVp) and 50 keV of DE in the Force but was insufficient in the Flash. Images acquired by the Force had a lower noise level and greater CNR compared to the Flash. Similar trends were seen at both dose levels.

CONCLUSION

Gadoxetate disodium shows promise as a viable contrast agent for CT cholangiography, with CNR similar to those seen clinically with an iodine-based contrast agent. DE CT or low kV SE CT is helpful to enhance the signal.

CLINICAL RELEVANCE/APPLICATION

Gadoxetate disodium, a Gadolinium-based hepatobiliary contrast agent, shows promise as a CT cholangiography contrast agent with contrast-to-noise ratios similar to iodine contrast-enhanced CT.

James Lovato, Winston-Salem, NC (*Abstract Co-Author*) Nothing to Disclose
David D. Childs, MD, Clemmons, NC (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To compare the diagnostic accuracy and relative value of CT and ultrasound (US) in the workup of cholecystitis in adult emergency department (ED) patients.

METHOD AND MATERIALS

A retrospective chart review conducted over a 5 year period identified adult ED encounters for right upper quadrant pain where patients were evaluated with CT and/or US. Those with prior cholecystectomy, current pregnancy, and acute trauma were excluded. Imaging studies were assessed for the reported presence of gallstones, gallbladder distension, wall thickening, and pericholecystic fluid/inflammation. A positive suspicion for cholecystitis required at least two findings, or a positive sonographic Murphy's sign with at least one additional finding. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated for each modality based on linked clinical, surgical, and pathology data. When both US and CT were performed, the second modality was determined to add value if it correctly identified cholecystitis when the first study was incorrect or provided a non-gallbladder alternative diagnosis for acute abdominal pain. The second study was determined to detract value if it was incorrectly positive or negative for cholecystitis when the first study was correct.

RESULTS

3495 ED encounters were reviewed, with 2859 meeting inclusion criteria. 91% of patients had one or more imaging studies performed, with US performed in 81%, CT performed in 30%, and both US and CT performed in 20%. 559 patients went on to cholecystectomy with pathology results available for 540. For US and CT, respectively: sensitivity 48% and 53%, specificity 93% and 93%, PPV 65% and 58%, and NPV 88% and 92%. Only NPV represented a statistically significant difference. When performed after CT, US added value in 8% and detracted value in 6% of cases. When performed after US, CT added value in 35% and detracted value in 2% of cases.

CONCLUSION

In this patient cohort, imaging diagnosis of cholecystitis by CT was non-inferior to the more commonly utilized gold standard of US. There was also little added value for use of US after already obtaining a CT.

CLINICAL RELEVANCE/APPLICATION

CT performance in the diagnosis of cholecystitis is essentially equivalent to ultrasound and has an advantage in supplying additional information for adult ED patients presenting with right upper quadrant pain.

SSM09-04 Development and Validation of Deep Learning Based Clinical Decision Supporting System for the Diagnosis of Neoplastic Gallbladder Polyps Using High Resolution Ultrasonography: Preliminary Results

PURPOSE

To investigate the added value of the deep learning based clinical decision supporting system for the differential diagnosis of neoplastic gallbladder (GB) polyps using high resolution ultrasonography (HRUS)

METHOD AND MATERIALS

We retrospectively collected 337 patients with GB polyps (>4 mm) proved by cholecystectomy. They were divided into training set (239 patients) and test set (98 patients) according to the time period. Based on pathology, all images of polyps (neoplastic: 1822 images in 137 patients, non-neoplastic: 2058 images in 200 patients) were manually cropped into a square box containing the polyp and labeled as either neoplastic or non-neoplastic. The binary classification convolutional neural network model was constructed by transfer learning based on Inception-v3 architecture. Using test set, two radiologists with different experience level, retrospectively graded the possibility of neoplastic polyp using a 5-point confident scale. After providing model's probability value on the test set for each patient, reviewers requested to re-evaluate the grade. Diagnostic performances were measured by ROC analysis and sensitivity, specificity, and accuracy were calculated.

RESULTS

For the diagnosis of neoplastic polyp, model itself provided AUC 0.920, sensitivity 82.1%, specificity 88.1%, accuracy 85.4% with optimal cut off >0.503 in training set and AUC 0.903, sensitivity 80.5%, specificity 85.3%, accuracy 82.8% with optimal cut off >0.726 in test set. On the first review, highly and less experienced reviewers showed AUC 0.944 and 0.775; sensitivity 88.6% and 71.4%; specificity 85.7% and 68.2%; accuracy 86.7% and 69.4%, respectively. On the second review with the supporting system, less experienced reviewer's AUC was improved from 0.775 to 0.859 (p=0.0513), whereas, highly experienced reviewer's AUC showed no significant change (0.944 to 0.940).

CONCLUSION

Our preliminary results suggest that deep learning based clinical decision supporting system for differential diagnosis of neoplastic GB polyp is helpful for improving diagnostic performance, especially in less experienced readers.

CLINICAL RELEVANCE/APPLICATION

Differential diagnosis of neoplastic GB polyp is important as it has a malignant potential. Our decision supporting system can improve the diagnostic performance of radiologists using HRUS.

SSM09-05 Differentiation Between Gallbladder Premalignant or Malignant Polyps and Cholesterol Polyps Using Contrast-Enhanced Ultrasound: Preliminary Study

PURPOSE

To differentiate between gallbladder (GB) premalignant or malignant polyps and cholesterol polyps using contrast-enhanced

ultrasound (CEUS).

METHOD AND MATERIALS

From September 2017 to March 2018, 20 patients with large GB polyps (>= 1 cm) who were scheduled to undergo cholecystectomy were prospectively enrolled. All patients underwent conventional US including color Doppler and CEUS prior to surgery. CEUS was performed using a LOGIQ E9 US scanner (GE Healthcare) after an injection of 2.5 ml of SonoVue® for 1 minute. After CEUS, perfusion US parameters including peak enhancement, mean transit time, fall time (FT), wash-in rate (WiR), and wash-out rate (WoR) were obtained using VueBox® software. Patients were separately classified into the cholesterol polyp group (n = 6) and premalignant or malignant polyp group (n = 14) according to the final histopathology. All US features and quantitative CEUS parameters between the two groups were compared using the Mann-Whitney U test. Diagnostic performances of the parameters were assessed using receiver operating characteristic (ROC) analysis.

RESULTS

Among US imaging features, there were significant differences in lesion size (2.20 cm for adenomatous polyps and 1.18 cm for cholesterol polyps) and internal homogeneity between the two groups (P<0.05); internal homogeneity was more commonly found in cholesterol polyps (5/6, 83%) than in malignant polyps (4/14, 28%). On quantitative analysis of CEUS parameters, FT and WoR demonstrated significant differences between the two groups (P<0.05), i.e., premalignant or malignant polyps showed significantly longer FT (12.74 sec) and smaller WoR (183.3 arbitrary units [a.u]) than cholesterol polyps (5.37 sec and 1068.3 a.u). On ROC analysis, an area under the curve (AUC) of 1.00, 100% (14/14) sensitivity, and 100% (4/4) specificity were demonstrated when the cut-off value was set at 9.62 sec for FT; and WoR yielded an AUC of 0.89, sensitivity of 100% (14/14), and a specificity of 75% (3/4) using a cut-off value of 784.4 a.u.

CONCLUSION

CEUS can be useful for the differentiation of premalignant or malignant GB polyps from cholesterol polyps >= 1 cm.

CLINICAL RELEVANCE/APPLICATION

CEUS can help distinguish premalignant or malignant GB polyps from cholesterol polyps >= 1 cm, thereby aiding in the selection of an optimal management option for large GB polyps.

SSM09-06 Fully Automated Detection of Primary Sclerosing Cholangitis (PSC) in 3D-MRCP Images Using Deep Learning

Wednesday, Nov. 28 3:50PM - 4:00PM Room: S503AB

Participants
Hinrich B. Winther, MD, Hannover, Germany (*Presenter*) Nothing to Disclose
Van Dai Vo Chieu, MD, Hannover, Germany (*Abstract Co-Author*) Nothing to Disclose
Christian Hundt, DIPLPHYS,PhD, Mainz, Germany (*Abstract Co-Author*) Nothing to Disclose

Frank K. Wacker, MD, Hannover, Germany (*Abstract Co-Author*) Nothing to Disclose
Kristina I. Ringe, MD, Hannover, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To automatically detect PSC-typical cholangiographic changes in 3D-MRCP images.

METHOD AND MATERIALS

428 patients (m = 274 / w = 154, age 42.5 ± 18.5 years) who underwent liver MRI including 3D MRCP were included in this retrospective study. The study population consisted of 206 patients with confirmed PSC (based on clinical, typical cholangiographic and confirmatory histologic findings) and 222 patients in whom this diagnosis was excluded. The patients were randomized into a training (n = 386) and validation group (n = 42). For each individual case, 20 uniformly distributed axial MRCP rotations, covering a total of 180°, were calculated, followed by a maximum intensity projection (MIP). This resulted in a training record of 7720 and a validation record of 840 2D images. An Inception ResNet (Inception-v4 arXiv: 1602.07261) was trained, which was initialized with weights previously learned from ImageNet. Finally, we fine-tuned the entire network with a small learning rate of 10-5.

RESULTS

The mean absolute error (MAE) on the validation record was 30% and therefore insufficient. This value could be improved to 7.1% (3/42) by applying an ensemble strategy. For this purpose, the 20 related MRCP projections of each patient were binned and a majority vote was conducted. With this approach, sensitivity, specificity, positive predictive and negative predictive value for the detection of PSC-typical cholangiographic changes were 95.0%, 90.9%, 90.5%, and 95.2% respectively.

CONCLUSION

The results of this study demonstrate the feasibility of transfer learning to detect PSC-typical cholangiographic changes in 3D MRCP images with an MAE of ~7%. Further validation with more and multicentric data should be made, as experience shows that neural networks tend to overfit the characteristics of the dataset.

CLINICAL RELEVANCE/APPLICATION

Automatic detection of PSC typical changes at MRCP may improve early detection and aid in follow-up imaging, especially of subtle changes.

chengfang@nhs.net

PURPOSE

To assess the additional benefit of microbubble ultrasound contrast agents (UCA) over conventional ultrasonography (US) to differentiate between neoplastic and non-neoplastic intra-testicular abnormalities among observers with various levels of experience in contrast enhanced ultrasound (CEUS).

METHOD AND MATERIALS

Seven blinded observers divided into experienced (n=3, 7-9 years experience) and inexperienced groups (n=4, 2-3 years experience) retrospectively reviewed testicular B-mode/color Doppler images and repeated this one month later with the addition of CEUS images. Observers rated each testicular lesion on a 5-point scale: 1-definitely non-neoplastic; 2-likely non-neoplastic; 3-don't know; 4-likely neoplastic; 5-definitely neoplastic. Electronic medical records were reviewed for histological results (n=59) and follow up US (n=32). Inter-observer agreement was calculated using kappa statistics and AUROC/Sensitivity/Specificity compared using McNemar test.

RESULTS

Ninety patients with 91 lesions, neoplastic (n=46) and non-neoplastic (n=45), were accessed from a database from 2008-2013. Overall, specificity (73.7% vs 54.9%, p<0.001), PPV (77.6% vs 67.8%, p=0.001), accuracy (81.6% vs 74.1%, p<0.001) were better with the addition of UCA, at the expense of slightly reduced sensitivity (89.4% vs 92.3%, p=0.04). Subgroup analysis showed that the addition of CEUS images significantly improved diagnostic specificity and accuracy for both experienced (Specificity: 71.1% vs 59.3%, P=0.005; Accuracy: 83.5% vs 76.9%, P=0.003) and inexperienced reader groups (Specificity: 75.6% vs 51.7%, p=0.005; Accuracy: 80.2% vs 72.0%, P<0.001). Significant inter-observer variability between experienced and inexperienced observer groups were observed for conventional US (Kappa 0.51 vs 0.68 respectively; p=0.03), but this was not detected with the additional of CEUS (Kappa 0.60 vs 0.69 respectively; p=0.24).

CONCLUSION

The addition of CEUS not only significantly improves the accuracy of subjective interpretation for both experienced and inexperienced blinded observers, but also eliminates variability between the two observer groups with different experiences.

CLINICAL RELEVANCE/APPLICATION

The use of CEUS in addition to conventional US improves diagnostic accuracy of differentiating neoplastic and non-neoplastic

intratesticular lesion, potentially reducing unnecessary orchidectomies.

SSM10-02 Cause of Avascular Hypoechoic Testicular Lesions Detected at Scrotal Color Doppler Ultrasound: Can They Be Considered Benign? Correlation with Histological, Clinical and Contrast-Enhanced Ultrasound (CEUS) Imaging Findings

dean.huang@nhs.net

PURPOSE

The purposes of this study were to determine the cause of avascular lesions detected at scrotal color Doppler ultrasound (CDUS) with histological and clinical correlations and to assess the added value of contrast-enhanced ultrasound (CEUS) in identifying benign testicular lesions.

METHOD AND MATERIALS

This retrospective study included 113 focal testicular lesions detected with CDUS and further assessed with CEUS. The sonographic features recorded were lesion size, the presence of focal calcification, and presence or absence of vascularity on CEUS. Also recorded were patient age, symptoms, and levels of serum tumor markers. The reference standard was histopathologic results or at least at least 6 months documented stability with serial follow-ups. Sonographic and clinical features associated with malignant, including 'burnt-out' tumors, and benign lesions were examined.

RESULTS

Of the 113 avascular lesions on CDUS, 6 (5.3%) were malignant and 107 (94.6%) were benign. 2 of the 6 patients (33.3%) with malignant lesions had elevated serum tumor marker levels. Histologically, malignant lesions include mixed germ cell tumors and 'burnt-out' tumors with metastatic lymphadenopathy. The size of a lesion or presence of calcification were not significantly associated with either the benign or the malignant nature of a lesion. 18 lesions (17.6%) showed enhancement on CEUS despite lack of signal on CDUS. Enhancement was demonstrated on CEUS in all 6 of the 6 malignant lesions (100%). The remaining lesions which demonstrated enhancement on CEUS include pathologies such as sarcoidosis, post-biopsy change, intra-testicular adenomatoid tumour, focal scarring with history of previous orchiopexy, and focal atrophy in a patient with Klinefelter syndrome. All 95 of 95 lesions with no enhancement on CEUS were of benign nature.

CONCLUSION

Although most avascular testicular lesions on CDUS are benign, our experience suggests that caution should be made in assuming benignity when a testicular lesion demonstrates no vascularity on CDUS. A proportion of these lesions are malignant and demonstrate vascularity with CEUS, which could improve diagnostic confidence for the benign nature of testicular pathologies.

CLINICAL RELEVANCE/APPLICATION

Caution should be made in assuming benignity lesions demonstrate no vascularity on CDUS. CEUS improves detection of vascularity and adds value to conventional CDUS in assessing testicular lesions.

SSM10-03 The Audiovisual Sexual Stimulation during Penile Duplex-Doppler Ultrasound: Is it a Tool to Avoid False-Positive Diagnostic of Venous Leak?

Wednesday, Nov. 28 3:20PM - 3:30PM Room: E353A

drcarneiro91@gmail.com

PURPOSE

Erection is a neurovascular phenomenon under hormonal control. It involves arterial dilatation, trabecular smooth muscle relaxation and activation of the corporeal veno-occlusive mechanism. Penile Duplex-Doppler ultrasound (PDDU) with intracavernous injection (ICI) is the first-line diagnostic modality used to determine the subtype of vasculogenic erectile dysfunction (ED). Unfortunately, anxiety and other psychological inhibitions may hinder the optimal response of cavernous arteries relaxation imparing the veno-occlusive mechanism leading to possible false venous leak diagnostic. Several methods to assist PDDU in order to avoid false-positive results have been suggested, including audiovisual sexual stimulation (AVSS). The purpose of the present study is to assess the use of AVSS in combination with PDDU in vasculogenic ED.

METHOD AND MATERIALS

Prospective study on adult patients with ED that were referred to PDDU by Urology Department. Twenty seven men (mean age =

62.7 years, range 26 to 80 years) were enrolled in the study. Each patient underwent 2 PDDU sessions. During session 1, patients were injected with ICI (20 µg of alprostadil) and after 5 minutes submitted to PDDU. During session 2, after the ICI injection, patients watched a 4 minute erotic movie before PDDU. The interval between the 2 sessions was 7 days. Cavernous artery flow was considered normal when peak systolic velocity (PSV) was >30 cm/s, while the corporeal veno-occlusive function was considered normal when ending diastolic velocity (EDV) was <5 cm/s) and resistant index (IR) >0.9. Penile vascular parameters were monitored and recorded before ICI administration, and 5, 10, 15 and 20 min after ICI.

RESULTS

The mean cavernous artery diameter was higher in session 2 (p = 0.003). The mean cavernous artery systolic velocity was higher in session 2 in the moment 15 and 20 minute (p= 0.022 and p= 0.026). The mean artery resistant index was higher in session 2 in the moment 15 minute (p = 0.043).

CONCLUSION

The AVSS improves smooth muscle relaxation of cavernous arteries and penile blood flow. Therefore, it is a good tool to avoid false-positive diagnostic of venous leak.

CLINICAL RELEVANCE/APPLICATION

AVSS during PDDU with ICI can improve penile blood flow and is recommended in all cases manly on anxious patients. The real venous leak has bad prognosis but the psicogenic ED (false venous leak) can be treated clinically. Diferenciate both is mandatory.

SSM10-04 Can Shear Wave Elastography of Endometrial and Subendometrial Lesions Provide Additive Information: Initial Experience

Wednesday, Nov. 28 3:30PM - 3:40PM Room: E353A

PURPOSE

-Evaluate the normal sono-elastographic characteristics of endometrium and its variability with menstrual phase-Investigate the role of Shear Wave Elastography (SWE) in distinguishing benign and malignant endometrial and subendometrial masses.

METHOD AND MATERIALS

A total of 110 women were enrolled in this ethically approved prospective study, and they were divided into two groups:Group I-55 women with pathologically proven endometrial masses, including 27 cases of endometrial carcinoma, and 28 cases of benign lesions (9-endometrial hyperplasia, 5-endometrial polyp and 5-focal adenomyoma, 9-submucosal fibroid)Group II- 56 women with normal endometrium (14 women each in menstrual, proliferative, secretory and post-menopausal phase)All patients underwent transvaginal ultrasound including B-mode and real time SWE (SuperSonic Aixplorer ultrasound system). The variability of mean elasticity value (in kPa) of endometrium in different menstrual phases and the difference in elasticity value of normal endometrium and various pathological sub-groups in Group I was analysed.

RESULTS

Normal endometrium (n=56) showed a mean elasticity value of 25.54 ± 8.56 kPa. There was no significant difference (p-0.227) in the mean elasticity value in women in different menstrual phases. In the evaluation of endometrial and subendometrial pathologies, the mean elasticity values of submucosal fibroid, focal adenomyoma and polyp were significantly (p<0.01) different from normal endometrium. However, there was no significant difference in the elasticity value of normal endometrium versus carcinoma (p-0.276), and carcinoma versus hyperplasia (p-0.191).

CONCLUSION

SWE is not useful to distinguish normal endometrium from hyperplasia or carcinoma. However, significantly different elasticity values obtained in case of submucosal fibroid, endometrial polyp and focal adenomyoma can be useful in confidently diagnosing these pathologies.

CLINICAL RELEVANCE/APPLICATION

This study shows that SWE, as an adjunct to ultrasound may play a role to increase the specificity of diagnosis of certain endometrial pathologies like submucosal fibroid and endometrial polyp and help to appropriately triage patients for more invasive testing. However, it is not a reliable tool to distinguish normal endometrium from carcinoma or hyperplasia.

SSM10-05 Diagnostic Pitfall for Early Complete Hydatidiform Mole by Transvaginal Ultrasound: A Large Cohort Study

PURPOSE

With the availability of hCG and transvaginal ultrasound, CHM diagnosis is typically made in the first trimester, rather than in the second trimester over the past two decades, which makes the difficulty of correct diagnose due to the lack of understanding about early features. In our study, we revealed sonographic features of early CHM in large cohort study, to improve the diagnose accuracy.

METHOD AND MATERIALS

This study included 337 retrospective and 182 prospective cases of histologically proven CHM in the first trimester in our institute 2003 to 2017. In additional, 519 missed abortion patients were matched with CHM cases on ultrasound scan date. The data were recorded: age, gestational age, the serum hCG level before evacuation, the sonographic features (the length, width and anteroposterior diameter of uterus and cavity mass, the extent of vesicular area, lutein ovarian cyst). The volume was calculated using the prolate ellipsoid formula. The software used for statistical analysis was SPSS 19.0 for Mac.

RESULTS

Among all CHM cases (mean gestational age 64.2±7.2 days), 335 cases (64.5%) were correctly diagnosed on the basis of the initial sonographic examination, but almost (94.6%, 105/112) cases of gestational age <42 days could not be made a definitive diagnose. Compared with missed abortion, the higher serum hCG level, the larger volume of uterus and cavity mass, the more severe extent of vesicular area were the significant index for CHM (all $p<0.05$). However, on the time scale of gestational age, the 95% confidence interval of four index in CHM overlapped with missed abortion group at the certain time points (such as before 42 days). Thus, it was hard to distinguish two entities in very early pregnancy by initial ultrasound exam. Among the 184 suspicious cases, 104 cases made a second scan 7 days later, the volume of cavity mass in CHM (42 cases) increased 2.3±0.9 fold, significantly higher than 1.6±1.0 fold in the missed abortion group (62 cases) ($p<0.05$)

CONCLUSION

The ultrasound diagnostic pitfall exists in early CHM, especially in the gestational age <42 days. For the case with suspicious findings in the initial ultrasound, the second scan after 7 days could help to improve the diagnose power for early CHM.

CLINICAL RELEVANCE/APPLICATION

The second ultrasound scan after 7 days is an easy method to improve the diagnose power for early CHM on the cases with suspicious findings in the initial exam.

SSM10-06 Sonographic Detection of Ovarian Cancer in Adnexal Cysts: Comparing IOTA Simple Rules, SRU Guidelines, and Original Radiologists' Interpretation

Wednesday, Nov. 28 3:50PM - 4:00PM Room: E353A

esadowski@uwhealth.org

PURPOSE

To evaluate the performance of the IOTA group simple rules, the SRU consensus statement guideline criteria and the original radiologist's report for detecting ovarian malignancy in women with adnexal cystic lesions presenting to academic radiology departments.

METHOD AND MATERIALS

An IRB-approved retrospective multicenter cohort study of ultrasound-detected adnexal cystic lesions with appropriate follow up was conducted. Lesions were classified into benign, indeterminate, or malignant categories according to criteria based on the IOTA simple rules, SRU guidelines and the original radiologist's report. The prevalence of non-neoplastic cysts, neoplasms, and malignant tumors was calculated. Sensitivity, specificity, positive predictive values (PPV), negative predictive values (NPV), accuracy and ROC analysis for the diagnosis of malignancy were performed.

RESULTS

697 women with 764 cystic lesions were included: 85.2% (651/764) were non-neoplastic, 12.2% (93/764) were benign neoplasms and 2.6% (20/764) were malignant. Nearly all malignancies were classified by imaging into indeterminate (7-10/20) or malignant (10-13/20) categories. The sensitivity/specificity/PPV/NPV/accuracy for malignancy were: IOTA = 90%/96.5%/29%/99.8%/96.4%, SRU = 100%/89.6%/14.9%/100%/89.8% and radiologist's report = 100%/82%/7.6%/100%/82.3%. From the ROC analysis, the performance of both the IOTA simple rules and SRU guidelines was superior to the original radiologist's report ($p<0.0001$).

CONCLUSION

All imaging classification methods evaluated were sensitive for identifying potential ovarian malignancies on ultrasound. Nearly all malignancies were classified into the malignant or indeterminate imaging categories. The PPV was low in a general population of women presenting to academic radiology departments and the appropriate management of indeterminate cystic lesions remains an open question warranting further investigation.

CLINICAL RELEVANCE/APPLICATION

Image-based classification systems are sensitive in detecting ovarian cancer; the PPV is low in our patient cohort and considering other clinical/imaging data may improve the PPV.

SSM11-02 The Value of Real Time Thoracic Radiology Consulting in an Integrated Lung Center Clinic: Bringing the Radiologist to the Center of Multidisciplinary Health Care

Wednesday, Nov. 28 3:10PM - 3:20PM Room: S403B

Participants
Eduardo J. Mortani Barbosa JR, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose
Sean Novak, MD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

We have established an integrated thoracic radiology reading room within a multidisciplinary Lung Center clinic (LC). While our subjective experience has been positive, we sought to quantify how this model affects radiology workflow and whether the referring practitioners perceive value in having real time access to a radiologist consultant

METHOD AND MATERIALS

One attending thoracic radiologist and one trainee continuously staffed the LC on regular work hours on a daily schedule. We assessed the impact on workflow by recording over six months the number, duration and type of face-to-face radiology consultations to LC practitioners. We also conducted an anonymous survey to assess how LC practitioners felt regarding the utility and value of our service.

RESULTS

Face-to-face consultations account for an average of 10% of total time spent by radiologists in the LC, though on busy clinical days this can reach 25-30%. Our survey response rate was very high (86.4%, n=51), with overwhelming positive response by referring practitioners, who unanimously rate the usefulness of this service as high (9.8%) or extremely high (90.2%). Not a single respondent had a negative or even neutral view of this service. Moreover, 90.2% thought that radiology consultations directly add clinical value in greater than 60% of episodes, whereas 86.2% responded that these alter management in greater than 40% of episodes.

CONCLUSION

Face-to-face radiology consultations in an integrated LC are numerous and comprise a sizable share of radiologist workload, but are not compensated under the current fee for service payment model. More importantly, the radiologist is highly praised as a consultant and this service is considered valuable and impactful for patient care.

CLINICAL RELEVANCE/APPLICATION

The integrated radiology practice setup we proposed can be implemented in most facilities across the country, however it will be crucial to steer the payment model away from emphasizing volume to emphasizing quality, effectiveness and clinical impact. The radiologist as a consultant is at the same time the future of our specialty and also a return to a past in which the interaction of radiologists and referring practitioners was the foundation of diagnosis and medical decision-making.

SSM11-03 Online-Results in Mammography: Do Patients Really Want to Wait?

kerri.vincenti@uphs.upenn.edu

PURPOSE

According to the American College of Radiology, all women, beginning at the age of 40 years old, should undergo yearly screening mammograms to aid in the detection of clinically occult breast cancers. Most women are contacted with the results of their examinations by postal service or by viewing their electronic medical record. Timing of results varies by institution from same day to several days following exam. Additionally, if an abnormality is detected, patients typically have to schedule additional workup for a later date. At our institution, all patients who undergo a screening mammogram receive online-results (patients wait for a radiologist to provide in-person results prior to leaving the breast center). Additionally, for women who need to undergo additional workup, our practice contacts referring physicians for additional imaging authorizations (if not conditionally ordered) for follow up imaging (diagnostic mammography with or without ultrasound). We aimed to query screening patients in the breast center to determine if the use of same-day and in-person results reduces their reported anxiety level. Additionally, we wanted to increase our understanding of patient preferences with regards to timing of results and who provides the results accounting for various demographic factors such as age, income level and ethnicity.

RESULTS

There were a total of 919 respondents to the survey during the study period. 680 patients completed the survey in its entirety (74%). Of the 680 patients with complete responses, most patients reported that they preferred to wait for results 64% (n = 437). 25% reported that it depended on wait time (n = 168)and only 8% preferred not to wait (n = 51). Most (65%) respondents did not have a preference with who provided results (n =441). For the remaining 239 patients who indicated a preference, the majority (90%) preferred to receive results from an attending or resident physician (n = 214) as opposed to a technologist or nurse. When queried about the prospect of a same-day biopsy, slightly more than half of patients stated that they would prefer a same day procedure (n = 364). Approximately one third of patients indicated that they would not want a biopsy performed on the same day (n = 197). The remaining patients indicated no preference. Most (68%) respondents indicated that their level of anxiety was decreased as a result of receiving same day results (n = 461). Responses did not vary significantly by age, income level, or ethnicity. The majority of patients indicated they preferred yearly mammographic screening (n = 542). Patients ranged in age from 31 to 86, with a median age of 56. The majority of patients were white 70% (n = 475), followed by African American 23% (n = 158), Asian 4% (n = 24), Hispanic 3% (n = 19) and other 1% (n = 4).

CONCLUSION

There are approximately 325,000 new cases of breast cancer diagnosed each year. The use of screening mammography aids in the detection of cancers before they become clinically evident and has been proven to decrease breast cancer mortality by over 30%. The United States Preventative Taskforce (USPTF) has criticized the use of yearly mammograms based on the 'harms of screening' including excess anxiety from false positive results, which includes the need for additional diagnostic imaging to further assess suspected abnormalities. As radiologists, we should aim to improve our practice patterns and workflow to reduce this anxiety when possible. Offering online-results and the opportunity to perform additional tests/interventions has the potential to decrease the degree of anxiety for patients. While this may require additional time on the part of the radiologist to provide results to waiting patients, this model allows patients to engage in face-to-face interactions with radiologists and offers opportunities for patients ask questions and gain a better understanding of their results. For our practice, the use of online-results has allowed radiologists in our breast center provide a service that we believe adds value to the patient care experience.

METHODS

The study was conducted following IRB Waiver for Human Subjects research. Questionnaires were given to all screening patients entering the breast center over a 2 week time period. Closed-ended questions were given related to preferences of wait time and regading who delivered test results. Patients were also asked about whether they preferred a same day biopsy option. Patients were also asked if received same day results reduced their level of anxiety. One question focused on patient preferences regarding how often to be screened with mammography. For demographic information, patients were given a closed-ended question regarding income and open-ended questions for age and ethnicity (sample survey included in PDF). Results were organized in an Excel spreadsheet and responses were coded into ordinal data. Any patients who did not answer all questions on the survey were excluded from analysis.

SSM11-04 A Contemporary Survey of Patient and Referring Physician Preferences for Direct Radiologic Reporting of Results

Wednesday, Nov. 28 3:30PM - 3:40PM Room: S403B

Participants
Janice Thai, MD, Staten Island, NY (*Presenter*) Nothing to Disclose
Raina Josemon, BS, Staten Island, NY (*Abstract Co-Author*) Nothing to Disclose
Shrita Smith, MD, New York, NY (*Abstract Co-Author*) Nothing to Disclose
Jose Morey, MD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose
Arnold Brenner, DO, Staten Island, NY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To identify contemporary preferences of patients and referring physicians for direct patient communication and notification of results by the radiologist.

RESULTS

368 patients completed the survey (39.9% male and 60.1% female). 168 referring physician surveys were completed [surgery (16.7%), pediatrics (18.6%), internal medicine (38.5%), emergency medicine (4.3%), obstetrics and gynecology (7.4%), and other (14.3%)]. Patient preference: 81.5% of patient responders preferred all results communicated from the radiologist within the same day. 65.9% of patients preferred same day results - if normal vs 65.8% if abnormal. 34.5% preferred to wait and review normal results with the referring physician. 41.5% preferred to wait and review abnormal results with the referring physician. It was found

that patients were more likely to strongly agree with waiting to review results with the referring physician if the results were abnormal, as opposed to normal (18.5% vs 11.9%, respectively; P < 0.0141). Physician preference: 36% of referring physicians preferred same day communication by the radiologist to the patient along with a report sent to their office. 12.4% preferred radiology reports to be sent to their office with a summary report sent to the patient. 59% preferred traditional communication with reports sent to their office. Conversely, 64% of physicians did not want results reviewed with their patients; 87.6% did not want a report sent to the patient by the radiologist, even after report was sent to their office.

CONCLUSION

58-82% of patients preferred same day radiologist communication of their results while 55-87.6% of physicians did not prefer same day radiologist communication of results directly with their patients. Our study examined and identified contemporary preferences of patients and their referring physicians regarding direct radiologic reporting of results. This could potentially impact the current movement in radiology towards a patient-centered care model by providing direct access to radiologic reports and direct communication of results by the radiologist.

METHODS

An anonymous survey was conducted between July 2017 and February 2018 of all patients undergoing radiologic imaging studies and their referring physicians. Two survey questionnaires were designed to examine patient and physician preferences for reporting of radiologic results. The surveys consisted of questions related to real time communication of results by the radiologist to the patient. The surveys elicited responses regarding preferences on a 5-point likert scale (Strongly disagree, disagree, neutral, agree and strongly agree), as well as indicated by responding yes or no to specific questions. All categorical variables were summarized using frequency counts and percentages. Comparisons between groups (Gender, age, medical specialty) with respect to responses to questions were analyzed using either the chi-square test or Fisher's exact test. Kappa statistics and Bowker's test of symmetry were used to determine if there was agreement in response within a patient, when examination results were assumed to be 'normal' or 'abnormal'. All statistical tests were two-sided at the alpha=0.05 level of significance.

SSM11-05 A Pilot Trial of a Decentralized General Ultrasound Imaging Consultation Service

Wednesday, Nov. 28 3:40PM - 3:50PM Room: S403B

Participants
Jason C. Birnholz, MD, Delray Beach, FL (*Presenter*) Consultant, Sonoscanner SARL

For information about this presentation, contact:

jbirnholz@gmail.com

PURPOSE

This study concerns the feasibility and utilization of an interactive consultation service provided by a Radiologist equipped with high performance portable ultrasound equipment at selected medical care facilities.

METHOD AND MATERIALS

Facilities selected for 'field testing of a portable ultrasound device with reporting in one or two visits' were a suburban family practice clinic (FPC) providing care for the indigent, a suburban OB/GYN practice (GYN) adjacent to a community hospital, a private Urology clinic (UROL) with associated facilities. A limited number of ultrasound exams performed at patient designated locations (HOME). Limited exams were performed as part of feasibility assessment at a free standing Mammography center and at 3, level III NICU's. Facilities were not informed that full services would be continued on request. Patients were selected by the attending physician; the Radiologist confirmed that ultrasound was appropriate and performed an interactive examination, deciding the extent and content of each session, reporting findingswhile the patient was in the facility. All examinations were performed with a high performance, adjustable, touch screen tablet sized, dynamic beam former instrument with 6 interchangeable, broadband, array transducers. Variable aperture settings enabled 180 degree field of view with the endocavitary probe and transfontanelle imaging with a linear array.

RESULTS

There were 150 patients with 4206 archived static images in the utilization group, characterized by frequency of 12 exam components for each venue. Every requested was able to be performed for all indications. Findings were reported in a context of individual patient management. One or more secondary findings occurred in 52% for GYN, 48% for FPC, 38% for HOME, and 74% for UROL. Each location requested that the service be continued. As the trial progressed, GYN broadened their study indications; UROL did not.

CONCLUSION

Feasibility of high level remote operation was noted in limited but clinically typical, prospective exam conditions. This on-site consultative model had wide diagnostic yield., but utilization of secondary findings varied.

CLINICAL RELEVANCE/APPLICATION

A consultative model warrants further evaluation for planning expanded diagnostic ultrasound coverage for selected patient and practice cohorts.

SSM11-06 Care Integration in Radiology: Screening Mammography Encounters as Opportunities to Improve Lung Cancer Screening Engagement

gxwang@partners.org

PURPOSE

A main barrier to uptake of lung cancer screening (LCS) for primary care providers (PCPs) is difficulty in identifying eligible patients, in part due to incomplete electronic medical record (EMR) data. Screening mammography (SM) is a common point of contact with the healthcare system for women within LCS age criteria. At our institution, detailed smoking history data is collected as a routine part of SM, but is not communicated to PCPs or integrated with the EMR in a way that facilitates its clinical use. We studied whether SM encounters at a community health center can be used to assist PCPs in identifying eligible patients for LCS.

METHOD AND MATERIALS

This IRB approved, HIPAA-compliant, retrospective study was performed at a community health center affiliated with a quaternary care academic medical center. Medical record review was performed of all consecutive SM patent encounters from 1/2018-3/2018 to extract patient demographic data, date of most recent LCS chest CT, and smoking history available prior to SM encounter and history obtained at SM. Determination of LCS eligibility was based on institutional criteria: age 55-77, smoked at least 30 pack-years, and either currently smoking or quit within 15 years.

RESULTS

There were 733 unique patient encounters during the study period. Smoking history was obtained at SM for 611 (83%): there were 75 (12%) current and 169 (28%) former smokers. Among current smokers, 14/75 (19%) met LCS eligibility criteria: 7 (50%) were not enrolled in LCS and 3 (21%) were overdue. 12/169 (7%) former smokers met LCS eligibility criteria: 8 (67%) were not enrolled, none overdue. Smoking status from SM was concordant with EMR data for 353/362 (98%) never smokers, 69/75 (92%) current smokers, and 132/169 (78%) former smokers. Among smokers with concordant smoking status, sufficient data to determine LCS eligibility was only available from SM data and not from EMR for 37/69 (54%) current and 87/132 (66%) former smokers.

CONCLUSION

Smoking history data in the EMR is often insufficient to allow determination of LCS eligibility, and can be supplemented with data obtained at SM. Furthermore, at the time of SM, most eligible patients are either not enrolled or are overdue for LCS.

CLINICAL RELEVANCE/APPLICATION

SM encounters can serve as opportunities to integrate radiology care, provide added value to PCPs, and decrease barriers to LCS participation by identifying eligible smokers for screening engagement.

PURPOSE

To investigate the association between DCE MRI features and tumor infiltrating lymphocytes (TILs) in breast cancer.

METHOD AND MATERIALS

We retrospectively analyzed two breast cancer cohorts, with 126 patients from the cancer genome atlas (TCGA) as discovery cohort and 106 patients from ACRIN 6657/I-SPY 1 TRIAL as validation cohort. 17 computational features were extracted from DCE MRI to characterize functional tumor volume, tumor morphology and texture as well as parenchymal enhancement patterns. The percentage of stromal TILs was evaluated on hematoxylin and eosin stained histologic whole-tumor sections by two experienced pathologists. From tumor molecular data, we computed two markers as surrogates for TILs, including the non-synonymous somatic mutational burden and cytolytic activity score. First, we evaluated the associations between individual DCE-MRI features and TILs read by pathologists. Multiple hypotheses testing was corrected by the Benjamini-Hochberg method using false discovery rate (FDR). Next, we built a composite prediction model for TILs by combining DCE-MRI features with molecular surrogates. Finally, we independently validated the prognostic significance of the built TILs model in the I-SPY cohort.

RESULTS

Four image features were significantly associated with TILs ($P<0.05$ and $FDR<0.2$). Among molecular and clinicopathologic factors, only cytolytic score showed significant correlation with TILs ($\rho=0.51$, 95% confidence interval [CI]: 0.36-0.63). A composite model combining an imaging signature and cytolytic score improved correlation with TILs ($\rho=0.62$, 95% CI: 0.50-0.72). Compared with molecular surrogates as baseline, the composite model showed significant improvement in distinguishing intermediate vs high and low vs high TILs groups, with area under the curve or AUC=0.76 and 0.94, as shown in Fig. 1A and B. In the validation cohort, the predicted TILs separated patients into two groups with distinct recurrence-free survival (log-rank $P=0.0008$) among triple negative breast cancer (Fig. 1C and D).

CONCLUSION

Specific DCE-MRI features of tumor and parenchyma are associated with TILs in breast cancer, and integrating imaging and molecular features may allow better prediction for TILs.

CLINICAL RELEVANCE/APPLICATION

Imaging may play an important role in the evaluation of TILs, by providing key complementary information in equivocal cases or situations that are prone to sampling bias (e.g., in core biopsy).

PURPOSE

This study aimed to develop and validate a radiomics-based nomogram for differentiation of pre-invasive lesions from invasive lesions that manifest as ground-glass nodules (GGNs) <=10 mm (sub-centimeter) in diameter at CT.

METHOD AND MATERIALS

542 consecutive patients with 626 pathologically confirmed pulmonary subcentimeter GGNs were retrospectively studied from October 2011 to September 2017, which were divided into a training-set (n=334) and a validation-set (n=292). Researchers extracted 475 radiomics features from the plain CT images and a radiomics signature was constructed with the least absolute shrinkage and selection operator (LASSO) based on multivariable regression in the training-set. Based on the multivariable logistic regression model, a radiomics nomogram was developed in the training-set. The performance of the nomogram was evaluated with respect to its calibration, discrimination, and clinical-utility and this was assessed in the validation-set.

RESULTS

The constructed radiomics signature, which consisted of 15 radiomics features, was significantly associated with the invasiveness of subcentimeter GGNs (P <0.0001 for both training-set and validation-set). To build the nomogram model Radiomics signature and mean CT value were used. The nomogram model demonstrated good discrimination and calibration in both training-set (C-index, 0.716 [95% CI, 0.632 to 0.801]) and validation-set (C-index, 0.707 [95% CI, 0.625 to 0.788]). Decision curve analysis indicated that radiomics-based nomogram was clinically useful.

CONCLUSION

A radiomics-based nomogram that incorporates both radiomics signature and mean CT value is constructed in the study, which can be conveniently used to facilitate the preoperative individualized prediction of the invasiveness in patients with subcentimeter GGNs.

CLINICAL RELEVANCE/APPLICATION

Using the radiomics nomogram in the current study to predict the invasiveness of subcentimeter GGNs adds more benefit especially with respect to the treat-all scenario or the treat-none scenario, which in meanwhile indicated that this tool could aid in clinical decision making and facilitate the individualized precision medical treatment.

SSM12-03 18F FDG Positron Emission Tomography (PET) Tumor Penumbra Texture Predicts Recurrence in Non-Small Cell Lung Cancer

Wednesday, Nov. 28 3:20PM - 3:30PM Room: E353B

PURPOSE

To identify computational imaging features (radiomics) in the tumor and surrounding area on Fluorodeoxyglucose (FDG) Positron Emission Tomography (PET) that predict time to recurrence in non-small cell lung cancer (NSCLC). We hypothesize that radiomic features can augment traditional metrics of stage and maximum standardized uptake value (SUVmax) to predict recurrence.

METHOD AND MATERIALS

We identified 300 patients with NSCLC from two cohorts acquired between 2008-2016 (training, n=145; validation, n=155). Two

We identified 300 patients with NSCLC from two cohorts acquired between 2008-2010 (training, n=145; validation, n=155). Two observers used commercial software to contour the Metabolic Tumor Volume (MTV) on pre-treatment PET images and added a 3-dimensional penumbra region that extended outward 1cm from the tumor surface. We generated 512 radiomics features from these volumes of interest. We selected features based on robustness to contour variations, and then applied randomized sparse regression (LASSO) to identify features that predicted recurrence in the training cohort. We built a Cox proportional hazards model in the training cohort and independently evaluated the model in the validation cohort.

RESULTS

SUVmax was a significant predictor of recurrence in the training (concordance=0.67, log-rank p<0.001) and validation cohorts (concordance=0.67, Noether's p<0.001). Stage was also a significant predictor in both cohorts (training: concordance=0.68, log-rank p<0.001; validation: concordance=0.70, Noether's p<0.001). The top radiomic feature selected by LASSO was the grey-level co-occurrence matrix maximum probability feature in the union of the MTV and penumbra regions. This texture feature was a significant predictor in the training (concordance=0.66, log-rank p=0.002) and validation cohorts (concordance=0.66, Noether's p<0.001). The radiomic feature integrated with stage and SUVmax significantly improved performance in both cohorts (training: concordance=0.73, log-rank p<0.001; validation: concordance=0.76, Noether's p<0.001), with both stage and texture being significant predictors in the multivariate model. Adding additional radiomic features to the model did not significantly improve performance.

CONCLUSION

A radiomics texture feature in the MTV plus surrounding penumbra improved upon staging and SUVmax for NSCLC recurrence prediction.

CLINICAL RELEVANCE/APPLICATION

PET radiomics may assist clinicians in stratifying patients at a higher risk of recurrence and could be used to recommend more aggressive personalized treatments options.

SSM12-04 Direct Validation of Quantitative MRI Cerebral Perfusion at Rest, Stress and Ischemia

PURPOSE

This study sought to assess the accuracy of a quantitative MRI-based (qMRI) measure of cerebral blood flow (qCBF) against reference stable isotope neutron capture microsphere-based cerebral blood flow quantification in an experimental model during normocapnia, hypercapnia and middle cerebral artery (MCAO)

METHOD AND MATERIALS

Five female, mongrel dogs (20-30 kg) each studied over two days. On day 1, qCBF images acquired during normocapnia (target PaCO2 30-40 mmHg) and hypercapnia (target PaCO2 > 60 mmHg) induced by CO2 gas inhalation (5% CO2/95% O2). On day 2 animals underwent angiographically verified permanent endovascular occlusion of the M1 segment while in a normocapnic state. Anesthesia selected to minimize the influence on cerebrovascular reactivity. Physiologic parameters kept within normal range except for PCO2 for hypercapnia. Microspheres injected at the time of qMRI acquisition to obtain reference-standard CBF values. qMRI acquired on a 3 Tesla unit using a 15-channel receive-only head coil a 'bookend dynamic susceptibility (DSC)' approach, which uses pre- and post-contrast T1 maps bookended to a DSC MRI sequence to calculate parenchymal T1 changes and calibrate the DSC scan for quantitative perfusion in ml/100 g/min. Quantitative T1 maps created using a standard inversion recovery Look-Locker imaging, co-localized to the DSC perfusion scan using a previously reported approach

RESULTS

MRI correlated strongly with microsphere perfusion (qCBFMRI = 0.93*qCBFSPHERES + 3.85 ml/100g/min; r2 = 0.96; p < 0.001), for individual CVR (CVRMRI = 1.17*CVRSPHERES - 0.95 %;CBF/mmHg CO2; r2 = 0.84; p < 0.001), and for post-occlusion CBF (qCBFMRI = 0.80*qCBFSPHERES + 12.9 ml/100g/min; r2 = 0.82; p = 0.002). Correction for delay and dispersion resulted in a significant improvement in the correlation between MRI and microsphere deposition in the ischemic state (qCBFMRI = 0.97*qCBFSPHERES + 2.58 ml/100g/min; r2 = 0.96; p < 0.001).

CONCLUSION

MRI derived values of CBF are strongly correlated with reference value microsphere deposition in normocapnia, hypercapnia, and MCAO ischemic stroke. Correction for delay and dispersion significantly improved the accuracy of this quantification during MCAO, underscoring the importance of this correction under focal ischemic condition

CLINICAL RELEVANCE/APPLICATION

Quantitative CBF by MRI perfusion accurately measures CBF, improving our ability to triage patients with acute ischemic stroke for treatment

SSM12-05 Utility of Radiomics Features to Detect Pancreatic Adenocarinoma

PURPOSE

Pancreatic adenocarcinoma is one of the leading causes of cancer related death. Recent advances in computer analytics offer the potential of computer aided detection of pancreatic adenocarcinoma. The purpose of this study is to determine if quantitative radiomics features can be used to differentiate pancreatic adenocarcinoma from normal controls.

METHOD AND MATERIALS

As an IRB-approved matched case-control study, 190 cases of pathologically proven pancreatic adenocarcinoma (PDAC) and 190 normal controls were retrospectively selected from the radiology and pathology databases. The whole pancreas boundary (including tumor region) were manually segmented from preoperative pancreatic protocol CT using dedicated software, VelocityAI (Varian Medical Systems, USA). The phenotype of pancreas on CT images was expressed with 478 radiomics features, which include the first order statistics, shape, texture, and texture features from wavelet and Laplacian of Gaussian filtering. The studies were randomly split into a training set (251 cases) and a testing set (129 cases). Feature reduction was performed by the minimum-redundancy maximum-relevance selection approach and random forest was applied for the PDAC classification.

RESULTS

The mean and standard deviation of PDAC masses were 4.4±2.0cm. The overall classification accuracy of the testing set was 0.992 (128 among 129 cases were correctly classified) with 0.999 of the area under the curve. The sensitivity was 0.98, only 1 among 62 PDAC cases were incorrectly classified, and specificity and PPV showed all 1.00. Most relevant features to differentiate PDAC include intensity uniformity, shape compactness, and texture features of gray level non-uniformity, skewness, fractal dimension from the original images and filtered images.

CONCLUSION

Radiomics features can differentiate pancreatic adenocarcinoma from normal pancreas with 3D segmented pancreas.

CLINICAL RELEVANCE/APPLICATION

Radiomics features can be used to differentiate pancreatic adenocarcinoma from normal pancreas, which can serve as one of the tools towards automatic detection of pancreatic adenocarcinoma.

PURPOSE

A wide variety of fungal processes can cause a chronic granulomatous reaction in the lungs manifesting as benign pulmonary nodules on CT. Visually to a radiologist, granulomas can appear similar to a malignant adenocarcinoma making them difficult to distinguish. However, these nodules differ in terms of the morphology of the nodule vasculature. The purpose is to model the distinct vessel tortuosity patterns and find associated deterministic dynamics. We sought to evaluate if fractal features of nodule vasculature on non-contrast CT are significantly different between granulomas and adenocarcinomas. We present a set of chaos-based fractal radiomic features of the vasculature (VFR) which transform the nodule vasculature to a low-dimensional discriminative feature space.

METHOD AND MATERIALS

Our study comprised non-contrast CT scans of 100 patients, including 50 adenocarcinomas and 50 granulomas, with pixel size

ranging from 0.42 x 0.42mm to 0.97 x 0.97mm. All patients had previously undergone resection for suspicious nodules. From nodule annotations provided by a trained radiologist, a region-growing algorithm was used to segment the surrounding vasculature (Fig 1a-d). A set of 6 chaotic features pertaining to the fractal analysis and the state space reconstruction of tumor vasculature were extracted from each nodule vasculature. The extracted features include fractal dimensions 1-dimension (D), 2D, and 3D, the mutual information, and the optimal delay of the state space reconstruction from each nodule vasculature. A linear discriminant analysis classifier was then used, in a 3-fold cross-validation setting, to identify adenocarcinomas.

RESULTS

VFR features (Fig 1 e-f, i-j) were capable identifying malignant nodules with AUC=0.70. Statistically significant difference was observed for one of the VFR features between adenocarcinomas and granulomas (p=0.009).

CONCLUSION

Adenocarcinomas can be distinguished from granulomas using VFR radiomics extracted from nodule vasculature.

CLINICAL RELEVANCE/APPLICATION

VFR radiomic markers could allow for improved discrimination of benign from malignant nodules, and could help reduce unnecessary surgical interventions for pathologic confirmation of nodule diagnosis.

PURPOSE

3D printing of cardiovascular anatomy can be used for radiology applications such as diagnostic software validation and image guided surgical training. We developed coronary tree phantoms from materials that are capable of sustaining physiological flow and pressure conditions while maintaining the stress and strain characteristics of human coronary arteries. The purpose of this research is to assess the accuracy of 3D printed patient-specific phantoms with coronary artery disease.

METHOD AND MATERIALS

Five patients underwent 320-detector row coronary CT angiography (CCTA) (Aquilion ONE, Canon Medical Systems). Reconstructed voxel size was 0.63 mm. The aortic root and three main coronary arteries were segmented (Vitrea, Vital Images) and 3D printed (Eden 260V, Stratasys). The patient-specific phantoms were connected into a pulsatile flow loop which replicated physiological flow and pressure gradients. Contrast was introduced and the phantoms were scanned using the same CT scanner model and same CCTA protocol as used for the patients. Patient and phantom CCTA images were segmented using Mimics Research (Materialise). The minimum vessel diameter and tortuosity (defined as shortest distance / vessel length) were measured for all three vessels at 20, 40, 60, 80, and 100 mm distances from the ostium for both patients and phantoms. Results were compared to assess the accuracy of the 3D printed patient-specific phantoms.

RESULTS

The average absolute difference between all minimum diameter measurements of the coronaries for the patient and phantom images was 0.73 ± 0.58 mm (~ 1±1 voxels), and in vessels with known stenosis (n = 5), the average absolute difference was 0.58 ± 0.20 mm (~ 1 voxel), range of 0.04 - 2.48 mm. The average absolute difference in tortuosity for the patients and phantoms was 0.06 ± 0.05, and in stenosed vessels was 0.05 ± 0.008, range of 0 - 0.17.

CONCLUSION

The phantoms showed high accuracy in maintaining the inner vessel lumen geometry and on average were within the scanner resolution, 1-2 voxels (630 µm each) of the patient images. Overall, the 3D printed patient-specific phantom accuracy has been evaluated and shown to replicate the patient images.

CLINICAL RELEVANCE/APPLICATION

Accurate 3D printing of patient-specific coronary phantoms allows for the replication of physiological blood flow conditions to allow precise evaluation of image-based diagnostic software.

SSM13-02 Reducing Operating Room Time by Using In-House 3D-Printed Models of Inferior Orbital Wall Fractures for Pre-contouring Osteosynthesis Implants

Wednesday, Nov. 28 3:10PM - 3:20PM Room: E353C

Participants

Philipp.Brantner@usb.ch

PURPOSE

To investigate if the use of CT data based 3D printed models for pre-contouring implants in inferior orbital wall fracture surgery is able to shorten operating room time.

METHOD AND MATERIALS

22 patients (11 m, 11 f, age: 52,38 ± 21,59 years) received an inferior orbital wall reconstruction with a titanium implant due to trauma (14 pts) or physical altercation (8 pts). For 12 patients a 3D mesh-model was created by segmenting the bone on the initial CT scan. The model was printed in 1:1 scale using either fused filament fabrication, stereolithography or polyjetting techniques. The 3D printed model was preoperatively used as a scaffold for pre-contouring a dedicated titanium mesh, which was implanted after sterilization using a mid-eyelid approach. Operating room times (incision to suture time points) were analyzed for both groups.

RESULTS

Overall the use of a 3D model to precontour the orbital floor implant shortened the mean operating room time significantly ($p<0.05$) from 96 min to 64 min (- 32 min). The model creation time including DICOM-export, segmentation and post-processing with pre-contouring of the implant took approx. 30 min. Printing time took between 2 to 4 hours, depending on the printer used.

CONCLUSION

A preoperative 3D printed model of orbital wall fractures significantly reduces operating room time while also supposedly improving patient care through shorter operating times. Since model creation and printing is less cost- and staff-intensive this workload shift from operating room to the 3D print lab represents a considerable cost reduction while at the same time offering an opportunity to expand the radiologic service through 3D printing.

CLINICAL RELEVANCE/APPLICATION

3D models in orbital wall surgery reduce costs and improve patient care by significantly reducing operating time.

SSM13-03 Utilizing Semantic Segmentation Method with Convolutional Neural Net to Model a Partial Nephrectomy Simulator for 3D Printing

CONCLUSION

We have developed a semantic segmentation method with CNN for modeling a partial nephrectomy simulator for 3DP. The parenchyma showed robust performance, but segmenting the relatively complex vessels was still challenging. However, this segmentation application could dramatically reduce the time for 3DP.

Background

The image segmentation is necessary for modeling a simulator for 3D printing (3DP). However, segmenting process is very tedious and labor intensive. Therefore, we proposed and evaluated a deep-learning-based segmentation method to model kidney surgical simulators and fabricate them by using 3DP.

Evaluation

Thirty-six patients with renal cell carcinoma (RCC) and normal kidney were enrolled. For 50 kidneys in this dataset, the artery, ureter, vein, and RCC connected to the kidney parenchyma were manually delineated for ground truth. Because the kidneys are symmetrically located on the left and right sides, a right kidney was flipped as left kidney to augment data. A certain margin was set based on the segmented kidney coordinates to extract the region of interest including the vessels connected to the kidney. The segmentation was performed using a 3D U-Net architecture of deep convolutional neural networks (CNN), with 80% and 20% for training and test, respectively. The segmentation performance on each class was evaluated using the Dice similarity coefficient (DSC). The mean and SD of DSC were 51.7 ± 21.0, 48.9 ± 12.7, 67.5 ± 15.8, 32.6 ± 34.8, 95.0 ± 3.6 % for artery, ureter, vein, RCC and parenchyma, respectively.

Discussion

The performance for parenchyma segmentation was the highest, while that of RCC was the lowest with large SD. Among the artery, ureter, and vein, vein accuracy was the highest. Using this method the time on modeling procedure for 3DP has been drastically reduced. The less complex parenchyma and ureter have been useful, but the blood vessels inside the parenchyma seem to be still challenging. The boundaries between parenchyma and RCC were not distinguished clearly, so more data is required.

SSM13-04 3D Printed and Augmented Reality Urologic Oncology Models: Impact in Patient Education

PURPOSE

To investigate the impact of using 3D printed and augmented reality (AR) urologic cancer models for patient education.

METHOD AND MATERIALS

Patients with renal cancer (nephrometry score >= 7, diameter >= 4cm, or polar lesions) or MRI visible prostate cancer (PI-RADS v2 score >= 3) scheduled to undergo partial nephrectomy, radical prostatectomy, or focal therapy for prostate cancer were enrolled in our ongoing prospective study. Upon enrollment, patients were randomized to receive a pre-operative, patient-specific 3D printed or AR cancer model. A Likert-scale questionnaire was administered to assess patient understanding of disease, cancer size, cancer location, and treatment plan before and after reviewing the patient-specific 3D printed or AR model. Survey responses were compared using a paired t-test. For a subset of patients, additional questions were included asking patients to rate from 1-10 to what extent the 3D model helped them learn about their anatomy, disease, procedure, and potential complications; and results for the 3D printed and AR models were compared with an unpaired t-test.

RESULTS

73 patients completed the questionnaire twice, once before and once after reviewing the 3D printed model (n=31) or AR model (n=42). Both the 3D printed and AR kidney and prostate cancer models outperformed conventional imaging. Patient understanding of disease, cancer size, cancer location, and treatment plan improved with the 3D printed models compared to imaging alone (range = 4.56-4.84/5 for 3D printed model vs. 4.20-4.36/5 for imaging; all $p<0.03$). For the AR models, only understanding of cancer size improved (4.31 ± 0.87 for AR model vs. 3.90 ± 0.91 for imaging, $p = 0.03$). Seventeen patients with 3D printed models and 25 patients with AR models completed the additional questions. For the question regarding how much the model helped improve understanding of disease, ratings were 9.6 ± 0.8 for 3D printed model and 8.5 ± 2.4 for the AR models, $p = 0.05$.

CONCLUSION

Overall, the 3D printed models performed better than both conventional imaging and AR models at helping patients to understand their disease and treatment plan.

CLINICAL RELEVANCE/APPLICATION

Patients frequently do not fully understand their disease or surgical plan using conventional imaging methods. By providing enhanced visualization and tactile feedback, 3D printed models may help to overcome this limitation.

CONCLUSION

Realtime use of in-vivo mpMRI derived 3D prostate and periprostatic anatomy information during laparoscopic RARP procedure via the da Vinci® surgical system can be advantageous to better tailor the surgery procedure and can improve spatial awareness. Future goals include use of the robot's stereo image viewer instead of HMD and advancement of the MRI-stereo image alignment for direct intraoperative use of mpMRI.

Background

Robotic-assisted radical prostatectomy (RARP) has become a more popular approach for prostate cancer (PCa) recently. Its 3D stereo-laparoscopic view allows for optimal spatial awareness. Recently, multiparametric magnetic resonance imaging (mpMRI) is more commonly used pre- and intraoperatively. Currently, surgeons can only utilize mpMRI data cognitively to guide surgery. In this study, we present use of mpMRI data and intraoperative stereo captures of RARP to create 3D virtual reality (VR) models which can guide surgeons during RARP to optimize spatial awareness.

Evaluation

Axial T2W MRI was utilized to create 3D models of the prostate, bladder, rectum, NVBs, seminal vesicles, urethra and PCa lesions by a manual contouring process. These contours were then used to create 3D mesh models for a commercially available VR platform with head mounted display (HMD) and touch controls (Oculus Rift®). During RARP, stereo images of the laparoscopic views were extracted using the da Vinci´s DVI outputs. Both models were then aligned to each other using an in-house algorithm and provided to urologists during RARP. When needed surgeons withdrew from the console and interacted with the 3D models using the HMD.

Discussion

VR system was used during 9 RARPs. All models were successfully generated and integrated into the VR system. The time between the stereo image capture to full applicability of the model was approximately 3 minutes. The VR system was utilized at 4 steps: General check before the surgery, prior to bladder neck separation, apical dissection and during separation of nerves from the prostate capsule in lesions with proximity to the NVB. The system was used for one minute during each step and did not interfere with routine workflow.

SSM13-06 Head Mounted Display Augmented Reality for Image Guided Procedures of the Spine

CONCLUSION

We demonstrated feasibility of using HMD-AR in facet and sacroiliac joint injections, and percutaneous discectomy. To the authors' knowledge, this is the first reported use of HMD-AR guidance in live surgery.

Background

Head Mounted Display Augmented Reality (HMD-AR) is a recent technological advancement that can be used to superimpose CT or MRI images on a patient in real space to visualize inner anatomical structures in three dimensions, as well as axial, sagittal, and coronal views. We used HMD-AR to perform three common image-guided spine procedures, facet and sacroiliac (SI) joint injections as well as percutaneous discectomy, with no real time fluoroscopic guidance on a 3D printed lumbar model. Finally, we successfully demonstrated the utility of HMD-AR by performing these procedures on live patients using HMD-AR guidance.

Evaluation

CT images were performed of a 3D printed lumbar phantom made of radiodense gypsum-based material encased in silicone. Suggested trajectories for instrumentation were embedded in the images, which were uploaded to the Microsoft Hololens using Novarad Open Sight system. Images were superimposed on the phantom, and localization of the facet joint, sacroiliac joint, and nucleus pulposus was performed by placing 18-gauge cannulated needles along holographic trajectories. Repeat CT images

confirmed accurate placement of the needles. Registration accuracy was determined by measuring deviation of model to hologram and was found to be roughly spherical with radius of 2.5 mm (STD 0.44 mm). Finally, a certified neuro-radiologist used the same method to localize the facet joint, sacroiliac joint and nucleus pulposus during three separate live procedures, all of which were confirmed with fluoroscopy.

Discussion

HMD-AR can be used to project holographic guidance trajectories within vital anatomic structures, allowing accurate interventional and surgical instrumentation, potentially decreasing operating and fluoroscopy time and reducing error for select procedures. HMD-AR can also utilize existing images, potentially reducing radiation exposure by minimizing need of fluoroscopy use intraoperatively.

PURPOSE

Furin is a membrane-bound proprotein convertase that is overexpressed in many types of tumors. It activates certain specific proteins associated with tumor progression, with the degree of expression correlating to 5-year survival rates. We have adapted the compound olsalazine, an anti-cancer agent that also exhibits chemical exchange saturation transfer (CEST) MRI contrast, with a synthetic peptide (RVRR) that is cleaved by furin. Our aim was to assess the imaging and therapeutic effects of the furin-catalyzed condensation reaction and subsequent formation of intracellular OLSA nanoparticles.

METHOD AND MATERIALS

NU/J immunodeficient mice (n=20) were subcutaneously injected with 1×106 HCT116 (furin-overexpressing) human tumor cells in the left flank and 1×106 LoVo (low furin-expressing) human tumor cells in the right flank. Animals received 0.14 mmol/kg furin-targeted RVRR-OLSA or 0.14 mmol/kg OLSA as non-targeted control injected i.v. In vivo CEST MRI was performed at different time points using a 11.7 T horizontal scanner. In three separate cohorts (n=4 each), animals received 0.07 mmol/kg RVRR-OLSA, 0.07 mmol/kg OLSA, or PBS only (as control) injected i.v. 8 times with 3-day intervals.

RESULTS

After i.v. injection of RVRR-OLSA, furin-overexpressing HCT116 tumors and low furin-expressing LoVo tumors could be clearly distinguished from each other in vivo on CEST MRI (Fig. 1a, shown at 2h post injection). No such differences were observed for OLSA without RVRR. Mice injected with RVRR-OLSA showed significantly reduced tumor sizes compared to those injected with OLSA alone for the HCT 116 tumor ($p<0.05$) but not the LoVo tumor (Fig. 1b). At day 33, average tumor volumes of HCT116 tumors and LoVo tumors for the RVRR-OLSA treated group were reduced to 38% and 61%, respectively, as compared to the control group.

CONCLUSION

Furin-induced intracellular formation of OLSA-NPs following administration of RVRR-OLSA enhances CEST contrast and reduces tumor size in vivo.

CLINICAL RELEVANCE/APPLICATION

The new nanotheranostic probe RVVR-OLSA may be further developed for imaging tumor aggressiveness and tumor response to furin-targeted therapy.

SSM14-03 Orthotopic Pancreatic Cancers: Molecular Imaging-Guided Radiofrequency Hyperthermia-Enhanced Immuno/Oncolytic Therapy

PURPOSE

To validate the feasibility of using interventional molecular imaging to guide radiofrequency hyperthermia (RFH)-enhanced local immune/oncolytic therapy of rat orthotopic pancreatic cancers.

METHOD AND MATERIALS

Luciferase-labeled rat pancreatic cancer cells and 24 Lewis rats with orthotopic pancreatic cancers in four groups (n = 6/group) were treated by (i) combination therapy of oncolytic virus (T-VEC, 10×106 pfu) plus RFH at 42? for 30 mins; (ii) oncolytic virotherapy-only; (iii) RFH-only; and (iv) saline. MTS and flow cytometry were used to analyze cell proliferation and apoptosis. Optical/x-ray imaging and ultrasound imaging were used to follow up and compare the therapeutic effects among various groups, correlated with subsequent pathologic examinations.

RESULTS

Both confocal microscopy and MTS assay demonstrated diminished number of viable cells with combination therapy (RHF+T-VEC) compared with other three treatments (Fig. A&B), as well as significant increase of cell apoptosis in flow cytometry (Fig. C). Optical/x-ray imaging demonstrated decreased tumor bioluminescent signal (Fig. D) and ultrasound imaging showed the smallest tumor volume of combination therapy, in comparison to other treatments (Fig. E). Imaging findings were well correlated with pathologic examinations, shown as (1) the smallest tumor size (Fig. F&G); (2) increased apoptosis with TUNEL staining (Fig. F&H); and (3) significantly decreased cell proliferation with Ki-67 stain (Figs. F&I) in the combination therapy group, compared to other treatment groups.

CONCLUSION

We validated the feasibility of using molecular imaging-guided interventional RFH to enhance immune/oncolytic therapy of pancreatic cancer, which may open the new avenues for effective management of pancreatic cancer, one of the deadliest malignancies worldwide.

CLINICAL RELEVANCE/APPLICATION

Molecular imaging-guided interventional RFH can enhance immune/oncolytic therapy of pancreatic cancer.

SSM14-04 Molecular Imaging-Monitored Radiofrequency Hyperthermia-Enhanced Intratumoral Herpes Simplex Virus-Thymidine Kinase/Ganciclovir Gene Therapy for Rat Hepatic Cancers

PURPOSE

To explore a new method using optical/ultrasound imaging to monitor RF hyperthermia(RFH)-enhanced herpes simplex virus-thymidine kinase/Ganciclovir(HSV-TK/GCV)suicide gene therapy of rat hepatocellular carcinoma(HCC).

METHOD AND MATERIALS

Rat liver cancer cells(MCA-RH-7777)were transduced with lentivirus/luciferase gene. Serial in-vitro experiments with luciferase-cells and in-vivo experiments of rat orthotopic HCC were divided into four groups :(i) HSV-TK/GCV combined with RFH; (ii) HSV-TK/GCV; (iii) RFH; and (iv) PBS. HSV-tk gene expression was qualified by western blotting, while cell viability was evaluated by confocal microscopy and MTS. Bioluminescence optical imaging and ultrasound imaging were used to monitor the photon signal and size changes of tumors in each groups at different time points. The imaging findings were correlated with histologic analysis.

RESULTS

Of in-vitro experiments, MTS assay demonstrated the lowest cell proliferation in the group of combination therapy, compared with other three groups (26.1±3.2% vs 50.4±4.6% vs 82.9±6.3% vs 100%,$p<0.01$), which was corresponding to the lowest number of survived cells with confocal microscopy and the lowest bioluminescence signal with the optical imaging. Of in-vivo experiments, ultrasound imaging showed the smallest tumor volumes in the combination therapy group, compared to other control groups (0.28±0.11, 1.28±0.23 vs 4.64±0.35 vs 6.37±0.36, $p<0.05$). Bioluminescent optical imaging further demonstrated a significantly decreased bioluminescence signal intensities in the combination group, compared with three control groups (0.57±0.09, 1.06±0.10

vs 3.43±0.27 vs 3.85±0.12, p<0.05). These imaging findings were further confirmed by significantly increased apoptotic cells in the combination therapy group.

CONCLUSION

It is feasibility using optical imaging and ultrasound imaging to monitor intratumoral RFH-enhanced HSV-TK/GCV gene therapy of rat HCC, which may provide a new image-guided interventional oncology technique for efficient management of liver malignancies by simultaneous integration of radiofrequency technology, interventional oncology, and direct intratumoral gene therapy.

CLINICAL RELEVANCE/APPLICATION

Optical imaging is a useful tool for monitoring intratumoral RFH-enhanced HSV-TK/GCV gene therapy of rat hepatic cancers, which may provide a new opportunity for effectively managing liver cancers

SSM14-05 2D Magnetic Titanium Carbide (Ti3C2 MXene) for Cancer Theranostics

PURPOSE

The aim of this part was to construct superparamagnetic 2D Ti3C2 MXenes for enhance MR molecular imaging and photothermal therapy (PTT).

METHOD AND MATERIALS

The fabrication of ultrathin Ti3C2 MXene nanosheets was based on an exfoliation strategy and the construction of superparamagnetic 2D Ti3C2 MXenes is based on the specific MXenes' surface chemistry for the in-situ growth of superparamagnetic Fe3O4 nanocrystals onto the surface of Ti3C2 MXenes. The magnetic Ti3C2-IONPs composite MXenes were modified with soybean phospholipid (SP) to guarantee high stability in physiological conditions. These MXenes were characterized via transmission electron microscopy (TEM), scanning electron microscopy (SEM), energy dispersive X-ray spectroscopy (EDS), electron energy loss spectroscopy (EELS), dynamic light scattering (DLS), zeta-potential, X-ray photoelectron spectroscopy (XPS) and UV-Vis-NIR spectra. The photothermal therapy, T2-weighted magnetic resonance imaging and the high biocompatibility of these composite nanosheets have also been evaluated in vitro and in vivo.

RESULTS

These magnetic Ti3C2-IONPs composite MXenes exhibit high T2 relaxivity of 394.2 mM-1s-1 and efficient contrast-enhanced magnetic resonance imaging of tumor, providing the potential for the therapeutic guidance. Importantly, these superparamagnetic MXenes have shown high photothermal-conversion efficiency (48.6%) to guarantee their efficient photothermal killing of cancer cells and ablation of tumor tissues, which has been systematically demonstrated both in vitro and in vivo.

CONCLUSION

For the first time, we have successfully illustrated that the superparamagnetic MXenes nanosheets feature the high intrinsic photothermal-conversion capability for PTT against tumor, which are also the first paradigm of integrated superparamagnetic IONPs acted as the contrast agents for T2-weighted MR imaging. The high biocompatibility of these elaborately designed magnetic Ti3C2-based composite MXenes guarantees their further potential clinical translation. This report paves a new way for the functionalization of MXene-based 2D nanosheets for broadening their novel applications based on the unique surface chemistry of MXenes, especially in theranostic nanomedicine.

CLINICAL RELEVANCE/APPLICATION

These superparamagnetic MXenes nanosheets feature the high intrinsic photothermal-conversion capability to against tumor and acted as the contrast agents for T2-weighted MR imaging.

SSM14-06 Gene Therapy Targeting of GDPD5/6 in Choline Metabolism of Breast Cancer

PURPOSE

Glycerophosphocholine (GPC) is an important 1H MRS-detected metabolite in choline metabolism1. The GDPD52,4/GDPD63 enzymes, which convert GPC to free choline, are overexpressed in breast cancer. Previously we have shown that GDPD5/GDPD6 silencing

increased cellular GPC5 levels and reduced migration and proliferation of breast cancer cells4. We are continuing our studies *in-vivo* to evaluate if lentiviral vector based silencing of GDPD5/GDPD6 will reduce tumor growth in breast cancer xenograft models. The metabolic effects of silencing were studied for identifying novel biomarkers and therapeutic targets for anti-cancer therapy.

METHOD AND MATERIALS

GDPD5 and GDPD6 were silenced in nude mice growing human breast cancer xenografts. In these mice, we injected lentiviral vectors expressing GDPD5-shRNA, or GDPD6-shRNA along with control vector expressing luc-shRNA. Once tumor sizes reached 150mm3, mice were treated with viral suspension. Upon necropsy, tumors were harvested and subjected to 1H MRS analysis.

RESULTS

Initially, tumors showed a gradual increase in size. Upon treatment, tumor growth was significantly reduced in the GDPD6-shRNA treated group compared to other groups. 1H MR spectra of tumor extracts showed significant differences in various metabolites (Fig 1A-B). A heatmap demonstrated % changes among the three treated groups (Fig 1C).Significant changes were observed in metabolites from metabolic pathways including amino acid and protein synthetic pathways and glycolysis, which are in accordance with the literature. Choline was decreased while GPC was increased in the GDPD6-shRNA treated group (Fig 1D). The PC/GPC ratio was lower in the GDPD6-shRNA treated group (Fig 1E), which was consistent with our previous findings4.

CONCLUSION

These data in breast tumor xenografts suggest that GDPD5 and GDPD6 silencing could be an effective molecular treatment strategy. Additional studies are continuing in our lab to corroborate these initial findings. Ref.: Glunde et al, Nat Rev Cancer 2011 Cao, et al, NMR Biomed 2012 Cao, et al, NMR Biomed 2016 4. Wijnen et al, NMR Biomed 2014 5. Krishnamachary et al, Can Res 2009

CLINICAL RELEVANCE/APPLICATION

Lentiviral gene silencing is emerging as efficient technique for suppressing genes of interest for cancer treatment. We are assessing effects of gene silencing by means of 1H MRS based metabolomics following silencing of two glycerophosphodiesterases GDPD5 and GDPD6.

PURPOSE

As diabetes becomes more commonplace, neuropathic arthropathy (NA) is a mushrooming problem in clinical interpretation. Although radiographic classification schema was well established, many of these patients come to MR for potential superimposed infections. Thus, it behooves us to develop MR imaging staging criteria for various temporal points of NA.

METHOD AND MATERIALS

An international expert panel of 6 musculoskeletal radiologists was formed and participated in a two-round Delphi survey. A total of 30 qualitative radiologic features associated with various NA stages were compiled after a comprehensive literature search of 9 papers. For round 1, experts were asked to rate the relevance of selected criteria for identifying NA at acute, intermediate, and chronic stages on a scale of 1-10, with 1 as not relevant at all and 10 as extremely important. For round 2, panelists resubmitted answers to the same questionnaire after distributing the group median, interquartile range, and range results from round 1. A Cronbach's a score was calculated to determine consistency of signs.

RESULTS

The median scores for each sign ranged from 2-9. The highest medians for diagnostic relevance of acute presentations were marrow edema with visible fracture, inhomogeneous marrow edema, and diffuse bone marrow edema with medians of 9, 9, and 8.5 respectively. The lowest medians were irregular bone shape on T2, ligament damage, and cartilage damage with medians of 4, 3, and 2 respectively. For chronic presentations of NA, the highest medians were subchondral sclerosis, new bone formation, and fibrosis with medians of 8.5, 8, and 6.5 respectively. The lowest medians were the ghost sign, T1 tapering of distal second and third metatarsals, and sinus tracts with medians of 4, 4, and 2.5 respectively. For intermediate presentations of NA, subchondral cysts scored a higher median of 6 than the 4.5 median for intra-articular bodies. Cronbach's a score of the first and second round of questionnaires were 0.69 and 0.79 respectively.

CONCLUSION

Results of the delphi survey suggest consensus of several qualitative MRI features of neuropathic arthropathy that are indicative of disease acuity/chronicity and show good consistency.

CLINICAL RELEVANCE/APPLICATION

Staging criteria for the acuity/chronicity of neuropathic arthropathy was established such that radiologists may interpret MR images at a similar level to current standards for radiographic images.

alessandrovidoni@icloud.com

PURPOSE

To describe a novel secondary sign of subchondral insufficiency fracture of the knee, the metaphyseal flare sign.

METHOD AND MATERIALS

A retrospective research of 7926 knee MRI examinations was performed. 48 scans were included in the study. The diagnosis of subchondral insufficiency fracture (SIF) was confirmed in a consensus review by one fellowship trained MSK radiologist and one radiology registrar. The presence of metaphyseal flare sign (soft tissue oedema in the meta-epiphyseal region of the affected condyle) was evaluated in the cohort.

RESULTS

41 patients were included in the study (21 male, 20 female). The mean age was 61.5 years (range 41 to 80 years). The anatomical location of the SIF were the medial femoral condyle (n=28), the lateral femoral condyle in (n=5) and medial tibial condyle (n=8). The metaphyseal flare sign was present in 45 of the 48 scans reviewed. The average craniocaudal length of the soft tissue oedema defined as metaphyseal flare sign was 7 cm (range 10.5 to 4.5).

CONCLUSION

The metaphyseal flare sign is an early, indirect sign of subchondral insufficiency fracture (SIF).

CLINICAL RELEVANCE/APPLICATION

The metaphyseal flare sign is an early, indirect sign of subchondral insufficiency fracture (SIF) particularly useful if the diagnosis is unclear to promptly begin the treatment and prevent the progression of the pathology.

SSM15-03 Uncovered Medial Meniscus Sign on Knee Magnetic Resonance Imaging: Evidence of Lost Brake Stop Mechanism of Posterior Horn Medial Meniscus

Wednesday, Nov. 28 3:20PM - 3:30PM Room: E450B

PURPOSE

To evaluate the association between anterior tibial translation and injuries on the posterior horn medial meniscus (PHMM) and the integrity of brake stop mechanism of the PHMM in anterior cruciate ligament (ACL) deficient knee.

METHOD AND MATERIALS

This retrospective study included 85 consecutive patients with arthroscopically confirmed complete ACL tear. Anterior tibial translation was quantitatively measured using sagittal MRI at the midpoint of the lateral femoral condyle. Uncovered medial meniscus sign was considered positive if a vertical line tangent to the posterior most margin of the medial tibial plateau intersected the PHMM at the midpoint of the medial femoral condyle on sagittal MRI. Concomitant injury on the structures of the posteromedial and posterolateral corners of the knee, including PHMM tear and meniscal ramp lesion, was recorded. Stratified subgroup analysis and multivariable regression analysis were performed to identify factors associated with anterior tibial translation.

RESULTS

The uncovered medial meniscus sign was positive in 21.2% (18/85) of patients and was significantly associated with anterior tibial translation. In the stratified subgroup analysis and multivariable regression analysis, positive uncovered medial meniscus sign consistently demonstrated a significant association with anterior tibial translation and generated an additional 3.5 mm of anterior tibial translation. Other injuries, including PHMM tear and meniscal ramp lesion, were not associated with anterior tibial translation.

CONCLUSION

The uncovered medial meniscus sign demonstrated a statistically significant correlation with anterior tibial translation and could be

The uncovered medial meniscus sign demonstrated a statistically significant correlation with anterior tibial translation and could be a useful marker for the lost brake stop mechanism of PHMM in the ACL deficient knee.

CLINICAL RELEVANCE/APPLICATION

1. An uncovered medial meniscus sign proved to have a statistically significant correlation with anterior translation of the tibia in patients with complete tear of the anterior cruciate ligament. 2. The uncovered medial meniscus sign could be a useful magnetic resonance imaging marker for a lost brake stop mechanism of the posterior horn medial meniscus in the knee. 3. A tear at the PHMM or meniscal ramp lesion itself should not be interpreted as an evidence of lost brake stop function of the PHMM.

SSM15-04 T2 Relaxation Times of the Anterolateral Femoral Cartilage in Patients After ACL-Repair with and Without a Deep Lateral Femoral Notch Sign

PURPOSE

To assess T2 relaxation times of the anterolateral femoral cartilage following anterior cruciate ligament (ACL)-repair with and without a positive deep lateral femoral notch sign (DLNS) at post-traumatic MRI.

METHOD AND MATERIALS

In 52 patients post-traumatic MRI as well as 12 months after ACL-rupture (ACLR) and surgical treatment were analysed. In 28 patients a positive DLNS was present at post-traumatic MRI. For quantitative analysis, T2 relaxation time measurements (7 TE: 10-70 ms) were performed at time of re-evaluation. Polygonal ROIs encompassing the full cartilage layer were placed in the anterolateral as well as adjacent femoral cartilage. Clinical assessment included Lysholm-Tegner-Activity-Score, Rasmussen's clinical score and modified Cincinnati-Rating-System-Questionnaire. Description and differences were calculations as means and confidence intervals of means, controlled for the cluster effect of person, if appropriate.

RESULTS

In patients with a positive DLNS after ACLR, relaxation times in the notch region were significantly prolonged compared to patients without a positive DLNS (Δ 7.4 ms, CI: 5.6 - 9.2; p-value <0.001) as well as to the adjacent anterior (Δ 5.7 ms, CI: 4.7 - 6.7; p-value <0.001) and central femoral cartilage (Δ 6.6 ms, CI: 5.7 - 7.6; p-value <0.001). No significant differences in the performed clinical scores between the two groups were noticed (p>0.05).

CONCLUSION

Significantly prolonged T2 relaxation times of the anterolateral femoral cartilage were found in patients with a positive DLNS following ACL-repair compared to patients without a DLNS. Based on these results, it has to be assumed that a positive DLNS is associated with higher cartilage degradation.

CLINICAL RELEVANCE/APPLICATION

The presented results implicate an impact on relaxation times in patients with a femoral notch sign after ACL-rupture. T2 analysis might help identifying patients at risk for earlier onset of Osteoarthritis, which might benefit from precocious surgical treatment.

SSM15-05 Decreased Vertebral Enhancement in Patients with Infectious Spondylitis, Presenting 'Black Vertebrae' as an Atypical Enhancement Pattern

Wednesday, Nov. 28 3:40PM - 3:50PM Room: E450B

Awards
Student Travel Stipend Award

Participants

PURPOSE

To investigate the characteristics of patients with infectious spondylitis who show decreased vertebral enhancement.

METHOD AND MATERIALS

From January 2010 to November 2017, 767 patients with reports containing terms about infectious spondylitis was collected for this retrospective study. After reviewing images and medical record, we included 456 patients suspicious for infectious spondylitis with 706 post-contrast MR exams. When affected vertebra showed markedly lower degree of enhancement than that of normal bone

marrow(BM) and when the area showing decreased enhancement was greater than 50% of the area of the vertebral body, the vertebra was recognized as 'black vertebra'. Finally 10 patients(M:F=5:5, mean age=66.4 years) with 10 MRI were identified as showing 'black vertebra'. In those patients, imaging findings of MRI and CT within 2 weeks interval from MRI were evaluated. Clinical characteristics including comorbidities, causative organism and treatment course were reviewed.

RESULTS

10 patients with black vertebra showed atypical findings as for infectious spondylitis. There was little BM signal alteration on T1-weighted image(n=9), or absence of fluid-equivalent discal signal intensity(SI) on T2-weighted image(n=5). However, 6 patients showed T2 signal voids in or around the vertebral body and 8 patients showed air burbles on CT images(average interval : -1.1days from MR), suggesting emphysematous infection. On follow-up MRI(average interval: 7.2weeks from initial MR), available in 5 patients, those atypical findings almost disappeared but marked progression of infection was evident: increased range of affected segments (n = 3); low T1 SI of affected vertebra(n = 5); and increased contrast enhancement(n = 3). 9 patients had underlying disease such as Diabetes mellitus(n =5) or connective tissue disease(n=2) or etc. Causative organisms were identified as Klebsiella pneumonia(n=3), Staphylococcus aureus(n=3), Escherichia coli(n=2) and etc. Finally, 5 patients underwent surgery due to uncontrolled infection despite antibiotic treatment.

CONCLUSION

'Black vertebra' on contrast enhanced image seems to be associated with early finding of emphysematous infection.

CLINICAL RELEVANCE/APPLICATION

Recognition of decreased enhancement of affected spine, 'black vertebra', would be important to diagnose early emphysematous infection, known to have worse course than typical infectious spondylitis.

SSM15-06 Leopard Spot Edema: An Osseous Stress, Healing and Reinjury Phenomenon in Professional Ballet Dancers Seen on MR

PURPOSE

Professional ballet dancers are subject to numerous overuse syndromes about the ankle and foot. Anecdotally, we observed a patchy bone marrow pattern on MR in the hindfeet of skeletally mature dancers, similar to the "starry night" pattern described as normal in children. We sought to describe this pattern of "leopard spot marrow edema" (LSME) at MR and explore its potential etiology and significance using clinical correlation and follow-up imaging.

METHOD AND MATERIALS

28 MR exams of the ankle/hindfoot in 19 professional ballet dancers were reviewed by 2 MSK radiologists. The presence of LSME was recorded along with age, gender, clinical indication and primary MR findings potentially related to symptoms. Follow-up MRs were reviewed and edema was graded as improved or progressive. Correlation with clinical findings was made.

RESULTS

LSME was observed in 14/18 subjects (78%) and 22/28 MRs (78.5%). 8/22 with LSME had repeat MR (interval 3-71, mean 33 months). 5/8 showed improvement of LSME including 2 with complete resolution, both of whom were not dancing at follow-up. 1 subject showed improvement at 5 months but progression at 24 months. 3/8 had progressive LSME, and all 3 were dancing in an active production at follow-up. For subjects with LSME, the age range was 22-35, mean 25 years. There was little gender difference as 9/11 females and 5/7 males had LSME. As for other MR findings, 9/18(50%) had focal osseous stress response or stress fracture, 7/18(39%) had findings of posterior impingement, 2 had lateral ligament injury, 2 had posterior tibial tendon injury, and 1 each had Achilles tendinopathy, Lisfranc sprain and peroneal tendinopathy. 2 subjects with LSME at 1st MR had stress fractures at follow-up.

CONCLUSION

"Leopard spot marrow edema" is a common but previously unreported finding at MR of the hindfoot in ballet dancers, and our series suggests progression with active dancing such that it may reflect a syndrome of microtrabecular injury, healing response, and re-injury distinct from the pediatric marrow pattern reported as normal.

CLINICAL RELEVANCE/APPLICATION

The observation of this bone marrow pattern in an active ballet dancer should raise concern for evolving osseous stress response and a period of limited activity should be considered. Worsening bone marrow edema suggests that a process of microtrabecular injury with a healing response and re-injury is present explaining the observed MR findings.

PURPOSE

To investigate the additional diagnostic value of gadoxetic acid-enhanced MRI to 18F-DOPA-PET/CT for liver staging in patients with medullary thyroid carcinoma (MTC).

METHOD AND MATERIALS

41 consecutive patients with histologically confirmed MTC who underwent gadoxetic acid-enhanced MRI and 18F-DOPA-PET/CT within one month between 2010 and 2015 were selected for this retrospective study. The 18F-DOPA-PET/CT and multiparametric gadoxetic acid-enhanced MRI data sets were analyzed by two blinded radiologists. A 5-point Likert scale (based on the LI-RADS criteria: 1-definitely benign, 2-probably benign, 3-intermediate risk for metastasis, 4-probably metastasis, 5-definitely metastasis) was used for lesion categorization in both modalities. The additional value of MRI was defined as detection of 18F-DOPA-PET/CT-occult category 5 lesions or a definitive categorization (category 1 or 5) of lesions remaining inconclusive on the 18F-DOPA-PET/CT scan.

RESULTS

We categorized a total of 212 liver lesions (166 lesions on 18F-DOPA-PET/CT, 212 lesions on MRI; 165 metastases, 37 cysts, 18 hemangiomas). Out of 165 category 5 lesions on MRI, only 94 were classified as category 5 lesions on 18F-DOPA-PET/CT. In 65 % (30/46) of inconclusively categorized lesions on 18F-DOPA-PET/CT (category 2-4), a definitive lesion classification was possible with MRI (change in categorization to categories 1 or 5, respectively). A change in lesion classification by MRI was made in 12 patients (lesions with a change in category from 2 to 1: n=10; from 3 to 1: n=3; from 4 to 5: n=12; from 3 to 5: n=5).

CONCLUSION

Complementary liver-specific MRI allows for the detection of 18F-DOPA-PET/CT-occult metastases and optimizes liver lesion classification in MTC patients.

CLINICAL RELEVANCE/APPLICATION

The definitive categorization of detected liver lesions and timely identification of liver metastases in MTC patients is essential in guiding treatment decisions on early surgical or interventional management.

SSM16-02 Radiotheranostics for Regionally Advanced and Metastatic Differentiated Thyroid Cancer: Outcomes Following Initial Treatment Strategy Informed By Diagnostic 131-I Scintigraphy with SPECT/CT

PURPOSE

Diagnostic staging 131-I scans with SPECT/CT (Dx scan) guide patient-individualized 131-I therapy for differentiated thyroid cancer (DTC). The objective of this study was to determine dynamic risk stratification outcomes after surgery and activity-adjusted 131-I therapy informed by diagnostic 131-I scintigraphy with SPECT/CT.

METHOD AND MATERIALS

Single-institution retrospective cohort study analysis of clinical outcomes in 350 patients with DTC associated with histopathologic risk factors, nodal metastases, and/or distant metastases treated at University of Michigan. Post-operatively all patients underwent Dx 131-I SPECT/CT scans for completion of staging and risk stratification. 131-I therapy was based on integration of information from histopathology, stimulated thyroglobulin (Tg) and scintigraphy. The patients were followed for 1-5 years (mean 39.6 ±23.4 months)

RESULTS

23 patients (6.6%) underwent re-operative neck dissection for removal of unsuspected residual nodal metastases identified on Dx scans. Dynamic risk stratification outcomes were: 84.3% complete response; 1.4% biochemical incomplete response; 2.3% indeterminate response and 12% structural incomplete response. Of the entire cohort only 8 patients (2.3%) had persistent iodine-avid metastatic disease which required repeated 131-I therapy. Of 31 patients with iodine-avid distant metastases identified on Dx scans, 13 patients (42%) achieved complete response with a single 131-I treatment.

CONCLUSION

Detection of regional and distant metastases on postoperative Dx scans permits adjustment of prescribed 131-I activity for targeted treatment, as compared to fixed-activity ablation. This approach resulted in complete response after a single 131-I treatment in 88% patients with histopathologic risk factors and regional metastases, and 42% patients with distant metastases. Most patients (81%) with structural incomplete response had negative follow-up 131-I scans and positive PET/CT and/or CT scans consistent with altered tumor biology (non-iodine avid disease).

CLINICAL RELEVANCE/APPLICATION

Postoperative Diagnostic 131-I scans with SPECT/CT are useful for identification of regional and distant metastases in thyroid cancer, informing 131-I therapy decisions. Elimination of iodine-avid regional and distant metastases with complete therapeutic response is achieved in the majority of patients after a single 131-I treatment based on radiotheranostics principles.

SSM16-03 I-131 Thyroid Dosimetry in Patients with Lung Metastases

PURPOSE

To protect bone marrow from excessive radiation, maximum permissible activity (MPA) of I-131 to treat thyroid cancer is the value that limits absorbed dose to blood (as a surrogate of marrow) to < 200 cGy. Pts with thyroid carcinoma pulmonary metastases potentially are a unique subgroup because I-131 uptake in the lungs could result in apparently accelerated blood clearance, which in turn could lead to an overestimation of MPA. The objective of this investigation was to test the hypothesis that in pts with diffuse lung metastases from thyroid carcinoma, MPA based on blood measurements alone is not affected by the presence of diffuse lung metastases.

METHOD AND MATERIALS

Data were analyzed retrospectively for 87 thyroid cancer pts (60±15 yrs; 45 female; 42 male) referred for determination of MPA prior to I-131 treatment. Method1 for determining MPA computed total absorbed dose to blood (DTotal) as the sum of mean whole-body γ ray dose component (Dγ) from un-collimated gamma-camera measurements, along with dose due to ß emissions (Dß) from blood samples. Method2 estimated DTotal from Dß alone, using linear regression to associate in-vitro blood sample measurements

alone to conventional Method1 DTotal. MPA was computed as 200 cGy/DTotal for each DTotal estimate for Method1 & Method2. All pts also underwent whole body imaging 48 hrs after I-131 administration.

RESULTS

Six pts had iodine avid diffuse lung metastases. MPA values were similar for Method1 & Method2 for all pts (14.3±8.9 versus 14.1±8.7 GBq, p = 0.34), pts with lung metastases (12.4±6.9 versus 11.7±6.4 GBq, p = 0.06) & for pts without lung metastases (14.4±9.0 versus 14.3±8.8 GBq, p = 0.52). MPA values were similar for pts with lung metastases & pts without lung metastases (12.4±6.9 versus 14.4±9.0 GBq, p = 0.59). Correlations between Method1 & Method2 MPA values were similar for all pts (r = 0.990, p < 0.0001), those with lung metastases (r = 0.999, p < 0.0001), & those without lung metastases (0.989, p < 0.0001).

CONCLUSION

Our data suggest that in pts with iodine avid diffuse lung metastases from thyroid carcinoma, MPA can be accurately estimated by measuring I-131 blood clearance alone without the need to perform un-collimated gamma camera whole body counting.

CLINICAL RELEVANCE/APPLICATION

MPA can be estimated by I-131 blood clearance alone in pts with lung metastases from thyroid carcinoma.

SSM16-04 Influence of Age on Multivariate Analysis of Disease Specific Survival in Differentiated Thyroid Cancer

jasnam61@gmail.com

PURPOSE

The aim of the study was to analyze the influence of age (<45 years versus >=45 years) on disease-specific survival (DSS) and its prognostic factors in patients with differentiated thyroid cancer (DTC).

METHOD AND MATERIALS

569 DTC patients were treated with I-131 (RAI) in our institution from 2001 to 2010. We analyzed DSS and its predicting factors in all 569 patients as well as in different age groups (Group I<45 years, 237 patients and Group II: >=45 years, 332 patients) by Kaplan-Meier's method. Statistical significance of differences was tested by Log rank test.

RESULTS

There were 185 (32.51%) high risk and 378 (66.43%) low-risk patients, while T was not defined in 5 (0.88%) patients; 132 (23.2%) males, 437 (76.8%) females; 57 (10%) follicular and 465 (81.7%) papillary carcinomas, while histology was not defined in 3 (0.53%) patients. Initial regional metastases were present in 202 (35.5%) patients. DSS was 96.5%; 93.5%; 87%, and 69.6% after 5,10,15 and 17 years, respectively. Prognostic factors that significantly influenced DSS were: gender (p=0.003), age (p=0.0001), T stage (p=0.02), initial metastases (p=0.0001), histology (p=0.039), type of initial treatment (p=0.01), while number of RAI course did not inlfuence the survival (p=0.087). In Group I, DSS after 5, 10 and 15 years was 99.1%. Prognostic factors that significantly influenced DSS in this group were: initial metastases (p=0.015) and histology (p=0.007), while gender, type of initial therapy, T stage, and number of RAI courses had no significant influence (p=0.89; p=0.143; p=0.969; p=0.504, respectively). In Group II, DSS after 5 years was 94%, after 10 years = 89.3% and after 15 years = 78%. Strong predicting factors were: gender (p=0.0001), initial metastases (p=0.0001), type of initial therapy (p=0.028), and number of RAI courses (p=0.031), while histology and T stage had no influence to DSS (p=0.275; p=0.101, respectively).

CONCLUSION

DSS prognostic factors differ among age groups. Young patients show longer DSS significantly influenced by the presence of initial metastases and histology. In contrast, elderly patients have shorter DSS with significant influence of gender, type of initial therapy, presence of initial metastases and number of RAI courses.

CLINICAL RELEVANCE/APPLICATION

In comparison to elderly, young DTC patients have longer DSS that is influenced by different prognostic factors.

SSM16-05 Feasibility of Parathyroid Adenoma Localization with Fluciclovine (18F) PET-CT

PURPOSE

Localization of parathyroid adenomas is essential for surgical planning. Uptake of fluciclovine (18F) by parathyroid cells has been reported in-vitro. We conducted a feasibility pilot study to evaluate the ability of fluciclovine PET-CT in comparison to 99m Tc sestamibi SPECT-CT for localization of parathyroid adenomas in patients with hyperparathyroidism.

METHOD AND MATERIALS

Four patients with hyperparathyroidism underwent PET-CT of the neck and upper mediastinum for 60 mins after IV injection of fluciclovine (351.5±28MBq). SUVmax of the adenomas, and target-to-background ratios (TBR) (SUVmax/SUVmean) utilizing blood pool (aortic arch), muscle (pectoralis) or thyroid gland as the background were compared with TBRs of the 45-minute sestamibi (798.3±26.8MBq)SPECT-CT in the same patient. Surgical confirmation was reference standard for truth.

RESULTS

Both modalities had 100% concordance in the localization of the adenomas at surgery (n=4). Mean SUVmax (±SD) of the adenomas were 3.5±1.67, 2.6±1.17, 2.1±0.81, 2.1±0.95, and 2.2±1.03 at 5, 10, 20, 35 and 50 minutes, respectively. The highest fluciclovine SUVs and TBRs were at the 5 min time-point with rapid washout. Sestamibi had significantly higher TBRs compared with fluciclovine (5 min) for blood pool (10.9±4.70 vs 1.3±0.57; p<0.01) and pectoralis muscle (5.8±3.01 vs 1.7±0.55; p<0.01) with a non-significant trend for thyroid gland (1.3±0.48 vs 1.1±0.45; p=0.73), respectively. After surgical resection of the adenomas, the post-operative parathyroid hormone levels decreased to normal. A 2x2 mm adenoma at surgery was not detected by either modality.

CONCLUSION

In this small series we found that parathyroid adenomas can be detected on fluciclovine PET-CT at early imaging but with rapid washout. In addition, adenoma conspicuity (TBR) was better with sestamibi compared with fluciclovine. Fluciclovine PET-CT does not seem promising in the detection and localization of parathyroid adenomas compared with sestamibi SPECT-CT. Studies in patients with negative sestamibi scans are encouraged.

CLINICAL RELEVANCE/APPLICATION

Parathyroid adenomas can be detected on fluciclovine PET-CT at early imaging; however, adenoma conspicuity (TBR) seems better with sestamibi compared with fluciclovine.

SSM16-06 Evaluating the Role of Tc99m Sestamibi Scan in Parathyroid Surgery: A 10-Year Institutional Experience

PURPOSE

In this study we aim to evaluate the (99mTc) sestamibi parathyroid scan as a single localizing modality, and we also assess its relation to the weight of the gland and to the preoperative parathyroid hormone (PTH) levels.

METHOD AND MATERIALS

We reviewed 744 patients from our hospital from 2007 to 2017, with a mean age of 56.6 years and a female to male ratio of 3.3:1. With primary hyperparathyroidism, all of them had (99mTc) sestamibi parathyroid scan for the localization of the parathyroid adenoma. Preoperative and postoperative PTH levels were recorded. The histopathology reports confirmed the diagnosis and weight of the diseased gland, which were recorded every time. The results were analyzed and correlated with the sestamibi results, to evaluate its accuracy.

RESULTS

506 patients (68%) of the 744 had an exact match (EM) sestamibi results, 227 (30.5%) had a partial match, and only 11 patients were reported as mismatch. Analyzing the mean weight of the gland in each group between matching (EM, PM) versus mismatch resulted in a mean difference of 0.823 g (1.05 and 0.247 g, respectively) P = 0.045. Hyperplasia to adenoma ratio was more in the partial matching group (18.5%) versus the exact matching group (7.6%). Finally the mean PTH level was higher in the EM group (36.8 pmol/L) compared to the mismatch group (10.1 pmol/L) P = 0.02. Overall sensitivity and specificity for the (99 mTc) sestamibi in our data was 98.1 and 97%, respectively.

CONCLUSION

(99mTc) sestamibi is a highly accurate test that can be employed as a single localizing modality for identifying a hypersecreting parathyroid, a parathyroid adenoma, or a parathyroidectomy. The weight of the gland plays an important role in the accuracy of the test, as also the preoperative PTH levels.

CLINICAL RELEVANCE/APPLICATION

(99mTc) sestamibi is a highly accurate test that can be employed as a single localizing modality for identifying a parathyroid adenoma.

PURPOSE

Differentiation of benign versus malignant metastatic lymph nodes in the head and neck currently relies on size, morphology and functional status, such as abnormal FDG metabolism. Dual energy CT (DECT) has shown potential in differentiating benign and malignant head and neck lesions in prior studies. Our aim was to evaluate the utility of DECT derived parameters in differentiating benign and metastatic lymph nodes in head and neck squamous cell carcinoma (HNSCC).

METHOD AND MATERIALS

This retrospective IRB approved study included 14 patients with HNSCC who underwent head/neck DECT and PET/CT within 60 days of each other. One reader placed regions of interest within multiple lymph nodes deemed metastatic (on PET/CT, histopathology or both), normal nodes and skeletal muscle in the same patients (32 metastatic, 49 normal nodes). Independent sample t-tests were used to compare differences in DECT parameters between the two groups, including node HU at 40keV, 50keV, 70keV, 140keV, HU40keV-HU140 keV, effective Z and iodine concentration after normalizing the values by creating node to muscle ratios. When gross necrosis was present in the nodes, ROIs including entire node and those that excluded the necrotic portion were separately studied.

RESULTS

Significant differences in node HU40keV and RATIO-HU40keV were seen between normal and metastatic nodes (207 vs 177 HU, p=0.048; 2.29 vs 1.91, p=0.027) when necrosis was excluded. Similarly, significant differences were seen in node HU140keV and RATIO-HU140keV between normal and metastatic nodes (30.4 vs 38.2 HU, p=0.003; 0.75 vs 0.62, p=0.012), as well as RATIO-HU40-140keV (p=0.047). The other DECT parameters studied did not reveal any differences between the two groups.

CONCLUSION

DECT derived lymph node HU at monochromatic 40keV and 140 keV and ratio of node to muscle HU at monochromatic 40keV and 140 keV are significantly different between normal and metastatic nodes in patients with HNSCC, implying that DECT could have utility, in addition to size and morphology of nodes, in distinguishing these groups. We plan to further study the thresholds that can be used for employing this in clinical practice.

CLINICAL RELEVANCE/APPLICATION

Since most patients with HNSCC undergo CT examination for disease workup, utilizing DECT based metrics for improving the differentiation of normal from metastatic nodes in patients with HNSCC without any additional radiation can help better stage disease.

SSM17-02 Diagnostic Value of Dual-energy Spectral Computed Tomography in Differentiating Parotid Gland Tumors

Wednesday, Nov. 28 3:10PM - 3:20PM Room: N228

Participants
Lin Li, MD, Beijing, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

linlin77216@sina.com

PURPOSE

To quantitatively evaluate the value of single-source dual-energy spectral computed tomography in differentiating parotid gland tumors.

METHOD AND MATERIALS

43 patients underwent enhanced neck dual-energy spectral CT scan before operation. The spectral CT scan protocol included tube current of 260mA, helical pitch of 0.984 and rotation speed of 0.7s/r. The material decomposition images and monochromatic images were reconstructed and transferred to a GEAW4.6 workstation for spectral analysis using the Gemstone Spectral Imaging (GSI) Viewer software. Tumors were divided into pleomorphic adenomas (PAs), Warthin tumors (WTs) and malignant tumors (MTs) types. The CT number as function of photon energy, iodine concentration (IC) and water concentration (WC) of tumors were measured. The slope value (λHU) of the spectral HU curve and normalized iodine concentration (to common carotid artery, NICA) were calculated and compared among the three types of tumors. The statistical analysis was performed with SPSS 13.0 software. ROC analysis was performed to evaluate the efficiency of these multiple parameters for the differential diagnosis.

RESULTS

52 tumors were confirmed by pathology and were included in our study, including 12 pleomorphic adenomas, 24 Warthin tumors (15 patients), and 16 malignant tumors. The IC, NICA and λHU values of WTs (2.45±0.82mg/ml, 0.33±0.08 and 2.76±0.08, respectively) were significantly higher than those of MTs (1.48±0.90mg/ml) which were in turn higher than those of PAs (0.59±0.28mg/ml) (all $P<0.05$). The optimal IC, NICA and λHU threshold was 0.91mg/ml, 0.15 and 1.09, respectively for differentiating PAs from MTs, achieving sensitivity of 91.7%, 91.7% and 91.7%, specificity of 95.0%, 85.0% and 95.0%, and accuracy of 94.2%, 86.5%and 94.2%, respectively for distinguishing PAs from MTs. The optimal IC, NICA and λHU threshold was1.46mg/ml, 0.20 and 1.72,achieving 91.7%, 95.8% and 91.7% sensitivity, 89.3%, 85.7% and 89.3% specificity, respectively. The accuracy was 90.4%, 90.4%and90.4%, respectively for distinguishing WTs from MTs.

CONCLUSION

The single-source dual-energy spectral CT-related measurements such as iodine concentration in parotid tumors in the enhanced CT scans are useful in the differential diagnosis of parotid tumors.

CLINICAL RELEVANCE/APPLICATION

The single-source dual-energy spectral CT imaging is helpful to differentiate various pathological types of parotid gland tumors.

SSM17-03 Comparison of Dual and Single Source Dual Energy CT in Head and Neck Imaging

matthias.may@uk-erlangen.de

PURPOSE

Aim of this study was to compare image quality of Single-Source Dual-Energy CT (SS-DECT) with third-generation Dual-Source dual energy CT (DS-DECT) in head and neck cancer.

METHOD AND MATERIALS

102 patients with histologically proven head and neck cancer were prospectively randomized to undergo radiation dose matched SS-DECT (n=51, 120 kV, split filter technique, 384 ref. mAs) or DS-DECT (n=51, 80/Sn150 kV, tube A 100/ tube B 67 ref. mAs). Inline default images (DI) and virtual monoenergetic images (VMI) for two different low energies (40 and 60 keV) were reconstructed. Objective image quality was evaluated as dose normalized contrast to noise ratio (CNRD) and subjective image quality was rated on a 5-point Likert-scale.

RESULTS

In both groups highest CNRD values for vessel and tumor attenuation were obtained at 40 keV. DS-DECT was significantly better than SS-DECT regarding vessel and tumor attenuation. Overall subjective image quality in the SS-DECT group was highest on the DI followed by 40 keV and 60 keV. In the DS-DECT group subjective image quality was highest at 40 keV followed by 60 keV and the DI. 40 keV and 60 keV were significantly better in the DS-DECT compared to the SS-DECT group (both $p<0.01$).

CONCLUSION

In split filter SS-DECT as well as DS-DECT highest overall image quality in head and neck imaging can be obtained with a combination of DI and low keV reconstructions. DS-DECT is superior to split filter SS-DECT in terms of subjective image quality, vessel and tumor attenuation.

CLINICAL RELEVANCE/APPLICATION

This is the first study comparing image quality of two different dual energy techniques of the same vendor in a radiation dose-matched setting for head and neck imaging.

SSM17-05 Iodine Quantification in Patients with Initially Diagnosed Head and Neck Cancer Using Dual-Layer

Detector Spectral CT: Which Factor Could Significantly Affect the Tumoral Iodine Concentration?

younghen@korea.ac.kr

PURPOSE

We aimed to investigate of impacts of patient- & tumor-related factors on the dual-layer detector spectral CT-derived iodine concentration(IC) in the patients initially diagnosed with head and neck squamous cell carcinoma(HNSCC).

METHOD AND MATERIALS

From July 2016 to March 2018, a total of 46 patients (M:F=41:5, mean age: 62.8years) initially diagnosed with HNSCC which were identified by contrast-enhanced neck CT examination using a double-layer detector spectral CT (IQon CT, Philips healthcare) were retrospectively enrolled. To obtain the IC of the primary tumors, an experienced neuroradiologist draw the region of interest (ROI) on the representative axial images after reviewing the corresponding MRI images, and then copied the same ROI on the additional iodine density map. In addition, other ROIs were drawn on the aortic arch and ipsilateral neck muscle for normalization. We statistically determined the variables which significantly influenced the IC and normalized IC (nIC) of primary HNSCC using a multivariate linear regression: age, gender, iodine concentration, body surface area, T stage, histologic grading and location of tumor.

RESULTS

According to our quantitative analysis obtained from contrast-enhanced neck CT examination with fixed scan delay (50-sec), only histologic grading significantly influenced the mean IC of primary HNSCC ($p<0.05$). The mean IC (mg/ml) was significantly highest in well differentiated (n=11;2.2±0.84), followed by those of moderately-(n=27;2.0±0.65), poorly differentiated (n=4;1.8±0.49) and that of non-keratizing type were lowest (n=4; 1.40±0.18).

CONCLUSION

Dual-layer detector spectral CT-derived mean IC could be used as useful predictor of histologic grading in patients initially diagnosed HNSCC.

CLINICAL RELEVANCE/APPLICATION

Dual-layer detector spectral CT-derived mean IC could be used as useful predictor of histologic grading in patients initially diagnosed HNSCC. Iodine quantification using dual-layer detector spectral CT might potentially improve the role of contrast-enhanced CT examination in the HNSCC.

SSM17-06 Preliminary Study on Spectral CT in the Diagnostic Value of Papillary Thyroid Microcarcinoma

Wednesday, Nov. 28 3:50PM - 4:00PM Room: N228

Participants
Lin Li, MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

The aim of the current study was to retrospectively analyze spectral CT images of papillary thyroid microcarcinoma (PTMC) and evaluate the detection and diagnostic value for PTMC.

METHOD AND MATERIALS

33 cases (35 lesions) of PTMC which were confirmed by surgical pathology from January 2015 to January 2016 were included in this retrospective study. All the patients underwent Spectral CT scan using Discovery CT750 HD scanner. All the spectral CT images were divided into 3 groups: polychromatic image (group A), optimal monochromatic image (group B), and the fused image which blended optimal monochromatic image with iodine-based material decomposition image together (group C). The image qualities of group A and B were evaluated objectively, and the detection abilities of the 3 groups were evaluated subjectively.

RESULTS

The optimal CNR level is (65.96±4.01)keV (range from 62 to 75keV). The CNR of optimal monochromatic image of spectral CT was higher than that of polychromatic image(t=-5.626,P=0.000), and the noise of optimal monochromatic image was lower than that of polychromatic image(t=12.00,P=0.000), and the differences were significant($P<0.05$). The detection rate of the 3 groups of images for microcarcinoma lesions were 91.4%(32/35),97.1%(34/35), and 100%(35/35) respectively, while the subjective scores of the 3 groups of images were 2.54±1.15,3.31±0.93, and 3.46±0.74 respectively. The detection ability of fused image was better than that of polychromatic image and similar to that of optimal monochromatic image. The characteristics of microcarcinoma were irregular shape (19 cases, 54.3%), indistinct margin (24 cases, 68.6%), heterogeneous density (24 cases, 68.6%), detection of microcalcification (16 cases, 45.7%), and lymph node metastasis (20 cases, 57.1%). The lesions' average iodine concentration, normalized iodine concentration, and the average spectral HU curve slope values were (25.0±10.3)×100μg/ml (range from (9~43)×100μg/ml), 0.33±0.14(0.14~0.61), and 2.99±1.59(-0.83~5.38), respectively.

CONCLUSION

Spectral CT could provide more detailed information for PTMC diagnosis, and the fused image which blended optimal monochromatic image with iodine-based material decomposition image may be useful for PTMC detection and diagnosis in the clinics.

CLINICAL RELEVANCE/APPLICATION

Spectral CT imaging is helpful to detect and diagnosis papillary thyroid microcarcinomas.

PURPOSE

Our study aims to quantitatively evaluate the treatment effect of endovascular treatment for patients with acute cerebral venous sinus thrombosis(CVST) by Magnetic Resonance Black-Blood Thrombus Imaging(MRBTI) for the first time.

METHOD AND MATERIALS

From 2014 to 2018, 34 patients diagnosed with acute CVST were included in this study, of whom 19 patients received endovascular treatment(experimental group) while 15 patients received anticoagulant therapy(control group). Initial MRBTI and MRV, follow-up MRBTI and MRV were performed on all these enrolled patients. Thrombus Volume (TV) of each person was measured between endovascular group and anticoagulant group on BTI images. Thrombosed segments, venous colleterals, degree of recanalization and modified Rankin Scale(mRS) were noted between these two groups.

RESULTS

In endovascular and anticoagulant groups, the volume of thrombus(VT) was 9538±5343 mm^3 and 6424±3633 mm^3($P>0.05$, $P=0.77$) before treatment, the volume of thrombus was 2028±3836 mm^3 and 2642±2234 mm^3($P>0.05$, $P=0.604$) respectively. The decreased volume after treatment were 7509±4660 mm^3 and 3782±2269 mm^3 ($P<0.01$, $P=0.009$). Before treatment, the thrombosed segments in experimental group and control group were 6.3±2.8 and 5.9±2.5($P>0.05$, $P=0.692$) and were 2.9 ±2.5 and 4.5 ±2.7($P> 0.05$, $P=0.109$) after treatment, and the decreased segments were 3.3 ±1.8 and 1.4 ±1.3($P< 0.01$, $P=0.002$), respectively. And the degree of recanalization in endovascular group is better than anticoagulant group ($P < 0.01$, $P=0.000$), which predict a satisfied prognosis. While as for venous collaterals, the venous collateral in anticoagulant group(control group) is more than endovascular group(experimental group).

CONCLUSION

MRBTI can quantitatively assess the effect of endovascular treatment for patients with CVST. Furthermore this technique should be the best imaging technique to follow up patients with CVST after treatment, which may help to judge prognosis of patients with CVST.

CLINICAL RELEVANCE/APPLICATION

The novel imaging technique-MRBTI to quantitatively assess the effect of endovascular therapy for the first time. It may help to predict the prognosis of patients with CVST.

SSM18-02 Amine Protons Were Increased in the Demented Patients: Evaluation of the Chemical Exchange Dependent Saturation Transfer MRI

Wednesday, Nov. 28 3:10PM - 3:20PM Room: N226

Participants
Na Young Choi, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Yeji Shin, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Young Hoon An, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

Bo Guem Choi, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Hak Young Rhee, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Chang-Woo Ryu, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Geon-Ho Jahng, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Chemical exchange dependent saturation transfer (CEST) MRI is sensitive to solid-like proteins and may detect mobile proteins and peptides in tissues. There is no study for investigating various substances such as amine, hydroxyl protons with a full Z spectrum. Therefore, the purpose of our study is to evaluate the characteristics of chemical exchange proton pools using a CEST MRI technique in dementia patients.

METHOD AND MATERIALS

Nineteen demented (mean=77.9 years, range=55-92 years) and 22 non-demented (mean=66.7 years, range=51-83 years) subjects were included in this study. Using two 3.0 Tesla MRI systems, the full Z spectrum data by total 38 dynamics from -5.00 ppm to 5.00 ppm frequency offset ranges were acquired with using a 3D turbo-spin-echo (TSE) sequence in the brain using alternative increased frequency interval of 0.25 ppm. To map the voxel-based exchangeable signals with the special frequency offsets of protons and the magnetization transfer ratio (MTR) asymmetry (MTRasym), we quantified exchangeable protons with the Lorentzian fitting method using the six-pool model consisted of amide, amine, hydroxyl, direct water saturation (DWS), nuclear overhauser effect (NOE) and magnetization transfer (MT). The voxel-based MTRasym maps were calculated at the frequency offsets of 1.00 ppm, 3.00 ppm, 3.50 ppm. The two sample t-test was used for comparison between two groups.

RESULTS

Based on the Lorentzian fitting, the amide was not significantly different between the two groups and the amine was significantly different between the two groups at the anterior cingulate, hippocampus, parahippocampal gyrus, and pons. MTRasym values were significantly different between the two groups at the anterior cingulate, hippocampus, and putamen for both 3 ppm and 3.5 ppm.

CONCLUSION

In the demented subjects, the amine and the MTR asymmetry values were increased, probably related with increased proteins, neurotransmitters, or metabolites. CEST MRI has several advantages compared with amyloid PET. Therefore, CEST MRI may be useful to investigate brain changes in demented patients without radiation exposure and with high resolution.

CLINICAL RELEVANCE/APPLICATION

CEST MRI technique in dementia patients can be effective for the evaluation of brain changes in demented patients without radiation exposure and with high resolution.

d.paech@dkfz.de

PURPOSE

The study purpose was to investigate the non-invasive predictability of IDH-mutation status, MGMT promotor methylation, and differentiation of lower versus higher grade glioma (LGG vs. HGG) in newly-diagnosed WHO grade I-IV glioma patients employing Chemical Exchange Saturation Transfer (CEST) magnetic resonance imaging (MRI) at 7.0 Tesla (7T).

METHOD AND MATERIALS

Thirty-four newly-diagnosed glioma patients were included in this prospective study (WHO grade I-II: 7/34=20.6%=LGG; WHO grade III-IV: 27/34=79.4%=HGG; IDH1-R132H status: 9/33=27.3% IDH-mutant; 24/33=72.7% IDH-wildtype, 1 patient not assessed; MGMT promotor methylation status 13/28=46.4% methylated, 11/28=39.3% unmethylated, 4/28=14.3% indeterminate, 2 patients not assessed). CEST MRI was performed at a 7T whole-body scanner followed by a multi-Lorentzian fit analysis. Nuclear Overhauser Effect (NOE) and amide proton transfer (APT) CEST signals were quantitatively investigated in the whole tumor area with regard to predictability of IDH-mutation, MGMT status, and differentiation of LGG vs. HGG. Statistics were performed using

receiver operating characteristic (ROC) and area under the curve (AUC) analysis.

RESULTS

The APT CEST contrasts yielded highest AUCs in IDH-mutation status prediction (dns-APT=0.92, p<0.01; sensitivity=81%, specificity=100%). NOE mediated CEST imaging yielded inferior performance in IDH status prediction (AUC=0.78, p=0.02; sensitivity=61%, specificity=83%). Furthermore, dns-APT metrics enabled significant differentiation of LGG vs. HGG (AUC: dns-APT=0.78, p<0.05; sensitivity=71%, specificity=100%). There was no significant difference regarding MGMT status at any CEST contrast (p>0.05).

CONCLUSION

CEST MRI at 7T, particularly APT imaging, enabled prediction of IDH-mutation status and differentiation of LGG vs. HGG and should therefore be considered as non-invasive MR biomarker to assess histologic and genetic subtypes in glioma patients in the diagnostic workup.

CLINICAL RELEVANCE/APPLICATION

Early identification of prognostic superior characteristics in glioma patients such as IDH-mutation and MGMT status is of great clinical importance. Our study demonstrates that CEST MRI at 7.0T enables non-invasive prediction of IDH mutation status and differentiation of LGG vs. HGG tumors. Consequently, CEST MRI may add valuable information as a non-invasive imaging biomarker in the preoperative diagnostic work-up of glioma patients.

SSM18-04 NODDI: A Promising Method for Assessing Glioma Grade and Cellular Proliferation

Wednesday, Nov. 28 3:30PM - 3:40PM Room: N226

lishihui9376@sohu.com

PURPOSE

To explore the diagnostic performance of neurite orientation dispersion and density imaging (NODDI) in grading gliomas and to evaluate the cellular proliferation.

METHOD AND MATERIALS

NODDI and diffusion-weighed imaging were performed on 80 patients with histopathologically proven glioma. Parameter maps of intra-cellular volume fraction (ficvf), isotropic volume fraction (fiso) and orientation dispersion index (odi) were calculated. Regions of interest were placed in the most solid parts of the tumor. These metrics were normalized to the contralateral normal-appearing white matter and correlated with Ki-67 expression.

RESULTS

Significant differences in normalized ficvf, odi and fiso were observed between low-grade gliomas and high-grade gliomas (ficvf: 0.213 ± 0.107 vs. 0.718 ± 0.234; odi: 0.962 ± 0.426 vs. 1.767 ± 0.636; fiso: 2.482 ± 2.040 vs. 0.109 ± 0.140; $p < 0.001$ for all) and between grade II and grade III (ficvf: 0.208 ± 0.104 vs. 0.603 ± 0.253; odi: 0.952 ± 0.428 vs. 1.762 ± 0.542; fiso: 2.550 ± 2.031 vs. 0.115 ± 0.133, $p < 0.001$ for all). Only normalized ficvf was significant different between grade III and grade IV (0.603 ± 0.253 vs. 0.803 ± 0.182, $p = 0.004$). Ki-67 labeling index was positively correlated with ficvf and odi ($r = 0.758$ and 0.616), and negatively correlated with fiso and ADC ($r = -0.523$ and -0.703).

CONCLUSION

NODDI can effectively grade gliomas, and also showed great potential in predicting Ki-67 expression.

CLINICAL RELEVANCE/APPLICATION

NODDI offers a novel and non-invasive method in grading gliomas and to evaluate the cellular proliferation in gliomas.

SSM18-05 T2 Nerve Imaging of the Brachial Plexus Using Compressed-SENSE Effect on Image Quality and Acquisition Time

Wednesday, Nov. 28 3:40PM - 3:50PM Room: N226

For information about this presentation, contact:

drvasanth@mahajanimaging.com

PURPOSE

In this study, compressed sensing is combined with the parallel-imaging or SENSE infrastructure, i.e., Compressed-SENSE (CSENSE),

for accelerating anatomical MR data acquisition by exploiting the multi-element receiver coil sensitivity variation and sparsity constraining. We quantitatively evaluate the dual role of CSENSE imaging in reducing scan time without loss in resolution and in improving resolution with minimal increase in scan time.

METHOD AND MATERIALS

Ten healthy volunteers were scanned on a 3.0T MRI (Ingenia, Philips) using a proprietary "3D NerveView Sequence" (NVS), a T2W TSE isotropic sequence (TR 2200, TE 170, 2 mm slice thickness). Three versions of NVS were developed, SEQ1 (no CSENSE), SEQ2 (CSENSE factor = 9) and SEQ3 (CSENSE factor = 9) with acquisition times 6:16, 3:22 and 8:19 minutes respectively. SEQ1 and SEQ2 had the same acquisition and recon matrix of 252X325 and 640X640 while SEQ3 had a higher resolution having acquisition and recon matrix of 316X414 and 720X720 respectively. Contrast-to-Noise Ratio (CNR) was measured in all at the levels of the nerve roots (C5 to T1 levels), trunks and cords using Shinkei's formula of CNR = (SI-Nerve - SI-Muscle)/ (SI-Nerve + SI-Muscle) where SI is average Signal Intensity in the region.

RESULTS

There was no significant difference in CNR for roots in all three sequences, i.e. SEQ1 - 0.7102±0.102, SEQ2 - 0.7040±0.044 and SEQ3 - 0.7253±0.035. In the trunks, SEQ3 performed as well as SEQ1 with a CNR of 0.567±0.10 against 0.5497±0.09. SEQ2 had a lower CNR of 0.4843±0.11. At the level of cords, SEQ1 outperformed both SEQ2 and SEQ3 with a CNR of 0.4248±0.17 against 0.3079±0.11 and 0.3505±0.19 respectively. We note that CSENSE performs better in areas where average CNR is on the higher side.

CONCLUSION

While CSENSE gives radiologists flexibility of reducing time or increasing resolution, the decision of when and how to use CSENSE depends on the clinical context. It can be used to reduce scan time when root lesions are suspected and improve resolution when lesions of the trunks and cords are suspected.

CLINICAL RELEVANCE/APPLICATION

Compressed Sensing for nerve imaging should be part of every radiologist and technologists' arsenal to conduct patient-specific personalised scanning. Lower scan time leads to improved patient comfort and hence less motion artefacts, and higher resolution improves diagnostic accuracy of the scan.

SSM18-06 Visualization of the Peripheral Branches of the Mandibular Nerve Using a Micro Surface Coil and Three-Dimensional Double-Echo Steady-State with Water Excitation Sequence

Wednesday, Nov. 28 3:50PM - 4:00PM Room: N226

Participants
Guixun Hong, MD, Guangzhou, China (*Presenter*) Nothing to Disclose
Zhiyun Yang, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To investigated the detectability of the branches of the mandibular nerve on a three-dimensional double-echo steady-state with water excitation sequence using a small surface coil.

METHOD AND MATERIALS

The maxillofacial regions of 52 volunteers were scanned unilaterally by a small surface coil combined with 3D-DESS-WE sequence. According to the Gray's anatomy atlas, MPR and CPR was done according to the anatomic position of mandibular nerve and the branches, the signal characteristics of the nerves and neighboring structures were analyzed, the displaying rate of the mandibular nerves and their branches were evaluated, the image quality and display of the nerve were subjectively scored, the signal intensity(SI) of the nerve and adjacent lateral pterygoid muscle were measured,the signal intensity ratio(SIR) of mandibular nerve/lateral pterygoid muscle (SIRN/M) was calculated.

RESULTS

Compared with the muscles, the nerve showed iso signal intensity. The subjective scores for all small coil 3D-DESS-WE images were 3.02±0.82. The displaying rates of the mandibular nerve trunk, anterior trunk, buccal nerve, posterior trunk, inferior alveolar nerve and lingual nerve were all 100%. The posterior trunk, inferior alveolar nerve and lingual nerve showed the best quality scores, which were all about 3 points, and the SIRN/M were about 1. The displaying rates of the auricular temporal nerve and masseter muscle nerve were also satisfied. The displaying rate of mylohyoid muscle nerve, medial pterygoid nerve and lateral pterygoid nerve was low.

CONCLUSION

The small surface coil combine with 3D-DESS-WE sequence demonstrated excellent visualization of the extracranial branches of the mandibular nerves in most volunteers, which has the potential for diagnosing mandibular nerve pathologies and preoperatively identifying peripheral cranial nerves to prevent surgical complications.

CLINICAL RELEVANCE/APPLICATION

Small surface coil combine with 3D-DESS-WE sequence performed high-quality in mandibular nerves imaging using MPR, CPR post-processing technology, which are suitable for clinical application.

PURPOSE

Numerous independent studies reported increasing T1w signal intensity (SI) of the dentate nucleus (DN) and the globus pallidus (GP) after repetitive administrations of linear Gadolinium-based contrast agents (LGBCA). Also, a recent study indicates that a high number of macrocyclic GBCA (MGBCA) administrations may also lead to an increase of SI. However, most previous studies were performed at small scale and predominantly by using manual ROI-based methods. In this study, we present results from a large-scale study that uses a completely automated high performance computing pipeline.

METHOD AND MATERIALS

In-house developed PACS/RIS mining software was used to locate and retrieve all native T1W MPRAGE datasets performed on patients that received at least 2 exams with GBCA. Datasets were histogram-normalized and segmented utilizing FSL and a cerebellum atlas. Calculations were performed overnight on a high performance computing cluster. SI increase was analyzed in a mixed effects model.

RESULTS

3021 consecutive patients receiving 11,922 MRI brain scans were included. Repeated administration of GBCA was associated with increased overall SI for both LGBCA (Estimate 0.23, 95% CI 0.07-0.39, p=.006) and MGBCA (Estimate 0.06, 95% CI 0.02-0.09, p<.001). Stratified among brain nuclei, significant SI increase was found only after LGBCA application in the DN (Estimate 0.6, 95% CI 0.077-1.12, p=.027) and the GP (Estimate 0.38, 95% CI 0.03-0.72, p=.033) but not for MGBCA. On the other hand, significant SI increase was found only after MGBCA in the thalamus, putamen, amygdala, caudate, hippocampus, and accumbens (Estimates up to 0.29, p<.001) but not for LGBCA.

CONCLUSION

Our findings confirm previous reports on increased SI after LGBCA application in the DN and GP, but not after MGBCA. However, we found increase in SI for other brain nuclei only for MGBCA. Based on our findings, Gadolinium accumulation in the brain may be more widespread than assumed and could occur with the use of both L- and MGBCA.

CLINICAL RELEVANCE/APPLICATION

Gadolinium accumulation in the brain may be more widespread than assumed and could occur with the use of both L- and MGBCA.

SSM19-02 The Correlation of GD Deposition with Administration of GBCAs and the Elimination Rates in Human Brain, Bone, and Skin

PURPOSE

The purpose of this study was to determine the correlation of Gadolinium (Gd) deposition between Brain tissue ,white matter (WM),Globus Paliidus (GP),Dentate nuclueus (DN) ,and Bone,Skin in human with administration of gadolinium-based contrast agents (GBCAs) and to determine the elimination rates.

METHOD AND MATERIALS

Under the IRB approved study , medical records of decedents coming to autopsy were reviewed, 35 cases were identified that received GBCAs including 13 who received only macrocyclic agents(gadoteridol, gadobutrol) and 8 decedents only linear type of agents (gadodiamide,gadobenate, gadoxetic acid, gadoversetamide and gadopentate) and 3 with mix type of agents.(gadoteridol and gadoversetamide, gadoteridol with gadopentate and gadobenate, gadoteridol and gadobenate). All cases are with normal renal function (eGFR>60) and have more than a week from last injection to death.11 cases not exposed to a GBCA during life are included as control. Tissue from WM, GP, DN along with bone and skin were collected. Inductively coupled plasma mass spectrometry (ICP-MS) analysis was used to quantify levels of Gd in tissue. The time from last injection of GBCA to death was determined for each case. Gd levels for each subject were plotted versus time interval from last contrast administration for each agent to compare elimination rates.

RESULTS

Median Gd concentrations significantly higher in GBCA cases than controls in WM, GP and bone. (<0.001).Macrocyclic agents group showed significantly lower deposition than Linear agent groups in WM ,GP, DN, Bone.(P<0.001).Gd deposition in all tissues ,WM, GP, DN, Bone, Skin were correlated with each other (rho ranging from 0.71to.86). And Bone had significantly higher deposition than all other tissues(P<0.001),whereas WM had significantly lower deposition(P<0.001).Graphical results of tissue concentration versus time from last administration showed the Macrocyclic subjects had more rapid decline and plateaued at a lower level than the linear subjects.

CONCLUSION

Gd deposition in each human tissues were correlated significantly and deposition in bone was much higher than other organs. Gd deposition with Macrocyclis agents showed more rapid elimination that appeared to plateau at a lower level of retained Gd concentration than linear agents.

CLINICAL RELEVANCE/APPLICATION

This study shows correlation of Gd deposition in human tissues with the administration of GBCAs and elimination rates.

SSM19-03 Gd Deposition in Rat and Human Cerebral Cortex After Systemic Administration of Gd-Containing Contrast Agents

PURPOSE

While Gd accumulation in the deep cerebellar nuclei (DCN) amd globus pallidus (GP), has received considerable attention, Gd accumulation in the cerebral cortex remains poorly characterized and of potential clinical concern given the central role of the

cortex in cognition, affect, and behavior. The purpose of this study was to analyze the degree and distribution of Gd deposition in the cortex. The study utilized high-resolution metallomic imaging mass spectrometry (MIMS) to anatomically localize and analytically quantify Gd in postmortem brains from rats and humans.

METHOD AND MATERIALS

IACUC/IRB protocols approved at our institute. Sprague-Dawley rats received Magnevist (dose: 2.4mmol/Kg x 3 times, IV) or volume-matched saline(control). Harvested brains fixed with 4% PFA. Human brain specimens (n=3) were analyzed, two specimens from subjects with antemortem Gd exposure and a third from a control subject without Gd exposure. MIMS was performed using a quadrupole ICP-MS (Thermo Scientific) custom hyphenated to a Nd-YAG laser ablation system. Calibration was performed with matrix-matched standards and NIST reference standard (SRM 612).

RESULTS

We detected non-homogeneous Gd retention in rat brain after Gd exposure. Cortical Gd accumulation was far greater in gray matter than adjacent white matter. We detected variation in Gd accumulation by cortical subregion (cingulate=medial prefrontal>piriform>insular>motor) and cortical layer (layers II-III>>layerI>layers V,VIa,sVib) and subcortical structures (caudate-putamen, GP, DCN>olfactory tubercle>nucleus accumbens). Gd accumulation also varied by cortex type: agranular>dysgranular>granular. We confirmed Gd accumulation with long post-exposure retention in human cortex.

CONCLUSION

Gd is retained in cerebral cortex after systemic Gd administration. Cortical Gd deposition is non-uniform and demonstrates regional, laminar, type variation. Gd accumulation in human cerebral cortex and persists long after Gdexposure and washout. These results raise concern about possible long-term functional effects of Gd accumulation in the brain.

CLINICAL RELEVANCE/APPLICATION

Our results suggest that Gd deposits not only in deep gray matter, but also in specific regions in cerebral cortex. As the cerebral cortex exerts a large influence on brain function and behavior, our study suggests that additional clinical/pre-clinical studies should be conducted and focused on the cortex.

SSM19-04 Evaluation of Chelating Agent Administration Following Exposure to Gadolinium-Based Contrast Agents in Rats

Wednesday, Nov. 28 3:30PM - 3:40PM Room: N227B

Participants
Janina Boyken, Berlin, Germany (*Abstract Co-Author*) Nothing to Disclose
Thomas Frenzel, PhD, Berlin, Germany (*Abstract Co-Author*) Employee, Bayer AG

PURPOSE

This study investigates the efficacy of the chelating agent calcium trisodium pentetate (Ca-DTPA) on the urinary excretion and presence of gadolinium (Gd) in the brain after single administration of gadodiamide and gadobutrol in rats.

METHOD AND MATERIALS

Rats received either a single injection of gadodiamide, gadobutrol (1.8 mmol/kg, n=18 per group) or saline. 7 weeks after GBCA injection, 6 animals of each group were sacrificed prior to chelation treatment. The remaining 12 animals received either 3 infusions of Ca-DTPA (180 µmol/kg, once weekly) or saline. Urine was collected daily for 3 days following each infusion. Gd measurements by ICP-MS were performed in urine and tissue samples obtained prior and post treatment.

RESULTS

After a Gd-free period of 7 weeks, urinary excretion of Gd under physiological conditions (saline infusion) was still observed for gadobutrol (sum of Gd in all urine samples: 33±12 nmol Gd, $p <= 0.0005$) but not gadodiamide (10±4 nmol Gd, $p=0.68$) when compared to animals which initially received a saline injection instead of GBCA (5±5 nmol Gd). Ca-DTPA increased the urinary excretion of Gd originating from gadodiamide (114±21 nmol Gd), but not from gadobutrol (30±11 nmol Gd). The highest Gd brain concentration in nmol/g tissue was present in the cerebellum after injection of gadodiamide (0.55±0.07), which was partially reduced by Ca-DTPA (0.47±0.08, $p=0.015$). The cerebellar Gd concentration from gadobutrol was 20-fold lower (0.024±0.006) and unaffected by Ca-DTPA (0.027±0.017).

CONCLUSION

Administration of a chelating agent increased the urinary excretion and partial elimination of the residual Gd in brain tissue originating from gadodiamide but not from gadobutrol. This indicates a pool among the chemical Gd forms present in the rat brain and other organs that can be mobilized and excreted by Ca-DTPA after the use of linear gadodiamide. The lower Gd tissue concentrations found for macrocyclic gadobutrol were associated with a continuous physiological urinary excretion which was not influenced by Ca-DTPA, indicating that this Gd represents the intact gadobutrol.

CLINICAL RELEVANCE/APPLICATION

Chelation treatment efficacy is dependent on the administered GBCA class.

SSM19-05 Experimental Sepsis Increases Brain Deposition of Gadolinium in the Rat

Wednesday, Nov. 28 3:40PM - 3:50PM Room: N227B

Kathryn A. Morton, MD, Salt Lake City, UT (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

kathryn.morton@hsc.utah.edu

PURPOSE

There is emerging concern that gadolinium based contrast agents (GBCA) may undergo dechelation, leading to deposition of potentially neurotoxic Gd3+ in the brain. Because GBCA do not cross an intact BBB, disruption of the BBB may result in enhanced deposition of Gd in the brain. We have previously reported that a lipopolysaccharide (LPS) endotoxemia sepsis model in rats results in secondary neuroinflammation, increased cerebral blood flow and blood brain barrier permeability. Septic patients often have neurocognitive compromise and frequently undergo CEMR. The purpose of this study was to determine whether experimental sepsis results in increased Gd deposition in the brain.

METHOD AND MATERIALS

Male Sprague Dawley rats (250 g) were injected intraperioneally with 10 mg/kg LPS. Control animals received no injection. 24h later, 100 ul of gadobenate dimeglumine (MultiHance®) MRI contrast was injected intravenously. The brains were harvested at 1 h, 24 h, 1 week, 3 weeks and 6 weeks post GBCA administration. Gd content in the brain was measured by inductively coupled plasma mass spectroscopy.

RESULTS

At 1 h post injection of GBCA, there was 56% greater content of Gd in the brain of LPS animals than controls. At 1 week, 3 weeks and 6 weeks post GBCA administration, further decreases in Gd content in the brains of both LPS-treated and control rats occurred, but at a much slower rate than between 1 h and 24 h. The percent of initial (1 h) Gd in the brain of LPS treated rats was 3.2% at 24 h, 2.7% at 1 week, 2.3% at 3 weeks and 2.3% at 6 weeks. At all time points beyond 1 h, there were statistically significant increases in the content of Gd in the brains of LPS-treated animals when compared to controls. LPS:control ratios of brain Gd were 3.2 at 24 h, 1.9 at 1 week, 2.4 at 3 weeks and 2.4 at 6 weeks.

CONCLUSION

When GBCA is administered to septic rats, there is a significantly higher deposition of Gd in the brain compared to control rats. In both LPS and control rats, the brain retains substantial Gd even at 6 weeks post GBCA injection.

CLINICAL RELEVANCE/APPLICATION

Consideration should be given to avoidance of GBCA in vulnerable patients who may have an increase in blood brain barrier permeability.

SSM19-06 Screening for Gadolinium Brain Retention in Patients Receiving Multiple Doses of Gadobutrol in a University Medical Center Over 10 Years

tobias.baeuerle@uk-erlangen.de

PURPOSE

Purpose was to screen a large MRI population for the frequency of applied doses of gadobutrol in patients with normal and impaired kidney function and to recall selected individuals for assessment of gadolinium brain retention.

METHOD AND MATERIALS

The database of the University Hospital Erlangen, Germany was searched for patients receiving gadobutrol between 2007 and 2017 and not any other intravenous MRI contrast agent in the patients' history. Patients with at least 5 (range 5-20) contrast-enhanced MRI scans and normal kidney function (group 1) and at least 1 (range 1-9) contrast-enhanced MRI scans and impaired kidney function (group 2) were matched with control patients receiving no MRI contrast agent before (groups 3 and 4). The aim was to recall all individuals from groups 1-4 performing the following brain MRI protocol: T1w morphology, T1/T2 mapping and quantitative susceptibility mapping (QSM).

RESULTS

Between 2007 and 2017, more than 35.000 patients at our institution received up to 26 single doses of gadobutrol only. Of these, 701, 1239, 94 and 409 patients matched the criteria of groups 1-4, respectively. After recalling 2.444 individuals, we were able to perform brain MRI in 220 individuals (groups 1-4: 76, 84, 25, 35, respectively). In the study population, no significant differences in T1w signal intensity ratios, T1/T2 mapping and QSM were found in the dentate nucleus and globus pallidus between patients of groups 1 and 2 and the matched controls.

CONCLUSION

In this recall study, we found no statistical evidence for gadolinium brain retention after administration of multiple doses of gadobutrol in patients with normal and impaired kidney function.

CLINICAL RELEVANCE/APPLICATION

To the best of our knowledge, here we present the first recall study on gadolinium brain retention in a large cohort of patients receiving multiple doses of gadobutrol and no other MRI contrast agent.

Kristin Lingle, The Woodlands, TX (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Report single insititution experience of interventions related to gastrojejunostomy tubes, their complications, and comparison of complication rates between gastrojejunostomy tube types and manufacturers.

METHOD AND MATERIALS

379 patients with a gastrojejunostomy tube (GJ tube) were retrospecitively reviewed from January 2016 through February 2018. PACS and electronic medical records were reviewed for GJ tube exchanges or conversions. Date of procedure, indication for procedure, complications associated with the GJ tube, GJ tube specifics, and patient demographics were entered into a HIPAA compliant database. Complications were defined as GJ tube condition that necessitated urgent exchange or conversion. Comparisons of complications were made using chi-square test between GJ tube length and manufacturer.

RESULTS

There were 1,792 interventions during the study period, with 641 conversions (35.8%) and 1151 (64.2%) exchanges performed in 379 patients. There were 810 GJ tubes from Applied Medical Technology, Inc (Brecksville, Oh), and 834 from Halyard (Alpharetta, Ga). Patients presented as outpatients (65.3%) through the emergency center (9.2%) or as inpatients (25.5%). There were 595 (53.5%) GJ tubes exchanged as routine, and there were 176 (27.9%) initial conversions, comprising 43% of interventions. 57% exchanges and conversions were performed due to complication. There was no difference between manufacturers and overall complications (p=0.243 for exchanges; p=0.821 for conversions). There was a signficant difference between complication and tube length (p=0.000054), with 15 cm length tubes having a complication rate of 52%, 22 cm of 40%, 30 cm of 44%, and 45 cm of 63%.

CONCLUSION

Gastrojejunostomy tubes are frequently replaced urgently do to tube malfunction or malposition, with increased rates seen in 15 cm and 45 cm length tubes. There is no difference between manufacturers for overall complications.

CLINICAL RELEVANCE/APPLICATION

GJ tubes have a high frequncey of complication, highlighting an area for significant quality improvement.

SSM20-02 Early Experience on the Impact of Contrast-Enhanced Ultrasound in Drainage Catheter Placement and Management

PURPOSE

To describe use of contrast-enhanced ultrasound (CEUS) in aiding drainage catheter management in children.

METHOD AND MATERIALS

An IRB-approved retrospective review identified13 drainage catheter procedures in which contrast-enhanced ultrasound (CEUS) prompted changes in management by illuminating the need for additional treatment or cessation thereof.

RESULTS

13 patients underwent drainage catheter placement with concurrent intracavitary contrast-enhanced ultrasound (CEUS). 6 abscess catheters were injected, revealing: noncommunicating locules in 2 of 6 cases (one inaccessible and one requiring an additional drain), safe accessibility in 3 of 6 cases with communicating locules without need for additional catheter, and confirmation of fistula to small bowel in a Crohn's patient in 1 of 6 cases. Simultaneous CEUS cholangiogram though a cholecystostomy tube and percutaneous biliary drain in a presumed case of Mirizzi syndrome showed patency of both the common bile and cystic ducts leading to catheter removal. CEUS injection in 1 chest tube showed multiseptated pleural effusion requiring t-PA via the drain, later shown at bedside with CEUS to have achieved complete lysis of septations. Injection of a catheter in a large renal cyst showed no connection to the collecting system where there was concern for urinoma and calyceal rupture, leading to drain removal. Injection of a sinus tract and cecostomy tube in a patient with peristomal leak showed an enterocutaneous fistula, requiring catheter placement through the fistula to promote diversion and healing. CEUS in 3 sclerotherapy cases showed adequate distribution of sclerosant in one lymphatic malformation and an inaccessible small, noncommunicating moiety of a second lymphatic malformation left untreated. In a third case, no connection was seen between a renal cyst and the renal collecting system, allowing for safe sclerotherapy. No adverse reaction to the agent occured.

CONCLUSION

CEUS is an adjunctive imaging modality allowing real-time catheter-directed provision of additional or cessation of medical treatment while reducing radiation dose to the patient.

CLINICAL RELEVANCE/APPLICATION

Intracavitary CEUS administration via drainage catheters can help in identifying clinical situations in the IR suite and at bedside where addition or cessation of treatment will improve patient outcome and shorten the time to drainage catheter removal while reducing radiation dose to the patient.

PURPOSE

To show that contrast-enhanced ultrasound (CEUS) may be leveraged during targeted soft tissue and organ biopsy to improve pathologic yield and differentiate benign from malignant lesions.

METHOD AND MATERIALS

An IRB-approved retrospective review identified 19 lesions biopsied with CEUS guidance in patients aged 2 mo to 19 years with median weight 30 kg (range 3.6-107 kg). Outcomes included concordance of CEUS enhancement with pathology and ability to differentiate benign from malignant lesions equal to or better than MRI. Concordance was defined as agreement between enhancement pattern and pathology diagnosis.

RESULTS

19 soft tissue and organ based lesions biopsied with CEUS guidance were reviewed. Biopsy or CEUS evaluation was recommended

19 soft tissue and organ-based lesions biopsied with CEUS guidance were reviewed. Biopsy or CEUS evaluation was recommended on pre-biopsy MRI in 18 cases. One patient with known lymphoma had a new hypermetabolic lesion on PET/CT requiring biopsy. Hyperenhancing areas of biopsy targets on CEUS correlated with hypermetabolic areas on PET, aiding accurate needle placement in high yield parts of lesions. There was concordance of CEUS enhancement pattern with pathologic diagnosis in 18 lesions (11 malignant and 7 benign). In the only discordant CEUS case, enhancement on both MRI and CEUS was concerning for malignancy showing brisk arterial enhancement with early washout, however pathology showed benign hepatic fibrosis. MRI enhancement patterns were discordant with pathology results in 3 of 18 lesions. Of those, 2 showed enhancement on CEUS which was concordant with pathology. Diagnostic specimens were obtained in all 19 cases. No adverse reactions to the contrast agent occurred.

CONCLUSION

Peri-procedural CEUS can further differentiate benign from malignant soft tissue and organ-based lesions and aids in their biopsy. In the future, this modality could reduce cost in the work-up of focal lesions requiring tissue diagnosis. Additional studies need to be performed to validate use of CEUS in pediatric biopsies.

CLINICAL RELEVANCE/APPLICATION

CEUS has equal or better lesion characterization compared to MRI and early experience shows it can be a powerful tool in biopsy guidance.

Dimitri A. Parra, MD, Toronto, ON (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Image guided sacroiliac (SI) joint injections are frequently requested in pediatric patients with sacroilitis, which is characterized by the inflammation of SI joints (+/- adjacent tissues) and it is commonly seen in enthesitis-related arthritis (ERA), a subtype of juvenile idiopathic arthritis (JIA). The treatment involves systemic therapy with or without corticosteroid joint injections. The aim of this study is to evaluate our experience performing SI joint injections in children in terms of indications, technique and efficacy.

METHOD AND MATERIALS

This is a retrospective study of all patients that were referred to the department of Image Guided Therapy for SI joint steroid injections (Jan 2004 -Jan 2018). Patient demographis and clinical histories were collected from Electronic Patient Charts (EPC) and procedural details from our Picture Archiving and Communication System (PACS).

RESULTS

51 patients underwent SI joint injections during the time of the study, 35 were boys (68.6%). Mean age was 13.8 y/o (8-18 y/o). The most common etiology was JIA (82.4%) followed by inflammatory bowel disease (13.7%). 78% had bilateral injections and 22% unilateral (45.5% Left; 54.5% Right). All procedures were technically successful. 78% of patients received general anesthetics and 22% sedation, The steroid of choice was triamcinolone hexacetonide (20 mg most common dose). Needle guidance and confirmation was done with CT fluroscopy in 55% and Cone Beam CT in 45%. Ultrasound was used in the initial needle guidance in 33.3%. 40 patients had long term follow up. 21 (52.5%) documented clinical improvement. 26 patients had a pre and post-procedure MRI, with 81% showing improvement based on imaging findings. No complications were encountered.

CONCLUSION

Image guided SI joint injections is a safe and technically feasible procedure in children. In our cohort, the majority of patients showed clincal and imaging improvement post procedure. Cone beam CT is our current imaging modality of choice for this intervention.

CLINICAL RELEVANCE/APPLICATION

This study will provide evidence and guidance to (pediatric) interventional radiologist performing SI joint injections in children.

SSM20-05 Recurrent Pediatric Thyroid Cancer: Diagnosis and Treatment Dilemma

jeng@bcm.edu

PURPOSE

Analyze the experience of a tertiary pediatric referral center with biopsy for recurrent thyroid cancer in children for a planned, future prospective trial using other minimally invasive techniques for treatment.

METHOD AND MATERIALS

278 thyroid biopsies were performed from 2004 to 2018. 25 biopsies were performed specifically for recurrent thyroid cancer in 18 patients (5 males, 13 females) with a total of 38 lesions sampled. 3 patients underwent 2 biopsies with 1 patient undergoing 5 biopsies. Age and weight at time of biopsy ranged from 13 y, 3 mo to 19 y 11, mo (median 17 yr) and from 33 kg to 124 kg (median 69.2 kg). 17 patients had a prior diagnosis of papillary thyroid cancer while 1 patient had a diagnosis of medullary thyroid cancer.

RESULTS

The technical success rate and diagnostic yield were both 100%. There were no complications. 25/38 (66%) of sampled lesions were malignant while 13/38 (34%) were benign. 20/25 (80%) of biopsies were malignant while 5/25 (20%) were benign. Benign and malignant lesions were evaluated based on size and TIRADS imaging criteria (composition, echogenicity, borders, calcifications, vascularity, shape, and punctate echogenic foci). Size was assessed using the Wilcoxon rank test and imaging characteristics were assessed using the Fisher's exact test with no significant difference between malignant and benign lesions. 7 patients have since undergone repeat surgery with the rest remaining on surveillance with suppressive thyroid hormone therapy.

CONCLUSION

Children who have had thyroidectomy and lateral neck dissection represent a surgical dilemma with early recurrence due to the difficulty of reoperation in an already treated field. No specific imaging criteria (including TIRADS) can easily distinguish between benign and malignant nodules in the surgical bed. FNA reliably provides accurate diagnosis of early recurrent thyroid carcinoma. When small lesions are confidently confirmed as recurrent disease, percutaneous treatments such as High Intensity Focused Ultrasound (HIFU) and Radiofrequency Ablation (RFA) may be a feasible alternative to a more complicated surgical approach.

CLINICAL RELEVANCE/APPLICATION

Recurrent pediatric thyroid cancer presents a surgical dilemma. FNA provides an accurate diagnosis of recurrence. Alternative minimally invasive methods for treatment (HIFU, RFA) should be considered

SSM20-06 Minimally Invasive CT- and US-Guided Biopsies of Mediastinal Masses in Pediatric Patients in a Large Pediatric Hospital

PURPOSE

Tissue diagnosis of mediastinal masses remains essential for directing subsequent medical or surgical management of patients. Minimally invasive procedures utilizing CT and ultrasound guidance are an alternative method to obtain biopsies, in comparison to open surgical approaches. However, analysis of procedural correlates associated with minimally invasive mediastinal biopsies such as sampling adequacy, patient risk level, and complications remain largely anecdotal.

METHOD AND MATERIALS

We therefore reviewed 25 mediastinal biopsy cases performed at the Texas Children's Hospital in which the procedure was performed before surgical intervention.

RESULTS

Risk characterization in patients: A number of patients demonstrated pre-existing compression of mediastinal structures that are known to increase risk for surgery and anesthesia, including airway (10/25), superior vena cava (8/25), pulmonary vessel (4/25), heart (2/5), and aorta (1/25). Pericardial effusions were found in 2/25 patients and pleural effusions were found in 5/25 patients. Atelectasis was detected in 7/25 patients. Results: The majority of the cases were located in the anterior mediastinum (80%), whereas 4% were in the middle mediastinum, and 16% in the posterior mediastinum. In 22/25 patients, biopsy samples had adequate tissue content for pathological diagnosis using histology and/or flow cytometry. In the three patients with inadequate biopsies, 2/3 patients required subsequent surgeries to gain additional tissue for definitive diagnosis, of which only 1/2 generated a different pathological diagnosis. Four patients had pre-existing airway compression. Minor complications were found in 3 patients post-procedure, which consisted of trace pneumothorax detected in 2 patients and minimal hemorrhage at the biopsy site in 1 patient, all of which resolved without need for further intervention.

CONCLUSION

Our data with CT- and US-guided mediastinal biopsies in a large quaternary pediatric treatment center show that it is a feasible method as a first-line for obtaining biopsies for definitive pathological diagnosis with minimal complications, even in patients with pre-existing risk factors for surgical intervention

CLINICAL RELEVANCE/APPLICATION

This will increase feasbility and speed of clinical diagnosis.

leng.shuai@mayo.edu

PURPOSE

Virtual mono-energetic images (VMIs) at lower keV can improve iodine contrast but have increased noise. For photon-counting-detector (PCD)-CT, spatio-spectral data redundancy exists between VMIs and the low-energy threshold (TL) images, which are reconstructed using all available photons and have the lowest noise. Here, we develop a denoising technique named spectral image constrained compressed sensing (SPICCS) that exploits this data redundancy to denoise VMIs and improve iodine contrast-to-noise ratio (CNR).

METHOD AND MATERIALS

A multi-energy CT phantom (Sun Nuclear) and iodine inserts of different concentrations (2, 5, 10, 15 mg/mL) were scanned on a whole-body PCD-CT using a routine abdomen protocol (140 kV, 100 mAs, energy thresholds = 25/75keV). VMIs at 40-70keV were generated using vendor-supplied software (Mono+, Siemens). The images were then denoised using the SPICCS algorithm which is applied in the image domain by minimizing an objective function consisting of a data fidelity term and a regularization term. The regularization term penalizes total variation (TV) of the VMIs and TV of the difference between VMIs and TL images. A uniform water phantom and a thin wire phantom were scanned to assess noise texture and spatial resolution, respectively. With IRB approval, patient images were acquired on the same PCD-CT (140 kV, 100 mAs, energy thresholds = 25/75keV). The iodine CNR was calculated from VMIs before/after SPICCS.

RESULTS

VMIs processed with SPICCS preserved iodine contrast and reduced noise compared to the original VMIs (129±51 vs. 128±27 HU before/after SPICCS, measured from 5mg/mL iodine insert at 50keV), which improved iodine CNR especially at lower keV (5.65 vs 10.3 at 50keV). Compared with TL images, SPICCS-processed VMIs had improved CNR at lower keV (e.g., 50keV). MTF and NPS data showed that SPICCS preserved resolution and noise texture compared to TL images and original VMIs. The 50 keV VMI from patient data demonstrated similar improvement in iodine CNR (1.8 fold increase in iodine CNR at 50 keV).

CONCLUSION

We developed a denoising framework to improve iodine CNR in VMIs acquired on PCD-CT using SPICCS, while preserving spatial resolution and noise texture.

CLINICAL RELEVANCE/APPLICATION

The proposed denoising scheme improved iodine CNR for VMIs acquired on a whole-body PCD-CT system while preserving spatial resolution and noise texture, which may improve clinical diagnosis.

SSM21-02 Multi-Energy (ME) CT Imaging for Large Patients Using Photon-Counting-Detector (PCD) Technology

leng.shuai@mayo.edu

PURPOSE

Imaging large patients with conventional dual-source dual-energy (DSDE) CT using energy-integrating-detectors (EIDs) is challenging due to artifacts in lower kV (80-100) images caused by photon starvation and electronic noise. Although the use of higher kV (e.g. 120) can reduce this effect, the energy separation is insufficient for multi-energy CT (MECT) imaging, even with the addition of a tin filter in the high kV beam. Photon-counting-detector (PCD) CT is more resistant to electronic noise and can provide spectral information with a single tube potential, which may be more suitable for MECT imaging on large patients. This work aims to evaluate the feasibility of MECT imaging on large patients assuming a dual-PCD acquisition system.

METHOD AND MATERIALS

An anthropomorphic CT phantom was padded with an additional 5 cm tissue-mimicking layer to simulate a large patient, and scanned on a conventional DSDE EID-CT system with 100 kV and Sn140 kV (i.e., 140 kV with additional tin filter) tube potentials. In addition, iodine inserts of known concentrations (2, 5, 10, 15 mg/mL) were attached to the phantom. The same phantom was then scanned on a whole-body PCD-CT system. This system was built based on a conventional DSDE CT platform, with the second EID replaced with a PCD. A dual-source, dual-PCD acquisition was emulated by scanning the object separately with tube potentials of 100 kV and Sn140 kV. Tube current for PCD scans was matched to that of EID scans. Material decomposition was then performed to generate iodine and water maps.

RESULTS

The low-energy image (100 kV) acquired on the conventional DSDE EID-CT system showed noticeable shading, which limited its use for clinical diagnosis. These artifacts were largely eliminated in images acquired on the PCD system. The iodine quantification root-mean-square-errors (RMSE) measured from iodine inserts was 2.3 mg/mL for EID and 2.1 mg/mL for PCD.

CONCLUSION

This work demonstrated the feasibility of MECT imaging for large patient assuming a dual-source PCD acquisition. The DS-PCD system out-performs conventional DS-EID CT system by reducing image artifacts and yet providing reasonable energy separation.

CLINICAL RELEVANCE/APPLICATION

Imaging large patients using DECT is known to be challenging. This work demonstrated the feasibility of MECT imaging for large patients using PCD, which allows all patients to benefit from MECT.

SSM21-03 Photon-Counting CT: Dependence of Noise Power Spectra, Task-Transfer Function, and Detectability Index (d') on Patient Size, Imaging Mode, and Reconstruction Kernel

jayasai.rajagopal@duke.edu

PURPOSE

To evaluate image quality in photon-counting CT due to change in patient size, imaging mode, and reconstruction kernel as measured by a tiered phantom

METHOD AND MATERIALS

The study utilized a five-tiered size variant phantom (Mercury Phantom, Gammex/Duke University). Images were acquired on a prototype photon-counting CT system (Siemens, Germany) using two imaging modes: Macro and Ultra High-Resolution (UHR) with effective voxel sizes of 0.5 and 0.25 mm, respectively, at a clinically-relevant dose (CTDIvol = 16 mGy). UHR scans were also done at maximum allowable mAs. Images were reconstructed with three kernels of increasing sharpness with 5 mm slice thickness. A task-based assessment was performed including calculation of noise power spectra, task-transfer function, and detectability index (d') of an iodine insert using the standard methodology of AAPM TG 233.

RESULTS

UHR had a higher d' of 8-88% across all reconstruction kernels and phantom sizes when compared to Macro mode. For softer kernels, TTFs were comparable between the two modes. The magnitude and shape of the noise power spectrum was different influencing d'. Sharp kernel showed edge enhancement with increased noise magnitude for UHR mode and different TTFs for different imaging modes. For ultra-sharp kernels, UHR mode showed a significant reduction of noise magnitude while preserving the shape of the spectra and the TTF. As expected, increasing dose led to a reduction in noise magnitude without affecting the task

transfer function.

CONCLUSION

UHR mode showed reduced noise and superior detectability for an iodinated task when controlling for patient size and reconstruction kernel. Task performance was dependent on selected reconstruction kernel and imaging mode.

CLINICAL RELEVANCE/APPLICATION

Ultra high-resolution mode in photon-counting CT offers improved spatial resolution and superior detectability compared to macro mode, and superior to conventional energy-integrating CT.

SSM21-04 Deep Inpainting for Photon-Counting Cone-Beam CT

elias.eulig@dkfz.de

PURPOSE

To provide an efficient method to close the gaps of large area photon counting detectors in x-ray imaging and cone-beam CT (CBCT).

METHOD AND MATERIALS

Photon counting detector technology promises improved CT image quality at reduced patient dose. Moreover, the new detectors have the potential to provide diagnostic image quality in cone-beam CT systems that, today, still suffer from inferior image quality. However, the limited size of the ASICs (typically about 3x3 cm) requires tiling of many detector modules in order to assemble detectors large enough for almost any medical application. Inevitably, one or more pixel wide gaps between the modules may occur. Prior to reading the x-ray images or to reconstructing the CBCT data, the gaps or dead pixels need to be closed by inpainting. Therefore, we developed a deep adversarial architecture based on a generator and discriminator network that trains itself to fill the dead pixels. Training was performed using uncorrupted CBCT thoracic and abdominal patient data with artificially induced pixel gaps. Since the adversarial approach is unsupervised the same architecture can be applied to photon-counting flat dectector data in the same way. The performance was compared to a linear inpainting, to a diffusion-based inpainting and to an exemplar-based inpainting algorithm. Our novel approach was implemented using the PyTorch Deep Learning framework and trained on 6400 samples for 20 epochs on a GeForce GTX 1080 Ti GPU.

RESULTS

The visual impression of the correction was best with the deep inpainting approach and the exemplar-based algorithm, second best with the linear interpolation and worst with the diffusion-based algorithm where the location of the gaps was clearly visible after inpainting. The computation time per 1024×768 projection was 83 ms, 52 s, 29 ms and 2 s, respectively. The network was running on the GPU while all the other algorithms were running on the CPU.

CONCLUSION

Deep inpainting has the potential to remove pixel defects or gaps between detector modules at least as good as exemplar-based inpainting while reducing computation times drastically.

CLINICAL RELEVANCE/APPLICATION

Photon counting detector technology has the potential to improve CT and CBCT imaging in the near future. An efficient inpainting approach, such as the deep inpainting algorithm presented here, brings the new detector technology one step closer to clinical routine.

SSM21-05 Can a Universal Protocol for Photon-Counting-Detector CT Provide Equivalent Iodine Detectability as Optimal kV Energy-Integrating-Detector CT: A Feasibility Study

zhou.wei1@mayo.edu

PURPOSE

To determine iodine detectability using a single-kV universal protocol on a photon-counting-detector (PCD) CT for different phantom sizes, and to compare with optimized-kV single-energy (SE) and dual-source, dual-energy (DSDE) CT using an energy-integrating-detector (EID).

METHOD AND MATERIALS

A 4-mm diameter hole in a water-equivalent cylinder was filled with iodine solutions at one of 4 concentrations (0.2, 0.5, 1.0 and 2.0 mgI/cc) and the cylinder was inserted into one of 3 abdomen phantoms (QRM, lateral widths of 30, 35 and 40 cm). The whole phantom was scanned on a 2nd generation DSDE CT with SE and DE protocols using a kV or kV pair adjusted for phantom size. The phantom was also scanned on a whole body PCD CT using a single-kV universal protocol for all phantom sizes: 140 kV, 25 and 75 keV energy thresholds. EID-SE tube current was automatically adjusted (CareDose4D, 120 kV, 200 QRM), resulting in CTDIvol of 6.9 to 17.7 mGy for different size phantoms. EID-DE and PCD tube current was adjusted to match the CTDIvol of the EID-SE scans. Scans were repeated 200 times for each of 24 conditions: 4 concentrations, 3 phantom sizes and 3 protocols. All images were reconstructed with a quantitative kernel (D30) and 5 mm thickness. Virtual monoenergetic images (VMI) at 50 keV were generated from PCD and EID-DE images. CNR and AUC of the ROC from a calibrated channelized hoteling observer (CHO) model were calculated as figures of merit for quantifying iodine detection for PCD VMI@50 keV, EID-SE, and EID-DE VMI@50keV.

RESULTS

VMI@50 keV from PCD and EID-DE showed higher iodine CNR than the EID-SE images for all phantom sizes. For 0.5 mg/cc iodine, VMI@50 keV from PCD (0.93) and EID-DE (0.94) showed comparable AUC for iodine detection on a 30cm phantom and superior AUC for 35 cm (PCD: 0.93; EID-DE: 0.90) and 40 cm (PCD: 0.81; EID-DE: 0.88) phantoms compared to that of EID-SE (30 cm: 0.95; 35cm: 0.83; 40 cm: 0.77). A similar trend showing preference for VMI from PCD and EID-DE was observed for other iodine concentrations.

CONCLUSION

VMI images from a single kV PCD acquisition demonstrated comparable or improved iodine detectability and CNR compared to SE images where kV was selected based on patient size.

CLINICAL RELEVANCE/APPLICATION

A universal PCD CT protocol can maintain iodine sensitivity, simplify protocol selection and avoid sub-optimal images from inappropriate kV (or kV pair) selection with EID CT.

SSM21-06 A Method of Calculating Lesion Detectability in Photon-Counting Spectral CT

matspers@stanford.edu

PURPOSE

To develop a method of calculating the lesion detectability attainable in photon-counting spectral CT and demonstrate it for a cadmium telluride detector in a simulation study.

METHOD AND MATERIALS

Using a Monte Carlo simulation of an X-ray beam incident on a 3 mm thick cadmium telluride detector with 0.5x0.5 mm2 pixels and five energy bins, the energy-dependent point-spread function and autocorrelation function were calculated. Correlation between pixels due to fluorescence and charge diffusion was included in the simulation model. A recently developed linear-systems methodology was used to calculate the optimal-linear-observer detectability, i. e. the maximal detectability that can be obtained through optimal weighting of the data from the five energy bins. This detectability was computed for nonenhancing (soft tissue) and enhancing (10 mg/ml iodine) spherical lesions of different sizes in a 250 mm soft tissue cylinder, for a system with detector-limited resolution and a 120 kVp spectrum with 2.5 mm Al filtration. The results were compared to an ideal detector with perfect spatial and energy resolution and to an energy-integrating detector with 1x1 mm2 pixels but otherwise ideal.

RESULTS

The ideal-linear-observer detectability, relative to the ideal detector, was 67%, 83% and 91% for nonenhancing lesions with 1 mm, 2 mm and 10 mm diameter. For enhancing lesions the corresponding values were 48%, 58% and 62%, respectively. This is an improvement of 6-98 % (nonenhancing) and 58-203% (enhancing) compared to the energy-integrating detector.

CONCLUSION

Whereas large-area image quality metrics such as CNR have been used to characterize photon-counting CT scanners in previous work, so far there has not been a method of calculating the attainable detectability for smaller objects with energy-resolving photon-counting detectors. This simulation study demonstrates for the first time how the detectability of lesions in a photon-counting CT scanner can be simulated, taking energy resolution, pixel size and cross-talk between pixels into account. The results show that the detector performance is closer to ideal for nonenhancing lesions than for enhancing lesions.

CLINICAL RELEVANCE/APPLICATION

With photon-counting CT scanners expected to become clinically available in a few years, the proposed method will enable comprehensive comparison of systems and optimization of imaging protocols.

PURPOSE

Machine learning for image segmentation is a potentially innovative approach to improve efficiency and promote standardization for radiotherapy treatment planning. We evaluated a new model that uses deep decision forests of image features to contour pelvic anatomy on treatment planning CTs.

METHOD AND MATERIALS

We anonymized 193 prostate treatment planning CTs (acquired 2012-2016 at 1 UK and 2 US sites, GE and Toshiba scanners, 512x512 pixels inplane, 1.25 or 2.5 mm between slices). A deep decision forest (DF) was trained to contour prostate, bladder, rectum, femurs, and seminal vesicles on 94 images from Site 1. Testing was done on 99 separate scans (n=35, 34, and 25 from Site 1, 2, and 3). Similarity between DF contours and clinical (ground truth) contours was measured with Dice score (DSC) in the validation datasets. DF performance was compared to four commercial tools on a random subset of images (n=20). Additionally, interobserver variability (IOV) between three physicians' contours and ground truth was evaluated on 10 random images and compared to DF performance with Student's t-test.

RESULTS

Across all sites, DF agreement with ground truth was: bladder, DSC 0.94-0.97 [interquartile range (IQR) 0.92-0.98], prostate, DSC 0.75-0.76 [IQR 0.67-0.82], rectum: DSC 0.71-0.82 [IQR 0.63-0.87], femurs: DSC 0.96-0.97 [IQR 0.94-0.97], seminal vesicles: DSC 0.49-0.70 [IQR, 0.31-0.79]. The results were similar across the three sites (e.g. median prostate DSC for each site was 0.76, 0.76, 0.75). In the commercial model comparison, DF had highest DSC for all organs, followed by the two model-based systems, with atlas-based systems having worst performance. For IOV data, variability between DF and ground truth was smaller than variability between raters for prostate (median DSC 0.87 vs 0.77, p=0.006) and femurs (median DSC 0.973 vs 0.968, p=0.002), and not significantly different for other contours (p>0.3).

CONCLUSION

Deep decision forests are effective at contouring pelvic anatomy for radiotherapy planning, with good performance relative to commercial programs, and agreement with ground truth was as similar as can be expected between human experts.

CLINICAL RELEVANCE/APPLICATION

Machine learning methods for automated treatment planning would be useful to improve clinical efficiency and increase standardization in radiation oncology.

SSM22-02 Nationwide Prostate Cancer Outcome Prediction Study of Permanent Iodine-125 Seed Implantation: Outcome Prediction Using Machine Learning Techniques with Cohort 1

Wednesday, Nov. 28 3:10PM - 3:20PM Room: E261

Participants
Taiki Magome, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The nationwide Japanese Prostate Cancer Outcome Study of Permanent Iodine-125 Seed Implantation (J-POPS) is a big novel data with the fundamental aim of collecting clinical data as a prospective cohort study. The purpose of this study is to predict prostate cancer outcome after brachytherapy based on machine learning techniques using J-POPS big data.

METHOD AND MATERIALS

Among 72 hospitals performing brachytherapy in Japan, 46 (64 %) hospitals provided 2,339 cases of the J-POPS cohort 1. Patient/family background, TNM classification, serum PSA level, Gleason score, brachytherapy and external radiotherapy parameters, adverse event and outcome information, etc. were included in the survey items. Two types of dataset were used for the prediction; i.e., the large dataset including the majority of survey items, and limited dataset including only the survey items which are considered as relevant items with the outcome by radiation oncologists. In this study, four machine learning algorithms, i.e., logistic regression (LR), support vector machine (SVM), random forest (RF), and deep neural network (DNN) were tested. Outcome information including biochemical failure and rectal/urinary toxicity were predicted by the machine learning techniques. The prediction accuracy, defined as (true positive + true negative cases) / all cases, was evaluated by 10-fold cross-validation test.

RESULTS

The prediction accuracy with the large dataset was higher than that with the limited dataset in each machine learning algorithm. Although 5.2 percent of cases showed the biochemical failure, the highest accuracy of biochemical failure prediction with a large dataset and limited dataset was 0.938 and 0.892, respectively, for test data. The prediction model using RF had the highest accuracy.

CONCLUSION

Our results showed a potential to predict the outcome of prostate cancer patients with the big nationwide data including many survey items.

CLINICAL RELEVANCE/APPLICATION

Prostate cancer outcome after brachytherapy could be accurately predicted with big nationwide data.

SSM22-03 Dose to the Bladder Neck in MRI-guided High Dose-Rate Prostate Brachytherapy

Wednesday, Nov. 28 3:20PM - 3:30PM Room: E261

PURPOSE

We aim to assess the impact of the dose to the bladder neck (BN) on physician and patient-reported GU toxicity after MRI-guided high dose-rate brachytherapy (HDR-BT) boost.

METHOD AND MATERIALS

Sixty-three patients were treated with a single 15-Gy MRI-guided HDR-BT implant followed by external beam radiotherapy. MRI-based treatment planning was used. The clinical target volume (CTV) was defined as the prostate and planning target volume was CTV + 2mm craniocaudal margin. BN was delineated in retrospect on T2-weighted images by a radiation oncologist (RO) and reviewed by an independent RO and a radiologist. Dosimetric parameters, acute (<=3 months) toxicity using CTCAE v.4 and health-related quality of life (HRQoL)using the expanded prostate index composite (EPIC) were collected prospectively. A minimally important difference (MID) was defined as a deterioration of HRQoL scores at 3 months compared to baseline >= 0.5 standard deviation of baseline score. Linear and logistic regression models were used to assess the impact of BN dose on GU toxicity and HRQoL. A p-value <=0.05 was considered statistically significant.

RESULTS

The median BN volume was 0.6 cc [interquartile range (IQR): 0.4-0.7]. Median maximum dose to the BN (BNDmax) and urethra (UDmax) was 24.9 Gy (IQR 18.8- 26.4) and 17 Gy (IQR 16.7- 17.7) respectively. Median dose to 2cc of the urethra was 52 Gy (IQR: 36-62). BNDmax was significantly associated with UDmax (p=0.027) and 7.7% of the total amount of variation in BNDmax was explained by the UDmax (R2=0.059, p=0.028). Grade 2+ GU toxicity was observed in 31% of patients. Among those, 4 patients had an acute urinary retention. No grade 4+ toxicity was reported. Furthermore 46% of patients reported a MID in EPIC urinary domain score at 3 months. None of the dosimetric parameters including BNDmax was associated with acute grade 2+ urinary toxicity or MID. However, 3 out of 4 patients with acute urinary retention had a BND max in the highest quartile; 26.4, 28.3 and 52.7 Gy (>175% of prescription dose).

CONCLUSION

MRI-based planning offers a unique opportunity to delineate and assess the dose to the BN. Although the predictive value of this parameter is yet to be determined in a larger population, it is worthwhile including BN contours and constraints into HDR-BT

treatment planning if an MRI-planning is available.

CLINICAL RELEVANCE/APPLICATION

Uncertainties exist regarding bladder neck definition.

SSM22-04 Machine Leaning Based Prediction of Prostate Cancer Recurrence After Radiotherapy with Radiosensitivity Related Proteins

Wednesday, Nov. 28 3:30PM - 3:40PM Room: E261

Participants

mizutaku17@gmail.com

PURPOSE

There are several reports that the expression of proteins in tumors related to radiosensitivity could be used as biomarkers for the outcome prediction after radiotherapy. The purpose of this study was to predict local relapse of prostate cancer after radiotherapy using a machine learning methodology with the combination of conventional factors and the protein information related to radiosensitivity.

METHOD AND MATERIALS

A total of 100 patients with localized adenocarcinoma of the prostate who were treated from 2001 to 2010 were included in this study. Support vector machine (SVM) was used as a machine learning methodology to predict local relapse of prostate cancer. Candidate input features for the prediction included 16 clinical features (age, Gleason score, PSA level, etc.), 16 radiation dose features (mean dose, dose per fraction, etc.) and 3 protein information related to radiosensitivity (Ku70, Ku86, XRCC4). Effective features for prediction were determined by a sequential forward selection using Akaike's information criterion. The prediction performance of the models with or without protein information were compared by a leave-one-out cross-validation test. Accuracy, sensitivity, specificity and Matthew's correlation coefficient (MCC) were used as prediction performance metrics.

RESULTS

The prediction performance was improved by considering the radiosensitivity related protein information, e.g., accuracy of the models with and without the protein information was 0.78 and 0.69, respectively. Ku70 was the most selected feature in the proteins related to radiosensitivity.

CONCLUSION

Our result showed the potential to predict local relapse of prostate cancer with the combination of conventional factors and the protein information related to radiosensitivity. Accurate outcome prediction after radiotherapy could be useful for personalized optimal selection of treatment modalities of cancer.

CLINICAL RELEVANCE/APPLICATION

Accuracy of the machine learning model for outcome prediction after radiotherapy could be improved with the radiosensitivity related protein information.

SSM22-05 Prostate Cancer: Assessment of Toxicity of Focal Dose Escalation of Radiotherapy Guided by Multiparametric Magnetic Resonance Imaging

Wednesday, Nov. 28 3:40PM - 3:50PM Room: E261

For information about this presentation, contact:

schmuecking@strahlentherapie-veritaskai.com

PURPOSE

To evaluate acute and late toxicity after moderately hypofractionated radiotherapy of prostate cancer with focal dose escalation guided by multiparametric magnetic resonance imaging (mpMRI) using intensity-modulated treatment planning and image-guided treatment (IGRT) delivery.

METHOD AND MATERIALS

58 patients (age 55-82y, cT2/cT3, initial PSA 3.3-16.4ng/ml, Gleason Score >3+4) were included into the study. Before implantation of three gold markers, each patient underwent mpMRI (T2-TSE, DCE, DWI) that detected a suspicious focal lesion (PIRADS 4+5) followed by image fusion with the radiation treatment planning CT. In total, a dose of 79.2Gy in 33 fractions (single dose 2.4Gy) were prescribed to PIRADS 4 and 5 intraprostatic lesions with a margin of 3mm (gross target volume + 3mm = planning target volume) delivered with a simultaneous integrated boost (SIB) by static field intensity-modulated radiotherapy (IMRT) or volumetric modulated arc therapy (VMAT). Further dose levels were 76.23Gy and 60.06Gy prescribed to the prostate and the

seminal vesicles, respectively. Patients with high risk prostate cancer received 46Gy to the pelvic lymphatics, lymph node metastases 60Gy in 25 fractions with SIB. Daily IGRT by cone-beam computed tomography (CBCT) in addition to gold markers. Acute and late gastrointestinal (GI) and genitourinary (GU) toxicity was evaluated using CTCAE v4.03.

RESULTS

Treatment was completed according to the treatment plan in all included patients. Acute GI and GU toxicity grade >=2 was observed in 13.8% and 39.6% of the patients, respectively, with 6.8% suffering from GU toxicity grade 3. Six weeks after treatment, the incidence of acute toxicity grade >=2 had decreased to 15.5%. With a median follow-up of 28 months, late GI and GU toxicity grade >=2 was seen in 1.7% and 8.6% of the patients, respectively. Three patients developed late toxicity grade 3 (GI n=2; GU n=1).

CONCLUSION

Moderately hypofractionated high-dose radiotherapy with further dose-escalation to mpMRI PIRADS 4 and 5 lesions resulted in acceptable rates of acute and late toxicity according to the current literature. Conformal IMRT / VMAT planning and accurate daily IGRT treatment delivery using goldmarker and CBCT may have contributed to these results.

CLINICAL RELEVANCE/APPLICATION

The use of mpMRI for focal dose escalation in patients with prostate cancer may enhance post-radiotherapeutic local control.

SSM22-06 Weekly Magnetic Resonance Imaging Using a Linear Accelerator Equipped with a 1.5 Tesla MRI (MR-Linac) Reveals Intra-Treatment Signal Variance in Regional Organs at Risk (OAR), An Exploratory Analysis

Wednesday, Nov. 28 3:50PM - 4:00PM Room: E261

William A. Hall, MD, Milwaukee, WI (*Abstract Co-Author*) Departmental research support, Elekta AB

PURPOSE

To investigate changes in quantitative signal variables of organs at risk (OAR) in serially obtained T2-weighted MR images, acquired on an MR-Linac, in patients being treated for prostate cancer.

METHOD AND MATERIALS

Four patients with prostate cancer undergoing treatment with radiation therapy (RT) were compiled from an ongoing prospective observational imaging trial using MR-Linac. All patients provided informed consent for weekly imaging; images were obtained between November 2017 and March 2018. Contiguous sections of rectal and bladder wall adjacent to the prostate were contoured and normalized to temporally corresponding regions of rectum and bladder removed from the planning target volume. Similarly, contiguous axial slices of Sartorius muscle outside of the regions of high dose RT exposure were also contoured as a normal control. The quantitative features considered included: max-to-mean ratio, kurtosis, mean, median, skewness, and standard deviation. A student's t-test was used to evaluate for statistically significant variance week-to-week.

RESULTS

Between weeks 1 and 2, significant variance in the mean and median signal values were seen in sections of rectal wall adjacent to the prostate (p=0.05, p=0.04). Bladder wall near the prostate also exhibited significant variance in the mean and median signal values between weeks 1 and 4 (p=0.05, p=0.04). No significant variance in signal values for the variables considered was observed in the Sartorius muscle control.

CONCLUSION

This is one of the earliest analyses examining quantitative signal value changes in regional organs (bladder and rectum), using an MR-Linac in patients being actively treated with RT for prostate cancer. Significant changes occurred after only 1 week of therapy in regional organs at risk during treatment with RT. Expanded data sets are needed to evaluate if these early changes correlate with clinical outcomes such as acute or late toxicity.

CLINICAL RELEVANCE/APPLICATION

Radiotherapy (RT) response assessment with a 1.5 Tesla MRI may allow for intra-treatment modification of RT plans to increase oncologic control and reduce toxicity. Increased understand of radiomic changes in OAR's will improve RT response assessment.

SSM23-01 Experimental Study of the Self-Expandable Partial-Covered Stent Insertion for the Treatment of Side-Wall Aneurysms in a Canine Model

Wednesday, Nov. 28 3:00PM - 3:10PM Room: E263

Participants
Yueqi Zhu, MD, Shanghai, China (*Presenter*) Nothing to Disclose
Yingsheng Cheng, MD, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

to test the safety and efficacy of a newly designed self-expandable partial-covered stents insertion for the treatment of side-wall aneurysms with a comparation to bared stents in a canine model

METHOD AND MATERIALS

Thirty-six saccular side-wall aneurysms were created in 18 dogs and were randomly divided into a partial-covered stent group (PSG; receive partial-covered stent insertion, n=9) to and a bared stent group (BSG; receive bared stent insertion, n=9) as control. Angiography was performed post implantation and at 1, 3 and 6 months follow-up to investigate aneurysm isolation, endoleak, stent angulation, parent-artery (PA) patency, and restenosis. Light and scanning electron (SEM) microscopy was used at each follow-up to identify aneurysmal sac thrombi, intima hyperplasia, and endothelial progress

RESULTS

Immediate angiography demonstrated complete isolation of 6 (33.3%) aneurysms, mild endoleak in 9 (50%) and obvious endoleak in 3 (16.7%) in the PSG, with a comparison to that were 0 (0%), 5 (27.8%) and 13 (72.2%) in the BSG. Follow-up angiography at 6 months revealed 17 (94.4%) aneurysms were completely occluded and mild endoleak in 1 (5.6%) aneurysm in the PSG and complete occlusion in 3 (16.7%), mild endoleak in 6 (33.3%) and obvious endoleak in 9 (50%) in the BSG. Mild stenosis (<30%) and occlusion was revealed in 2 and 1 PAs in the PSG. Light microscopy revealed that all aneurysm sacs were filled with thrombi and small residual sac was found in the aneurysm with endoleak filling in the PSG. Endothelial progress was almost complete at 6 months after partial-covered stent insertion and endothelial cell coverage was closely correlated with the occurrence of endoleak

CONCLUSION

this new kind of partial-covered stent was technically feasible and effective to occlude aneurysm sac in canine models

CLINICAL RELEVANCE/APPLICATION

The self-expandable partial-covered stent insertion is safe and leads to satisfied occlusion to aneurysm sac in canine models, thus this device may further be applied for the treatment of brain aneurysms in clinical.

SSM23-02 Placement Of Laser-Cut Stents Within Flow Diverters Enhances Anatomic Results Of Flow Diverters

Wednesday, Nov. 28 3:10PM - 3:20PM Room: E263

Participants
Osman Ocal, MD, Ankara, Turkey (*Presenter*) Nothing to Disclose
Ahmet Peker, MD, Ankara, Turkey (*Abstract Co-Author*) Nothing to Disclose
Anil Arat, MD, Madison, WI (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

drosmanocal@hotmail.com

PURPOSE

To evaluate the effect of better wall apposition of flow diverters by placement of laser-cut stents with higher radial force within the flow diverters during the same treatment session.

METHOD AND MATERIALS

Patients treated using a Surpass flow diverter (SFD) in a single institution with and without placement of a laser-cut stent were retrospectively evaluated. Patients with flow diverter placement inside a scaffolding stent, adjunctive use of another flow diverter, intrasaccular treatment and previously placed stents were excluded from study. Patient and aneurysm characteristics and clinical and imaging follow-up results were compared.

RESULTS

Of the 68 patients (mean age 50.4±14), 35 patients (41 aneurysms) were treated with SFD only ("SFD-only group") and in 33 patients (35 aneurysms) a stent was placed within SFD for better apposition ("apposed group"). No statistical difference was noted between two groups in age, body weight, gender, history of thromboembolic events, smoking, hypertension, hyperlipidemia, diabetes mellitus and malignancy or rate of procedure-related complications. Aneurysms of apposed group were significantly larger than SFD-only group (14.8 vs 9.1 mm, P<0.001). There was no difference between two groups with respect to aneurysm location in anterior versus posterior circulation (P=0.326) or proximal versus distal location with regard to the circle of Willis (P=0.281). In spite of a trend for earlier aneurysm occlusion in the apposed group, complete aneurysm occlusion rates were similar at 0-3 and 3-6 months imaging follow-up (73.3% vs. 61.3%, P=0.466 and 83.9% vs. 72.9%, P=0.432). On 9-12 months follow-up, a significantly higher proportion of aneurysms in the apposed group achieved complete occlusion compared to SFD-only group (93.8% vs. 73.2%, P=0.049). There was no significant difference in complete aneurysm obliteration rates after one year (93.3% vs. 78.0%, P=0.154).

CONCLUSION

Enhancement of flow diverter wall apposition increases rate of aneurysm occlusion. We propose that placement of laser-cut stents with higher radial force within flow diverters is a safe method for improved wall apposition.

CLINICAL RELEVANCE/APPLICATION

Enhanced wall apposition of FD with higher radial force laser-cut stents increases flow diverter efficiency with safety profile.

SSM23-03 Perioperative Result of Carotid Artery Stenting in Patients with Atherosclerotic Extracranial Internal Carotid Artery near Occlusion

Wednesday, Nov. 28 3:20PM - 3:30PM Room: E263

Participants
Ferdi Cay, MD, Ankara, Turkey (*Presenter*) Nothing to Disclose

ferdicay@hotmail.com

PURPOSE

'Near occlusion' of the carotid artery (NOCA) is not a well-defined entity. Recently, NOCA has been subclassified into two forms: 1) NOCA with collapse of the carotid artery, 2) NOCA without collapse. We aimed to compare the technical success and perioperative complication rates of these two sub-types to see whether there is a clinical correlate of this classification.

METHOD AND MATERIALS

We retrospectively evaluated all patients with atherosclerotic extracranial carotid stenosis treated by carotid artery stenting (CAS) in a single medical institution between January 2014 and January 2018. Patients with NOCA were identified based on cerebral DSA findings. Patient demographics, presence of vessel collapse distal to the stenosis, technical success rate and perioperative (<=30 day) complication rate were analyzed.

RESULTS

We identified 59 NOCAs in 58 (46 male, 12 women) patients; one patient had bilateral NOCA. The mean age of patients was 67.4 (range 46 to 86) years. Twelve cases (20.3%) had NOCA with collapse and 47 cases (79.6%) had NOCA without collapse. The NOCAs were symptomatic in 42 cases (71.1%) and asymptomatic in 17 cases (28.8%). Fifty-eight of the 59 CAS procedures were successful. In one case of NOCA, we were not able to pass through the stenosis because of significant patient motion; the patient was advised to undergo stenting under general anesthesia but refused this procedure. The overall perioperative complications included hyperperfusion (HP; 8.6%) and minor stroke (1.7%). Compared to patients with NOCA but no collapse (4.2% of 47 cases), those with NOCA resulting in vascular collapse (27.2% of 11 cases stented) had significantly higher rates of post-intervention HP (Fisher's exact test, p=0.042). Permanent morbidity and mortality rate was 1.7% and 1.7%, respectively.

CONCLUSION

CAS is feasible in the setting of NOCAs with and without collapse. Care should be taken for HP risk, especially in the subgroup of patients with collapse.

CLINICAL RELEVANCE/APPLICATION

Special care should be taken for HP in the treatment of NOCA by CAS

SSM23-04 Intraaneurysmal Air After Flow Diverter Treatment of Intracranial Aneurysms: Incidence, Characteristics, and Clinical Significance

Wednesday, Nov. 28 3:30PM - 3:40PM Room: E263

Participants
Osman Ocal, MD, Ankara, Turkey (*Presenter*) Nothing to Disclose
Anil Arat, MD, Madison, WI (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

drosmanocal@hotmail.com

PURPOSE

To describe the rate and characteristics of air bubble retention within cerebral aneurysms treated by flow diverters.

METHOD AND MATERIALS

Patients with cerebral aneurysms treated by flow diversion in a single institution over 30 months were identified. Patients were excluded if selective intrasaccular treatment was also attempted or performed in the same session. Among the remaining patients, those with immediate postprocedure flat detector CT (FDCT) images were identified. FDCT studies were included unless there were surgical or endovascular materials previously used to treat the target aneurysm or other aneurysms interfering with image interpretation. 66 FDCT studies in 66 patients were identified and were scrutinized for presence of air in the aneurysm. Clinical outcome, aneurysm characteristics and imaging features of air within the aneurysm were evaluated.

RESULTS

Intraaneurysmal air bubbles were noted in eleven aneurysms (16.9%). Six aneurysms were saccular and remaining five were fusiform/dissecting. Seven were located in the anterior circulation. All of these aneurysms except one were large or giant and were significantly larger than aneurysms without air bubbles (mean diameter 16 mm versus 9.7 mm in 55 aneurysms, P=0.0277). Air bubbles were more frequently encountered when multiple devices/stents were used for flow diversion as compared to a single flow diverter (P=0.0275). There was a single air bubble in 6 patients, two bubbles in three patients and three bubbles in one patient. All of the bubbles were in the rostral portion of the aneurysm sac, were smaller than 5 mm in maximum diameter (mean diameter 2.6 mm). None of the patients had postprocedural change in neurological status. Air had spontaneously disappeared on all postprocedure follow-up CT images (available in 9 patients) at a mean CT follow-up duration of 2 days.

CONCLUSION

Intravascular microbubble formation probably occurs in all endovascular procedures despite rigorous attention to technique. Flow diverters probably result in the intraaneurysmal entrapment of these microbubbles. In this study this finding was common, incidental, self-limited and without clinical consequences.

CLINICAL RELEVANCE/APPLICATION

The finding of intraaneurysmal microbubble within cerebral aneurysms treated by flow diverters is clinical inconsequential and self-limited.

SSM23-06 Initial Experience and One Year Follow-Up with Neuroform Atlas™ Stent System for the Treatment of Brain Aneurysms

Wednesday, Nov. 28 3:50PM - 4:00PM Room: E263

For information about this presentation, contact:

palolarueda84@gmail.com

PURPOSE

The Neuroform Atlas Stent System is a recently introduced modification of the classical Neuroform stent consisting of a hybrid design with open and closed cells. Initial experience, technical considerations, treatment outcomes and one year follow up using the Atlas stent in combination with coil embolization are reported.

METHOD AND MATERIALS

Thirty unruptured aneurysms (from 30 patients) were treated with stent reconstruction. Control angiography and clinical assessment were performed inmediately, at four-month and at twelve-month after treatment.

RESULTS

The stents were delivered and positioned without difficulty in 29 cases. There were technical complications in one case, related to the displacement of the stent during its delivery. Only in one case occurred procedure-related clinical complications, with no permanent neurological deficit. We aimed for intial complete aneurysm occlusion with coils whenever technically feasible.The control angiography shortly after procedure showed class 1 or 2 occlusion (Raymond Roy classification) in 29 of 30 aneurysms. At one year angiographic follow-up, all 30 patients were clinically stable, 18 of 30 aneurysms were total occluded and two presented recanalizations. The objective ATLAS implantation was treatment stability. The treatment stability remained in 93% of our patients at four mounts and one year follow-up. In aneurysms with initial complete occlusion, this was maintained by the ATLAS system, while aneurysms with neck remnants showed no progression of the degree of closure. Our series of patients treated with ATLAS stents showed a very low rate of technical incidents (during the implantation and release of the stent) with permanent clinical complications (0%), compared with a review of series treated with other devices (1.4% to 4.3%).

CONCLUSION

The ATLAS stent is technically simple to implant and has a low thrombogenic potential. There are fewer problems associated with implantation, thromboembolic complications and hemorrhagic events compared with other types of stent, including braided stents. On the other hand, because of its low thrombogenic potential, partially occluded aneurysms or those with aneurysm remnants do not progress to complete occlusion.

CLINICAL RELEVANCE/APPLICATION

ATLAS stent implantation is useful to remaind the treatment stability of wide-neck auneurysms with complete initial occlusion with out or minimal procedure-related complications.

jiayweitsauo@qq.com

PURPOSE

To evaluate the effect of portal decompression on pulmonary gas exchange in patients with Budd-Chiari syndrome (BCS) and hepatopulmonary syndrome (HPS).

METHOD AND MATERIALS

From June 2014 to June 2015, all patients with BCS undergoing balloon angioplasty and transjugular intrahepatic portosystemic shunt creation at our institution were eligible for inclusion in this study. The primary endpoint was the changes in alveolar-arterial oxygen gradient (A-aO2) before and over 3 months after portal decompression.

RESULTS

Eleven patients with HPS (mean age, 51.7 years; six males) and 14 patients without HPS (mean age, 47.2 years; nine males) were included. Of the 11 patients with HPS, dyspnea was found in three (27.3%), all of which (100%) reported improvement in dyspnea after portal decompression. However, this improvement was not maintained at 3-month follow-up in two (33.7%) patients. For patients with HPS, the mean change in A-aO2 was statistically significant before and at 1 month (-11.7 ± 6.4 mmHg; P < .001) but not at 2-3 days (-3.2 ± 11.9 mmHg; P = .412) and 3 months (-1.3 ± 12.5 mmHg; P = .757) after portal decompression. For patients without HPS, the mean change in A-aO2 was not statistically significant before and at 2-3 days (+1.4 ± 8.3; P = .543) and 1 (+3.5 ± 8.1 mmHg; P = .137) and 3 months (+1.3 ± 8.2 mmHg; P = .565) after portal decompression. The overall mean changes in A-aO2 before and over 3 months after portal decompression was statistically significant for patients with HPS (-5.4 ± 6.9 mmHg; P = .035) but not for patients without HPS (+2.0 ± 7.6 mmHg; P = .333).

CONCLUSION

Portal decompression can improve pulmonary gas exchange in patients with BCS and HPS, but this effect is not sustainable at 3 months.

CLINICAL RELEVANCE/APPLICATION

1. Hepatopulmonary syndrome are common in patients with Budd-Chiari syndrome. 2. Portal decompression via balloon angioplasty and transjugular intrahepatic portosystemic shunt creation is effective and safe for the treatment of hepatopulmonary syndrome in patients with Budd-Chiari syndrome. 3. The treatment effect of balloon angioplasty and transjugular intrahepatic portosystemic shunt creation on hepatopulmonary syndrome is not sustainable at 3 months in patients with Budd-Chiari syndrome

SSM24-02 Outcomes in Cirrhotic Patients with Recurrent Ascites Who Received TIPS (Transjugular Intrahepatic Portosystemic Shunt) and/or Paracentesis

PURPOSE

Many cirrhotic patients who cannot undergo liver transplantation are symptomatically treated for recurrent ascites with paracenteses and/or transjugular intrahepatic portosystemic shunts (TIPS). Placing TIPS earlier in the cirrhotic disease process can potentially decrease the cost and inconvenience of repeated paracenteses. This study aimed to determine if there were differences in paracenteses and hospital admissions from bacterial peritonitis, variceal bleeds, and hepatic encephalopathy between cirrhotic patients who did and did not receive TIPS.

METHOD AND MATERIALS

A retrospective analysis was performed on all cirrhotic patients, age 18 and older, with refractory ascites between January 1, 2008 and December 31, 2016 at our institution. Demographics, cirrhosis etiology, lab values, paracentesis, TIPS, and hospitalization information were documented. A shared frailty model with TIPS placement as a time-varying covariate was used to calculate the association of time between paracentesis with TIPS placement, while chi-square tests examined the association between hospitalization rates for each outcome with TIPS placement.

RESULTS

A total of 344 patients with refractory ascites and a median age of 57 (IQR=50-62) were included. Of these, 92 (26.8%) received TIPS. Median MELD score at refractory date was higher among patients without TIPS compared to patients with TIPS (18 and 13, respectively; $p<0.01$). TIPS and the risk of paracentesis for ascites were highly associated ($p<0.01$). A 60% reduction in the risk of a paracentesis post-TIPS was observed regardless of MELD score, age, or gender (HR=0.40, 95%CI=0.33, 0.49). There was no significant difference in hospitalizations for bacterial peritonitis ($p=0.13$), variceal bleeding ($p=0.23$), or hepatic encephalopathy ($p=0.46$) between patients with and without TIPS.

CONCLUSION

This study found that cirrhotic patients with refractory ascites have a 60% reduction in the risk of receiving a paracentesis for symptomatic ascites after TIPS is placed with no change in hospitalizations for TIPS-associated outcomes. This suggests that TIPS placement should be considered earlier in the cirrhosis disease process to improve symptomatic control and decrease the need and associated costs of frequent paracenteses.

CLINICAL RELEVANCE/APPLICATION

Early placement of TIPS in cirrhotic patients reduces risk of repeat paracenteses without effecting hospitalization rates for common complications of ESLD.

SSM24-03 Optimal Energy Level in Assessment of TIPS Stent Luman in Dual-Energy CT Portal Venography in Liver Cirrhosis: A Prospective Study

Wednesday, Nov. 28 3:20PM - 3:30PM Room: E264

Participants
Jian Dong, PhD, Beijing, China (*Presenter*) Nothing to Disclose
Fuliang He, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
ChunYan Zhang, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

dongjianradiology@163.com

PURPOSE

To investigate the optimal energy level in monochromatic imaging of portal vein for the assessment of transjugular intrahepatic portosystemic shunt stent (TIPSS) lumen using 16-cm wide-detector spectral CT.

METHOD AND MATERIALS

Thirty-seven patients with TIPSS for portal hypertension performed spectral CT (Revolution, GE Healthcare) portal venography (CTPV) in our study. 120 kVp-like images as well as 4 groups of monochromatic images from 55 to 85 keV with an interval of 10 keV were collected. CTPV images at main portal vein, proximal, middle and distant level of stent were evaluated. Objective image quality indexes for portal vein and stent lumen included CT attenuations, noise, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were measured. Two experienced radiologists subjectively evaluated image quality independently with a 5-point scale on image quality and diagnostic confidence was obtained.

RESULTS

Within 37 patients with TIPS, 3 were classified into grade A, 24 were classified as grade B while 10 were graded C according to Child - Pugh staging. In portal vein and stent lumen, CT attenuations, SNR and CNR decreased with the increase of keV (all $P<0.01$). CT attenuations were higher than 200 HU in 55 keV (287.6 ± 36.9 HU) and 65 keV (223.1 ± 42.7 HU) in portal vein and stent lumen. Images at 55 keV demonstrated the highest objective indexes (CT attenuations, SNR and CNR). However, the subject score was the lowest (2.1± 0.7), with 9 (24.3%) of undiagnosed rate. Images at 65 keV exhibited highest subjective image quality score (3.6 ± 0.8) and diagnostic confidence (3.3 ± 0.6) while the second best CT attenuations, noise, SNR and CNR (all $P<0.01$). Subjective as well as objective indexes at 75 keV showed no statistical difference from 120 kVp-like group (all $P>0.05$), and these 75 keV indexes were inferior to 65 keV group, and superior to 85 keV group.

CONCLUSION

In monochromatic imaging of portal vein for the assessment of transjugular intrahepatic portosystemic shunt stent (TIPSS) lumen

In monochromatic imaging of portal vein for the assessment of transjugular intrahepatic portosystemic shunt stent (TIPSS) lumen using 16-cm wide-detector spectral CT, images at 55 keV manifested best objective image quality (CT attenuation, SNR and CNR), while 65 keV images demonstrated best subjective image quality and diagnostic confidence.

CLINICAL RELEVANCE/APPLICATION

It is recommended to conduct CT portal venography using 16-cm wide-detector spectral CT for the visualization of TIPS stent lumen in liver cirrhosis patients at 65 keV.

SSM24-04 Metal Artifact Reductions with Monochromatic Imaging in Spectral CT Portal Venography after Gastric Coronary Vein Embolization (GCVE) in Portal Hypertension: A Comparative Study

Wednesday, Nov. 28 3:30PM - 3:40PM Room: E264

Participants
Jian Dong, PhD, Beijing, China (*Presenter*) Nothing to Disclose
Fuliang He, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

dongjianradiology@163.com

PURPOSE

To investigate the clinical value of metal artifact reductions (MARs) combined with monochromatic imaging in spectral CT portal venography (CTPV) after gastric coronary vein embolization (GCVE) by comparison with 120 kVp-like imaging.

METHOD AND MATERIALS

Thirty-one patients with GCVE artifacts were performed CTPV with spectral CT in our study. All raw data were reconstructed as 120 kVp-like imaging without MARs (group A), and monochromatic imaging with MARs at 65 keV (group B) and 74 keV (group C), respectively. Three slices of CTPV images were evaluated, including main portal vein, heaviest artifacts and no artifacts level from all groups. Objective indexes for portal vein included signal intensity (SI), standard deviation (SD), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) and artifact index (AI). Subjective indexes were assessed by two radiologists separately with 5-point scale. Statistical analyses were analyzed.

RESULTS

With the use of MARs, AI in group B (29.1 ± 3.6)and C (35.6 ± 4.4) are much lower than group A (87.2 ± 11.3)($P<0.01$). As for the quantitative indices of main portal vein, group B demonstrates the highest SI (243 ± 20.6), SNR (22.1 ± 3.7) and CNR (11.5 ± 2.6) than the other two groups (all $P<0.01$), while there is no statistical differences in SI (184 ± 19.7 Versus 179 ± 21.6), SNR (20.4 ± 3.1 Versus 21.6 ± 3.7) and CNR (9.2 ± 2.4 Versus 9.6 ± 2.9) between group A and C (all $P>0.05$). For subjective assessment, group B (3.8 ± 1.6) is superior to group A (2.1 ± 1.4)and (3.1 ± 1.1) ($P<0.01$).

CONCLUSION

Combination of MARs with monochromatic imaging decreased metal artifacts, and improved image quality in spectral CT portal venography with GCVE, with 65 keV as the optimal energy level.

CLINICAL RELEVANCE/APPLICATION

It is recommended that 65 keV with MARs as the optimal CTPV protocol for liver cirrhosis patients with GCVE.

SSM24-05 Role of Preoperative MSCT and MRI for Endovascular Procedures in Budd-Chiari Syndrome with Inferior Vena Cava (IVC) Obstruction: A Retrospective Study of 112 Cases

Wednesday, Nov. 28 3:40PM - 3:50PM Room: E264

For information about this presentation, contact:

xinwu0401@163.com

PURPOSE

This article focuses specifically on the obstructive characteristics, collateral vessels and floating thrombus demonstrated on preoperative imaging, to determine the role of preoperative MSCT and/or MRI for endovascular procedures.

METHOD AND MATERIALS

This retrospective analysis included 112 patients who underwent endovascular procedures for BCS between October 2009 and Jun 2017 in our institution. All patients had preoperative MSCT and/or MRI imaging. Two radiologists independently assessed (on a 5-point scale) the imaging data to evaluate diagnostic accuracy, inter-reader agreement, and association between imaging presentation and interventional procedures.

RESULTS

Eighty-two patients had preoperative MSCT data and corresponding sensitivities were 83.33%, 86.96%, 88%, and 81.25% for reader 1, and 83.33%, 91.30%, 92.00%, and 81.25% for reader 2. Thirty two patients had preoperative MRI data and corresponding sensitivities were 88.89%, 100%, 100%, and 83.33% for reader 1, and 100%, 100%, 100% and 100% for reader 2. Areas under the receiver operating characteristic curves (AUCs) for judging IVC secondary thrombus were 0.88 for reader 1, 0.87 for reader 2 in group MSCT, and 0.975 for reader 1, 0.933 for reader 2 in group MRI. Inter-reader agreement was substantial or excellent for diagnostic accuracy (κ=0.745-0.927).

CONCLUSION

In patients with BCS, it is important to focus preoperatively on the degree and extent of the obstruction, collateral vessels and floating thrombus, to optimize interventional procedures and minimize complications.

CLINICAL RELEVANCE/APPLICATION

Interventional therapy is the preferred microinvasive therapeutic for patients with BCS, however, varying degree of procedure-related complications still exist. If we properly estimate obstructive characteristics preoperatively and detect risk factors, such as dangerous collateral vessels and IVC secondary thrombosis, we can design a reasonable interventional program and minimize complications.

SSM24-06 The Feasibility and Utility of the Overlay Technique Under Cone-Beam Computed Tomography Guidance for Portal Vein Puncture During Transjugular Intrahepatic Portosystemic Shunt

Wednesday, Nov. 28 3:50PM - 4:00PM Room: E264

Participants
Cheng Sun, Tianjin, China (*Presenter*) Nothing to Disclose
Changlu Yu, Tianjin, China (*Abstract Co-Author*) Nothing to Disclose
Kefeng Jia, Tianjin, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The purpose of this study was to investigate the feasibility and utility of the overlay technique under cone-beam computed tomography (CBCT) which was used as a navigation method for portal vein puncture during transjugular intrahepatic portosystemic shunt (TIPS).

METHOD AND MATERIALS

From February 2016 to April 2017, 15 consecutive cirrhotic patients (12 males and 3 females; mean age 58 years, range from 44 to 68 years) received TIPS treatment and prospectively enrolled in this study. An initial CBCT image acquisition was performed before TIPS and we applied the overlay technique by register the preoperative contrast enhanced CT or MRI portal venous phase images with the newly acquired CBCT images. According to the overlaid images, a planned needle path was made and displayed simultaneously on the axial, sagittal and coronal plane. The angle from hepatic vein to portal vein was calculated manually on three planes and intended for the interventional radiologists' reference. The contrast material consumption, number of needle puncture attempts, radiation dose and fluoroscopic time were recorded from hepatic vein catheterization to portal vein entry.

RESULTS

The overlay technique was technically feasible in 14 of 15 patients (93%). The only failure was due to the overlay misregistration caused by progress of ascites. No complications were observed postoperative monitoring. The mean (± SD) contrast material consumption was 38 ± 9.2ml, number of needle attempts was 1.9 ± 1.1 punctures(range 1 to 4), dose area product (DAP) was 138 ± 55.8 Gy·cm3 ,fluoroscopic time was 19 ± 5.5min.

CONCLUSION

The overlay technique under CBCT guidance is a feasible and safe method for TIPS portal vein puncture. It contributes to the creation of TIPS and facilitate the portal vein pressure reduction.

CLINICAL RELEVANCE/APPLICATION

The overlay techique under cone-beam computed tomography for portal vein puncture during TIPS is feasible, safe and helps portal puncture vein pressure reduction.

PURPOSE

Women with a personal history of breast cancer have an elevated lifetime risk for a second breast cancer. However, the current American Cancer Society guidelines do not recommend MRI screening in this population. Multiple studies have demonstrated that the sensitivity of Abbreviated breast MRI (AB-MRI) is similar to full diagnostic protocols (FDP-MRI). In this study, we retrospectively evaluate the use of surveillance AB-MRI in women with a personal history of breast cancer.

METHOD AND MATERIALS

An IRB approved and HIPAA compliant reader study was performed on 398 consecutive women with a personal history of breast cancer who underwent full protocol clinical breast MRIs from 9/13-12/15. There were 14 cancers detected (3.8%). An enriched reader study was performed consisting of 68 cases including the 14 cancer cases. Non-cancer cases had at least 1 year of follow-up. Interpretations from a limited image set simulating an AB-MR protocol (T2, pre, and post contrast) were compared with interpretations of the FDP-MRI clinical study.

RESULTS

The AB-MR interpretations were compared with those from the full, clinical protocol. The sensitivity (SN), specificity(SP), positive predictive value (PPV), and the negative predictive value (NPV) for the simulated AB-MR vs the FDP-MRI interpretations were: SN - 50% vs 71%, SP - 96% vs 77%, PPV- 74% vs 43%, NPV - 88% vs. 91%. The mean difference between reader 1 and reader 2 was 0.29 with 95% confidence interval: [-0.33, 0.90]. There were significantly fewer false positives with AB-MRI than FDP-MRI, but more false negatives were observed with AB-MRI.

CONCLUSION

Our preliminary results show higher specificity at the expense of sensitivity in our simulated AB-MRI reads compared to FDP-MRI in women with a history of breast cancer. Further evaluation is warranted.

CLINICAL RELEVANCE/APPLICATION

A simulated AB-MRI protocol resulted in fewer false positive exams than with a full, clinical MR protocol in women with a personal history of breast cancer, however, more research is needed.

SSQ01-02 Abbreviated Breast MRI : 'Ultrafast' DISCO Acquisition for Lesion Characterization

Thursday, Nov. 29 10:40AM - 10:50AM Room: E450A

For information about this presentation, contact:

audrey.milon.am@gmail.com

PURPOSE

The purpose of our study was to evaluate the diagnostic performance of a dynamic acquisition over-sampling the first minute after contrast administration in an abbreviated dynamic-contrast-enhanced (DCE) breast-MRI.

METHOD AND MATERIALS

153 women were retrospectively consecutively included between July 2016 and March 2017, regardless of indication. All these women had a full breast- MRI protocol, including a DISCO ultrafast acquisition with 7 phases, and an enhanced lesion histologically proven (age= 55 (28-88)). Two readers analyzed 179 lesions (73 benign, 5 B3, 101 malignant lesions) with BIRADS classification for each protocol: an abbreviated protocol (T1-weighted, T2-wheigthed, DISCO, T1-fat suppressed VIBRANT 2mn after contrast administration) and a standard full protocol with late post-contrast phases. Then readers studied DISCO's early enhancement curve with the following semi-quantitative parameters: Wash-In Rate (WIR), Maximal Slope Increase (MSI), Enhancement Amplitude (EA), and Time of Half Rising (THS). Heterogeneity was also assessed using Standard Deviation (STD) at the different DISCO phases.

RESULTS

176/179 (98%) lesions were detected by the abbreviated protocol regarding to the full protocol : 122 mass and 57 non-mass-like enhancement or foci (medium size : 18mm). The 3 undetected lesions were benign. Malignant lesions showed a WIR, a MSI a EA higher, a THS shorter and were more heterogeneous at all DISCO phases than benign lesions ($p<0.01$). In the group of masses with benign morphology (n= 42), THS was shorter for the malignant lesions (39.1 sec) than for the benign lesions (44.6 sec) ($p=0.01$).

CONCLUSION

Including an additional ultrafast-scan in an abbreviated breast-DCE-MRI protocol enables the early enhancement study that is useful for lesion characterization and is time efficient.

CLINICAL RELEVANCE/APPLICATION

DCE-abbreviated breast-MRI with ultrafast-scan is efficient for lesion detection and characterization; so might be considered as a screening tool in intermediate-risk women.

SSQ01-03 Ultrafast Breast DCE-MRI in the Evaluation of Tumor Size: Potential Utility in Moderate to Marked Background Parenchymal Enhancement

river7774@gmail.com

PURPOSE

Ultrafast breast DCE-MRI allows imaging of early kinetics within the first 30 seconds after contrast injection, when the background parenchymal enhancement (BPE) is minimal. This study was performed to explore the clinical utility of ultrafast MRI focusing on tumor size evaluation according to the level of BPE.

METHOD AND MATERIALS

A total of 360 consecutive women (median age, 54 years; range, 26 - 82 years) with 361 tumors (49 DCIS and 312 invasive) who underwent both the ultrafast and conventional breast MRI before surgery were included. Ultrafast MR images were obtained using TWIST or 4D-TRAK sequence (temporal resolution, 4.5 sec; voxel size, 1.1×1.1×1.0 mm3, TR/TE 4.1/1.3 ms). Then, conventional DCE-MR images were obtained using 3D FLASH sequence (temporal resolution, 90sec; voxel size, 0.8×0.8×1.0 mm3, TR/TE 4.7/1.7 ms). Tumor size was independently measured on each scan, respectively. Agreement between tumor sizes on MRI and those on surgical histopathology was assessed using the intraclass correlation coefficient (ICC) analysis.

RESULTS

The ICC on ultrafast MRI was comparable to that on conventional MRI (ICC = 0.657 vs. 0.634, P =.598). For conventional MRI, the ICC was lower in women with moderate to marked BPE (ICC = 0.568) than in women with minimal to mild BPE (ICC = 0.650) with borderline significance (P =.080). However, no difference was found on ultrafast MRI (ICC = 0.625 for moderate to marked vs. 0.663 for minimal to mild BPE, P =.385). In women with moderate to marked BPE, the ICC was slightly higher on ultrafast MRI than that on conventional MRI, although the difference was not statistically significant (ICC = 0.625 vs. 0.568, P = .236). No difference was found for the ICC according to the age, menopausal status, family history, histologic type, ER positivity, HER2 positivity, and lesion type on MRI (mass vs. non-mass enhancement) (All P >.05).

CONCLUSION

In women with moderate to marked BPE, tumor size measurement might be more accurate on ultrafast MRI than on conventional MRI.

CLINICAL RELEVANCE/APPLICATION

In women with moderate to marked BPE, ultrafast MRI can be applied for more accurate evaluation of tumor extent.

SSQ01-04 Maximum Slope as a Kinetic Parameter Based on Ultrafast Dynamic Contrast-Enhanced MRI of the Breast Using K-Space Weighted Imaging Contrast

amaoh@kuhp.kyoto-u.ac.jp

PURPOSE

To investigate the diagnostic performance and inter-reader agreement of the maximum slope (MS) in breast malignant from benign lesions obtained by ultrafast dynamic contrast-enhanced magnetic resonance imaging (DCE MRI). Comparison with washout index (WI) was performed with the focus on discrepant cases.

METHOD AND MATERIALS

In total, 141 enhancing lesions (89 malignant, 52 benign) were included. Ultrafast DCE MRI sequences were acquired using a k-space-weighted imaging contrast (KWIC) sequence, obtained 0 to 1 min after gadolinium injection (3.75 s/frame; 16 frames) and followed by standard DCE MRI. The MS was calculated its percentage relative enhancement per second (%/s). The inter-reader agreement of MS values by two radiologists were evaluated using intra-class correlation coefficients (ICC). As a semi-quantitative parameter for conventional DCE MRI, washout index (WI: signal intensity [SI] delay - SI early) / SI pre × 100 (%) was calculated. The diagnostic performance (malignant/ benign differentiation) of the MS and WI was compared using ROC analysis.

RESULTS

Intra-class correlation coefficients (ICC) of the reading was 0.98 (95% confidence interval 0.97-0.99) for all, 0.96 (0.95-0.98) for malignant lesions and 0.99 (0.97-0.99) for benign lesions. The average MS was 25.4%/s (standard deviation: SD, 11.2 %/s) for malignant lesions and 11.8%/s (SD, 10.7 %/s) for benign lesions. The AUC of the MS (ICC: 0.98) was almost same as that of the WI (0.83 vs. 0.82, respectively; P = 0.80). Using the optimal cut-off points determined by the Youden index (>9.76% /s for the MS and <-23 % for the WI), MS tended to have higher sensitivity (92.1%) and specificity (65.4%) compared with WI (91.1% and 61.5%, respectively). False positive cases based on MS were FA (n=5) and intraductal papilloma (n=1), while false positive cases based on WI were fibrocystic change (n=6), intraductal papilloma (n=2) and flat epitherial atypia.

CONCLUSION

The overall diagnostic performance of MS in breast lesion was similar to the conventional kinetic parameter, with AUC of over 0.8. Excellent ICC was obtained. MS helped to reduce false positive in fibrocystic change, while FA tended to be false positive on MS.

CLINICAL RELEVANCE/APPLICATION

Our results suggest that maximum slope can be an alternative kinetic parameter to conventional kinetic curve, potentially shorten scan time, with excellent inter-reader agreement.

SSQ01-05 Combination of an Ultrafast TWIST VIBE Dixon Sequence Protocol and Diffusion-Weighted Imaging to a Highly Accurate Clinically Applicable Classification Tool for Suspicious Masses in Breast MRI

Thursday, Nov. 29 11:10AM - 11:20AM Room: E450A

Participants

PURPOSE

To develop a statistical model for classification of suspicious masses in breast MRI when using TWIST VIBE Dixon (TVD) dynamic sequences in combination with diffusion-weighted imaging (DWI) and compare it to a model based on a combination of conventional dynamic contrast enhancement (DCE) and DWI. As ultrafast TVD sequences offer the potential to shorten breast MRI protocols, diagnostic accuracy might be hampered due to reduced kinetic information. A special focus of this study was thus to maintain high diagnostic accuracy in lesion classification.

METHOD AND MATERIALS

65 patients underwent clinically indicated breast MRI between 02/2014 and 04/2015, with 83 reported lesions (60 malignant, 23 benign). Inclusion criteria were suspicion of breast cancer or pre-therapeutic staging. Patients with non-mass-enhancements only were excluded. The protocol consisted of our institute's standard protocol complemented by an ultrafast TVD sequence. The apparent diffusion coefficient (ADC) and the peak enhancement of the TVD sequences were used to calculate a generalized linear model (GLM) for prediction of malignancy. A second model was calculated using ADC and the curve type derived from the conventional DCE sequence for the sake of comparison. Generalizability was ensured by applying leave-one-out cross validations. For easy application of the GLMs in clinical workflows, nomograms were created.

RESULTS

The GLM based on peak enhancement of the ultrafast TVD sequences and ADC performed comparably accurate to the model based on conventional DCE and ADC (Sensitivity 93.3% vs. 93.3%, specificity 91.3% vs. 87.0%, positive predictive value 96.6% vs. 94.9%, negative predictive value 84.0% vs. 83.3%; no significant differences).

CONCLUSION

This study presents a method to integrate ultrafast TVD sequences into a breast MRI protocol and reduce examination time while maintaining diagnostic accuracy. A GLM based on the combination of TVD-derived peak enhancement and ADC provides high diagnostic accuracy. The GLM can easily be applied in clinical routine using the supplied nomograms.

CLINICAL RELEVANCE/APPLICATION

One limiting factor hampering the comprehensive application of breast MRI is time. This study presents a breast MRI protocol with less than 5 minutes duration along with a classification scheme reaching high diagnostic accuracy. Use of this protocol could improve patient throughput and strenghten the role of breast MRI in screening.

SSQ01-06 Ultrafast Dynamic Contrast-Enhanced MRI for Detection of Invasive Components in Cases of Breast Ductal Carcinoma in Situ by Biopsy

Thursday, Nov. 29 11:20AM - 11:30AM Room: E450A

Participants

Kei Takase, MD, PhD, Sendai, Japan (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

naokomori7127@gmail.com

PURPOSE

To evaluate whether ultrafast dynamic contrast-enhanced (DCE) MRI could identify invasive components in cases with ductal carcinoma in situ (DCIS) diagnosed by percutaneous biopsy.

METHOD AND MATERIALS

Fifty-three consecutive women with 53 lesions diagnosed with DCIS by biopsy underwent IRB-approved ultrafast DCE-MRI including a pre- and 18 post-contrast ultrafast 3D bilateral scans using a 3T system. Ultrafast 3D bilateral scans were acquired with temporal resolution of 3 seconds per image. We evaluated the heterogeneity of enhancement in a target lesion using model-based analysis. Regions of interest (ROIs) were placed where the strongest and weakest signal increases were found in ultrafast DCE-MRI to obtain kinetic curves of maximum and minimum enhancement, respectively. The kinetic curve obtained from ultrafast DCE-MRI was analyzed using an empirical mathematical model: $\Delta S(t)=A*(1-e-at)$. Where A is the upper limit of the signal intensity, a (min-1) is the rate of signal increase. The initial slope of the kinetic curve is given by 'A*a'. Amax, Amin, amax, amin, A*amax, and A*amin were obtained from ROIs for maximum and minimum enhancement, respectively. We obtained the following derivations for diagnostic parameters showing heterogeneity of enhancement: A difference=Amax - Amin; a difference= amax -amin; A*a difference= A*amax - A*amin.

RESULTS

Surgical specimens revealed 32 lesions with pure DCIS and the remaining 21 lesions with DCIS with invasive components (DCIS-IC). The A difference for DCIS-IC (132±235) was significantly higher than that of pure DCIS (49±34) ($p = 0.013$). No significant difference was found for a difference and A*a difference ($p = 0.24$ and 0.46, respectively). Receiver operating curve analysis revealed that the area under the curve of A difference was 0.70. The most effective threshold for A difference was 68, and the sensitivity, specificity, positive predictive value and negative predictive value were 62% (13/21), 72% (23/32), 59% (13/22), and 74% (23/31), respectively.

CONCLUSION

The A difference could suggest the presence of invasive components in cases with DCIS diagnosed by biopsy.

CLINICAL RELEVANCE/APPLICATION

The A difference showing the heterogeneity of enhancement of lesions in ultrafast DCE-MRI might suggest the presence of invasive components in cases of DCIS by biopsy.

SSQ01-07 Ultrafast Dynamic Contrast Enhanced Breast MRI in Differentiating between Subcentimeter Carcinomas and Benign Lesions: Quantitative versus Qualitative Assessments

PURPOSE

Ultrafast dynamic contrast enhanced (UF-DCE) breast MRI, characterized by high temporal and spatial resolution, enables image acquisition at multiple time points starting simultaneously with the beginning of contrast injection. In a preliminary study comparing several quantitative parameters calculated from UF-DCE MRI, we determined bolus arrival time (BAT) and maximum slope (MS) were most useful in the differentiation between subcentimeter carcinomas and benign lesions. This study aims to compare the performance of these parameters with qualitative assessments of UF-DCE MRI.

METHOD AND MATERIALS

We identified female patients between February-October 2017 with a: 1) UF-DCE MRI as part of hybrid protocol with conventional DCE MRI performed with a 3.0T MRI with a 16-ch coil and 2) biopsy proven BI-RADS 4-6 lesion. UF-DCE MRI were acquired continuously 15 times during the approximately 60 sec (temporal resolution, 3.0-4.3 sec) starting simultaneously with the beginning of contrast injection. BAT and MS were computationally calculated based on 3D volumetric segmentation. Qualitative assessments were visually performed by a reader, identifying the time from scan start to the beginning of lesion enhancement (vBAT) and evaluating the degree of enhancement relative to background parenchymal enhancement (vE) by a 4-point grading scale from 'prominent' to 'indistinguishable'. Wilcoxon signed-rank test or Pearson's chi-squared test were used for the statistical analyses. P value <0.05 was considered satistically significant. The diagnostic performance was evaluated using areas under the receiver operating characteristic curve (AUC).

RESULTS

In total, 77 subcentimeter lesions (carcinomas, 33 [43%]; benign lesions, 44 [57%]) were analyzed. BAT, MS and vBAT presented significant difference between carcinomas and benign lesions (p=0.0004, p<.0001, p=0.0063), while vE did not (p=0.0607). AUCs of BAT (0.737) and MS (0.790) were higher than those of vBAT (0.683) and vE (0.605).

CONCLUSION

Quantitative assessments of UF-DCE MRI presented higher performance than qualitative assessments in differentiating between subcentimeter carcinomas and benign lesions.

CLINICAL RELEVANCE/APPLICATION

There is no standardized way to evaluate ultrafast DCE breast MRI. Although diagnostic utility of some quantitative parameters is known, little is known about the performance of qualitative assessment, especially for subcentimeter lesions.

SSQ01-08 Comparison of Machine Learning Based Measurement and Visual Assessment of Fibroglandular Tissue and Background Parenchymal Enhancement in Breast MR Imaging: A Preliminary Study

Thursday, Nov. 29 11:40AM - 11:50AM Room: E450A

Participants
Heeyoung Chung, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Sung-Hun Kim, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

hoonhoony@naver.com

PURPOSE

To design and validate a machine learning model for the measurement of fibroglandular tissue (FGT) and background parenchymal enhancement (BPE) in breast MR imaging, and compare with estimation of radiologist according to BI-RADS categories.

METHOD AND MATERIALS

195 women (mean age, 54.9 years; range 30 - 86 years) who were diagnosed with invasive breast cancer and underwent preoperative breast MR, between January and December 2017 were enrolled in this study. Two radiologists independently assessed the categories of FGT and BPE of contralateral breast, using with axial precontrast, early dynamic contrast enhancement T1-weighted image, and subtraction image between them. In case of discordance, two radiologists reached consensus. Machine learning model was designed to measure the volume of whole breast, FGT and BPE, using nonnegative matrix factorization (NMF). In this study, 50 and 145 samples were assigned to train and valid, respectively. Areas under the receiver operating characteristic curve was used to assess model performance of predicting dense breast (FGT category c, d) and prominent BPE (BPE category c, d). Correlation between the visual assessment of radiologist and machine learning based measurement was assessed using Spearman correlation analysis.

RESULTS

With the machine learning model, AUC of prediction of dense breast were 0.971 (0.880-0.998) in training set and 0.902 (0.784-0.968) in validation set. AUC of prediction of prominent BPE were 0.959 (0.912-0.985) in training set and 0.819 (0.746-0.848) in validation set (P < .001). Correlation between machine learning based measurement and visual assessment by radiologist was r = 0.871 of FGT, and r = 0.523 of BPE, respectively (P < .001).

CONCLUSION

Machine learning model showed reliable predictive power for FGT and BPE assessment and close correlation with FGT assessment by radiologist.

CLINICAL RELEVANCE/APPLICATION

FGT and BPE are known as risk factors for breast cancer and are associated with poor prognosis. Machine learning can provide quantitative and objective information of FGT and BPE volume in breast MR imaging and can be helpful to predict patient's prognosis.

SSQ01-09 Deep Learning of Breast MRI Tumor Volume Improves Tumor Proliferation Marker Ki-67 Estimation

PURPOSE

Ki-67 is a commonly used immunohistochemistry marker for cellular proliferation in invasive tumors. A few recent studies showed some association between Ki-67 and DCE-MR imaging features. We performed an investigation to compare effects of a 3D deep learning approach versus conventional radiomic features in deriving breast DCE-MRI information to predict Ki-67 rate.

METHOD AND MATERIALS

In an IRB-approved retrospective study of 141 patients, we identified 141 breast DCE-MRI scans (2011-2016) at our institution. All patients have the Ki-67 proliferation rates measured that are further categorized into High vs Low category according to a clinically defined threshold of 14. Breast tumor volume were automatically segmented in 3D space from the first post-contrast breast MR sequence images. From the segmented 3D tumor volume, we extracted 30 common radiomic features, including morphological and contrast enhancement kinetic characteristics of the tumor volume; those features were fed to a logistic least absolute shrinkage and selection operator (LASSO) regression model to predict High vs Low Ki-67 categories. Also, a 3D convolutional neural network (CNN) deep learning model was used to perform the same prediction but directly using the original image of the segmented 3D tumor volume (i.e., here no any pre-defined imaging features extracted nor used). We performed 10-fold cross-validation for both logistic regression and deep learning model evaluation and used average AUC as the metric of model classification accuracy.

RESULTS

There are 102 and 39 patients in the High and Low Ki-67 category, respectively. The average of the Ki-67 was 28.05%±21.63. The AUC of the logistic regression model was 0.74 (95% CI: 0.73-0.75) for 4 LASSO-selected top ranked radiomic features (1 morphological and 3 contrast-enhancement related), while the 3D deep learning model achieved an AUC of 0.80 (95% CI: 0.75-0.85).

CONCLUSION

In this study, the 3D CNN deep learning-based approach that automatically identifies and organizes hierarchical imaging features for predicting Ki-67 outperformed the LASSO regression model coupled with pre-defined radiomic features.

CLINICAL RELEVANCE/APPLICATION

Deep learning of breast DCE-MRI tumor volume using CNN models may improve interpretation on the association between radiological images and the immunohistochemistry tumor proliferation marker Ki-67.

PURPOSE

Pulmonary Angio-CT is the first diagnostic choice for the evaluation of pulmonary embolism and usually performed with iodinated contrast media (CM) injection. The purpose of this study is to evaluate the lower amount of iodinated CM required in order to obtain a diagnostic quality pulmonary Angio-CT with the new Dual Source CT technology.

METHOD AND MATERIALS

36 patients (16 males, 20 females; mean age 40 years) were enrolled with medium-high pre-test probability of pulmonary embolism and underwent a 3rd generation Dual Source CT (Somatom Force Siemens Healthineers) scan. Three groups of 12 patients each one were randomized using 400 mgI/mL iodinated CM with different doses: group A (<5 ml), group B (<10 ml) and group C (<15 ml). The Hounsfield Unit (HU) values were sampled at predefined points of the pulmonary arteries. Each exam was also assessed qualitatively with a 5-point scale.

RESULTS

HU evaluation did not show statistically significant difference between groups A and B, while they showed statistically significant difference between group C and groups A-B (Kruskal-Wallis, p=0.025). Qualitative analysis did not find statistically significant difference between groups A, B and C (Kruskal-Wallis, p=0.12).

CONCLUSION

The new 3rd Dual Source CT technology allows for an optimization of pulmonary angio-CT study in order to obtain a diagnostic quality images with low doses of iodinated CM.

CLINICAL RELEVANCE/APPLICATION

The purpose of this study is to evaluate a reduced contrast media administration in patients with suspected pulmonary embolism in an emergency setting, especially in patients with higher risk of contrast-induced nephropathy (CIN) (i.e. nephropatic or type 2 diabetic patients).

SSQ02-02 2D-PC MRI Measurement of Pulmonary Artery Blood Flow and Left Atrial Function in Smokers: A Correlational Research

PURPOSE

To investigate the correlation between main pulmonary artery blood flow and left atrium functional parameters in smokers using two-dimensional phase contrast magnetic resonance imaging (2D-PCMRI).

METHOD AND MATERIALS

Twenty-eight smokers (all men, mean age: 39.8±7.0 years) were enrolled in this study. All of them underwent main pulmonary artery 2D-PC and cardiac scan at 3.0T MR from December 2017 to March 2018. Blood flow parameters include Peak Positive Velocity (PPV) (cm/s), Peak Negative Velocity (PNV) (cm/s), Average flow (AF) (ml/beat), Average Positive Flow (APF) (ml/beat), and Average Negative Flow (ANF) (ml/beat). The correlation between main pulmonary artery blood flow and left atrial functional parameters was analyzed.

RESULTS

There is a statistically correlation between pulmonary artery PPV and left atrial active ejection fraction (LAEFa) (p=0.022, r=0.431), and left atrium total ejection fraction (LAEFt) (p=0.032, r=0.406) respectively. Similarly, there is a statistically correlation between pulmonary artery AF and left atrium maximum volume (LAVi max) (p=0.048, r=0.378), LAEFa (p=0.040, r=0.391) and LAEFt (p=0.008, r=0.488) respectively. There is a statistically correlation between APF and LAVi max (p=0.039, r=0.392), LAEFt (p=0.028, r=0.415), respectively.

CONCLUSION

There is a positive correlation between the main pulmonary artery blood flow and left atrium function in smokers.

CLINICAL RELEVANCE/APPLICATION

This correlational research of pulmonary artery blood flow and left atrium function is helpful in further to understand and reveal the effect of smoking on the cardiovascular system.

SSQ02-03 Quantification of Pulmonary Emboli Burden by Novel 3D-Based Computed Tomography Method: Comparison with Qanadli Score, Biomarkers, and Clinical Information

Thursday, Nov. 29 10:50AM - 11:00AM Room: S404AB

leocleobest@gmail.com

PURPOSE

Dedicated descriptions of pulmonary emboli (PE) morphology, total emboli burden, and the possible impacts on hemodynamics and diagnostic biomarkers remained largely unexplored.

METHOD AND MATERIALS

We consecutively studied subjects suffered from acute PE who visited emergency department. On arrival hemodynamics, oxygenation status, and markers of Troponin-I/D-dimer were all obtained. Contrast enhanced spiral computed tomography (CT) for pulmonary vasculature and 3-dimensional (3D) measures of emboli burden were performed (IntelliSpace Portal [ISP] 9.0 Philips Medical Systems Nederland B.V.).

RESULTS

Among 116 subjects (mean age: 70.1±16.0, 64% female) with clinical information and CT-based 3D embolism quantification available, the mean total emboli size were 8.6cm3, Qanadli scores was 7.4, 4.6, and 12.1 for right, left side and total pulmonary trunk (reference range: 0-20), respectively. Both greater total emboli mass and pulmonary emboli Qanadli score were positively associated with higher Troponin I level (r=0.23 & 0.33, both p<0.05), and marginally associated with lower on arrival oxygenation saturation (SpO2) (by blood gas, r=-0.38, p=0.05). Instead, total emboli burden within lung parenchyma was strongly inversely associated with SpO2 (r=-0.48 & -0.42, both p<0.05).

CONCLUSION

Total thromboemboli burden assessed by quantitative CT-based modality served as a useful index for stressed cardiopulmonary circulation, and possibly provide insights into oxygenation/perfusion status.

CLINICAL RELEVANCE/APPLICATION

Total thromboemboli burden assessed by quantitative CT-based modality served as a useful index for stressed cardiopulmonary circulation.

SSQ02-06 Evaluation of Coronary Artery in Kawasaki Disease By 3D Magnetic Resonance Coronary Angiography

Thursday, Nov. 29 11:20AM - 11:30AM Room: S404AB

Participants
Chuan Fu, BS,BMedSc, Chengdu, China (*Presenter*) Nothing to Disclose

Rong Xu, Chengdu, China (*Abstract Co-Author*) Nothing to Disclose
Hui Liu, Chengdu, China (*Abstract Co-Author*) Nothing to Disclose

45209242@qq.com

PURPOSE

Kawasaki disease causes inflammation that is inclined to cause heart complications, such as coronary artery vasculitis, myocarditis, and heart valve problems. Our study is aimed to assessment of coronary arteries in Kawasaki disease by 3D magnetic resonance imaging

METHOD AND MATERIALS

The study group consisted of 16 pediatric patients aged 2 to 10 years (males, 87.5%; mean age, 4.8 year) with Kawasaki diseases from Jan. 2017 to Mar. 2018. All patients underwent three-dimensional (3D) whole-heart magnetic resonance imaging (1.5T, Phiilps;) using two different sequences (3D TEE sequence; 3D BTEE sequence;). Sweep time were record and the image quality was graded (from 0 to 5).

RESULTS

there were six patients with enlarged left and right ventricles (37.5%), three patients with enlarged whole-heart (18.75%), two patients with double superior vena cavas and enlarged left atrium and ventricle (12.5%). The scan time of 3D TEE sequence was One minute and forty seconds to two minute and thirty seconds (1min 40s to 2 min 30s), The scan time of 3D BTEE sequence was five minute and twenty seconds to six minute and thirty seconds (5 min 20s to 6 min 30s). For the grade of imaging quality, five patients were classes as 0-2 grade (31.25%), 11 patients were 3-5 grade (68.75) by the 3D TEE sequence, and six patients were 0-2 grade (37.5%), 11 patients were 3-5 grade (62.5%) by the 3D BTEE sequence.

CONCLUSION

3D whole-heart coronary arteries magnetic resonance imaging could obtain similar imaging quality with less scan time, it may be an excellent method to image, evaluate, diagnose, and follow-up coronary arteries lesions in pediatric patients with Kawasaki diseases.

CLINICAL RELEVANCE/APPLICATION

(dealing with 3D coronary arteries magnetic resonance imaging) 3D whole-heart coronary arteries magnetic resonance imaging could obtain similar imaging quality with less scan time.

PURPOSE

Both cardiac and pulmonary morphology and function can be simultaneously assessed during a single MR scan. Previous studies have shown an association between obstructive lung disease with cardiac dysfunction. Our aim is to evaluate the relationship between lung volumes and cardiac impairment in a population-based cohort study using whole-body MR scans.

METHOD AND MATERIALS

We studied 400 subjects who underwent whole-body MRI as part of the KORA FF4 cohort study, excluding subjects with established cardiovascular disease. Lung volumes were derived semi-automatically through an in-house algorithm (coronal acquired T1w sequences). Using Pearson correlation and multivariate regression (adjusted for age, sex, smoking status and BMI), lung volumes were compared with cardiac parameters of left and right ventricle (LV/RV, acquired from cine-SSFP sequences using cvi42), and standardized to body surface area.

RESULTS

A total of 356 subjects presented an average MRI-based lung volume of 4.0±1.1L and mostly standard values for cardiac parameters. In univariate analysis, a negative correlation of LV and RV stroke volume to lung volume was observed. After multivariate adjustment, stroke volume as well as end-diastolic volume of both LV (ß=-2.75, p=0.001; ß=-1.71, p=0.001) and RV (ß=-2.14, p=0.02; ß=-1.45, p=0.004) showed negative associations with lung volume, while ejection fraction, peak ejection rate and myocardial mass were not associated with lung volumes (Figure 1). These values were stronger for the LV than for the RV. In addition, for the LV, early but not late diastolic filling rate was negatively associated with lung volume.

CONCLUSION

Cardiac function and volume parameters derived from non-dedicated whole-body MRI, such as stroke volumes and biventricular end-diastolic volumes were significantly associated with lung volumes in a patient cohort without cardiovascular disease.

CLINICAL RELEVANCE/APPLICATION

These results suggest, that MRI could be an accurate, radiation-free, and possibly one-stop-shop screening tool, with the potential for early detection of subclinical heart disease in patients with emphysema and subclinical cardiovascular dysfunction.

SSQ02-08 Double Region of Interest Timing Bolus Technique to Perform Aortic CT Angiography with 40 Ml of Contrast Medium

PURPOSE

We developed a novel method to track the peak of the injected contrast medium by placing two regions of interest (ROI) at the timing bolus image. The purpose of this study was to compare the enhancement of the aorta when CT angiography was performed with 40 mL of contrast medium using the novel double ROI timing bolus (DRTB) technique with the enhancement using the conventional method.

METHOD AND MATERIALS

We prospectively included 21 patients from February to March 2018 who underwent repeated CT angiography of the aorta. In the prior scan, a total of body weight × 1.7 mL of contrast medium was injected for 25 s, and the scan timing was determined by the bolus tracking technique. The tube potential was 120 kVp and the table speed was set as fast as possible to acquire the entire aorta. In the DRTB method, timing bolus technique was performed using 9 mL of contrast medium at the level of the aortic root. An ROI was placed at the ascending and descending aorta, respectively. Time density curves of the two ROIs were drawn and the difference of the peak time (Tdiff) was recorded. The blood flow of the aorta was calculated by dividing the length of the thoracic aorta by Tdiff. The main scan was performed with a tube potential of 100 kVp. We injected 40 mL of contrast medium for 9 s and adjusted the table speed to follow the peak of the injected contrast bolus. We evaluated the attenuation of the aorta at the level of aortic root, arch, descending, celiac trunk, and iliac bifurcation.

RESULTS

The injected contrast medium during the main scan significantly reduced from 87 ± 11 to 40 mL (p <0.001). The attenuation of the aorta at the level of the aortic root, arch, descending, celiac trunk, and iliac bifurcation using the DRTB method were 408 ± 125, 425 ± 99, 421 ± 96, 414 ± 96, 417 ± 101 HU, respectively, which were all significantly higher than using the conventional method (341 ± 72, 370 ± 61, 362 ± 59, 349 ± 96, 362 ± 70 HU, respectively, all p <0.05).

CONCLUSION

DRTB method could dramatically reduce the contrast medium during aortic CT angiography while improving the enhancement than the conventional method.

CLINICAL RELEVANCE/APPLICATION

Aortic CT angiography using the DRTB method would reduce the risk of contrast induced nephropathy and also widen the indication of aortic CT to patients with chronic kidney disease.

SSQ02-09 Subclinical Changes in Cardiac Functional Parameters as Determined by Cardiovascular Magnetic Resonance (CMR) Imaging in Patients with Sleep Apnea and Snoring: Findings from UK Biobank

PURPOSE

Obstructive sleep apnea (OSA) is a common disorder that shows an increased risk for left ventricular (LV) and, more rarely, right ventricular (RV) dysfunction. Most studies to date have examined populations with manifest cardiovascular disease and have used echocardiography to analyze ventricular dysfunction, with little or no reference to ventricular volumes or myocardial mass. We hypothesized that there would be stepwise increase in LV mass and RV volumes from the unaffected, to the snoring and the OSA group.

METHOD AND MATERIALS

We analyzed cardiac MRI data from 4493 UK Biobank participants free from cardiovascular disease. Participants were allocated into three cohorts: (i) with OSA; (ii) with self-reported snoring; and (ii) without OSA or snoring (n=38; 1919; and 2536 respectively). We determined ventricular volumes, ejection fraction and LV mass from balanced cine-SSFP sequences.

RESULTS

Trend analysis showed a stepwise increase for LV mass in both genders ($p<0.001$) and for LV and RV ejection fraction (EF) and stroke volume (SV) as well as LV end diastolic volume in males ($p<0.02$). There was no significant difference when comparing the OSA group to the unaffected group but we found a significant difference when comparing snoring to unaffected in LV mass of females (ß=1.45±0.55g; p=0.009) and in LVEF and RVEF as well as LVSV and RV end systolic volume of males (ß=0.80±0.28%; p=0.005, ß=1.17±0.28%; $p<0.001$, ß=1.68±0.76ml; p=0.027 and ß=-2.41±0.90ml; p=0.008) respectively.

CONCLUSION

Our study suggests that the transition from snoring to OSA is an evolving process which is associated with LV hypertrophy. The different results based on the gender in the pilot data point to a gender specific progression. Separate prospective studies are needed to further explore the direction of causality.

CLINICAL RELEVANCE/APPLICATION

Sleep apnea and snoring lead to gender specific alterations in cardiac function which may require diversified prevention and treatment strategies.

SSQ03-03 Free-Breathing Coronary CT Angiography Using 16-Cm Wide-Detector for Challenging Patients: Comparison with Invasive Coronary Angiography

Thursday, Nov. 29 10:50AM - 11:00AM Room: S404CD

Participants
Tao Shuai, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To detected the superiority of free-breathing coronary computed tomography angiography (CCTA) with 16-cm wide-detector CT for challenging patient who cannot hold breath.

METHOD AND MATERIALS

A total of 76 patients (62% with either heart rate >75bpm or arrhythmia) unable to hold breath underwent both free-breathing CCTA and ICA were included. Two reviewers evaluated coronary arteries on the per-segment (using 18-segment model), per-vessel and per-patient basis for image quality using a four-point scale and stenosis degree. CCTA results were compared with ICA to calculate the diagnostic accuracy, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV).

RESULTS

Out of 1368 total segments, 228(16.7%) were less than 1.5mm in diameter and were excluded in CT, 32(2.3%) with calcification and 26(1.9%) with motion artifacts and were considered positive in CT. 1082 segments (79.1%) were evaluated both on CCTA and ICA and 128(11.8%) segments had stenosis >=50% on ICA. The diagnostic accuracy, sensitivity, specificity, PPV, and NPV of CCTA were 90.8%, 88.3%, 91.1%, 57.1% and 98.3% on a per-segment basis; 93.4%, 90.6%, 94.2%, 80.5% and 97.4% on a per-vessel basis; and 92.1%, 100%, 85%, 85.7% and 100% on a per-patient basis. For patients with high heart rates or arrhythmia, 81% (vs. 79.1%) segments were evaluable, and the accuracy, sensitivity, specificity, PPV, and NPV were statistically the same as the entire study population.

CONCLUSION

Free-breathing CCTA using 16-cm wide-detector CT has high accuracy for detecting coronary artery stenosis for challenging patients in comparison with ICA.

CLINICAL RELEVANCE/APPLICATION

Wide-detector CT has high clinical value for detecting coronary artery stenosis in CCTA for patients unable to hold breath.

SSQ03-05 Influence of Contrast Media Parameters on Image Quality in Cardiac Computed Tomography: Insights from a Multicenter Registry

ludovicolagrutta@hotmail.it

PURPOSE

A retrospective, multicenter, observational study on the use of contrast media (CM) in patients undergoing cardiac computed tomography (CCT) was conceived. The primary aim of the registry was to determine the influence on image quality of CM use.

METHOD AND MATERIALS

The registry included 1842 consecutive patients (>=50 per site; CCT indicated for suspected coronary artery disease) in 20 cluster sites. Every center collected demographics, CT scan parameters, CM administration protocols, radiation dose records, and adverse reactions reports. Image datasets were sent to a core lab who evaluated qualitative (intracoronary enhancement, motion artifacts) and quantitative (HU attenuation values, signal-to-noise ratio - SNR, and contrast-to-noise ratio - CNR) parameters.

RESULTS

The registry enrolled 891 men and 951 women (mean age 63±14 years, mean body mass index 26±4) who underwent CCT performed with >=64 detector rows CT scanners and several iodine contrast media protocols and molecules (iodixanol, iopamidol, iohexol, iobitridol, iopromide, and iomeprol). The core lab reported the following mean vascular attenuation: 504±147HU in the aorta, 451±146HU in the right coronary artery, 474±146HU in the left main, 451±146HU in the left anterior descending artery, and 441±149HU in the circumflex artery. SNR and CNR were improved with high iodine concentration CM (29±17 vs. 24±13 of low iodine concentration CM, p<0.0001; 35±19 vs. 30±15, p<0.0001) and >5ml/s flow rate (29±17 vs. 26±14 of <=5ml/s flow rate, p<0.0001; 35±19 vs. 32±16, p<0.0001), while they were not affected by decrease in CM volume <=80ml (28±17 vs. 27±14 of CM volume >80ml, p=0.0681; 34±20 vs. 32±16, p=0.1175). If compared to 120kV scanning, the use of low kV (n=393) improved SNR (33±21 vs. 25±13, p<0.0001) and CNR (39±23 vs. 31±16, p<0.0001). The use of iterative reconstructions (n=562) improved SNR (33±19 vs. 25±13, p<0.0001) and CNR (39±22 vs. 30±15, p<0.0001). In 80 patients the image quality was not satisfactory due to poor intra-coronary enhancement.

CONCLUSION

In a multicenter CCT registry image quality is influenced by the selection of CM parameters. The CM bolus geometry is affected by iodine concentration and flow, but it can be further refined by low kV scanning and iterative reconstructions.

CLINICAL RELEVANCE/APPLICATION

Optimization of CM parameters in conjunction with low kV scanning and iterative reconstructions improves image quality of CCT.

SSQ03-07 Deep Learning Analysis in Coronary Computed Tomographic Angiography Imaging for the Evaluation of Patients with Coronary Artery Atherosclerosis Stenosis

Thursday, Nov. 29 11:30AM - 11:40AM Room: S404CD

Participants
Dan Han, MMed, DMRD, Beijing, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

hd7226021218@sina.com

PURPOSE

To evaluate the feasibility of using deep learning and transfer learning approaches for coronary computed tomographic angiography (CCTA) imaging (termed coronary artery heart disease-artificial intelligence (CHD-AI)) in coronary artery atherosclerosis stenosis.

METHOD AND MATERIALS

A CCTA reconstruction pipeline was built by using deep learning and transfer learning approaches to generate simulated CCTA images from a series of two-dimensional (2D) CT images. A deep semantic segmentation network (SSN) was trained to identify coronary artery branch vessels, coronary lumen with more than 10,000 CCTA cases, which was treated as the Coronary BASE model. Based on the BASE model, retrospective CCTA images of 100 patients diagnosed with CHD by DSA were used to train a new model by transfer learning to further identify calcified plaque, non-calcified plaque and various degrees of coronary stenosis. The new model was then evaluated in 50 CHD patients by comparing the simulated CCTA images to CCTA images with digital subtraction angiography (DSA) images as the gold standard. Analysis of Kappa consistency test was used for statistical analysis to compare CHD-AI reconstruction with CCTA and DSA in detecting various degrees of coronary stenosis.

RESULTS

With only 100 CCTA cases as the training dataset, based on transfer learning, CHD-AI provided a relatively accurate simulated CCTA imaging with a Kappa value of 0.327 for detecting calcified plaque and non-calcified plaque compared to CCTA (P<0.001). For detecting coronary artery atherosclerosis with moderate and above stenosis, CHD-AI provided good sensitivity of 72% (11% more than CCTA) and negative predictive values of 80% (only 4% less than CCTA). Specificity (51%), coincidence (58%) and positive predictive values (40%) were relatively low.:

CONCLUSION

The proposed CHD-AI allows the generation of simulated CCTA images from a series of 2D CT images. This approach provides good sensitivity and negative predictive value for detecting stenosis and is relatively accurate for detecting calcified plaque and non-calcified plaque compared to CCTA. But it is still relatively high in false-positive rate.

CLINICAL RELEVANCE/APPLICATION

This CHD-AI can omit some CCTA reconstruction steps to some extent, reduce diagnostic time and the error of human eyes in assessing the degree of coronary stenosis compared with current CCTA imaging.

SSQ03-08 Deep Learning Enables Inline Image Reconstruction of Accelerated, Single-shot Coronary QISS MRA in Patients with Congenital Heart Disease

Thursday, Nov. 29 11:40AM - 11:50AM Room: S404CD

Participants
Daming Shen, Evanston, IL (*Presenter*) Nothing to Disclose

Cynthia K. Rigsby, MD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
Daniel Kim, PhD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Our previous study demonstrated the feasibility of 1-shot, real-time coronary Quiescent-Interval Slice-Selective (QISS) MRA in children with congenital heart disease using compressed sensing (CS). While CS produced clinically acceptable image quality, it is a poor fit for inline image reconstruction because of its slow reconstruction time (~60 s per image). Deep learning (DL) is an alternative framework for reconstructing MR images with considerably higher speed. The purpose of this study is to demonstrate the feasibility of inline image reconstruction of accelerated coronary QISS MRA using DL.

METHOD AND MATERIALS

This study entailed 2-fold accelerated, 2-shot coronary QISS MRA data sets obtained from 26 pediatric patients (mean age = 16.4 ± 7.9 years; 16 boys and 10 girls) scanned on a 1.5T scanner (Aera, Siemens). The QISS data were undersampled by an additional factor of 2 (i.e., 1-shot, real-time) and reconstructed using CS with total variation (TV) and a deep convolutional neural network adapted from a U-Net (layer depth = 5, 64 features on the first layer, GPU based tensorflow framework in Python). We fed 1-shot and 2-shot QISS images from first 20 patients (283 images) as input and output pairs to train the U-Net. Subsequently, images from the remaining 6 patients (69 images) were used to validate the trained U-Net. Using the 2-shot QISS with CS as control, we measured the DICE coefficients as a metric of reproducibility for 1-shot QISS with zero padding, 1-shot QISS with CS and 1-shot QISS with U-Net.

RESULTS

Both 1-shot QISS with CS and DL produced image quality that is comparable to 2-shot QISS (Fig. 1). The mean DICE coefficients for 1-shot QISS with zero padding, 1-shot QISS with CS and 1-shot QISS with U-Net images were 77.3 ± 7.4%, 90.0 ± 4.4% and 87.3 ± 4.1%, respectively. While the differences in DICE were significantly different for all pairs ($p < 0.05$), the difference between CS and U-Net was only 3%. The reconstruction time for U-Net (0.42 ± 0.04 s) was significantly lower ($p < 0.05$) than CS (52.3 ± 2.1 s).

CONCLUSION

This study demonstrates the feasibility of performing inline reconstruction of single-shot coronary QISS MRA using DL.

CLINICAL RELEVANCE/APPLICATION

Pediatric patients with congenital heart disease who require non-invasive evaluation of coronary origins for planning a surgical intervention may benefit from non-contrast, 1-shot coronary QISS MRA with inline image reconstruction using deep learning.

PURPOSE

Radiomics is a field of study that extracts features from medical images using data characterization algorithms. It has been applied to classify pulmonary nodule malignancy. Recent development in computer vision shows that deep learning is a powerful tool to extract image features. This paper systematically compares a deep learning (DL) method and previously established radiomics methods to extract features from chest CT scans to predict nodule malignancy.

METHOD AND MATERIALS

We collected CT scans of 463 patients from LIDC (a public dataset) and of 915 patients from a collaborating hospital. Each CT scan contained one nodule whose malignancy was pathology proven. The whole dataset was randomly separated into a training dataset (1154: 391 from LIDC) and a testing dataset (224: 72 from LIDC). Three methods were used to extract nodule features. (1) radiomics condition, all nodules were segmented first, and 1008 features were extracted from each nodule using PyRadiomics (van Griethuysen et al, 2017). PCA was applied to select 95.3%, 96.2%, 97.8%, 98.4% and 99.2% information from the original features. (2) DL condition, we used a 3D-CNN model and average pooling to extract 128 features based on the same segmented nodules. The same PCA method was applied to DL features. (3) radiomics&DL condition, we concatenated the features from both (1) and (2) after the PCA processing. In all 3 conditions, we trained a random forest classifier based on outputs from PCA to predict nodule malignancy. We replicated the experiment 10 times to average out randomness caused by random forest.

RESULTS

As shown in Table 1, (1) radiomics condition achieved classification AUCs between 0.840 and 0.845; (2) DL method's AUCs ranged from 0.841 to 0.858. (3) radiomics&DL condition (AUCs: 0.855 to 0.872) outperformed the above two conditions. Figure 1 shows ROC plot of the 98.4% situation in Replication 1.

CONCLUSION

Radiomics combined with DL consistently achieved significantly higher AUCs than the DL or radiomics method alone, and DL performed marginally better than radiomics at nodule malignancy prediction. This study suggests that features extracted by DL can to some extent complement information extracted by radiomics.

CLINICAL RELEVANCE/APPLICATION

This paper shows that deep learning methods could extract extra features from CT images to complement traditional radiomics methods to improve clinical evaluation of pulmonary nodule malignancy.

SSQ04-02 A Novel Prediction Model for Pulmonary Nodule Diagnosis Combining Plasma Biomarkers, Radiomics, Conventional Imaging Features, and Clinical Data

PURPOSE

For both screening and incidental findings it is important but also challenging to classify pulmonary nodules as benign or malignant at first presentation. The objective of this study is to develop a novel prediction model for lung cancer diagnosis combining plasma biomarkers, radiomics, conventional imaging features and clinical data.

METHOD AND MATERIALS

We performed a retrospective study with 121 NSCLC patients and 117 controls. Specific tumor-derived autoantibodies were analyzed in plasma of all patients. The nodules were contoured by a thoracic radiologist from chest CT images and texture features were extracted using the PORTS radionics library. Another thoracic radiologist (blinded to the outcomes) evaluated semantic features including size, shape, density, emphysema, etc. All plasma biomarker variables, texture features, clinical and semantic features were input into a LASSO penalized logistic regression model. The most significant input variables for this regression are then determined and used to generate a new logistic regression model. We performed 5-fold cross-validation for the model to generate ROC curves. The AUC for these ROC curves was computed and the 95% confidence interval determined.

RESULTS

There were 11 plasma tumor biomarkers, 8 clinical and semantic features and 4 texture features selected by the LASSO penalized logistic model. The cross-validated AUCs for the model with all 23 plasma tumor biomarkers, clinical and imaging variables was 90% (CI:0.807-0.972), higher than the model with only clinical and imaging features with the AUC of 86%(CI:0.746-0.961).

CONCLUSION

Using a novel combination of plasma tumor biomarkers, radiomic texture features, conventional clinical and semantic features, our model classifies nodules with a AUC of 90% after cross-validation, which is higher than the performance reported by other models. The combination of these 4 sets of features outperforms each separate set of features in pulmonary nodule diagnosis.

CLINICAL RELEVANCE/APPLICATION

Combining plasma biomarkers, radiomics, conventional imaging features and clinical data has the potential to improve and facilitate management of pulmonary nodules.

PURPOSE

ES-NSCLC has up to a 55% risk of recurrence following curative resection with a OS ranging between 35-50%. The ability to predict aggressiveness and prognosticating survival of ES-NSCLC from pre-treatment CT scans can aid oncologists in identifying which patients will benefit from adjuvant chemotherapy following curative resection.

METHOD AND MATERIALS

The single site study comprised 316 ES-NSCLC patients who had curative surgery and/or chemotherapy. Following retrospective chart review, pre-treatment CT scans with clinical follow-up and outcome data was obtained for each patient. All patients underwent surgery with the primary tumor having relapsed in 75 total cases. This cohort was randomly divided into a training

(n=60) and independent validation set (n=256). A total of 124 intratumoral (IT) and peritumoral (PT) radiomic textural features were extracted from every patient.

RESULTS

The top six most predictive features included a combination of two intratumoral (Gabor, Haralick) and four peritumoral (Laws-Laplace, Collage, Gabor) from an annular ring 0-12 mm outside the nodule. These features were also found to be relatively stable with an ICC of 0.8 calculated on the RIDER CT test-retest dataset. These features separated patients who recurred from those who did not (AUC=0.65; p<0.001) and also were prognostic of 5-year recurrence-free survival (RFS) (p<0.005) on the independent validation set (n=256).

CONCLUSION

We identified radiomic texture features from within and outside the lung nodule that are able to predict recurrence in early stage non-small cell lung cancer. These features were also found to be prognostic of 5-year RFS.

CLINICAL RELEVANCE/APPLICATION

ES-NSCLC patients who were predicted to recur based off diagnostic CT scans would be ideal candidates for treatment escalation including adjuvant chemotherapy following curative surgical resection.

SSQ04-04 CT-Based Quantitative Radiomic Features Predict Brain Metastasis in T1 Stage Lung Adenocarcinoma

PURPOSE

To retrospectively evaluate the use of computed-tomography (CT) based quantitative radiomic features (QRF) to predict brain metastasis (BM) in patients with T1 stage lung adenocarcinoma (LAD).

METHOD AND MATERIALS

Eighty patients with pathologically confirmed lung adenocarcinoma were collected. T1 stage was established by the 8th edition of the TNM staging system. All patients had brain MRI scans (BM+: 26; BM- :54). In total, 1160 QRFs were calculated from the primary lung cancer tumor in each patient. Three machine-learning algorithms were applied sequentially to build the radiomic prediction model. Firstly, unsupervised hierarchical clustering was used to exclude highly correlated QRFs; secondly, the minimum Redundancy Maximum Relevance (mRMR) feature selection algorithm was employed to rank QRFs according to their relevance to BM and redundancy with other features; finally, the K-Nearest-Neighbor (k=5) classification algorithm was adopted to construct model by using the informative and non-redundant QRFs. The area under the receiver operating characteristic (ROC) curve (AUC) and the ten-fold cross-validation were employed to evaluate the prediction model. Yuden's Index for the ROC curve was calculated to determine the optimal sensitivity and specificity.

RESULTS

The radiomic prediction model achieved AUC (95% CI) of 0.879 (0.694, 0.959), and sensitivity and specificity of 0.808 and 0.815, respectively. The most significant QRFs to build the prediction model were LoGU ('Uniformity of Laplacian of Gaussian Filter') and MGE ('Maximal Gabor Energy'), which were designed to characterize tumor homogeneity and boundary sharpness, respectively. We found that tumors with BM+ were of higher LoGU and MGE values than those with BM- (both p-values <0.001).

CONCLUSION

CT-based radiomic features could be used to predict brain metastasis in T1-stage LAD. For T1-stage LAD, solid tumor with sharp boundary were more prone to BM than those with ground glass opacity and unclear boundary.

CLINICAL RELEVANCE/APPLICATION

Radiomic features extracted from noninvasive and routinely acquired CT can be applied to help radiologists to predict brain metastasis in patients with T1 stage lung adenocarcinoma.

SSQ04-05 The Radiomics Prognostic Score (RadScore): The New Prognostic Imaging Biomarker After Stereotactic Body Radiation Therapy in Patients with Lung Cancer

PURPOSE

To develop the radiomics prognostic score (RadScore) for the patients with lung cancer treated with stereotactic body radiation therapy (SBRT) and to evaluate prognostic impact on progression free survival

METHOD AND MATERIALS

In this retrospective study approved by our institutional review board, we reviewed 241 patients who underwent SBRT for lung cancer between July 2006 and November 2016. After excluding patients who had no pathological diagnosis, no pretreatment computed tomography (CT) and clinical diagnosis of Stage III/IV, 43 patients were analyzed. The RadScore was developed using the linear predictor of multivariate Cox proportional hazard regression with LASSO (Least Absolute Shrinkage and Selection Operator) method for shrinkage of variables. The variables for the regression were the results of histogram (kurtosis and skewness) and texture analysis (gray level co-occurrence matrix) for solid part within the region of interest for the lung cancer which was placed on pre- and post-contrast-enhanced axial CT images. To reveal the impact of RadScore in the prediction of progression free survival (local / distant recurrence or death), an another multivariate Cox proportional hazard regression analysis was performed.

RESULTS

Among the 132 variables by histogram and texture analysis, 2 variables by histogram analysis and 2 variables by texture analysis were selected. In the multivariate Cox regression, the RadScore was the only significant predictive factor for progression free survival (95% confidence interval of hazard ratio: 1.89-24.14, p<0.005), whereas the following variables were not significant: male (0.53-4.34, p=0.44), age (0.94-1.12, p=0.53), pathological diagnosis of adenocarcinoma (0.81-7.06, p=0.11), and clinical stages (IB: 0.59-3.96, p=0.38; IIA: 0.17-15.33, p=0.67; IIB: 0.42-56.65, p=0.21).

CONCLUSION

The RadScore was an independent prognostic factor for progression free survival in patients of post-SBRT for lung cancer.

CLINICAL RELEVANCE/APPLICATION

The RadScore was a prognostic factor for progression free survival in patients of post-SBRT for lung cancer. The RadScore have potential to become one of indications of SBRT for lung cancer.

SSQ04-06 CT-Based Quantification of Lung Disease in Cystic Fibrosis Using Radiomics

Thursday, Nov. 29 11:20AM - 11:30AM Room: E353A

PURPOSE

To build imaging biomarkers from chest computed tomography (CT) using radiomics to evaluate the severity of lung disease in adults with cystic fibrosis (CF).

METHOD AND MATERIALS

This single-center, retrospective, observational study was approved by an institutional ethics committee and the need for patient consent was waived. One hundred and sixty-two CF outpatients referred for unenhanced chest CT during follow-up between January 2013 and December 2015 were included and randomly divided into 2 equal cohorts. After lung segmentation, 38 imaging features were extracted. Chest CT from the development cohort were used to build 5 CT scores, each with a different machine learning technique (lasso, ENET, ridge regression, decision tree and SVM). The aim was to correlate these scores with a clinical prognostic score (Nkam score). Correlations between radiomics-based CT scores and 3 prognostic scores (Nkam, Liou and CF-Able), forced expiratory volume in 1 second (FEV1) and respiratory tract exacerbations were evaluated in the validation cohort.

RESULTS

Four of the 5 radiomics-based CT scores correlated well with the Nkam score in the validation cohort (R = 0.54 to 0.69; p<0.001) while they all correlated well with the Liou (R=-0.64 to -0.74; p<0.001), and moderately with the CF-able (R=0.46 to 0.62; p<0.001) scores. All CT scores correlated well with FEV1 (R=-0.65 to -0.77; p<0.001) and moderately with the number of pulmonary exacerbations in the 12 months after the CT exam (R=0.47 to 0.56; p<0.001).

CONCLUSION

Radiomics can be used to build imaging biomarkers that correlate well with clinical prognostic scores in adult CF patients

CLINICAL RELEVANCE/APPLICATION

Radiomic models were trained to predict the Nkam score, and were also well correlated with FEV1 and the Liou score, another prognostic score for CF, as well as with individual variables known to be markers of CF lung disease severity.

SSQ04-07 Radiomics Approach for Survival Prediction in Chronic Obstructive Lung Disease

PURPOSE

To apply radiomics analysis on overall survival (OS) prediction in patients with chronic obstructive lung disease (COPD) and to evaluate prediction performance of the generated radiomics signature (RS).

METHOD AND MATERIALS

The study included 371 adult COPD patients (mean age, 64.2). Patients were followed up for an average of 68 months and 45 cases of mortality were observed. From 3-D volumetric chest CT data of each patient, 525 radiomics features were semi-automatically extracted. Radiomics features were extracted from four phenotypical compartments of COPD; emphysema, airway measurement, pulmonary vessels, and air-trapping. In order to remove features that were highly related to one and another, pairs with correlation coefficients greater than 0.9 were identified and the feature with lower c-index (Harrell's concordance index) was eliminated. Then, least absolute shrinkage and selection operator (LASSO) Cox regression model and used to select the features most useful for OS prediction. Afterward, a RS was generated through the summation of selected features multiplied by their respective coefficients and cut-off value was determined by X-tile plot analysis. The difference of survival between low and high RS groups was evaluated with Kaplan-Meier survival analysis.

RESULTS

Five features which remained after LASSO analysis were as follows: (1) Low attenuation area (LAA-950), (2) PI-10 at 6th generation bronchi, (3) Average vessel cross-section area at 18mm from pleural surface, (4) Lobar heterogeneity of PI-10, (5) Z-axis heterogeneity of WA%. On multivariate Cox regression analysis, prediction performance (c-index) of the 5 features was 0.774. The c-index for pulmonary function test (PFT) results alone (DLCO, FEV1, FEV1/FVC) was 0.758. When radiomics features were combined with PFT, c-index was increased to 0.805. Patients who were classified into the high-risk group based on the generated RS demonstrated significantly worse OS than the low-risk group (log-rank test, $p < 0.001$; hazard ratio, 7.18:1).

CONCLUSION

The radiomics signature demonstrated good survival prediction performance in COPD patients and adequately classified patients into high and low-risk groups.

CLINICAL RELEVANCE/APPLICATION

The radiomics approach yielded a reliable survival prediction performance in this study and could potentially be adopted as an effective imaging biomarker for estimation of OS in COPD patients after further validation.

SSQ04-08 Radiomic Prediction of Survival in Patients with Rheumatoid Arthritis-Associated Interstitial Lung Disease Based on Deep-Learning, Hyper-Curvature, and Texture Features of Lung CT Images

PURPOSE

To evaluate the comparative performance of deep-learning, hyper-curvature, and texture features of lung CT images in the prediction of the overall survival of patients with rheumatoid arthritis-associated interstitial lung disease (RA-ILD).

METHOD AND MATERIALS

We retrospectively collected 70 RA-ILD patients with thin-section lung CT and serial pulmonary function tests. After automated extraction of the lung regions on the CT images, an experienced observer delineated regions of interest (ROIs) and labeled them into one of four ILD patterns (ground-class opacity, reticulation, consolidation, and honeycombing). We computed deep-learning features by training a 5-layer convolutional neural network on these ROIs for classifying the 4 patterns and by extracting the output of the last convolutional layer. We also computed hyper-curvature features including principal curvatures, curvedness, bright/dark sheets, cylinders, blobs, and curvature scales for the lungs as well as gray-level co-occurrence matrix texture features on the ROIs. An elastic-net penalty method was used to select and combine these features with a Cox proportional hazards model for predicting patient survival. Concordance index (C-index) was used as a measure of the prediction performance of the feature combinations with bootstrapping by 1,000 replications, in comparison to an established clinical prognostic biomarker known as the gender, age, and physiology (GAP) index by a two-sided t-test.

RESULTS

Bootstrap evaluation yielded C-index values of (a) GAP: 78.3%, [95% confidence interval (CI): 70.1, 86.5]; (b) hyper-curvature features: 80.8% [CI: 71.9, 89.7], P<0.01 in comparison with (a); (c) deep-learning features: 81.8% [CI: 71.9, 89.7], P<0.01; and (d) combined radiomic features: 86.9% [CI: 81.3, 93.1], P<0.0001. Kaplan-Meier survival curves of patients stratified to low- and high-risk groups based on combined radiomic features showed statistically significant (P < 0.0001) difference.

CONCLUSION

The combined radiomic features yield higher performance than GAP in the prediction of overall survival. Thus, they can be an effective imaging biomarker for predicting overall survival of patients with RA-ILD.

CLINICAL RELEVANCE/APPLICATION

Combined radiomic features that are automatically calculated from lung CT images can provide an effective prognostic imaging biomarker for precise management of patients with RA-ILD.

SSQ04-09 Radiogenomics of Non-Small Cell Lung Cancer: Predictive Modeling of miRNA Signature and CT Imaging Features

PURPOSE

Radiomics and genomics characteristics have been widely explored to predict tumor responses to radiotherapy and in recent years, the combined application of them, radiogenomics, have increased. In this study, we developed a radiogenomics signature to estimate tumor responses to radiotherapy in patients with non-small cell lung cancer (NSCLC) and optimize management of this disease.

METHOD AND MATERIALS

This study consisted of 87 patients with non-small cell lung cancer and was approved by the institutional ethical board. The CT-based radiomics features were extracted by LIFEx. MiRNAs associated radiosensitivity was obtained from our previous study and literature retrieval. Then a radiogenomics signature was generated by LASSO and was associated with tumor responses to radiotherapy in non-small cell lung cancer patients. The Recist 1.1 was used for short-term effect and the overall survival (OS) was used for long-term effect evaluation. Multivariate Cox regression validated the radiogenomics signature as an independent biomarker. Then a radiogenomics nomogram with this signature was constructed, which was assessed to validation, calibration and discrimination.

RESULTS

The radiogenomics signature was significantly associated with radiosensitivity and OS, independent of other clinic pathologic factors. The radiogenomics nomogram has displayed a good performance for estimation of OS (C-index: 0.78, 95% confidence interval [CI]: 0.75, 0.80). Calibration curve for it was almost satisfactory, which indicated its clinical usefulness.

CONCLUSION

The radiogenomics signature is an independent biomarker and the nomogram combining it with other clinic pathologic factors could be used as a model to predict tumor responses to radiotherapy in non-small cell lung cancer, which might make a step forward individualized medicine.

CLINICAL RELEVANCE/APPLICATION

a biomarker to predict the radiosensitivity in non-small cell lung cancer

PURPOSE

To assess the changes of regional ventilation (V) and perfusion (Q) status in COPD patients after pharmacologic treatment using combined xenon-enhanced V and iodine-enhanced Q dual-energy CT (DECT).

METHOD AND MATERIALS

Combined V and Q DECT were performed at baseline and after 3-month pharmacologic treatment in fifty-three COPD patients. Virtual noncontrast images, V and Q maps were anatomically co-registered with in-house software. Normalization of V and Q values of each pixel were performed. For visual analysis, V/Q pattern was determined to be matched, mismatched, or reversed-mismatched and compared with the regional disease patterns-emphysema, bronchial wall thickening, or normal lung-in each segment in baseline and follow-up. Mean V, Q, and V/Q values, standard deviation of V/Q (V/QSD), and proportions of lung area with reversed-mismatch (Rev), mismatch (Mis) and match (Mat) of each patient were quantified and compared with pulmonary function test (PFT) parameters in baseline and follow-up. Changes of quantified CT parameters and PFT results between baseline and follow-up were compared.

RESULTS

Most of segments showed a matched V/Q, whereas about thirty percent of segments with bronchial wall thickening showed a reversed-mismatched V/Q. On follow-up, V/Q pattern did not change in most of segments with matched and mismatched V/Q. In about forty percent of segments with reversed-mismatched V/Q, V/Q pattern changed into matched. Quantified mean V, Q, V/Q and Rev values of baseline and follow-up CTs were positively correlated with PFT parameters, respectively ($r = 0.286$-0.630, $p < 0.05$), while V/QSD values were negatively correlated with PFT parameters ($r = -0.528$ and -0.375; $p < 0.05$). Changes of mean V, V/Q and Mat were positively correlated with change of FEV1 ($r = 0.315$-344; $p < 0.05$) and changes of Rev were negatively correlated with change of FEV1 ($r = -0.353$; $p = 0.010$).

CONCLUSION

Quantitative and visual analysis of combined V and Q DECT showed that the improvement of ventilation and V/Q mismatch may be associated with the response to pharmacological treatment in COPD patients.

CLINICAL RELEVANCE/APPLICATION

Combined V and Q DECT imaging can be applied to assessment of changes of regional V and Q status after pharmacologic treatment in COPD patients.

SSQ05-02 Quantitative Assessment of Emphysema Heterogeneity in Patients with Lung Cancer Using Volumetric Chest CT

Thursday, Nov. 29 10:40AM - 10:50AM Room: E353B

Participants
Edgar Karanjah, MBChB, Orange, CA (*Abstract Co-Author*) Nothing to Disclose
Anastasia Cruz, DO, Orange, CA (*Presenter*) Nothing to Disclose

Sang Min Lee, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

In COPD patients, distribution of emphysema shows various patterns (diffuse, unilateral, or focal), however, there is no report about distribution of emphysema in lung cancer patients. The purpose of the research is to compare heterogeneity of emphysema between lung cancer patients and lung cancer screening patients.

METHOD AND MATERIALS

Total 109 subjects with smoking history and thin section chest CT (51 patients with lung cancer M : F = 29 : 22, age = 68.10 ± 9.26, 58 lung cancer screening patients; M : F = 31 : 27, age = 64.03 ± 6.65) were retrospectively enrolled. Using commercial software (AVIEW, Coreline soft, South Korea), volume and low attenuation area under -950 HU were semi-automatically quantified in whole lung and each lobe by two radiologists. Emphysema index (EI) and emphysema heterogeneity were calculated. Intra-class correlation coefficient (ICC) and independent t-test were performed. ANOVA was performed for subgroup analysis according to cancer pathology.

RESULTS

ICC of each lobe volume among two radiologists were 0.993, 0.987, 0.999, 0.999, and 0.999. EI in RUL, RML, RLL, LUL, and LLL of two groups were 6.43 ± 9.94, 6.80 ± 9.28, 3.66 ± 5.54, 5.86 ± 6.60, and 3.83 ± 5.86 in the cancer group, and 6.56 ± 7.82, 8.24 ± 8.44, 5.68 ± 7.08, 7.16 ± 7.05, and 5.28 ± 6.66 in the screening group. EI and emphysema heterogeneity in whole lung of two groups were 5.10 ± 6.56, and 12.20 ± 5.14 respectively in the cancer group, and 6.43 ± 6.95, 8.44 ± 4.92 in the screening group. EI showed no significant difference between two groups. However, emphysema heterogeneity of the cancer group was significantly larger than that of the screening group ($p < 0.001$). In subgroup analysis, emphysema heterogeneity of the cancer subtypes of adenocarcinoma and squamous cell carcinoma were significantly larger than that of screening group ($p = 0.006$ and 0.042).

CONCLUSION

Semi-automated quantification of emphysema in each lobe was feasible. Smokers with lung cancer showed more heterogeneous distribution of emphysema than smokers without lung cancer.

CLINICAL RELEVANCE/APPLICATION

Quantification of regional and whole lung heterogeneity of emphysema may potentially help in risk stratification of COPD patients in developing lung cancer.

SSQ05-03 Hyperpolarized Xenon-129 MRI for Detection of Gas Exchange in Healthy Subjects and Lung Cancer Patients

PURPOSE

To determine whether a novel functional magnetic resonance imaging (MRI) technique using hyperpolarized Xenon-129 (HPX) can quantify the xenon gas transfer dynamics (XGTD) from alveoli into the Pulmonary Tissue and Blood Plasma (PTBP), and Red Blood Cell (RBC) compartments of the lungs, and identify XGTD differences in patients with COPD and lung cancer pre and post radiation.

METHOD AND MATERIALS

A novel spectroscopic MRI technique was developed using Iterative Decomposition of water and fat with Echo Asymmetry and Least-square estimation (IDEAL) approach. This technique allowed acquisition of the time-series IDEAL gas, PTBP and RBC compartment images of lungs with various gas transfer times in a single breath-hold interval. The time-series IDEAL gas, PTBP and RBC compartment images were acquired from five healthy subjects at two different time points. XGTD curves were obtained from 10 scans (n=10) that represented the control group. The control group was compared to two lung-cancer patients before radiation therapy started and after radiation therapy ended.

RESULTS

In the control group, there was no statistical difference in XGTD between the left and right lungs (P-value >0.4). XGTD in the control was statistically different than the lung cancer patients (P-value <0.01) suggesting that the novel time-series IDEAL technique was sensitive to the gas exchange abnormalities. Additionally, the ratio of XGTD from the irradiated lung to un-irradiated lungs was compared pre and post radiation therapy. We found that xenon gas in the alveoli diffused into the PTBP compartment with a slower rate of 20-35% in the radiated lungs from the lung cancer patients.

CONCLUSION

The feasibility of the novel IDEAL MRI technique has been successfully demonstrated in healthy subjects and lung cancer subjects. To our knowledge, this is the first-in-man study showing the time course of arrival of Xenon-129 gas from the alveoli to PTBP and RBC compartments of the lungs and to the pulmonary vasculature and the left ventricle of the heart in healthy subjects and patients with COPD and lung cancer.

CLINICAL RELEVANCE/APPLICATION

This technique may have potential clinical applications ranging from the detection of regional differences in gas transfer on imaging to the detection of early-stage radiation-induced lung injury.

SSQ05-04 Effect of Aging and Smoking on Regional Air Volume Change Distributions in Normal Chest CT

para2727@gmail.com

PURPOSE

Image registration has been increasingly used to assess pulmonary dynamics between paired inspiratory and expiratory CT images in patients with pulmonary disease. However, information of pulmonary dynamics of normal subjects is insufficient. The purpose of the study is to describe regional air volume change distributions of subjects with normal CT and to investigate the effects of aging and smoking.

METHOD AND MATERIALS

242 subjects (114 male, 128 female) over the age of 18 years with normal inspiration and expiration CTs were included in the study. VIDA Apollo software (Coralville, IA) and an image registration technique were used to compute regional distribution of air and tissue volumes, air volume fractions, and the relative regional changes between inspiration and expiration, including relative regional air volume changes (RRAVC). In each lobe, the upper lobes, the lower lobes, and the whole lung, the mean values and standard deviations were correlated with aging and compared to those of smoking groups. Regional volumetric changes were further analyzed using 3D visualization of acinar scale parenchymal units.

RESULTS

Inspiratory air volume of the lower/upper lobes decreased with age in both nonsmoking males and females ($r=-0.388$; $p=0.006$ and $r=-0.258$; $p=0.004$, respectively). RRAVC map demonstrates the increase of air volume change from apico-ventral to dorso-basal region in non-smokers, representing gravitational dependency in normal pulmonary dynamics. In comparison, the directionality of gravitational dependency of regional volume change tends to against normality in smokers, and the coefficient of variation (CV) of RRAVC decreased in the whole lung in the smokers (0.64 and 0.35, $p=0.020$).

CONCLUSION

The air volume of the lower/upper lobes tends to decrease with aging, and the directionality of gravitational dependency of the air volume change appeared to be against normality in smokers. Visualization of RRAVC map helped recognize these findings more easily.

CLINICAL RELEVANCE/APPLICATION

Regional air volume change distribution helped understand the gravitational volume change of the lung in normal adults, and so it is expected that the localized functional abnormalities of the lung effected by aging and smoking are easily comprehended.

SSQ05-05 Whole-Lung Dynamic Contrast-Enhanced Perfusion Area-Detector CT: Capability for Pulmonary Function Assessment and Morphological Change Evaluation in Stage IA Non-Small Cell Lung Cancer

PURPOSE

To prospectively and directly compare the capability of whole-lung dynamic contrast-enhanced (CE-) perfusion area-detector CT

(ADCT) for pulmonary functional loss assessment and morphological change evaluation in Stage IA non-small cell lung cancer (NSCLC) patients.

METHOD AND MATERIALS

63 consecutive NSCLC patients (39 males, 24 females; mean age 68 years) underwent dynamic CE-perfusion ADCT performed at two or three different positions as single examination, pulmonary function test, surgical treatment, and pathological examination. From all perfusion ADCT data in each subject, whole lung total perfusion (TP), pulmonary arterial perfusion (PAP) perfusion, systemic arterial perfusion (SAP) maps were computationally generated based on dual-input maximum slope method by previously reported software. In each subject, regional perfusion parameters were assessed by ROI measurements, and averaged to determine mean values. According to pathological examination results, all ROIs within operated lung were divided into following four structure groups: normal lung, emphysema, non-specific interstitial pneumonia (NSIP) and usual interstitial pneumonia (UIP). To determine the capability of each perfusion parameter for pulmonary function, Pearson's correlation was performed. To compare each perfusion parameter among all structure groups, Tukey's HSD test was performed. Finally, discrimination accuracy for morphological change evaluation was compared among all indexes and combined method.

RESULTS

All perfusion parameters except SAP had significant correlation with each pulmonary function parameter (TP: 0.47 **CONCLUSION**

Whole-lung dynamic first-pass CE-perfusion ADCT is useful for pulmonary functional loss assessment and morphological change evaluation in stage IA NSCLC patients.

CLINICAL RELEVANCE/APPLICATION

Whole-lung dynamic first-pass CE-perfusion ADCT is useful for pulmonary functional loss assessment and morphological change evaluation in stage IA NSCLC patients.

SSQ05-06 Denoised Ultra Low Dose for Screening Lung Cancer

Thursday, Nov. 29 11:20AM - 11:30AM Room: E353B

PURPOSE

To assess the effect of a denoising method (D) for ultra low dose CT (ULDCT) LungRADS categorization.

METHOD AND MATERIALS

36 consented patients, referred for an outpatient chest CT, underwent 2 scans: a normal dose CT (NDCT), 120 kVp and automatic current modulation, with or without contrast media, immediately followed by an ULDCT, 120 kvp and fixed current at 10 mA for bmi <29 and 20 mA for bmi>=29. Reconstruction for lung and soft tissue kernels were performed for each scan. Consecutively, each ULDCT was denoised using a locally-consistent non-local-mean (LCNLM) algorithm to obtain a high signal to noise ratio (SNR) version of the ULDCT. The LCNLM algorithm leverages large databases of image patches extracted from high-SNR chest CT scans to denoise ULDCTs while enforcing local spatial consistency to preserve fine details and structures in the image. Blinded to all clinical information, a chest radiologist separately assessed the NDCT, ULDCT, and denoised ULDCT (D), documented findings, assigned a LungRADS category and a subjective suspicion for highly suspicious lesions for lung cancer (H).

RESULTS

Radiation dose using NDCT reduced the radiation for patients with a BMI > 29 by an average of 93% and for those with a BMI of up to 29 by an average of 96% . For patients with a BMI > 29 the average effective radiation dose for ULDCT was 0.41 mSv, whereas for those with a BMI of up to 29 it was 0.24mSv. For the three imaging methods, the same score was seen in 63.9% (n=23) and a different score in 36.1% (n=13). There was complete agreement on LungRADS 4A (or higher) between NDCT and D, but ULDCT categorized one of the 4A patients as LungRads 2. One lesion assigned as LungRads 4X by ULDCT was assigned LungRads2 by D and NDCT. Of the 8 patients highly suspicious for lung cancer by NDCT, D indicated so in all 8 whereas ULDCT indicated so only in 4.

CONCLUSION

Interpretation of ULDCT may cause errors in LungRADS categorization but implementation of the LCNLM algorithm for denoising improves ULDCT images so that LungRADS categorization is similar to normal dose scans.

CLINICAL RELEVANCE/APPLICATION

Denoising ULDCT with the LCNLM algorithm enables screening for lung cancer with dose reductions of greater than 90%.

PURPOSE

To compare self-gated non-contrast enhanced functional lung MRI (SENCEFUL) and V/Q (ventilation/perfusion) scintigraphy regarding detection of lung perfusion defects in patients with chronic thromboembolic pulmonary hypertension (CTEPH).

METHOD AND MATERIALS

Following review board approval and informed consent, 16 patients diagnosed with CTEPH and pathologic findings in V/Q scans were included into this prospective study. Patients were scanned at 3T using the SENCEFUL approach based on a 2D-FLASH sequence. Color-coded maps of the lung perfusion and the local blood arrival time i.e. the pulsation phase were manually segmented and rated for perfusion defects in lung quadrants by three independent radiologists using a 6-point Likert scale. Coronal V/Q scan images were rated by a nuclear medicine physician accordingly. Due to variation of slice thickness between both techniques, covered lung volumes were divided into four sectors in coronal orientation each containing four quadrants to improve comparability. Statistical tests included intraclass correlation coefficient (ICC) and Mann-Whitney-U-test.

RESULTS

Comparison of quadrant-wise rating between SENCEFUL-MRI and V/Q scans revealed good agreement between all raters when the lung perfusion and pulsation phase maps were rated simultaneously (ICC 0.75, 95% CI 0.69-0.80, $p<0.05$) and an improvement to perfusion rating alone (ICC 0.61, 95% CI 0.52-0.69, $p<0.05$). Interrater reliability of the radiologists for combined perfusion/pulsation phase rating was good (ICC 0.77, 95% CI 0.69-0.82, $p<0.05$). Analysis of a peak-to-offset ratio of pulsation phase histograms showed a significant difference between lung quadrants rated pathologic in scintigraphy and quadrants rated healthy ($p<0.05$).

CONCLUSION

SENCEFUL-MRI showed good agreement for detection of perfusion defects compared with V/Q scans being the current screening method for CTEPH. Analysis of MRI maps by a peak-to-offset ratio of pulsation phase showed a significant difference between quadrants rated pathologic and healthy by V/Q scans suggesting a quantifiable value for future determination of threshold values in SENCEFUL-MRI.

CLINICAL RELEVANCE/APPLICATION

SENCEFUL-MRI could be an alternative screening method for detection of lung perfusion defects in patients with suspected CTEPH without the need of contrast agent administration or radiation exposure.

SSQ05-08 Applicability of Monochromatic Energy with 40 keV for Pulmonary Embolism Detection in the Pulmonary Embolism CT Angiography: Experience Using a Dual-Layer Detector Spectral CT

PURPOSE

Previous studies have shown that the optimal energy level of virtual monoenergetic images (VMI) for pulmonary artery (PA) enhancement is 40 keV in spectral CT. The aim of this study is to evaluate the applicability of VMI at 40 keV for pulmonary embolism (PE) detection in the CT angiography (PECT).

METHOD AND MATERIALS

A total of 876 consecutive PECT using spectral CT were identified between August 2016 and March 2018. Of these, PE at least 4 mm in diameter was detected in 73 PECT. Among these, suboptimal enhancement of PA (<250 HU) was shown in 19 cases. Contrast-to-noise ratio (CNR), signal-to-noise ratio (SNR) of VMI at 50 keV, 60 keV, 70 keV, and conventional 120-kVp images (COV) were compared with VMI at 40 keV in all PECT and suboptimal PECT. Readers' subjective scores for PE detection was also recorded. The mean diameters of PE were measured, and they were compared between VMI at 40-70 keV and COV. The frequency of significant PE diameter reduction (>40%) in VMI compared with COV was also recorded and compared between VMIs. The cut off

value of the minimum visible PE diameter at 40 keV was investigated in COV.

RESULTS

There was no significant difference in CNR between 40 keV and 50 keV, although the highest CNR and SNR were obtained at 40 keV. In the suboptimal subgroup, there were no significant differences in both CNR and SNR between 40 keV and 50 keV. The subjective scores was significantly lower at 40 keV, compared with other algorithms in both all PECT and the suboptimal subgroup ($P<0.05$). The mean diameters of PE were significantly decreased in 40 keV and 50 keV, compared with those in COV (40 keV, 5.6±5.8 mm; 50 keV, 7.2±5.3 mm; COV, 8.9±4.9 mm; all $P<0.05$). The frequency of significant PE diameter reduction was significantly higher in 40 keV than in 50 keV (36.8% vs.12.8%, $P<0.001$). The cut off value of the minimum visible PE diameter at 40 keV was 6.4 mm in COV.

CONCLUSION

VMI at 40 keV was not the best option for PE detection, although the best CNR and SNR were obtained at 40 keV. The diameter of PE was often decreased and small PE was not even detected at 40 keV.

CLINICAL RELEVANCE/APPLICATION

We propose that not only 40 keV but also other algorithms such as 50 keV should be used for PE detection to ensure that we do not miss small PEs.

SSQ05-09 Fluorine-19 MRI Ventilation Defect Analysis in Cystic Fibrosis

PURPOSE

The purpose of this study is to investigate the ability of novel fluorine-19 (19F) based MRI to characterize ventilation in subjects with cystic fibrosis.

METHOD AND MATERIALS

Coronal images of nine healthy controls and twelve subjects with CF were acquired using a multinuclear capable 3.0 T MRI scanner (PRISMA, Siemens) along with spirometry. Subjects inhaled 19F labelled perfluoro-propane (PFP) gas mixed with 21% O2 or room air during the wash-in phase of the scan. Fifteen second 19F GRE vibe breath hold images were obtained following three breaths of PFP for five cycles. This was repeated five times after switching PFP gas to room air for the wash-out phase. A 19F maximum intensity projection image over time was created and segmented using a semi-automatic approach with an empirically determined ventilation threshold. Anatomic 1H series taken at full inspiration were then manually segmented for all subjects. After correcting for differences in respiratory effort by comparing apex-base measurements of the lung in 19F and 1H series, the ventilation defect volume (VDV) was computed by subtracting 19F segmentation volume from 1H volume and a ventilation defect percentage (VDP) was also computed relative to 1H volume.

RESULTS

In healthy controls, the mean ventilation defect percentage (VDP) was 10% (SD 11%); for mild CF 13% (SD 25%); and for severe CF 31% (SD 24%). A significant difference was found when comparing all CF patients to normal ($p=0.0275$ via t-test with Satterthwaite correction). VDP had a negative correlation with FEV1 (-0.56 via Spearman correlation, $p=0.011$). The rate constant for gas filling ($\tau 1$) was significantly increased in CF patients compared with controls, suggesting delay in filling. No safety concerns were detected throughout the study.

CONCLUSION

This study showed the ability of novel 19F ventilation MRI to rapidly and safely quantify regional ventilation defects and gas wash-in and wash-out dynamics. 19F MRI identified ventilation defects in cystic fibrosis subjects even in the setting of normal spirometry with some variability in healthy volunteers.

CLINICAL RELEVANCE/APPLICATION

This novel imaging technique has advantages over xenon ventilation MRI including cheaper contrast material and inert compound allowing functional imaging with multiple image sets. We anticipate applications for many other lung diseases including pediatric lung malformations, lung resection, COPD monitoring, and bronchiectasis.

djdisantis@gmail.com

PURPOSE

To quantify 21st century abdomen radiograph volume trends as an indicator of that examination's current relevance, both clinically and in our training curriculum.

METHOD AND MATERIALS

Nationwide Medicare procedure data from 2000 through 2016 were analyzed to quantify volume trends for the three most common abdomen radiograph studies: • SINGLE VIEW ABDOMEN • TWO VIEW ABDOMEN (SUPINE plus UPRIGHT OR DECUBITUS) • COMPLETE ABDOMEN SERIES (TWO VIEW ABDOMEN plus FRONTAL CHEST)

RESULTS

In the latest year with data available (2016), 11.29 million abdomen radiographs were performed in the United States. Single view abdomen volume grew by a quite surprising 37% between 2000 and 2016, to 7.55 million. In contrast, two view abdomen 2016 volume fell 43% from its peak year of 2002, to 2.04 million. Similarly, 2016 acute abdomen series volume fell 55% from its peak year of 2004, to 1.7 million .

CONCLUSION

Despite the ascendancy of cross-sectional imaging, supine frontal abdomen radiograph volume has shown not merely resilience but remarkable growth in the 21st century.

CLINICAL RELEVANCE/APPLICATION

With over 11 million studies yearly, abdomen radiograph interpretation will remain a necessary skill in radiology practice, and our residency curricula must reflect that reality.

linyajun20002004@163.com

PURPOSE

To explore the feasibility of differentiating pseudomyxoma peritonei from ascites due to cirrhosis on the basis of quantitative spectral features using spectral CT imaging.

METHOD AND MATERIALS

Six patients with pseudomyxoma peritonei and 5 patients with ascites due to cirrhosis were examined by spectral imaging of revolution CT. And pseudomyxoma peritonei was confirmed by subsequent operation and pathology. Using GSI viewer, various CT imaging parameters(CT values of different mono energy level , iodine-water concentration) were calculated and compared between the 2 groups. Thirty-seven regions of interest (ROI) were placed on pseudomyxoma peritonei and 52 ROIs were placed on cirrhotic ascites. The difference of these spectral parameters between the 2 groups was calculated statistically by independent sample t test.

RESULTS

From 40 to 140 keV images, the mono energy CT values of the 2 groups has statistical significant difference ($P<0.05$). On 60keV images, the difference of CT values of the 2 groups was the largest, the mean CT values of pseudomyxoma peritonei [(18.45±4.58)Hu] was significantly higher than that of cirrhotic ascites[(10.54±4.14)Hu] ($t=-8.32$, $P<0.00$). The iodine-water concentration of pseudomyxoma peritonei [(3.28±0.99)g/L] was significantly higher than that of cirrhotic ascites[(2.72±1.10) g/L] ($t=-2.22$, $P=0.01$).

CONCLUSION

The CT spectral curve and spectral imaging parameters of pseudomyxoma peritonei is found to be different from ascites due to cirrhosis. Revolution spectral CT imaging may provides a new multiparameter method to differentiate pseudomyxoma peritonei and ascites due to cirrhosis.

CLINICAL RELEVANCE/APPLICATION

The CT spectral curve and spectral imaging parameters may be helpful in differentiating pseudomyxoma peritonei and ascites due to cirrhosis.

SSQ06-03 Automated Spleen Volumetry Based on MR Hepatic Proton Density Fat Fraction Imaging in Patients with Nonalcoholic Fatty Liver Disease

PURPOSE

In patients with nonalcoholic fatty liver disease (NAFLD), spleen volume is a marker of disease progression and can predict the likelihood of nonalcoholic steatohepatitis (NASH) and portal hypertension. Manual spleen segmentation for accurate spleen volumetry is laborious and impractical for routine use. Convolutional neural networks (CNNs) can automatically segment spleen volume using dedicated spleen imaging sequences, but are not well suited to estimate hepatic proton density fat fraction (PDFF) and are not routinely acquired in NAFLD research exams. It would be more practical to measure spleen volume on MR hepatic PDFF imaging sequences already obtained, even though the sequences are not optimized for spleen imaging. Here we assess the

feasibility of using an automated CNN method to measure spleen volume based on PDFF sequences.

METHOD AND MATERIALS

We retrospectively identified 172 patients (ages 28 to 71; 67% female) with confirmed NAFLD who underwent MR PDFF exams for clinical care at our institution. Each exam included a magnitude-based PDFF sequence comprising six gradient-echo images at sequential nominally out- and in-phase echo times. Manual-segmentation-determined spleen volumes were measured by an image analyst on 5th echo images for all 172 exams to serve as ground truth. We developed a spleen-segmentation CNN using a 2D U-Net to compute spleen volume separately on each of the six echoes to capture a range of T2* weighting. We trained the CNN in 100 of the 172 patients selected at random and then evaluated its accuracy (Dice score, linear regression, and Bland-Altman analyses) against the ground truth in the other 72 patients.

RESULTS

In the test cohort, spleen volumes were 318±148 mL for manual segmentation of the 5th echo, and 300±137 mL for automated segmentation of all six echoes. Mean Dice score was 0.88 ± 0.09. Regression slope and intercept were 0.90 and 13.0 mL with R2=0.94. The CNN underestimated spleen volume by 17 mL (p<0.0001) with Bland-Altman 95% limits of agreement of [-88 mL, 52 mL].

CONCLUSION

Automated spleen segmentation based on MRI-PDFF is feasible, but further CNN refinement is needed to ensure robust spleen volumetry amongst all patients and signal weightings.

CLINICAL RELEVANCE/APPLICATION

A CNN can measure spleen volume automatically based on MR PDFF images. With further refinement, this CNN may aid in monitoring disease progression in NAFLD and other diseases.

SSQ06-04 Characterization of Abdominal Lymph Node Enlargement: Value of Dual-Energy CT-Based Iodine and Fat Quantification

simartin@outlook.com

PURPOSE

To investigate the potential of dual-energy computed tomography (DECT)-derived iodine and fat quantification for the differentiation of varying entities in patients with abdominal lymph node enlargement.

METHOD AND MATERIALS

In this retrospective study, 94 patients (51 men; mean age, 64.5 years) with histopathologically confirmed diagnosis of malignant lymphoma, lymph node metastasis, or inflammatory lymph node enlargement were included. For each lesion, contrast-enhanced attenuation, as well as DECT-derived iodine density and fat fraction measurements were recorded. Mean attenuation and material density values were compared between different entities. The receiver operating characteristic (ROC) curve analysis was adopted to estimate the optimal threshold for the diagnosis of lymph node metastasis. A control group (n = 95) was analyzed for comparison of attenuation and material density values of normal abdominal lymph nodes.

RESULTS

Assessment of DECT-derived iodine density and fat fraction values revealed significant differences between lymph node metastases (1.7±0.4 mg/ml and 15.5±7.3%), malignant lymphomas (2.5±0.5 mg/ml and 26.7±12.2%), and inflammatory lymph nodes (2.9±0.7 mg/ml and 20.1±10.3%) (P<=0.022). Attenuation values showed no significant differences between the different entities (P>=0.054). Normal lymph nodes revealed an iodine density of 2.4±0.8 mg/ml and fat fraction of 24.1±10.8% with no significant differences compared to malignant lymphomas (P<=0.1.65). An iodine concentration of 2.0 mg/ml represented the optimal threshold for the diagnosis of lymph node metastasis with a sensitivity of 91% and a specificity of 89%.

CONCLUSION

The differentiation of enlarged lymph nodes due to inflammation, primary and secondary malignancy is feasible using DECT iodine density and fat fraction analysis.

CLINICAL RELEVANCE/APPLICATION

DECT material density analysis optimizes the clinical workflow in patients with abdominal masses as iodine density and fat fraction values differ significantly between malignant abdominal lymphomas, lymph node metastases, and inflammatory lymph nodes. This may be beneficial in order to reduce the frequency of additional MRI and ultimately, lymph node biopsy.

SSQ06-05 CT-Based Quantification of Abdominal Aortic Calcification is Superior to the Framingham Risk Score for Predicting Cardiovascular Events in Asymptomatic Adults

Thursday, Nov. 29 11:10AM - 11:20AM Room: E350

soconnor@mcw.edu

PURPOSE

Determine if abdominal aortic calcification (AAC) predicts cardiovascular (CV) events independent of Framingham risk score (FRS).

METHOD AND MATERIALS

This retrospective HIPAA-compliant study was approved by the institutional review board. Electronic health records for 829 asymptomatic patients (mean age, 57.9 years; 451 women, 378 men) who underwent unenhanced screening CT colonography between April 2004-March 2005 were reviewed to identify patients with subsequent CV events (defined as MI, CVA, CHF, or death); mean follow-up interval was 11.2±2.8 years. CT-based AAC was quantified as a modified Agatston score using a semi-automated tool (V3D-Calcium Scoring, Viatronix). Kaplan-Meier curves and Cox proportional hazards models were used for time-to-event analysis; ROC curves and net reclassification improvement (NRI) were used to compare predictive abilities of AAC and FRS.

RESULTS

An index CV event occurred after CT in 156 (18.8%) of 829 subjects (6.7±3.5 years after CT). AAC was significantly higher in the CV event cohort (mean AAC, 3478 vs 664). AAC was a strong predictor of CV events at both univariate and multivariate Cox modeling, independent of FRS ($p<0.0001$). KM plots showed better separation with AAC over FRS. The ROC-AUC was higher for AAC than FRS at all evaluated time points (eg, AUC =0.819 versus 0.642 at 2-years; AUC for FRS-AAC combined =0.819). Using a cut-point of 200, AAC improved upon FRS risk categorization with NRI of 35.4%.

CONCLUSION

CT-based AAC is a strong predictor of future cardiovascular events, outperforming the FRS. This suggests a potential opportunistic role in abdominal CT scans performed for other clinical indications.

CLINICAL RELEVANCE/APPLICATION

Abdominal aortic calcification (AAC), which can be quantified at abdominal CT performed for other indications, can serve as a useful biomarker for estimating risk for future cardiovascular events.

PURPOSE

To investigate if the warming of gadoxetic acid affects the frequency and degree of artifacts in the arterial phase of magnetic resonance (MR) imaging.

METHOD AND MATERIALS

Two hundred and seventy-one patients who underwent gadoxetic acid-enhanced abdominal MR imaging were included in the study. All dynamic MR imaging was performed with a 1.5 T MR scanner (Achieva, Philips). Either warmed (37°C, n = 137) or non-warmed (24°C, n = 134) gadoxetic acid (Primovist; Bayer HealthCare) was intravenously injected at a dose of 0.025 mmol/kg for 5 seconds, followed by 20 mL of saline. Breath-hold time of each phase was fixed at approximately 20 s. Two abdominal radiologists evaluated the severity of artifact of precontrast, arterial and portal phase images in a consensus fashion as follows: 1 = none; 2 = mild; 3 = moderate; and 4 = severe. Comparison of artifact scores in precontrast, arterial and portal phases as well as patient background was performed between the 37 °C group and the 24 °C group.

RESULTS

There was no significant difference between the 37 °C and the 24 °C groups in terms of age, sex, body weight, body mass index or frequency of underlying medical conditions (liver cirrhosis, ascites, pleural effusion and pulmonary disease). The mean artifact score of the arterial phase in the 37 °C group was significantly lower than that in the 24 °C group (1.38 ± 0.78 vs 1.62 ± 0.92, $p < 0.05$), whereas those of the precontrast and portal phases did not show a significant difference between the two groups. The rate of substantial artifact (score = 3 or 4) in the arterial phase was significantly lower in the 37 °C group than in the 24 °C group (11.2% vs 21.1%, $p < 0.05$). The rate of patients that showed high artifact score in the arterial phase compared to the precontrast image was also lower in the 37 °C group than in the 24°C group (21.6% vs 36.0%, $p < 0.01$).

CONCLUSION

Warmed gadoxetic acid could reduce the artifact in the arterial phase of dynamic MR imaging. Since the viscosity of gadoxetic acid decreases as temperature increases, we speculate the warmed gadoxetic acid may get more homogenous in the vessel early after injection than non-warmed one. This homogeneity could influence the degree or frequency of the artifact.

CLINICAL RELEVANCE/APPLICATION

(dealing with MR artifacts) The artifact in the arterial phase of dynamic MR imaging can be easily reduced by warming of gadoxetic acid without spending time and effort.

SSQ06-07 Leakage After Laparoscopic Sleeve Gastrectomy (LSG): What Is the Role of Routine Postoperative CT Scan?

Thursday, Nov. 29 11:30AM - 11:40AM Room: E350

PURPOSE

LSG has become one of the most common bariatric procedures; even so, gastric leak remains the most feared complication of this procedure with a difficult treatment. Our aim was to investigate the role of routine postoperative CT scan in the early identification of factors representing potential substrates of leakage after LSG.

METHOD AND MATERIALS

We enrolled 170 patients(112F,58M;43±12years;43±6.4kg/m2)who underwent primary LSG between September 2015 and February 2018. CT scan was performed within 72 hours from surgery; CT protocol included the use of intravenous and oral contrast. Imaging post processing consisted in measurement of the distance proximal from the pylorus to the first staple firing(stapler to pylorus distance - StP). We also evaluated the presence of perigastric hematoma and of any twisting of the stomach remnant(defined as rotation of all or part of the stomach around its longitudinal axis).

RESULTS

8 patients suffered from gastric leak(4.7%). The mean StP was 38.7±16.7mm; this distance was significantly lower in patients who suffered from gastric leak(24.2±11.9mm vs. 40.3±16.4mm; p=.005). By means of ROC analysis we identified as best threshold for StP 29.9mm below which patients demonstrate a higher risk of gastric leak(AUC:.83;Se:81.8%;Sp:75.4%). Hematoma was found in 9 patients(5.3%); patients with hematoma were found to be more likely to develop gastric leak after LSG(33.3%; p=.005). 15 patients developed twist of stomach remnant(8.8%); we identified two types of twist: type A(10 patients,5.9%), if the twist involves the first third of the gastric remnant; type B(5 patients,2.9%), if it involves its middle and distal part. 4 out of 5 type B patients suffered from gastric leak, while no gastric leak was found in type A group. Type B twisting of the gastric remnant significantly increases the probability of gastric leak after LSG(p=.004). A stepwise multivariate analysis identified this CT sign as the strongest risk factor for gastric leak after LSG(p=.005).

CONCLUSION

On routine postoperative CT scan the assessment of Stp<3cm and the presence of perigastric hematoma and type B twisting of gastric remnant are to be considered risk factors for leakage after LSG.

CLINICAL RELEVANCE/APPLICATION

Routine postoperative CT scan has a promising role in the risk stratification of patients who underwent LSG.

SSQ06-08 Real-Time MRI of the Gastroesophageal Junction: Dynamic Imaging in Patients with GERD-Like Symptoms After Surgical Fundoplication

Thursday, Nov. 29 11:40AM - 11:50AM Room: E350

PURPOSE

To assess the diagnostic potential of dynamic real-time MRI in patients with persistent or recurrent GERD-like (gastroesophageal reflux disease) complaints after surgical fundoplication.

METHOD AND MATERIALS

22 consecutive patients (male n=11; female n=11; median age 59y) presenting with recurrent or persistent GERD-like symptoms after surgical fundoplication were enrolled between 2015-2017. Median duration of GERD-like symptoms was 21 months. MRI was performed at a median of 5 years after initial surgery. Real-time MRI at 3.0 Tesla was performed with temporal resolution of 40 ms. based on undersampled radial fast low angle shot (FLASH) acquisitions with iterative image reconstruction by regularized nonlinear inversion (NLINV). Dynamic MRI movies visualized bolus transit of pineapple juice through the gastroesophageal junction, position of the fundoplication wrap as well as recurring hernia or reflux during Valsalva maneuver. MRI results were compared to endoscopic findings.

RESULTS

Real-time MRI was successfully completed in all patients without adverse events and average examination time of 15 minutes. A morphological correlate for GERD-like symptoms was evident in 20 patients (90.1%): Gastric reflux was present in 19 of these cases. Nine patients (40.1%) were diagnosed with wrap disruption and recurrent gastric hernia. Wrap migration or telescoping hernia were detected in 9 patients (40.1%). Only 1 patient presented with continued reflux despite intact wrap. Esophageal dysmotility with delayed bolus passage was observed in 1 case. On endoscopy, gastric hernia or wrap migration were diagnosed in 6 cases. Repeated fundoplication was performed in 12 patients (54.4%) with gastric hernia or wrap migration based on MRI findings.

CONCLUSION

Real-time MRI is a fast and safe modality for dynamic imaging after fundoplication, without radiation exposure or administration of gadolinium-based contrast media. In a relevant number of cases real-time MRI reveals correlates for GERD-like symptoms.

CLINICAL RELEVANCE/APPLICATION

Dynamic real-time MRI is a novel imaging technique for postsurgical detection and characterization of fundoplication failure. Different patterns on MRI may assist planning of redo fundoplication.

SSQ06-09 Novel Murine Model of Liver Microbleeding Using Electric Field Ablation

Thursday, Nov. 29 11:50AM - 12:00PM Room: E350

Participants
Patrick T. Hangge, MD, Phoenix, AZ (*Presenter*) Nothing to Disclose
Avery A. Witting, Phoenix, AZ (*Abstract Co-Author*) Nothing to Disclose

Hassan Albadawi, MD, Phoenix, AZ (*Abstract Co-Author*) Nothing to Disclose
Rahmi Oklu, MD,PhD, Phoenix, AZ (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Approximately 5% of gastrointestinal bleeding (GIB) cannot be identified on initial workup. Over two years, an average of 7.3 diagnostic tests, 5 hospitalizations, and 46 units of blood per patient are required during workup. Improved diagnostic approaches of obscure GIB are needed. To evaluate emerging diagnostic agents, we describe a novel murine GIB model using irreversible electroporation (IRE) which can be detected with contrast enhanced micro-computed tomography (micro-CT).

METHOD AND MATERIALS

C57BL/6 mice (n=10) were placed under anesthesia. Prior to the IRE procedure, 200U/kg heparin was injected followed by 300µl 1:1 v/v heparinized saline and 350mg/ml iohexol. The mice were divided into two experimental groups: 60 and 120V/mm IRE treatment. IRE was performed using 1cm2 tweezer electrodes applied to both sides of the right median liver lobe. Microperfusion was measured using Laser Speckle Contrast Analysis (LASCA) at baseline and at 2, 10, 20, 30 min post-IRE. Prior to euthanasia, another 300µl of heparinized saline-ioxhexol was injected. Whole body contrast enhanced micro-CT scan was performed with settings of: 32µm pixel size, 55kV, 181µA, rotation step 0.25°, frame average 3, with a 0.5mm aluminum filter. Liver tissues were harvested for additional micro-CT and histology.

RESULTS

Visual inspection of the IRE site showed evidence of contusion within the tissue in both groups. LASCA imaging demonstrated decreased, but maintained perfusion. 30min post-IRE perfusion for 60V/mm and 120V/mm was 71% and 35% of baseline, respectively (p=0.006). Micro-CT showed increased attenuation at the liver IRE site, suggestive of bleeding. Extravasation of erythrocytes within the hepatic parenchyma was evident on microscopy with a greater effect seen in the 120V/mm group.

CONCLUSION

We demonstrate a novel, non-traumatic model of liver microbleeding which can be identified using non-invasive micro-CT imaging and confirmed by histology. Although trauma induced animal hemorrhage models exist, this is the first described model of microbleeding of the abdomen. This model can be useful to test emerging bioengineered hemostatic and imaging agents.

CLINICAL RELEVANCE/APPLICATION

A GIB model can help test emerging diagnostic and therapeutic agents which can be targeted to sites of microbleed. New agents have potential to improve costs, morbidity and mortality of obscure GIB.

PURPOSE

To investigate the 3-year progressive-free survival (PFS) of extramural vessel invasion (EMVI) and the nodal status detected with contrast MDCT in patients with clinical T4a gastric cancer.

METHOD AND MATERIALS

Between January 2009 and February 2015, 143 patients with preoperative ceMDCT diagnosed T4a gastric cancer based on the criteria of the AJCC 8th were included in this retrospective study. All patients underwent curative D2 gastrectomy, adjuvant chemotherapy and conventional follow-up. Potential prognostic factors including clinical and pathological N status, EMVI tumor location/growth pattern, histological type/tumor differentiation and tumor size were recorded. Disease progression was defined as the presence of radiological or/and pathology-confirmed metachronous metastases, local recurrence, or gastric cancer related death. Survival estimated for PFS were obtained in patients according to the following four categories: ctEMVI+/ctN+, ctEMVI+/ctN-, ctEMVI-/ctN+, ctEMVI-/ctN-, by using the Kaplan-Meier product limit. Hazard ratios for 3-year PFS were generated using a Cox proportional hazard regression on ceMDCT tumor characteristics.

RESULTS

The prevalence of EMVI detected with ceMDCT was 55.9% (80/143) in the entire cohort of patients with clinical T4a patients. The 3-year PFS according to ctEMVI and CT detected nodal status were ctEMVI+/ctN+ 25.0%, ctEMVI+/ctN- 53.1%, ctEMVI-/ctN+ 75.6% and ctEMVI-/ctN- 64.7%, respectively. There was significant difference in 3-years PFS with ctEMVI+/ctN+ (as the reference) and the other three groups (ctEMVI+/ctN-, ctEMVI-/ctN+, and ctEMVI-/ctN-) (Logrank test, $P<0.05$). In a Cox proportional hazards regression analysis, ctEMVI+/ctN+ was demonstrated as the independent factors for reduced 3-year PFS with HR of 2.169 (95%CI:1.300-3.618, $P=0.003$) .

CONCLUSION

EMVI combined with nodal status detected with ceMDCT, could be an more valuable preoperative factor to counsel patients regarding ongoing risks of metastatic disease, implications for surveillance, and systemic chemotherapy.

CLINICAL RELEVANCE/APPLICATION

Clinical N staging combined with the status of CT detected EMVI could be used as an independent poor prognostic predictors for the T4a gastric cancer patients. EMVI and ctN both positive might be a useful risk-stratified factors to balance benefit of survival with induced long-term toxicities from neoadjuvant chemotherapy for regional advanced gastric cancer.

SSQ07-02 Diffusion Kurtosis Imaging: Assessment of Poor Response to Neoadjuvant Chemotherapy in Advanced Gastric Cancer

PURPOSE

To assess effectiveness of diffusion kurtosis (DK) imaging in treatment response to neoadjuvant chemotherapy in locally advanced gastric cancer.

METHOD AND MATERIALS

This study was approved by the local institute review board. A total of 28 patients (median age, 60.3years; age range, 35-79years) with gastric cancer were enrolled in this prospective study, and underwent MR imaging on a 1.5T MR scanner. All patients were underwent DKI examination (b=0,200,500, 800, 1000, 1500, 2000s/mm2) and conventional diffusion-weighted imaging (b = 0, 800s/mm2) before and after chemotherapy. ADC value, diffusivity (D), Kurtosis (K) were measured. Change value (ΔX) and ratio (%ΔX) of these parameters were calculated. The response to neoadjuvant chemotherapy was evaluated according to pathological tumor regression grade scores (NCCN) as the standard reference (good responders TRG 0-2, poor responders, TRG 3). Mann-Whitney U test, ROC curve were used for statistical analysis.

RESULTS

There were 16 cases of good response and 12 cases of poor response. The Kpre and Kpost values in poor response group were significantly higher than those in good response group [(0.671±0.026) and (0.641±0.019) vs. (0.584 ± 0.023) and (0.519±0.018) respectively, p<0.001)]. ADCpost and Dpost in the poor response group were significantly lower than those in good response group (p<0.05). In addition, significant difference were also observed for parameters %ΔK, ΔD andΔK between the two groups (p<0.05). The operating characteristic curve for the assessment of poor response was highest using Kpost (0.958, cutoff value=0.614) compared with other parameters. The Kpre and Kpost respectively had highest sensibility (91.70%) and specificity (93.8%) compared with other image indices.

CONCLUSION

Both DKI and conventional DWI exhibit potential in evaluation of treatment response in gastric cancer with neoadjuvant chemotherapy. The DKI parameters, especially K, showed better performance in differentiating poor response.

CLINICAL RELEVANCE/APPLICATION

DKI is a non-invasive imaging technique that may be useful in monitoring poor responser for advanced gastric cancer.

SSQ07-03 Predicting Gastric Cancer Response to Neoadjuvant Chemotherapy Using a Non-Gaussian Fractional Order Calculus Diffusion Model

Thursday, Nov. 29 10:50AM - 11:00AM Room: E351

mkaraman@uic.edu

PURPOSE

To investigate whether pre-treatment MRI can predict tumor response grade (TRG) to neoadjuvant chemotherapy (NAC) of gastric cancer using a non-Gaussian fractional order calculus (FROC) diffusion model.

METHOD AND MATERIALS

With IRB approval, 30 patients (9 females and 21 males) with gastric cancer underwent MRI scans at 1.5T prior to NAC. The histologic TRG was evaluated based on the following grading system: TRG0: complete, TRG1: moderate, TRG2: minimal, and TRG3: poor response. According to this criterion, 3 patients were identified with TRG0, 2 with TRG1, 12 with TRG2, and 13 with TRG3. For analysis, TRG0-TRG2 groups were combined as low-TRG to be compared with high-TRG (TRG3) group. The MRI protocol included T1-weighted (VIBE), T2-weighted (turbo spin echo with respiratory trigger), and diffusion-weighted (DW) imaging with 11 *b*-values (0 to 2000 s/mm2). Diffusion coefficient *D*, fractional order parameter *ß* (which correlates with tissue heterogeneity), and a microstructural quantity *μ* were calculated by fitting the DW images to a FROC model. Apparent diffusion coefficient (ADC) was also computed using *b*=50 and 800 s/mm2 images. For group analysis, the test parameters were computed as the mean value from the tumor region-of-interest for *ß* and *μ*. For D or ADC, the mean values were computed from the lower 25% of their histograms to improve robustness against contamination from the body fluid. The low- and high-TRG groups were compared using a Mann-Whitney U test. A receiver operating characteristic analysis was performed to assess the performance of FROC model for predicting TRG in comparison with ADC.

RESULTS

The FROC parameters, *D* and *μ*, were significantly lower in high-TRG than low-TRG group (*p*-values<0.05), whereas ADC or *ß* did not show significant difference between the groups. The combination of *D* and *μ* produced higher accuracy (76% vs. 64%), specificity

(70% vs. 60%), sensitivity (80% vs. 70%), and area under the curve (80% vs. 60.6%) than ADC in differentiating low- and high-TRG groups.

CONCLUSION

The combination of pre-treatment FROC parameters, *D* and *μ*, improved the performance over ADC in predicting TRG in gastric cancer patients receiving NAC.

CLINICAL RELEVANCE/APPLICATION

The pre-treatment FROC diffusion model parameters can be used to predict gastric cancer response to NAC.

SSQ07-04 Prognostic Ability of Risk-Stratification Defined By ceMDCT of Patients with Gastric Cancer

Thursday, Nov. 29 11:00AM - 11:10AM Room: E351

fengcaizhen2016@163.com

PURPOSE

To investigate the risk-stratification defined by preoperative abdominal contrast-enhanced multiple-row detector computed tomography (ceMDCT) in predicting 1-year DFS of patients with gastric cancer.

METHOD AND MATERIALS

Between January 2009 and December 2015, 237 patients with pathological-proved gastric cancer were included in this retrospective study. Two radiologists reviewed all abdominal ceMDCT images and reached a consensus on categories of tumor and lymph node (ctT/ctN), the presence of ctEMVI, tumor location/growth pattern, and tumor size. Kaplan-Meier method was used to compare the 1-year DFS rate between ctEMVI-positive and ctEMVI-negative group. Cox proportional hazard regression was used to find the independent risk factors of 1-year DFS rate. According to the number of independent risk factors, the patients were classified to the different risk stratifications, and the difference of 1-year DFS rate between different risk stratifications was compared.

RESULTS

The ctEMVI-positive group had significantly lower 1-year DFS rate (55.3%) than the ctEMVI-negative group (90.2%) (Log-rank test, $P < 0.0001$). In a Cox proportional hazards regression analysis, ctT, ctN and ctEMVI were identified as independent prognostic factors of 1-year DFS with hazard ratio (HR) of 3.35 (95% CI: 1.25-8.99, $P = 0.018$), 1.99 (95% CI: 1.08-3.63, $P = 0.0269$) and 3.40 (95% CI: 1.79-6.47, $P = 0.0002$), respectively. The risk stratification analysis showed that with the increase of the number of independent risk factors, 1-year DFS rate decreased gradually in patients with gastric cancer ($P < 0.0001$).

CONCLUSION

Preoperative TN stage and EMVI diagnosised by ceMDCT were independent risk factors for the prognosis of gastric cancer, and can be used for risk stratification to predict 1-year DFS rate of gastric cancer.

CLINICAL RELEVANCE/APPLICATION

Preoperative risk stratification based on TN stage and EMVI defined by ceMDCT can be used to predict 1-year DFS rate of gastric cancer.

SSQ07-05 CT-Based Radiomics Analysis for Evaluation of Serosa Invasion in Gastric Cancer

Thursday, Nov. 29 11:10AM - 11:20AM Room: E351

Participants
Rui-Jia Sun, Beijing, China (*Presenter*) Nothing to Disclose
Mengjie Fang, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

Sun Ying-Shi, MD, PhD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The purpose of this study was to develop and validate a radiomics model for evaluating serosa invasion in gastric cancer.

METHOD AND MATERIALS

We enrolled 428 patients (252 in the primary cohort and 176 in the validation cohort) with pathological confirmed T3 or T4a gastric cancer, the contrast enhanced CT images of three phases (arterial, portal, and delayed) of lesions were manually segmented. The subjective CT findings (nodular, cord, perigastric fat infiltration, high enhanced serosa sign) of serosa invasion were evaluated. Conventional hand-crafted features and convolutional neural network (CNN) based deep learning features were all automatically extracted based on CT images. The 2-sample t-test and the min-redundancy and max-relevance method were used for feature selection, whereupon 3 radiomics signature were built with support vector machines. Multivariable logistic regression analysis was

then used to develop a radiomics model incorporating the radiomics signature and subjective CT findings. A nomogram was displayed. The receiver operating characteristic (ROC) curve was constructed for each cohort and the area under the curve (AUC) was calculated to measure the diagnostic ability. DeLong test was used to verify whether there were statistical differences between the ROC curves.

RESULTS

The radiomics signature comprised 273 hand-crafted features and 30 features extracted based on the CNN. The individualized radiomics model, which incorporated the arterial radiomics signature and three CT findings (nodular, perigastric fat infiltration, high enhanced serosa sign) showed moderate discrimination. The AUC (95% confidence interval) in primary and validation cohort was 0.815 (0.759-0.870) and 0.804 (0.739-0.868), respectively. The accuracy, sensitivity and specificity of the primary cohort was 0.770, 0.798, 0.719, respectively. The prediction accuracy, sensitivity, and specificity of the validation cohort was 0.744, 0.756 and 0.734, respectively.

CONCLUSION

Based on the contrast enhanced CT images of three phases, we developed a radiomics model, which may be used to identify serosa invasion and provide reference for individualized clinical treatment.

CLINICAL RELEVANCE/APPLICATION

The radiomics model we developed and the derived nomogram that incorporates the radiomics signature and CT findings provides patients and doctors with an effective tool for evaluating serosa invasion and for determining further treatment plans.

SSQ07-06 Diagnostic Accuracy of Dual-Energy CT-Based Nomogram to Predict Lymph Node Metastasis in Gastric Cancer

Thursday, Nov. 29 11:20AM - 11:30AM Room: E351

Participants
Jing Li, Zhengzhou, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

lijingqingqing@163.com

PURPOSE

To develop and validate a dual-energy CT based nomogram for the preoperative prediction of lymph node metastasis (LNM) in patients with gastric cancer (GC).

METHOD AND MATERIALS

A total of 210 surgical confirmed GC patients (159 males, 51 females; mean age: 59.8 ± 7.7 years, range: 28-79 years) who underwent spectral CT scans were retrospectively enrolled and split into a primary cohort (n=140) and validation cohort (n=70). Clinical information and follow up data including overall survival (OS) and progression free survival (PFS) were collected. The iodine concentration (IC) of the primary tumours at the arterial phase (AP) and venous phase (VP) were measured and then normalized to aorta (nICs). Univariate analysis, multivariable logistic regression analysis and Cox regression analysis were performed to screen predictive indicators for LNM and outcome. A nomogram for risk factors of LNM was developed and its performance was measured using ROC, accuracy and Harrell's concordance index (C-index).

RESULTS

Tumour thickness, Borrmann classification and ICVP were independent predictors for LNM. The nomogram was significantly associated with LN status (P <0.001). The AUCs for predicting LNM were 0.760 (95% confidence interval [95% CI], 0.680-0.840) in primary cohort and 0.793 (95% CI, 0.678-0.908) in validation cohort. The nomogram also exhibited a prognostic ability with C-indices of 0.675 (95% CI, 0.571-0.779; P <0.001) for PFS and 0.643 (95% CI, 0.518-0.768; P =0.025) for OS.

CONCLUSION

This study presented a dual-energy quantification based nomogram, which can be used to facilitate the preoperative individualized prediction of LNM in patients with GC.

CLINICAL RELEVANCE/APPLICATION

Dual-energy CT based nomogram enables superior preoperative individual prediction of LNM in GC.

PURPOSE

To evaluate iodine concentration measurement by dual energy CT scan on tumor angiogenesis and predicting prognosis for patients with advanced gastric adenocarcinoma.

METHOD AND MATERIALS

This retrospective study included 97 patients with advanced gastric adenocarcinoma who had preoperative enhanced dual-energy CT scan. Standardized iodine concentration (SIC) of the primary tumor was measured. The correlations between SIC and clinical, pathological, angiogenic findings compared with patient survival were analyzed. The Kaplan-Meier test was employed to evaluate the patients' disease free survival (DFS) and overall survival (OS) . COX regression model was adopted to improve the multiple factors analysis .

RESULTS

Different values of SIC values were found 0.81 at diffuse, 0.54 at both intestinal and mixed type (F=18.717,P<0.001); 0.52 at non-T4 and 0.66 at T4 group (t=-2.728,P=0.008); 0.53 at N0 and 0.64 at N1-3 group (t=-2.084,P=0.040); 0.50 at non-III staging and 0.68 at III staging group (t=-4.135,P<0.001); 0.48 at VEGF negative and 0.69 at positive expression group (t=-4.684,P<0.001); 0.55 at low and 0.67 at high MVD group (t=-2.802,P<0.05); 0.72 at recurrence and 0.55 at non-recurrence group (t=3.791,P<0.001), respectively. DFS of low SIC (< mean value of 0.62) and high SIC (>= 0.62) groups were 28 and 22 months (X2=11.920,P=0.001). OS of the two groups were 29 and 26 months (X2=12.907,P<0.001). Invasion, metastasis, pTNM and SIC were identified as the independent risk factors affecting to DFS (0.195,0.379,6.623 and 2.802, respectively). Invasion, pTNM and SIC independent risk were affecting to OS (0.281, 7.225 and 2.835, respectively).

CONCLUSION

The SIC of advanced gastric adenocarcinoma has the relationship with Lauren classification, invasion depth, lymph node metastasis, pathological TNM staging and tumor angiogenesis. The SIC as a independent risk factor could affect DFS and OS, and has the potential to be used for predicating the patient prognosis.

CLINICAL RELEVANCE/APPLICATION

The SIC of advanced gastric adenocarcinoma has the relationship with Lauren classification, invasion depth, lymph node metastasis, pathological TNM staging and tumor angiogenesis. The SIC as a independent risk factor could affect DFS and OS, and has the potential to be used for predicating the patient prognosis.

SSQ07-08 Diagnostic Value of Multiparameter Dual-Energy CT in Regional Lymphatic Metastasis of Gastric Cancer

Thursday, Nov. 29 11:40AM - 11:50AM Room: E351

1443832806@qq.com

PURPOSE

To evaluate the value of dual-energy CT iodine concentration and overlay combining with conventional morphological measurements in metastatic lymph nodes of gastric cancer.

METHOD AND MATERIALS

A total of 141 regional lymph nodes were collected from 40 gastric cancer patients who underwent dual-energy CT scan and confirmed by surgery and pathology. The short diameter, length, and CT value, iodine concentration, and overlay value of each lymph node were measured, and the short length ratio and enhanced CT value at the arterial phase were calculated. Independent sample t-test was used to compare the short diameter, short length ratio, CT enhancement values, iodine concentration and overlay values between the two groups.The ROC analysis was used with statistically significant parameters and diagnostic efficacy was calculated with each individual parameter and joint parameters.

RESULTS

Of the 141 regional lymph nodes, 73 were metastatic lymph nodes and 68 were non-metastatic lymph nodes. The iodine concentration, overlay value, short diameter and enhanced CT values of the metastatic lymph node at the arterial phase were (1.64±0.68) mg/ml, (29.06±11.42) HU, (7.35±3.38) mm, (26.34±14.98) HU, respectively; while the corresponding values of the non-metastatic lymph nodes were (2.51±0.68) mg/ml, (38.90±14.61) HU, (5.32±1.34) mm, (33.57±15.91) HU, and the difference was statistically significant (all P<0.05). There was no significant difference in short length ratio (P>0.05). The AUC of the diagnosing lymph node metastasis was 0.708, 0.650, 0.808, 0.695 for short diameter, CT enhancement, iodine concentration, and overlay value at the arterial phase, respectively. Four indicators combining to diagnose lymph node metastasis, the series sensitivity and specificity were 21.9% and 98.5%, and the parallel was 100.0% and 80.9%.

CONCLUSION

Multiparameter dual-energy CT combining with conventional morphological measurements can improve the diagnostic efficiency of lymph nodes in gastric cancer and has a role in the differential diagnosis of regional lymph nodes in patients with gastric cancer.

CLINICAL RELEVANCE/APPLICATION

It has a role in the differential diagnosis of preoperative regional lymph nodes in patients with gastric cancer.

SSQ07-09 Diagnostic Accuracy of CT for Lymph Node Metastasis in Gastric Cancer: Comparison of Spectral Parameters Developed Dual-Energy CT and Conventional CT

Thursday, Nov. 29 11:50AM - 12:00PM Room: E351

Participants
Yaru Chai, MD, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the optimal diagnostic threshold and accuracy of spectral parameters for metastatic lymph nodes of gastric cancer with dual energy CT and to compare with conventional CT parameters.

METHOD AND MATERIALS

This study received institutional review board approval, and all participants provided written informed consent. From December 2014 to December 2016, 86 patients with gastric cancer confirmed by gastroscope pathology underwent preoperative enhanced CT that included precontrast, arterial phase(AP) and venous phase(VP) in Discover GSI CT scanner. The spectal parameters(iodine value of lymph nodes in AP and VP) and the conventional parameters(short diameter, long diameter, the ratio of short to long diameter and CT number in AP and VP) were measured and recorded in iodine based images and monochromatic images at 70 keV respectively. The diagnostic efficiency of each factor to lymph nodes metastasis was assessed by using t test and receiver operating characteristic(ROC) curve analysis.

RESULTS

Among 552 lymph nodes found in CT images, 338 nodes were positive and 214 were negative with pathological results as the gold standard. The results of t test showed that the short diameter, the ratio of short to long diameter, the CT number and iodine value in AP and VP of positive lymph nodes were higher than these of negative lymph nodes(all $P<0.05$). The area under curve of the short diameter, the ratio of short to long diameter, the CT number in AP and VP, the iodine value in AP and VP of lymph nodes were 0.600, 0.880, 0.832, 0.755, 0.864, 0.835, respectively. The diagnosis accuracy of iodine value in AP and VP were 86.9%, 82.2%, respectively with threshold of 9.65,15.65(100ug/cm3). These were higher than the CT number in AP and VP(86.9% vs 69.9%, 66.9% vs 82.2%, both $P<0.05$). Taking the ratio of short to long diameter over 7.25 as optimal diagnosis threshold, the diagnosis accuracy was 75.6%. Combined the ratio of short to long diameter with the iodine value in AP, the diagnosis accuracy was 89.2%.

CONCLUSION

The diagnosis accuracy of dual-energy CT parameters was higher than conventional CT for lymph nodes metastasis in gastric cancer and could be improved by combining size and spectral CT parameters.

CLINICAL RELEVANCE/APPLICATION

Multifunctional parameters of spectral CT can improved the diagnosis accuracy of lymph node metastasis in gastric cancer.

Rachna Madan, MD, Boston, MA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

We assessed effect of a new fully iterative reconstruction technique (FIRST) on lesion detection and image quality of routine abdominal CT at radiation dose <1 mSv

METHOD AND MATERIALS

24 patients (age 64±1 years, BMI 27±3 kg/m) undergoing routine abdomen CT on 640-slice MDCT (Aquillion One, Canon Medical System), gave written informed consent for acquisition of an additional ULD CT series immediately after their clinically-indicated regular dose CT (SD). The ULD CT series were reconstructed with FIRST (at STD (Standard) and STR (Strong) levels), and SD CT series with filtered back projection (FBP). Two radiologists performed the subjective image evaluation on a five-point scale (1 = image quality better than SD CT; 5 = image quality unacceptable) to assess subjective image quality,and presence of artifacts on all image series (SD (n=24) and ULD (n=72). Lesions were first detected on ULD FBP images. ULD FIRST (STD and STR) and ULD FBP images were then compared side-by-side to SD-FBP images in an independent,randomized, and blinded fashion. Patient demographics, radiation dose descriptors (CTDIvol, DLP) and image noise were recorded. Descriptive statistics and inter-observer variability were calculated for data analysis

RESULTS

Mean CTDIvol for SD and ULD CT were 13±3 mGy and 2.2±0.4 mGy, respectively. There were 46 'true positive' lesions detected on SD CT. Radiologists detected 38/46 lesions on ULD FIRST STD series compared to 26/46 lesions on ULD FIRST STR series. Twenty lesions (0.5-1.5 cm) missed on ULD FIRST STR images (pancreatic lesions, liver and kidney cysts) were seen in patients with BMI >27.6. Eight lesions (liver and kidney cysts, pancreatic lesions, sub-cm peritoneal lymph node) missed on ULD FIRST STD were seen in patients with BMI>25.8. Diagnostic confidence for lesion assessment was optimal in ULD FIRST STD setting in most patients regardless of their size. The inter-observer agreement (kappa-value) for overall image quality were 0.98 and 0.84 for ULD FIRST STD and STR levels, respectively

CONCLUSION

FIRST enabled optimal lesion detection, and diagnostic confidence in submSv abdominal CT in most non-obese adult patients compared to SD CT at 85% lower radiation dose levels

CLINICAL RELEVANCE/APPLICATION

The new fully iterative reconstruction (FIRST) technique can allow routine abdominal CT at less than 1 mSv with sufficient diagnostic confidence in smaller patients (<27.6 BMI)

SSQ08-02 Contrast Volume Reduction Using Measured Lean Body Weight and Related to Image Quality for Abdomen CT Examinations: Preliminary Results of a Prospective Multicentric Study

Thursday, Nov. 29 10:40AM - 10:50AM Room: E352

PURPOSE

To assess i.v. contrast media (CM) volume differences correlated to image quality (IQ) when using lean body weight (LBW) or total body weight (TBW) for abdomen CT examinations.

METHOD AND MATERIALS

A CT scanner i.v. contrast media (CM) volume optimization protocol based on LBW was implemented in a multicenter medical imaging group (8 CT scanners) following a dose optimization program according to clinical indication. Patients assessed for a suspected liver, pancreas or renal lesion, were prospectively included. A single i.v. CM (iopamidol 370mg/ml) was used. In phase 1, a 600mg/kg of TBW injection protocol was applied. 948 prospective patients were included (Group 1): M:438/F:510, mean age: 59, mean BMI: 26.06 (range 13.8-44.6). In phase 2, a 750mg/kg of LBW injection protocol was applied. 124 prospective patients were included (Group 2): M:59/F:65, mean age: 60, mean BMI: 26.3 (range 16.45 - 37.55). LBW was measured using a bi-frequency tetrapolar bioelectrical impedance technique (BIA-ACC®, Biotekna, Italy). Contrast volume and injection rate were recorded in a single dose management software (Dosewatch™, GE). IQ (level of enhancement) was assessed by two independent readers in pre- and post-contrast portal phase images on 3mm axial reconstructions, with quantitative HU measurements for liver parenchyma enhancement (Δ target: 50HU), using ROIs of identical size and location. Image noise was also quantitatively reported using image Hounsfield unit standard deviation (SD) values indicated with the ROI density measurement. Mann-Whitney U Test and One way Annova test were used to assess differences as appropriate.

RESULTS

Injected i.v. CM volume is statistically significantly different (-26%) between group1 (median: 118.3ml) and 2 (median: 87.6ml) ($p<0.001$). Enhancement of liver parenchyma (median group1/group2: 60/50, SD:15.7/17.3) presents a statistically significant difference ($p<0.05$), but remains in target range. There is no statistically significant difference between readers for image quality assessment (parenchymal enhancement): reader 1/2, group 1: 60/61 (SD16.3/15.1), group 2 : 49/50 (SD17.6/17).

CONCLUSION

For abdomen CT examinations, injected i.v. CM volume is significantly less when using LBW instead of TBW, without impairing image quality.

CLINICAL RELEVANCE/APPLICATION

Excessive amounts of i.v. CM is delivered when using TBW instead of LBW for abdominal CT examinations.

SSQ08-03 Personalized Contrast Media Injection Protocols for Abdominal CT Studies

PURPOSE

To compare Abdomen CT exams performed using power injector generated customized contrast media (CM) injection protocols based on total body weight (TBW) and kV to fixed CM injection protocols.

METHOD AND MATERIALS

A total of 384 patients underwent abdominal CECT studies (GE Revolution and Siemens Edge). 263 of 384 patients were scanned using 100kV and 121 with DECT (65 keV). CM (370 mgI/mL, Iopamidol) was administered using a software platform (P3T, Certegra, Medrad), connected to the power injector, which customized the CM injection (*Cinj*) based on TBW in kg's. In 149-*Cinj* patients (80 with 100kV; 69 with DECT) a comparison with 120kV exams was available using fixed CM injections (*Finj*) using TBW based thresholds ([TBW]<= 59 kg, 80 ml= Group A; 60-89 kg, 90 ml= Group B; >=90 kg, 120 ml= Group C). Subjective image quality and mean HU and CNR were calculated from ROIs within the liver, pancreas, portal vein, and aorta.

RESULTS

In the 384-*Cinj* patients a mean CM volume of 85.7±14.8 was injected, 9.4% lower than using TBW. Group A received a mean CM volume of 70.3±1.2 vs 80ml (-12%), group B of 82.3±9.3 vs 90ml (-8.5%), and group C 108±6.9 vs 120ml (-10%). All exams were

judged diagnostic. In comparison to 120 kV *Finj*, 100kV-*Cinj* images showed comparable HU mean and significantly higher CNR (+36-87%; p=<0.05) in all three groups. DECT-*Cinj* images showed significantly higher HU (+7-22%; p=<0.05) and CNR (+14%-86%) mean.

CONCLUSION

The software platform (P3T) with power injector enables personalized CM injection protocols using substantially lower iodine dose for low kV/keV exams while yielding diagnostic quality images with comparable/higher attenuation and CNR values compared to 120kV exams using fixed CM injection volumes.

CLINICAL RELEVANCE/APPLICATION

Automation of Customized CM injection protocols using a power injector platform entails reduction of the iodine load with optimized image quality. There are potential benefits for the patients safety, CT workflow and lowering exam cost.

PURPOSE

Deep learning is part of a broader family of machine learning methods based on learning data representations, as opposed to task-specific algorithms. We developed a new image processing reconstruction method, Deep Learning based Reconstruction (DLR), which could generate CT image with better quality using deconvolution neural network trained by CT images which are scanned with sufficient radiation dose and reconstructed with model-based iterative reconstruction. The purpose of this study was to confirm clinical feasibility of our method compared with conventional hepatic CT images targeting hypervascular hepatocellular carcinoma.

METHOD AND MATERIALS

We evaluated 43 hypervascular hepatocellular carcinomas in 40 patients who had undergone hepatic dynamic CT. The CT images at arterial phase were reconstructed with DLR and hybrid iterative reconstruction (Hybrid-IR). A radiologist measured standard deviation of the attenuation measured in the paraspinal muscle as image noise, and calculated contrast-to-noise ratio (CNR) = (ROIL - ROIT)/N, where ROIL is the mean attenuation of the liver parenchyma, ROIT is the mean attenuation of the tumor, and N is noise. Each liver lesion was reviewed by other two radiologists and graded on a 5-point confidence scale ranging from 1 = cannot identify to 5 = can detect lesion without diagnostic compromise. The difference between CT images processed with Hybrid-IR and DLR was determined using two-sided Wilcoxon signed-rank test.

RESULTS

Image noise was significantly lower on images with DLR compared to Hybrid-IR (median 12.8 and 20.0 HU for DLR and Hybrid-IR, respectively, p<0.01). In addition, CNR on images with DLR was significantly higher than that on images with Hybrid-IR (median 2.3 and 1.5 for DLR and Hybrid-IR, respectively, p<0.01). Confidence score for liver lesions was significantly higher on images with DLR compared to those with Hybrid-IR (p<0.01).

CONCLUSION

The DLR improved quantitatively and qualitatively image quality of abdominal CT for evaluation of hypervascular hepatocellular carcinoma.

CLINICAL RELEVANCE/APPLICATION

DLR yielded better image quality of abdominal CT compared to Hybrid-IR, indicating that DLR can improve identification and characterization of hypervascular hepatocellular carcinoma.

SSQ08-05 Prior Iterative Reconstruction (PIR) to Lower Radiation Dose and Preserve Radiologist Performance for Multiphase Liver CT: A Multi-Reader Pilot Study

PURPOSE

Prior Iterative Reconstruction (PIR) is an iterative reconstruction technique for multiphase CT (MCT) exams that spatially registers the multiple phases and uses them collectively to inform the image reconstruction and reduce image noise. We evaluated PIR in contrast-enhanced MCT imaging of the liver.

METHOD AND MATERIALS

Patients with archived projection MCT data with proven malignant or benign liver lesions by reference criteria were included. Reference criteria for malignancy included histopathology or progression/regression, with stability on CT/MR > 6 months required for benign lesions. A validated noise insertion tool created reduced dose MCT images (50% dose in 2 phases, 25% dose in 1 phase). For each patient, the phase of enhancement most relevant to the diagnostic task was selected for evaluation. Four abdominal radiologists reviewed routine dose and lower dose PIR images in randomized and blinded fashion in two reading sessions, interpreting a patient's images once/session, and marking benign and malignant lesions, rating confidence for malignancy, and scoring image quality metrics. JAFROC Figures of Merit (FOM) were calculated for each dose/reconstruction using -0.10 as a limit of non-inferiority.

RESULTS

30 patients with 27 primary liver malignancies, 6 metastases, and 26 benign lesions were included. Pooled JAFROC FOM for malignancy for routine dose MCT was 0.615 (95% CI: 0.464, 0.767) compared to 0.662 for PIR (95% CI: 0.527, 0.797). The estimated difference between the routine dose and lower dose PIR images was + 0.047 (95% C.I.: -0.023, + 0.116). GEE sensitivity and specificity for routine dose images was 70%/68% compared to 73%/66% for lower dose PIR. Lower dose PIR had lower diagnostic image quality (mean 3.8 vs. 4.2, p = 0.0009) and was less sharp (mean 2.3 vs. 2.0, p = 0.0071).

CONCLUSION

PIR is a promising method to substantially reduce radiation dose for multiphase contrast-enhanced abdominal CT, preserving observer performance despite small reductions in image quality. Further work to develop and validate this technique is warranted.

CLINICAL RELEVANCE/APPLICATION

While multiphase CT is of great diagnostic importance, radiation is of concern. PIR is a promising method to reduce radiation dose while maintaining observer performance for multiphase exams.

PURPOSE

To prospectively evaluate colorectal cancer (CRC) hepatic metastasis detection and characterization between reduced-dose (RD) and standard dose (SD) contrast-enhanced CT (CECT) of the abdomen and to qualitatively compare between reconstruction algorithms.

METHOD AND MATERIALS

Fifty-one adults with biopsy-proven CRC and hepatic metastases by prior CT underwent portal venous phase SD-CECT followed by RD-CECT in the same breathhold. Three readers, blinded to reconstruction details and comparison examinations, performed detection and characterization of lesions 2-15 mm in size on the SD filtered back projection (SD FBP) and RD adaptive statistical iterative reconstruction-V 60 % (ASIR-V 60%) series. Readers then qualitatively assessed overall image quality and lesions side-by-side between 8 different reconstructions (SD FBP, SD ASIR 80%, SD ASIR-V 30%, SD ASIR-V 60% and RD model-based iterative reconstruction (MBIR), RD ASIR 80%, RD ASIR-V 30%, RD ASIR-V 60%) on a 0 to -4 Likert scale with 0 being best. Two, non-blinded consensus reviewers established the reference standard.

RESULTS

RD-CECT mean CTDIvol was 11.77 ± 3.28 mGy resulting in a mean radiation dose reduction of 53.86% compared to SD-CECT. Of the 260 lesions detected by reference standard (233 metastatic; 27 benign), RD-CECT only detected 82% of lesions, while SD-CECT detected 97% of lesions ($p<0.0001$); pooled data demonstrated a sensitivity of 0.79 and 0.93 ($p<0.0001$) and accuracy of 0.75 and 0.84 ($p=0.0005$), respectively. Mean qualitative scores for each series, in order from best to worst, were SD ASIR-V 60%, SD ASIR-V 30%, SD ASIR 80%, SD FBP, RD ASIR-V 60%, RD ASIR-V 30%, RD ASIR 80%, and RD MBIR.

CONCLUSION

Reduced radiation dose CECT demonstrates inferior diagnostic performance for detecting low-contrast liver lesions. Qualitative image evaluation suggests that performance of the RD scan may have been worse had FBP, ASIR or a lower percentage ASIR-V been utilized; the findings also suggest that SD exams benefit from iterative reconstructions.

CLINICAL RELEVANCE/APPLICATION

Oncologic CT evaluation of low contrast liver lesions is compromised in the setting of modest radiation dose reduction and iterative reconstructions appear to only partially mitigate this reduced performance. If the clinical task requires the detection of possible small, low-contrast liver lesions, proper radiation dose levels should be maintained with reference to the ACR dose index registry.

SSQ08-07 Comparison of Iterative Model-Based Reconstruction (IMR) with Hybrid Iterative Reconstruction (iDose-4) Technique for Assessing Small Hypervascular Hepatocellular Carcinomas Using Low Tube Voltage 256 Slice Multi-Detector Computed Tomography

PURPOSE

To compare iterative model-based reconstruction (IMR) with hybrid iterative reconstruction (iDose-4) technique for assessing small hypervascular hepatocellular carcinomas (HCCs) using low-tube voltage (100 kVp) 256 slice multi-detector Computed Tomography scans.

METHOD AND MATERIALS

We prospectively evaluated 50 patients (Male:Female:45:5;average age- 60.68yrs) with 50 HCCs (3cm or less) between January 2016-December 2017,who underwent standard multiphase CT(HCC protocol) using 256 slice CT.Arterial phase (AP) was taken with 100kVp,two delayed phases(DP) at 90sec (100kVp,IMR) and 104sec (120 kVp,iDose-4) respectively. Reconstructed images with iDose-4,IMR were evaluated for tumor conspicuity, image noise.For subjective analysis,tumor conspicuity is graded on a 5-point scale on the AP and DP,with 5(definitely distinct),4(fairly distinct),3(moderately distinct,2(barely distinct), and 1(not distinct).Subjective image noise with diagnostic confidence is graded as follows:5(well seen with minimum/no noise),4(mild noise with high diagnostic confidence),3(average noise with moderate diagnostic confidence),2(above average noise with low diagnostic confidence),and 1(unacceptable noise).

RESULTS

Contrast-to-noise ratio of HCCs (CNR-HCC) in AP was significantly higher in IMR (9.1+/-6.6) compared to iDose-4 (5.6+/-3.5) , $P<0.0001$. CNR-HCC in DP was significantly higher in IMR (2.5+/-2.1) compared to iDose-4(1.7+/-1.4), $P<0.0001$. Image noise was significantly lower in IMR (arterial-6.8+/-3.7; delayed-7.4+/-4.2) than in iDose-4 (arterial-9.8+/-3.4; delayed-9.3+/-3.2), in both AP ($P<0.0001$) and DP ($P<0.0001$).The subjective analysis showed that, tumor conspicuity was significantly better in IMR both in AP(IMR-4.8+/-0.3; iDose-4 -4.3+/-0.5 ,$P=0.012$) and DP (IMR-4.8+/-0.4 ; iDose-4 -4.5+/-0.5, $P=0.001$) with the good interobserver agreement (kappa value for IMR: AP-0.78; DP-0.86,and iDose-4:AP-0.91, DP-0.91).The subjective analysis also showed that Image noise was significantly lower both in AP (IMR-4.8+/-0.3; iDose-4 -3.9+/-0.2, $P=0.0004$) and DP (IMR-4.8+/-0.4; iDose-4 -4.1+/-0.3, $P=0.04$) with the good interobserver agreement (kappa value for IMR:AP-0.81, DP-0.85,and iDose-4: AP-0.77,DP- 0.78).

CONCLUSION

IMR provides better tumor conspicuity than iDose-4 for small HCCs with a considerable decrease in noise, even at low kVp.

CLINICAL RELEVANCE/APPLICATION

IMR confidently detects small HCCs,even with low kVp CT and can positively impact treatment.

SSQ08-08 Participants Quantitative Comparison of Metal Artifact Reduction Techniques in Abdominopelvic CT

PURPOSE

To compare the performance of various metal artifact reduction (MAR) approaches for different metals on low-tube voltage single energy CT, and dual-energy CT exams.

METHOD AND MATERIALS

In this phantom study, seven metal implants from titanium [Ti] or cobalt chromium [CoCr] (n=2 hip prosthesis, n=2 embolization coil, and n=3 spinal hardware) were suspended, sequentially, in an iodinated gelatin medium (0.4%; CT density 40-50HU). The phantom was scanned on three CT scanners (Somatom Definition Flash (scanner A) and Edge (scanner B); Siemens HC, and Discovery 750HD (scanner C); GE HC) using SECT (120/100/80kVp), and DECT (80/140 kVp) acquisitions. SECT images and high-energy (110-140keV) VMC images from DECT were reconstructed with and without vendor-specific MAR algorithms (iMAR; Siemens HC, and MARS; GE HC). Metal-related artifacts/noise (SD) was measured in the near (<3cm) and far (>3cm) fields. Differences among MAR approaches were tested using ANOVA.

RESULTS

Metal-related noise was comparable for Ti and CoCr on 120kVp images from all scanners (p=0.23), except on scanner C, where lower near-field noise was observed for Ti (48±12SD vs. 122±24SD; p<0.01). Higher near- and far-field noise on low-kVp images (37-54%) decreased substantially (63-72%) when using different modes of iMAR (p<0.001). High-keV VMC reduced both near- (16 to 32%) and far-field noise (32-41%) for both metals, with a slight variability between vendors. MARS (on scanner C) showed significant near-field noise reduction (59-91%) for both metals when added to VMC images (p<0.001). However, no effect on far-field noise was observed for Ti (14±8 vs. 13±1SD; p=0.51).

CONCLUSION

CT platforms from different vendors show variable metal-related noise, depending on the metal type. MAR algorithms applied to 80 or 100kVp have significant benefit for noise/artifact reduction and yield lower noise than 120kVp without MAR. While high-keV VMC alone reduce metal-related noise, further reduction is achieved by including MAR algorithms.

CLINICAL RELEVANCE/APPLICATION

Knowledge about existing MAR-approaches is desired for consistent IQ across vendors and to use MAR algorithms tailored to specific types of metallic implants.

Markus.Obmann@ucsf.edu

PURPOSE

The purpose of this study was to evaluate the ability of different dual-energy CT (DECT) platforms to reduce peristalsis artifact in a bowel phantom.

METHOD AND MATERIALS

In a water filled cylinder we placed a z-direction 1.7 Hz oscillating air filled 3 cm diameter corrugated tube to simulate peristalsing bowel. We scanned the phantom at similar CTDIvol 5 times on each of four different DECT platforms: spectral-detector (SD), rapid-

kVp-switching (RS), split-filter (SF) and dual-source (DS) DECT. Material decomposition (iodine and virtual unenhanced (VUE)) and 120 kVp-like images were reconstructed. On 50 random slices for each scanner, both material decomposition images and 120 kVp-like images were rated for overall artifacts (4-Point Likert-scale: none (0), mild (1), moderate (2), severe (3)) on 50 random slices. The value of material decomposition images to assess pseudoenhancement was rated (reveals pseudoenhancement (0), no added value (1), falsely confirms true enhancement (2)). Comparisons between images and scanners were made using ANOVA with Bonferroni correction.

RESULTS

120kVp-equivalent images showed moderate to severe artifacts on all 4 DECT platforms, but were less severe for the DS (1.5±0.84) and SF (1.72±0.78) systems than for SD (2.56±0.73, $p<0.001$) and RS (2.52±0.65, $p<0.001$). Peristalsis artifacts were markedly reduced in iodine images for SD- (1.00±0.08, $p<0.001$) and RS-DECT (1.34±0.07, $p<0.001$), and were unchanged or worse on the VUE images. For DS and SF-DECT artifacts were more severe on both the iodine (2.36±0.14 & 2.6±0.09, respectively) and VUE images (2.38±0.14 & 2.62±0.09, respectively) ($p<0.001$ for each). Iodine images helped reveal true from pseudoenhancement on SL-detector and RS-DECT on all evaluated slices, but at DS and SF-DECT did not exclude pseudoenhancement.

CONCLUSION

DECT scanners reduce bowel peristalsis artifact. For SD and RS-DECT, iodine images minimize peristalsis artifact and reveals artificial hyperdensities as pseudoenhancement. For DS and SF-DECT, mixed 120 kVp-like images are preferred. Inter-scanner differences likely relate to geometry and postprocessing.

CLINICAL RELEVANCE/APPLICATION

Peristalsis artifact reduction is a valuable benefit of DECT, knowledge of scanner-type allows for selection of appropriate image reconstructions to minimize artifact and associated pseudoenhancement.

PURPOSE

To investigate the utility of T1ρ MRI for the assessment of fibrosis in renal allografts.

METHOD AND MATERIALS

T1ρ imaging was performed at 1.5T in 15 patients with stable functional allograft (M/F 9/6, mean age 56y) and 10 patients with chronic dysfunctional fibrotic allograft (M/F 4/6, mean age 50y). Repeatability of the T1ρ measurement, as determined by coefficient of variation (CV) measurements, was tested in 4 patients. Average T1ρ values in ROIs in the cortex and medulla were quantified. Differences in T1ρ values between the groups were assessed using Student t-tests. ROC analysis was employed to determine the diagnostic performance of T1ρ for differentiation between functional and fibrotic allografts. In 12 patients who had renal biopsy within one year of the MRI exam, quantitative analysis of Masson's trichrome stained sections was performed to determine collagen content. The correlation between T1ρ and Masson's trichrome stained fractions was assessed using Spearman correlation analysis.

RESULTS

T1ρ measurements were more repeatable in the cortex than in the medulla (mean CV T1ρ cortex 6.4%, medulla 14.6%). While T1ρ values were not significantly different between functional and fibrotic allografts in the medulla (T1ρ medulla functional 122.6±20.8 ms, fibrotic 128.0±16.9 ms, P=0.503), significant differences were observed in the cortex (T1ρ cortex functional 99.0±11.0 ms, fibrotic 113.3±17.6 ms, P=0.020). ROC analysis showed an AUC of 0.80 (sensitivity 80.0%, specificity 86.7%, T1ρ threshold 106.9 ms) for differentiation between functional and fibrotic allografts. Cortical T1ρ was significantly associated with Masson's trichrome stained fractions (r=0.629, P=0.032).

CONCLUSION

In this preliminary study, we observed significant elevation of cortical T1ρ in fibrotic renal transplants. The significant correlation between cortical T1ρ and Masson's trichrome stained fraction suggests a direct association of cortical T1ρ with collagen content.

CLINICAL RELEVANCE/APPLICATION

T1ρ may be a suitable MRI biomarker for noninvasive assessment of fibrosis in renal transplants.

SSQ09-02 T1-Mapping and Diffusion-Weighted Imaging for Evaluation of Chronic Renal Allograft Rejection in a Translational Mouse Model

PURPOSE

Non-invasive assessment of renal pathology in a mouse model of chronic rejection after allogenic and isogenic kidney transplantation (ktx) using T1-mapping und diffusion-weighted imaging (DWI).

METHOD AND MATERIALS

Chronic rejection was induced by allogenic transplantation of BALB/c-kidneys into C57BL/6-mice with short ischemia times (n=13). Mice after isogenic ktx without rejection (n=8) and non-transplanted, healthy animals (n=22) served as control group. Using a 7T MRI system respiratory-gated DWI- (7 b-values, 0-800 s/mm2) and inversion recovery EPI-sequences (13 inversion times, 30-8000 ms) were acquired 3 and 6 weeks after ktx and in healthy controls. T1-relaxation times and apparent diffusion coefficients (ADCs) were calculated. Mean values and the heterogeneity of parameters within kidneys were determined using ROI- and histogram-based analysis. MRI results were compared to histopathological analysis of inflammation and fibrosis.

RESULTS

Chronic rejection after allogenic ktx was associated with a significant prolongation of T1-relexation time after 3 (1995 vs 1457 ms, p<0.001) and 6 weeks (1899 vs 1397 ms, p<0.001) compared to isogenic kidney grafts. Mean ADC after isogenic and allogenic ktx was similarly reduced compared to healthy controls (week 3: 1.27 and 1.41*10-3 mm2/s vs 1.61*10-3 mm2/s, week 6: 1.39 and 1.44*10-3 mm2/s vs 1.61*10-3 mm2/s). However, in the allogenic group, increased heterogeneity of ADC-values was observed compared to isogenic kidneys (standard derivation, entropy and interquartile range, p<0.001). In accordance with MRI results, only allogenic kidney grafts showed serve inflammation and graft fibrosis (p<0.001 vs controls and isogenic ktx).

CONCLUSION

T1-mapping und DWI enable assessment of renal pathologies in chronic renal allograft rejection. The combined quantitative assessment of mean values and data heterogeneity provides additional information on renal allograft pathology.

CLINICAL RELEVANCE/APPLICATION

Functional MRI allows assessment and monitoring of chronic renal allograft rejection. In patients, it may refine characterization of renal allograft pathology and help to improve patient management.

SSQ09-03 Multiparametric MRI of Renal Transplant: Preliminary Comparison of Advanced MRI Parameters in Renal Transplant Patients with Stable Allograft Function and Chronic Allograft Dysfunction with Established Fibrosis

octavia.bane@mountsinai.org

PURPOSE

The goal of our study is to develop a quantitative multiparametric MRI (mpMRI) protocol for the evaluation of renal transplant fibrosis.

METHOD AND MATERIALS

25 patients including 15 with functional renal allografts (M/F 9/6, mean age 55y, MDRD serum eGFR 47.6-87 ml/min/1.73m2) and 10 with chronic dysfunction and fibrosis (M/F 4/6, mean age 50y, eGFR 11.8-62.7 ml/min/1.73 m2, biopsy 150 ± 48 d before MRI) were enrolled in this prospective study. All patients underwent mpMRI at 1.5T (Aera, Siemens) including intravoxel-incoherent motion DWI (IVIM-DWI), diffusion tensor imaging (DTI), blood oxygen level dependent (BOLD) and T1 mapping. Parameters were measured from circular ROIs placed in the cortex (Cx) and medulla (Med) at the upper, middle and lower renal Tx poles. IVIM-DWI parameters (true diffusion D, pseudodiffusion D*, perfusion fraction PF) were obtained by Bayesian fitting. Corticomedullary differences [100 x (cortex-medulla)/cortex] in ADC (ΔADC), FA (ΔFA), R2* (ΔR2*), and T1 (ΔT1), were calculated. Banff scores ci for interstitial fibrosis (IF), ct for tubular atrophy (TA) and iIFTA for inflammation in area of IF/TA were evaluated by an expert renal pathologist on biopsies from 13 patients (stable/fibrosis 4/9).

RESULTS

Cx ADC (functional/fibrosis 2.10±0.14/1.90±0.15 10-3 mm2/s, p=0.006) and D (functional/fibrosis 1.78±0.16/1.65±0.18 10-3

Cx ADC (functional/fibrosis 2.10±0.14/1.90±0.15 10-3 mm2/s, p=0.006) and D (functional/fibrosis 1.78±0.16/1.65±0.18 10-3 mm2/s, p=0.033) as well as Med ADC (functional/fibrosis 2.07±0.11/1.90±0.13 10-3 mm2/s, p=0.006) were significantly decreased in fibrotic allografts. Cx T1 was significantly elevated (functional/fibrosis 1149.34±185.10/1354.53±226.8ms,p=0.038) and ΔT1 significantly decreased (-36.95±15.14/-11.52±14.62 %,p=0.0031) in fibrotic allografts. Cx D was negatively correlated with ci (Fig. 1; Spearman's r=-0.64, p=0.017), and T1 had a strong positive correlation to ct (Fig. 1; r=0.72, p=0.008).

CONCLUSION

Our study confirms earlier findings of decreased diffusion parameters and ΔT1 with renal allograft fibrosis. The negative correlation of true diffusion coefficient D with IF shows restricted water diffusion due to collagen deposition in fibrosis, while the positive correlation of T1 with the TA score shows prolonged T1 in the context of edema and inflammation associated with TA.

CLINICAL RELEVANCE/APPLICATION

IVIM-DWI and T1 parameters are sensitive to renal allograft fibrosis. The value of MRI metrics in combination for characterizing renal transplant fibrosis will be confirmed in a larger study.

SSQ09-04 High Renal Donor Visceral Adipose Tissue Predicts Decreased Donor Recovery of Function and Functional Decline

wardr3@ccf.org

PURPOSE

High donor Body Mass Index (BMI) has long been recognized as a risk factor for adverse outcomes in kidney donation. Recent data has shown a significant short-term decline in donor renal function in patients with an elevated visceral adipose tissue (VAT) to subcutaneous adipose tissue ratio on preoperative computerized tomography (CT). We evaluated the relationship between donor VAT with histologic changes in the renal allograft and mid-term renal function decline.

METHOD AND MATERIALS

VAT was measured on pre-donation CT scans at a single lumbar level in 210 donors from 2010 to 2015 using semiautomated segmentation (Terarecon). Kidney histology, obtained from implant biopsy during transplant, was available in 162 patients. Chronic histologic change was defined as the presence of at least 2 of the following 3 features: > 5% global glomerulosclerosis, interstitial fibrosis, or arteriosclerosis. The decline in renal function from pre-donation to 2 years post-donation was assessed using estimated glomerular filtration rate (eGFR) with paired T-testing, repeated measures analysis (MANOVA), and linear regression analyses.

RESULTS

Mean donor age was 42 and 60% were female. Mean BMI and VAT were 27±3 kg/m2 and 96±64 cm2, respectively. On univariate linear regression, there was a significant association between elevated VAT and decreased recovery of donor renal function, ($p < 0.0001$, Figure). On MANOVA, high VAT predicted decreased renal recovery at 1, 6, 12, and 24 months (p=0.03). Biopsies from donors with high VAT were more likely to have chronic histologic changes than donors with low VAT ($p < 0.001$). On univariate analyses both BMI and VAT were associated with chronic histologic change and decreased renal function recovery, however, on multivariate analyses VAT remained independently associated with both outcomes, while BMI did not.

CONCLUSION

Preoperative VAT appears to be a more significant indicator of renal decline in living donors than BMI. This is further evidenced by the chronic histologic changes seen in kidneys from donors with high VAT. Morphometrics, including the measurement of VAT, should be incorporated into the standard preoperative evaluation of potential kidney donors.

CLINICAL RELEVANCE/APPLICATION

Elevated preoperative VAT leads to decreased post-operative renal recovery and biopsy findings of chronic histological changes.

SSQ09-05 Preliminary Application of Incoherent Motion Diffusion Weighted Imaging (IVIM) in Renal Function Assessment of Diabetic Nephropathy

Thursday, Nov. 29 11:10AM - 11:20AM Room: S103CD

PURPOSE

To evaluate renal function impairment in patients with diabetic nephropathy using IVIM technology.

METHOD AND MATERIALS

20 patients(average age 56.60±9.38)with clinically diagnosed diabetic nephropathy were enrolled as the observation group, and 20 healthy volunteers(57.60±6.08)as the control group. All diabetic nephropathy patients were enrolled according to laboratory tests of glomerular filtration rate (eGFR) before admission.The IVIM(b=0,50,100,150,200,400,600,800sec/mm²)and Diffusion weighted imaging(DWI,b=50,800 sec/mm²) sequence were obtained on a 3T scanner(Skyra, Siemens Healthineers). A total of 12 regions of interest were drawn for each subject in the cortex and medulla region of the upper pole, the renal hilum and the lower pole of the kidneys.The average value of all results is taken to ensure consistency of measurement results.ADC map was automatically generated on the Siemens MRWP workstation after DWI sequence executed. IVIM parameters(ADC,D,f and D* values) were generated by using a prototype software body diffusion toolbox(Siemens healthineers). A two-sample t-test was used to compare the difference in ADC,D, f, and D* values between the two groups of the cortex and medulla of the observation group and the control group. The Pearson correlation analysis was performed to determine the relationship between the ADC, D, f, and D* values in patients with diabetic nephropathy and eGFR.

RESULTS

In the two groups, the ADC, D, f, and D* values of the renal cortex were higher than that in medulla. Compared with the control group, the ADC, D, F, and D* values of the renal cortex and medulla in the observation group were all decreased, with statistical significance ($p<0.0001$) (Figure 1,Table 1).ADC,D,F and D* values in patients with diabetic nephropathy were positively correlated with glomerular filtration rate. ($p<0.0001$) (Figure 2).

CONCLUSION

IVIM is feasible in the examination of diabetic nephropathy. IVIM can supply useful information for kidney damage cause by diabetic nephropathy. Combined with the eGFR, the progress of diabetic nephropathy can be monitored.

CLINICAL RELEVANCE/APPLICATION

IVIM can help provide a more scientific basis for clinical changes in diabetic nephropathy, reflect the changes in microstructure, and have potential application value in the evaluation of renal function.

SSQ09-06 Magnetic Resonance Magnetization Transfer Imaging in Patients with Diabetic Nephropathy

PURPOSE

Magnetization transfer(MT)technique used in the evaluation of renal function in patients with diabetic nephropathy.

METHOD AND MATERIALS

Two-kidney gradient echo sequence (GRE) imaging was performed on 40 subjects (including 20 patients with clinically diagnosed diabetic nephropathy and 20 healthy subjects) using Siemens Skyra 3.0 T MRI scanner. MT study was conducted using a 3D fast low angle shot(FLASH) sequence, this sequence was run two times; first one without a MT saturation pulse(MToff), second one with a MT(MTon) saturation pulse. For MT imaging postprocessing, MTR =(MToff-MTon)×100/MToff, MTR values were expressed in percentage units.The magnetization transfer rate (MTR) of the renal cortex and medulla was measured on the MT map of each subject using the region of interest method.Multiple regions of interest are drawn and averaged in the medullitary region of the upper kidney, renal hilum, and lower pole.A two-sample t-test was used for statistical analysis. The glomerular filtration rate (eGFR) for diabetic nephropathy patients was recorded and correlation between MTR and eGFR was analysed.

RESULTS

eGFR was significantly reduced in patients with diabetic nephropathy compared to healthy controls. The renal cortical MTR of the diabetic nephropathy group (824.15±77.45)%, was significantly higher than healthy control group(572.60±59.18)% ($P<0.0001$) (Figure 1,Table 1); there was no significant difference about renal medullar MTR between patient and normal groups. Pearson correlation analysis showed that there was a significant correlation between MTR and eGFR in renal cortex of diabetic nephropathy renal cortical($r=-0.880$, $P<0.0001$) (Figure 2).

CONCLUSION

Renal cortical MTR was higher in diabetic nephropathy patients than control subjects, and which has a certain correlation with eGFR.There was no significant change in the medulla MTR between patient and control groups.

CLINICAL RELEVANCE/APPLICATION

MT can provide non-invasive information about renal function, reflect the changes in microstructure.MTR may be a potential use as a observation index during clinical treatment.

SSQ09-07 DTI of the Kidney in Healthy Controls and in Patients with ARPKD

Thursday, Nov. 29 11:30AM - 11:40AM Room: S103CD

Participants

Juan Calle Toro, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose
Suraj D. Serai, PhD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose
Hansel J. Otero, MD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose
Kassa Darge, MD,PhD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose
Erum Hartung, MD, Philadelphia, PA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Diffusion tensor imaging (DTI) has the potential to quantitatively assess the microstructure and morphology of tissues, including kidney. Fractional anisotropy (FA) describes the degree of anisotropy reflecting the fiber density and axonal diameter. Autosomal recessive polycystic disease (ARPKD) causes displacement of coherent renal fiber orientation, which can potentially be measured using DTI. Our aim was to evaluate the feasibility of using DTI and its derived FA values to compare normal controls and patients with ARPKD.

METHOD AND MATERIALS

In this IRB-approved study, we evaluated the use of DTI to compare FA values in 'healthy' controls (patients with no history of renal disease) vs patients with ARPKD. A 20 direction DTI with b-values of b=0 and b=400 s/mm2 was used to acquire data in coronal direction using a fat-suppressed spin-echo echo-planar sequence (TR/TE 2600-3600/64-74 msec). A slice thickness of 4 mm, a matrix size of 128x96, acceleration factor of 2, and a bandwidth of 1698 Hz/pixel were used. For the DTI analysis and segmentation, Diffusion Toolkit version 0.6 and TrackVis version 0.6 were used. Tractography was reconstructed using a deterministic fiber tracking algorithm with a minimum FA threshold of 0.10 and a maximum turning angle of 55° between two adjacent voxels based on published parameters for renal tractography. TrackVis was used to draw ROI covering the entire volume of the renal parenchyma, excluding the collecting system by evaluating the anatomical images, ADC and FA maps. These images were used to avoid problems of alignment related to patient motion in-between sequences. The FA values based on the ROI data, and the mean length and volume of the tracks based on the fiber track data were exported.

RESULTS

14 healthy controls with no known history of renal disease (mean age = 9.5 years ± 3.7; 11/14 females; mean FA =0.47) and 8 patients with ARPKD (mean age = 15.5 years ± 4.7; 2/8 females; mean FA = 0.25) were included in the study. FA values were significantly lower in patients with ARPKD versus controls ($p<0.0001$) (Figure 1).

CONCLUSION

DTI was feasible and successfully performed on kidneys of patients with renal disease. Significantly lower FA values were observed in patients with ARPKD as compared to patients with normal renal function.

CLINICAL RELEVANCE/APPLICATION

DTI of the kidney offers a novel approach for detecting renal disease based on changes in diffusion anisotropy.

PURPOSE

To evaluate whether magnetic resonance T2 mapping of the kidneys can deliver novel and rapidly assessable quantitative imaging biomarkers for monitoring disease severity in patients with ADPKD.

METHOD AND MATERIALS

One-hundred forty-one ADPKD patients from the AD(H)PKD registry and 10 healthy controls underwent magnetic resonance imaging on a clinical 1.5T system. Height-adjusted total kidney volume (htTKV) was calculated on axial T2-weighted images using a standard post-processing platform. T2 mapping was acquired using a Gradient-Spin-Echo (GraSE) T2 mapping sequence covering both kidneys. Kidney cyst fraction and mean T2 relaxation times of both kidneys (kidney-T2) were calculated using a plugin for Osirix. For calculation of T2 times of the residual kidney parenchyma (parenchyma-T2), a region of interest (ROI) was manually placed at 3 distinct slices per kidney and results were averaged over all 6 ROIs. ADPKD patients were divided into 3 groups

according to kidney cyst fraction (<35%, 36-70%, >70%) as a surrogate marker for disease severity and Glomerular filtration rate (GFR) was recorded.

RESULTS

Calculation of parenchyma-T2 was 6- to 10-fold faster than calculation of htTKV and kidney-T2 (0.78 ± 0.14 vs. 4.78 ± 1.17 min., p<.001; 0.78 ± 0.14 vs. 7.59 ± 1.57 min., p<.001). Parenchyma-T2 showed a similar strong correlation to cyst fraction (r=0.77, p<.001) as kidney-T2 (r=0.76, p<.001) and allowed for the most distinct separation of patient groups divided according to cyst fraction (Fig. 1A). In contrast, htTKV showed an only moderate correlation to cyst fraction (r=0.48, p<.001) and did not allow for clear group separation (Fig. 1A). These observations were even clearer when considering only patients with preserved kidney function (GFR > 90 ml/min/m2; n=47; Fig. 1B) with similar correlations to cyst fraction (parenchyma-T2: r=0.81; kidney-T2: r=0.79; htTKV: r=0.48, p<.001 for all).

CONCLUSION

T2 mapping provides interesting novel parameters with potential to serve as quantitative imaging biomarkers in ADPKD. Especially the rapidly assessable parenchyma-T2 shows a strong association with disease severity and is far superior to the established imaging biomarker htTKV.

CLINICAL RELEVANCE/APPLICATION

Parenchyma-T2 has potential to serve as a novel imaging biomarker in ADPKD and should be examined in future studies with respect to its predictive value for disease progression.

SSQ09-09 Assessment of Renal Fibrosis in a Rat Model of Unilateral Ureteral Obstruction with Diffusion Kurtosis Imaging: Comparison with a-SMA Expression and 18F-FDG PET

Thursday, Nov. 29 11:50AM - 12:00PM Room: S103CD

Participants
Anqin Li, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose
Zhen Li, MD, PhD, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose
Daoyu Hu, Wuhan, China (*Abstract Co-Author*) Nothing to Disclose
ziling zhou, wuhan, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

lianqin11@hust.edu.cn

PURPOSE

To investigate the utility of diffusional kurtosis imaging (DKI) magnetic resonance imaging (MRI) in evaluation of renal fibrosis in rats with unilateral ureteral obstruction (UUO).

METHOD AND MATERIALS

Eighteen rats had UUO that was created by complete ligation of the left ureter and three normal rats without UUO were included as control. DKI was performed on a 3.0T MRI scanner before ligation and on days 1, 3, 5, and 7 after ligation. All rats then underwent 18F-fluorodeoxyglucose (FDG) dynamic positron emission tomography (PET) to evaluate metabolic activity in the kidneys, followed by histological analysis to examine a-smooth muscle actin (a-SMA) expression. DKI metrics were assessed among the time points and between both sides, and they were compared with renal function index standardized uptake value (SUV) and expression of the fibrosis marker a-SMA.

RESULTS

The axial kurtosis (Ka) on days 3 and 7, mean diffusivity (MD) on days 1 and 3, and fractional anisotropy (FA) on days 5 and 7 of cortex and medulla between the UUO sides and contralateral sides were significantly different. The medulla MD and FA of the UUO sides on days 1, 3, 5 and 7 were significantly lower than those of normal control group (all $P < .05$). FA of medulla was positively correlated with SUV ($r = 0.826$, $P < .001$), and MD of cortex was negatively correlated with a-SMA expression on the UUO sides ($r = -0.661$, $P = .002$).

CONCLUSION

DKI shows high potential in noninvasive assessment of renal fibrosis induced by UUO.

CLINICAL RELEVANCE/APPLICATION

DKI metrics may be useful noninvasive biomarkers for monitoring the severity of renal fibrosis in patients with chronic kidney disease.

PURPOSE

The purpose of this study is to assess the clinical relevance of focal prostate lesions complementing the PI-RADS scoring method using a Radiomic approach and machine learning systems.

METHOD AND MATERIALS

94 patients with a Contrast Enhanced (CE) multiparametric prostate MR (mpMR) and lesions covering all the PI-RADS score range were collected from the hospital archive. For all the lesions a confirmative biopsy was available. 23 out of 94 patients with PI-RADS score 3/5 (7 malignant and 16 benign) were selected form preliminary tests. PI-RADS score 3/5 represents an intermediate condition associated to diagnostic uncertainty. In this pilot study the analysis was limited to T2 weighted (T2w) and CE sequences. Parametric maps were calculated from CE sequences to spatially characterize the wash in/wash out curves. 700 imaging features were extracted using the PyRadiomics platform from T2w images and parametric maps. Shape, texture and intensity based features were calculated. Using a genetic search method the most discriminating subsets of features were identified using four ML systems: linear discriminant analysis (LDA), k-nearest neighbour (kNN), naive Bayes classifier (NB) and C4.5 decision tree. Classification accuracy was evaluated by 5 fold cross-validation.

RESULTS

LDA showed the best performances with 100% sensitivity and 94% specificity. KNN, ND and C4.5 provided 86%, 86% and 71% sensitivity and 100% specificity. Selected features derived both from T2w images and from parametric maps. In particular average and maximum enhancement maps and time-to-peak maps seems to provide the most useful information.

CONCLUSION

Preliminary analysis limited to patients with PI-RADS 3/5 score (n=23) showed promising results, encouraging further development of a Radiomic approach complementing the PI-RADS scoring method.

CLINICAL RELEVANCE/APPLICATION

The identification of malignancy within suspicious prostatic lesions classified by the proposed mpMR radiomic approach can improve the diagnostic workflow while minimizing procedure invasiveness.

SSQ10-03 Manual Versus Robotic Assisted MRI Guided Prostate Biopsies

andrea.masperi@ieo.it

PURPOSE

To compare the procedure time and the percentage of positive samples per prostate cancer (PC) patient between manual and robotic in-bore MR guided prostate biopsy (MR-PB).

METHOD AND MATERIALS

All consecutive in-bore MR-PB performed in our Institution between January 2015 and March 2018 using either a manual or robotic device were retrospectively analyzed and grouped as follows: Group 1, the first 30 consecutive MR-PBs using a manual device (n=30); Group 2, the last 30 MR-PBs performed using the manual device after 2 years of experience (n=30); Group 3, the first 27 biopsies using a robotic device (n=27). The same 1.5 T MRI scanner was used for all MR-PBs. For each of the three groups, we calculated the overall procedure time, time to first biopsy and time for every additional sample, as well as the percentage of positive cores in patients who were diagnosed with PC.

RESULTS

Average overall procedure time was 57.5min (Interquartile range -IQR-: 47-63.5min; Group 1), 37.7min (IQR:31-43min; Group 2) and 31.1min (IQR:27.3-35min; Group 3); average time to first biopsy was respectively 29.4min, 22.5min and 26.5min; average time for every additional sample was 9.5min, 4.9min and 3.8min. 12 patients were positive for PC in Group 1 (average core involvement 44.6%), 19 in Group 2 (average core involvement 52.3%) and 16 in Group 3 (average core involvement 52.1%), with a percentage of positive cores per PC patient of 76.31%, 73.7% and 83.8%, respectively.

CONCLUSION

MR-PB using a robotic device decreased procedure time and increased the percentage of positive cores per PC patient. This has the potential to improve patient comfort as well as PC characterization in clinical practice.

CLINICAL RELEVANCE/APPLICATION

Robotic devices for in-bore MR guided prostate biopsy decrease the procedure time and increase accuracy of samples, thus facilitating its application in clinical routine.

SSQ10-04 Free-Hand Transperineal MRI/US Fusion-Guided Targeted Biopsy with Virtual Navigation Platform in the Diagnosis of Clinically Significant Prostate Cancer: Preliminary Experience

Thursday, Nov. 29 11:00AM - 11:10AM Room: S102CD

elena.bertelli3@gmail.com

PURPOSE

Free-hand transperineal MRI/US fusion-guided targeted biopsy (fhTFTB) is a promising technique that may reduce biopsy core's number, possible complications and overdiagnosis/overtreatment. The aim of this study was to evaluate the impact of fhTFTB with virtual navigation platform in the diagnosis of clinically significant prostate cancer (csPCa).

METHOD AND MATERIALS

We retrospectively selected 68 patients with a positive MRI result (PIRADS v2 score >=3) who underwent fhTFTB, from 160 prostate multiparametric MRI performed for suspicious PSA levels. fhTFTB included 3-4 targeted cores for each lesion plus at least 8 random cores and was performed under local anesthesia.

RESULTS

Overall biopsy detection rate (DR) was 63% and the Gleason Score (GS) was >=7 in 47% (32/68). In all patients with a positive histopathological report, PCa was detected in at least one of the targeted cores and in one or more random cores in 13/43 patients (30%). PCa was identified in 41/52 patients with a PIRADS score >=4, so the DR was 79% in PIRADS 4 patients, 100% (16/16) in PIRADS 5 and 12,5% (2/16) in PIRADS 3. Among the PIRADS 5 patients the 93,8% of them had a csPCa, followed by the 44% and the 6% in those with a PIRADS score of 4 and of 3, respectively. Overall, the 60% of patients with a csPCa had a PIRADS score >=4. 30/68 patients had anteriorly located lesions on MRI, the 70% (21/30) of them had a positive histopathologic report. No major complications were noted. Overall mean biopsy time was 40 minutes.

CONCLUSION

In our experience, fhTFTB with virtual navigation platform is a valid tool in the diagnosis of csPCa. Thus, biopsy technique is fast, safe and cost effective. Moreover, a transperineal approach provides an accurate sampling of anteriorly located prostate lesions. A follow-up is necessary in patients with a negative histopathological report.

CLINICAL RELEVANCE/APPLICATION

Free-hand transperineal MRI/US fusion-guided targeted biopsy with virtual navigation platform is a fast, safe and cost-effective technique for the diagnosis of clinically significant prostate cancer.

SSQ10-05 Interreader Variability of Radiologists in Segmentation of the Prostate and Its Anatomic Zones: How Good Does Artificial Intelligence Have to Become?

Thursday, Nov. 29 11:10AM - 11:20AM Room: S102CD

Participants
Anton S. Becker, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose
Krishna Chaitanya, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Khoschy Schawkat, MD, Bern, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Andreas M. Hoetker, MD, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Ender Konukoglu, Sophia Antipolis, France (*Abstract Co-Author*) Nothing to Disclose
Olivio Donati, MD, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To investigate interreader variability of radiologists in segmenting prostatic contours and anatomical zones of the prostate on prostate MRI and compare it to published accuracy metrics of segmentation algorithms in the machine learning literature.

METHOD AND MATERIALS

In a retrospective search, we collected 67 patients who had undergone prostate MRI for workup of suspected prostate cancer at our institution. Three board certified radiologists with extensive experience in multiparametric prostate MRI segmented the prostate into two distinct zones: Peripheral (PZ) and transitional zone (TZ). The central zone and AFMS were counted as transitional zone. Furthermore, the seminal vesicles (SV) were segmented. We used the open-source software ITK-snap for segmentation. Interreader variability/congruence of segmentations was assessed with the dice coefficient. For the descriptive statistics, median and interquartile range (IQR = 1st-3rd quartile) were computed.

RESULTS

Highest agreement was found for the TZ with a median dice coefficient of 0.85 (IQR: 0.80-0.89), 0.85 (0.81-0.89) and 0.85 (0.80-0.89). The dice coefficients for the SV were 0.81 (0.75 - 0.85), 0.77 (0.72-0.82) and 0.76 (0.70-0.84). For the the PZ, the Dice coefficients were 0.77 (0.71-0.81), 0.75 (0.70-0.79) and 0.74 (0.69 - 0.79). Variability was low when considering all structures with dice coefficients of 0.89 (0.86-0.91), 0.88 (0.85-0.90) and 0.87 (0.86-0.91).

CONCLUSION

There is considerable variability in expert segmentation of the prostate into its anatomic zones. Variability between different lies within or slightly below published performance of state-of-the-art algorithms in methods using artificial intelligence.

CLINICAL RELEVANCE/APPLICATION

Physicians treating men with prostate cancer by means of focal therapy should be aware that there is a small but considerable variability in segmentation of the prostate even if performed by expert radiologists. Future machine learning research should focus on robustness rather than achieving 'perfect' accuracy for segmentation.

SSQ10-06 Magnetic Resonance Elastography of the Prostate: Feasibility of Using High-Frequency Transurethral Vibrations.

wangjin3@mail.sysu.edu.cn

PURPOSE

To demonstrate the feasibility and diagnostic value of magnetic resonance elastography (MRE) in evaluating prostate disease using high-frequency transurethral vibrations.

METHOD AND MATERIALS

Following ethics committee approval with a waived informed consent requirement, 23 patients were enrolled in this study. The patients had a silicone urinary catheter in place and underwent prostate MRE with 60-, 90-, 120-, 150-, and 200-Hz vibration frequencies using a transurethral driver developed at Mayo Clinic. These patients were divided into three groups: 12 patients with benign prostatic hyperplasia (BPH), 5 with clinically significant prostate cancer (PCa) and 6 with prostatitis. The success of prostate MRE was defined as having visually detectable wave propagation in the prostate. The MRE-processing confidence map was used to summarize the MRE image quality. The stiffness of the prostate was recorded. The MRE confidence and stiffness were compared across the different frequencies. Receiver operating characteristic (ROC) analysis was performed to assess the diagnostic performance for detecting clinically significant PCa.

RESULTS

From 60 to 150 Hz, all MRE acquisitions with the transurethral driver were successful, but 13 cases failed at 200 Hz (Figure 1). The confidence values were significantly lower at 60 and 90 Hz than at 120 and 150Hz (all pairs $P<0.001$). The stiffness of clinically significant PCa was significantly higher than the peripheral zone (PZ) of BPH at each frequency, and higher than prostatitis and the

central gland (CG) of BPH at 90 and 120 Hz (all $P<0.05$). The sensitivity, specificity and accuracy for differentiating PCa from other tissues are shown in Table 1.

CONCLUSION

Prostate MRE using a transurethral driver had a 100% success rate in this study using vibration frequencies of 60-150 Hz, however image quality is better at higher frequencies (120, 150Hz). Prostate MRE may have the potential to differentiate PCa from BPH and prostatitis at these higher frequencies. Additional studies are warranted to investigate its utility.

CLINICAL RELEVANCE/APPLICATION

This study presents a potentially new approach for performing prostate MRE with high resolution using a transurethral driver at high vibration frequencies.

SSQ10-08 To Evaluate the Role of Gallium-68 PSMA PET/CT Scan For Prostate Cancer

Thursday, Nov. 29 11:40AM - 11:50AM Room: S102CD

Participants
Sikandar M. Shaikh, DMRD, Hyderabad, India (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

idrsikandar@gmail.com

PURPOSE

Prostate cancer is one of the commonest biologically and clinically a heterogeneous disease in males which has varied diagnostic challenges. The biggest challenge in this is to detect recurrent disease. Biochemical response using Prostate Specific Antigen (PSA) and various imaging modalities including F FDG PET-CT has limited role as most of them have poor sensitivity and specificity. Thus we evaluated the role of Ga68-PSMA (Prostate Specific Membrane Antigen) imaging in prostate cancer, which is a new PET tracer.

METHOD AND MATERIALS

We evaluated Ga68-PSMA PET scans of 65 patients with diagnosed prostate cancer. Whole body PET-CT was done after injecting Ga68-PSMA for either staging or re staging to evaluate the response to therapy.

RESULTS

65 PSMA scans were performed initially . Ga68-PSMA scan showed more number of areas involved by extra-prostatic disease in 53.2% of cases when done at baseline before commencing any treatment. The sensitivity of Ga68-PSMA at baseline when compared with histopathological diagnosis was 95% with 95% CI ranging from 86% to 98%. The positive predictive value was high at 98% with 95% CI ranging from 91% to 99%. In 7 (12%) patients who underwent surgical management post therapy Ga68-PSMA scan was able to detect disease progression / post surgical relapse in 100% of cases. The outcome of post surgical prostate cancer was compared with other cases where surgery was not done. In those who did not surgery due to higher staging these cases showed better response by hormone therapy (p 61; 0.03) and radiotherapy (p 61; 0.01) on Ga68-PSMA. The sensitivity of Ga68-PSMA response with biochemical response was 66.7% with 95% CI ranging between 46 %- 82.7%. Ga68-PSMA response did not correlate with biochemical response.

CONCLUSION

Thus Ga68-PSMA has very good sensitivity for diagnosis, staging, restaging, evaluation of therapy response and prognostication in prostate cancer.

CLINICAL RELEVANCE/APPLICATION

Thus PET-CT PSMA has very high sensitivity as compared with F FDG PET-CT.

SSQ10-09 Technique and First Results: Targeted MRI and [68Ga]-PSMA PET/MRI Ultrasound Fusion-Guided Transperineal Prostate Biopsies

Thursday, Nov. 29 11:50AM - 12:00PM Room: S102CD

PURPOSE

The aim of this study was to examine whether patients with elevated PSA-levels benefit from targeted MRI and [68Ga]-PSMA PET/MRI ultrasound fusion-guided biopsies, compared to systematic saturation biopsy.

METHOD AND MATERIALS

This retrospective study evaluated 219 patients with increased PSA-level (median PSA 8.3ng/ml) examined according to a multiparametric prostate protocol on a 3T MR-scanner (PI-RADSvs2). Additionally, 23 patients were examined on an integrated 3T PET/MRI-scanner. [68Ga]-PSMA-11 PET/MR-images were assessed for major functional (SUVmax) and for morphological variables (e.g.lesion delineation, diffusion restriction). All patients underwent systematic transperineal prostate biopsy and targeted MRI biopsy using rigid image-fusion (MiM software, USA) in case of PI-RADS 3-5 lesions (median 26 systematic cores and 9 targeted cores). Detection rates for prostate cancer (WHO grading system) of MRI and [68Ga]-PSMA-11 PET/MRI targeted ultrasound fusion-guided biopsies were compared to systematic transperineal saturation prostatic biopsy.

RESULTS

Altogether 5979 systematic cores, 1407 MRI-targeted cores and 217 PET/MRI-targeted cores were obtained. Per core targeted MRI ultrasound fusion-guided biopsy (35%, positive target lesions 247/716) and [68Ga]-PSMA PET/MRI ultrasound fusion-guided biopsy (48.5%, positive target lesions 49/101) showed a significantly higher detection rate of prostate cancer than non-targeted systematic biopsies (17.5%, positive systematic cores 492/2800). Altogether 2287 systematic biopsy cores revealed no atypical proliferation compared to 726 MRI- and PET/MRI-targeted cores. In the saturation prostatic biopsy histological grading was distributed as follows: grade groups (1) 15.7%; (2) 32.7%; (3) 14.3%; (4) 5.8% and (5) 2.5%. MRI- and PET/MRI-targeted biopsies identified clinically significant prostate cancer with following histological distribution: grade groups (1) 19.7%; (2) 30.1%; (3) 14.8%; (4) 6.6% and (5) 9.5%.

CONCLUSION

The [68Ga]-PSMA PET/MRI ultrasound fusion-guided biopsy is a promising technique for histological tissue verification. It contributes to accurate prostatic biopsies at a considerably lower level of biopsy tissue cores.

CLINICAL RELEVANCE/APPLICATION

Patients with elevated PSA-levels may benefit from targeted MRI- and PET/MRI ultrasound fusion-guided biopsy by a lower biopsy strain and at the same time by a higher confidence for targeting clinical significant prostate cancer.

dvining@mdanderson.org

CONCLUSION

Structured reporting provides a means to prompt radiologists to record essential information to describe disease processes, and when applicable, automate the determination of -RADS assessment categories.

Background

With the success of BI-RADS for improving mammography report quality, there has been a proliferation of other -RADS schema including C-RADS, CAD-RADS, HI-RADS, LI-RADS, Lung-RADS, NI-RADS, PI-RADS, and TI-RADS. Unless a radiologist is well-versed in one of these practice areas, it is often difficult to recall the details of a particular -RADS schema. We have developed a structured reporting system that prompts a radiologist to record salient disease features, and when applicable, automate the determination of the appropriate -RADS assessment category based on the recorded disease features.

Evaluation

We developed a structured reporting system that captures key images and verbal descriptions of image findings, tags the finding with metadata describing the anatomical location and radiological finding using natural language processing, and assembles a multimedia report. When a particular finding is recorded (e.g., lung nodule or colon polyp), the system prompts the radiologist with menus to record certain disease features. If the radiologist mentions the features in the dictation, the system will automatically populate the appropriate fields using natural language processing. If the radiologist fails to mention particular features, the radiologist can then select them from the menu display. Upon completion of data entry, the system automatically calculates the appropriate -RADS assessment category based on the anatomy and findings for inclusion in the Impression section of the structured report.

Discussion

The various -RADS schema are intended to improve the content and clarity of radiology reporting, especially for the communication of suspicious findings during screening examinations. However, these schema are difficult to recall for most radiologists unfamiliar with the details of how they are implemented. We demonstrate that a structured reporting system that records discrete features of disease can be used to automate the determination of the appropriate -RADS assessment category.

SSQ11-02 The MESH Incubator: Accelerating Core Competency in Technological Innovation, Artificial Intelligence, and Design Thinking in Radiology Training

Thursday, Nov. 29 10:40AM - 10:50AM Room: S103AB

msucci@mgh.harvard.edu

CONCLUSION

The MESH Incubator and MESH Core Innovation Design Curriculum rotation demonstrates that education in technological innovation, informatics, and artificial intelligence is in high-demand by radiology trainees.

Background

Radiology lacks core competency training in the basic tenants of innovation. This includes but is not limited to training in idea generation and validation, artificial intelligence and informatics, device and software prototyping, intellectual property, and entrepreneurship. To elevate radiology's position as a value-player in the evolving healthcare reimbursement landscape landscape, we must train our residents, fellows, and staff in these fundamental competencies.

Evaluation

The Medically Engineered Solutions in Healthcare (MESH™) Incubator was created at an academic radiology training program. MESH is a novel innovation center initially composed a physical invention workshop integrated in the clinical reading room and an innovator lecture series to foster industry alliances. At the one-year point, we conducted a Likert survey of current radiology residents, building on prior feedback. Key metrics revealed that 100% had little or no idea how to develop and idea from bedside to prototype, 95% had little or no understanding of 3-D printing and its clinical use in radiology, and 50% planned to be involved in a startup in the future. Notably, 75% agreed or strongly agreed that core competency in technological innovation should be part of the residency curriculum. Based on this feedback, a novel resident rotation in technological innovation, artificial intelligence, and informatics was designed. Qualitative and quantitative performance measures were collected.

Discussion

The MESH Core Innovation Design Curriculum is the first core curriculum in technological innovation in any residency program. MESH also includes a technological prototyping workshop and lecture series to foster product creation, intellectual property licensing, and industry collaboration. Our data demonstrates a clear desire by our trainees to institute core competency in technological innovation as part of the radiology training.

SSQ11-03 Medical Students' Attitude Towards Artificial Intelligence: A Multicenter Survey

PURPOSE

Artificial intelligence (AI) and deep learning have recently gathered a lot of attention in radiology. Some senior radiologists describe being approached by students asking whether choosing radiology training could be a mistake considering that algorithms could potentially take over the task of interpreting images. However, apart from anecdotal episodes little is known about how students feel with respect to AI and deep learning in radiology and medicine.The aim of this study was therefore to perform a questionnaire-based survey amongst students and to assess their attitude towards these topics.

METHOD AND MATERIALS

A questionnaire was designed and implemented in SurveyMonkey (Surveymonkey, Portland, Ore). The questionnaire consisted of various parts (demographics, self-assessment, potential application of artificial intelligence in radiology, attitude towards artificial intelligence in radiology and medicine in general). A corresponding link was sent out via email to students of three major medical schools.

RESULTS

A total of 263 students responded (166 female, 94 male, median age 23 years). Around half (52.8%) were aware that AI is being discussed in radiology, but only around one third (30.8%) stated that they had a basic understanding of the technologies involved.The majority of students agreed that AI could be able to detect pathologies in imaging exams (83.7%) but only around half agreed that it would be able to automatically make a diagnosis (56.7%).While the majority was convinced that AI will revolutionize radiology and medicine in general (77.2% and 73%), they were confident that radiologists and physicians will not be replaced in the foreseeable future (82.9% and 96.6%). There was strong agreement that the use of AI will lead to improvement in care (85.5% and 83.6%).Most respondents agreed on the need of AI being included in medical training (70.1%).

CONCLUSION

Contrary to the what could have been expected, medical students are quite aware of the potential of AI in radiology and medicine but do not expect radiologists or physicians to be replaced in the foreseeable future. Basic principles of AI and computer science should be included in medical curricula.

CLINICAL RELEVANCE/APPLICATION

As one of the first subspecialties to broadly discuss the impact of artificial intelligence on medicine, radiology should take the lead in educating students on these emerging technologies.

SSQ11-04 Thyroid Nodule Biopsy: A Novel Mobile Phone App to Facilitate and Standardize the Decision Making Process

CONCLUSION

This study presents a novel mobile phone App which simplifies and standardizes real-time decision making on when to proceed with thyroid nodule FNAC, providing the clinican with a user-friendly tool to assess thyroid nodules and provide guideline supported clinical practice.

Background

Thyroid nodules are prevalent and demonstrate a wide spectrum of sonographic characteristics. No single feature is pathognomonic of malignancy. The decision on when to proceed to fine needle aspiration cytology (FNAC) is not clear-cut, and is facilitated by a large number of international guidelines which mostly use a pattern-orientated approach. As such, they are difficult to apply in real-time in the clinical setting and can lead to interuser variation.We introduce a novel locally-derived mobile phone application ('App') to streamline this process.

Evaluation

We present an App which guides the user through the evaluation of a thyroid nodule using multiple parameters with pictorial examples (including consistency, heterogeneity, edge, margin, halo, echogenicity, vascularity and calcification) which feature in the risk stratification process of international guidelines (ACR-TIRADS, ATA 2016, ASRU 2005, AACE 2016, BTA 2014, Kim 2002, Korean 2016, Zayadeen 2016, Sanchez 2014, Russ 2011, EU-TIRADS 2017 and Kwak 2011). On completion of nodule assessment, a summary table provides the recommendation (in Yes/No format) of the international guidelines on whether to proceed with cytological sampling. An overall consensus recommendation is also provided. A worked through sample case would be presented to demonstrate the App in use, and highlight it's ease and swiftness of use.

Discussion

Numerous international guidelines, each with their strengths and limitations, have attempted to simply the decision making process on when to perform thyroid nodule biopsy. This novel App both simplifies and standardizes this process, providing the user with guideline supported practice that limits unnessary sampling of benign nodules without missing biologically active malignancy.

SSQ11-05 Advancing Interoperability of Image Annotations: Automated Conversion of Image Annotations in PACS to the Annotation and Image Markup Format for Longitudinal Lesion Tracking

Thursday, Nov. 29 11:10AM - 11:20AM Room: S103AB

CONCLUSION

As quantitative imaging becomes more prevalent in radiology, interoperability of image annotations gains increasing importance. Our work provides a mechanism to leverage image annotations in vendor systems and utilize it in automated lesion tracking. Our approach may facilitate large-scale analysis of image annotations and aid in the generation of high-quality labels for deep learning.

Background

Sharing radiologic image annotations among multiple institutions is important in many clinical scenarios such as tracking cancer lesions; however, interoperability is prevented because different vendors' PACS store annotations in non-standardized, proprietary formats. Interoperability of image annotations is also crucial for data sharing efforts such as the RSNA Image Share initiative and for mining training data for deep learning efforts. Our goal was to develop software to automate conversion of image annotations in a commercial PACS to the Annotation and Image Markup (AIM) standardized format and match lesion measurements across timepoints to enable lesion tracking.

Evaluation

Utilizing the Pixelmed toolkit for DICOM and AIM application programming interface (API), we created software in Java to parse the DICOM presentation state (DPS) objects for imaging studies exported from a commercial PACS (GE Centricity v3.x). Our software

identifies line annotations encoded within the DPS objects and exports the annotations in the AIM format. A separate Python script processes the AIM annotation files to match line measurements (lesions) across timepoints by tracking the 3D coordinates of annotated lesions. To validate the interoperability of our approach, we exported annotations from Centricity PACS into ePAD (http://epad.stanford.edu), a freely available AIM-compliant workstation, and the lesion measurement annotations were correctly matched across timepoints.

Discussion

Our work demonstrates that proprietary image annotations in a vendor system can be automatically converted to a standardized metadata format such as AIM, enabling interoperability and automated lesion matching across timepoints. Conversion of AIM to DICOM-SR is also possible. This effort could be extended for use with other vendors' PACS.

CONCLUSION

We demonstrate that a linear SVM classifier with TF-IDF on bag-of-words embeddings can predict the need for intravenous contrast for CT examinations with high accuracy.

Background

Incorrect ordering of CT contrast by clinicians leads to unnecessary communication between radiologists and clinicians. An automated tool for determining contrast assignment would reduce incorrect contrast ordering and increase workflow efficiency. We developed a natural language processing (NLP) model to predict whether intravenous contrast is needed for various CT examinations, based on free-text clinical history provided by requesting physicians.

Evaluation

We extracted 15,456 reports of CT studies from a single institution. A radiologist labeled each unique study type with ground truth label of whether the study was a contrast enhanced one or not. For each report, the clinical history was extracted and preprocessed using word normalization, negation detection with NegEx, stopword removal, and replacement of synonyms using RadLex. The dataset was then split into 80% training and 20% test sets. We trained a text classification model with a linear support vector machine (SVM) classifier on term frequency - inverse document frequency (TF-IDF) vectors constructed from bag-of-words representations of the clinical history. The test set consisted of 2,767 clinical histories with corresponding ground truth label of CT contrast assignments. Various accuracy measures of the machine learning classifier were reported.

Discussion

The model achieved an AUC value of 0.89 on the ROC space, an F1 score 0.86 along with 81% recall, and 90% precision. Most important words for contrast studies were 'PE, abscess' while for no contrast studies were 'low dose, fall' (Figure 1). Data visualization with latent semantic analysis confirmed adequate separation of contrast vs no contrast categories. Error analysis by clinical radiologist revealed that the most important and inherent limitation of the prediction was due to inadequacy of provided clinical history (e.g. 'pain' as clinical history).

SSQ11-07 Biomarker Assessment Tool for Evaluation of Treatment Response

Thursday, Nov. 29 11:30AM - 11:40AM Room: S103AB

daniel.l.rubin@stanford.edu

CONCLUSION

Assessing the treatment response is important for decision making in clinical trials and tools are needed to automate computation and comparison of different imaging biomarkers of response. Our plugin to ePAD permits computing and comparing imaging biomarkers for assessing treatment response.

Background

Imaging biomarkers are key indicators of the response of cancer to treatment. Although tumor size is the most commonly used biomarker that is used in criteria such as RECIST, it is recognized that simple linear measures are limited, and there is great interest in acquiring data to validate the utility of new imaging biomarkers. Our objective is to develop tools to streamline capturing these data in large scale as part of routine workflow of viewing and evaluating cancer images.

Evaluation

The electronic Physician Annotation Device (ePAD) is a web-based quantitative imaging platform that allows researchers to view and annotate radiological images, and it is extensible through a plugin mechanism. We developed an image annotation and analysis plugin for ePAD that computes image biomarker assessments in longitudinal imaging studies and analyzes and compares treatment response based on those image biomarkers by producing waterfall plots of cohort-based response. We evaluated our plugin by collecting 8199 annotations in ePAD from 419 cancer patients who had one baseline and several follow up CT scans. Our plugin generated waterfall plots using longitudinal measurement (RECIST criteria) and standard deviation of pixel intensity as an alternative biomarker. The output plots produced by our ePAD plugin permits comparing different imaging biomarkers in terms of effectiveness in showing treatment response (see Figure 1).

Discussion

Our ePAD plugin permits automated summary of the response of patient cohorts to treatment (see Figure 1) as well as comparing response based on using different imaging biomarkers of response. It may thus give valuable insight to the effectiveness of different imaging biomarkers for use in clinical trials. The charts can also be exported easily to be used in radiology reports.

SSQ11-08 Natural Language Processing for Automated Radiology Pathology Correlation of PIRADS and TIRADS Lesions

Thursday, Nov. 29 11:40AM - 11:50AM Room: S103AB

Participants
Geoffrey D. McWilliams, DO, Sacramento, CA (*Presenter*) Nothing to Disclose
Thomas W. Loehfelm, MD, PhD, Atlanta, GA (*Abstract Co-Author*) Nothing to Disclose

CONCLUSION

Using NLP and structured reporting, radiology and pathology report data can be mined to automate performance outcome tracking.

Background

Structured reporting systems convey estimates of malignancy risk for thyroid nodules (TIRADS) and prostate lesions (PIRADS). There is no automated system to track biopsy yield and link those results back to the structured radiological estimate. Such a tool would be invaluable for individual and group-level performance metrics. We describe a method involving natural language processing (NLP) to extract malignancy risk estimates from radiology reports and cancer diagnoses from pathology reports.

Evaluation

Using cTAKES, an open-source NLP tool for clinical text, we analyzed more than 120,000 radiology and pathology reports, sampled from the previous 5 years at our institution. We first segmented the reports using regular expressions. Then with NLP, we identified unique anatomic concepts referring to prostate and thyroid tissue by mining them from the "specimen" section of pathology reports. Next, from the "diagnosis" section of the pathology reports, we mined unique disease/disorder concepts which referred to clinically significant malignancy. We then extracted PIRADS and TIRADS classifications from structured radiology reports using basic RegEx pattern matching.From these sets of annotations, we can correlate the radiologist's estimate of malignancy with the biopsy or resection rate, and with rate of malignancy detection. This information is provided in an easy to use dashboard that provides radiologists with automated feedback on their diagnostic accuracy, including anonymous comparisons with their peers.

Discussion

This system makes performance outcomes easily trackable by radiologists. We expect that by providing radiologists with feedback on pathology outcomes from their diagnoses, radiologists will ultimately improve their performance. We plan to expand this system to other risk stratification systems (e.g. BIRADS, LIRADS), and eventually to all diagnostic reports by linking pathology specimens to anatomic terms and organ-specific disease entities used in radiology reports.

SSQ11-09 RapRad: Validation of an E-Learning Platform with Gamification, Rapid Case Reading, and Instant Gratification

Thursday, Nov. 29 11:50AM - 12:00PM Room: S103AB

Participants
David J. Winkel, MD, Basel, Switzerland (*Presenter*) Nothing to Disclose
Philipp Brantner, MD, Basel, Switzerland (*Abstract Co-Author*) Nothing to Disclose
Tobias Heye, MD, Basel , Switzerland (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

davidjean.winkel@usb.ch

PURPOSE

The rise of social media with seemingly shorter attention span prompts e-Learning platforms to motivate and engage users during participation. The purpose of this study was to validate a new e-Learning concept featuring gamification elements, rapid case

reading, a large case number and instant feedback.

METHOD AND MATERIALS

An e-Learning concept was devised offering various game levels, blocks of questions to be read in rapid succession with instant feedback, health/experience points to be gained/lost and player level-up, if successful. The first version focusses on training pneumothorax detection in 321 cases. The user's task is to locate the pneumothorax, if present, on chest x-rays by mouse click; receives instant feedback per case. The levels were designed as follows: entry test (n=15), three training levels with increasing difficulty and a final test (n=30; 15 entry test + 15 new cases). 126 participants (medical students, 1st-year radiology residents and technicians) were invited to participate via e-Mail and asked to fill in a survey before and after playing the game.

RESULTS

59 participants responded to the first survey and finished the game (47%), while 29 of these responded to the second survey after completion the game (49%). Confidence in pneumothorax detection improved significantly from 4.3 ± 2.1 to 7.3 ± 2.1; $p < 0.01$ (mean+/-SD, 10-point scale, 10 highest score) after using RapRad. 97% of the participants would recommend the use of RapRap to others; 93% would use RapRap for learning purposes again; 86% had fun using RapRad (7% neutral, 6% negative) and 62% indicated their interest in Radiology increased (28% neutral, 7% negative). The error-rate, number of failed attempts to answer a question correctly, was 38.8% for the entry test and 21.8% for the final test following training.

CONCLUSION

The RapRad e-Learning concept is capable of improving diagnostic confidence, reducing error rates and offering fun in the interaction with the platform.

CLINICAL RELEVANCE/APPLICATION

Gamification elements and rapid case reading e-Learning can assist residency training by offering fun elements, friendly competition and promote an accelerated learning curve.

kaiyuediao@qq.com

PURPOSE

The purpose of this study was to test if the distribution of creatine shown on Chemical Exchange Saturation Transfer (CEST) MRI could differentiate infarct myocardium from the normal on pigs, by referring to LGE images and pathologic results.

METHOD AND MATERIALS

We prospectively enrolled 27 Bama miniature pigs. MI model was built by applying a ligation at the remote ending of the left anterior descending artery. CMR scan was arranged at 3 days and 2 months later for the AMI and CMI group on a 3 T whole-body scanner. A single SAX slice was used for CEST scanning by using Amide proton transfer (APT) sequence before the injection of contrast. 36 samples were collected from a saturation frequency offset from -5.0 ppm to + 5.0 ppm. The scanned pigs were humanely euthanized under deep anesthesia with KCl and the heart was excised. Triphenyl tetrazolium chloride was used to manifest the infarcted region. CEST values at the frequency of ~1.8ppm, ~2.5ppm, ~2ppm and ~3ppm were recorded respectively for each pig and Color code map was plotted based on the CEST values at a frequency offset of ~1.8ppm (Matlab). Statistic analysis was performed on R project.

RESULTS

A total of 5 AMI pigs (M, 7 months, 16.6 ± 1.2 kg), and 14 CMI pigs (M, 9 months, 27.8 ± 2.1 kg), were finally included. Statistic differences were observed for Cr, ATP, and Glu between the infarct myocardium and the normal myocardium for CMI pigs, while only Cr and ATP for AMI pigs. The color code CEST maps showed a prominent larger abnormal region with a lower concentration of creatine than the MI regions recognized on the LGE sequences and the pathology images.

CONCLUSION

This study demonstrated that the metabolic conditions measured on CEST imaging could be used for infarcted myocardium recognition and the region of myocardium with a lower creatine concentration was larger than the region confirmed with infarction, which again provided proof of the existence of the injured or stunned myocardial tissue surrounding the infarction region.

CLINICAL RELEVANCE/APPLICATION

CEST MRI provided a promising invasive way to observe metabolism status of infarcted myocardium and further studies on MI patients would be needed to validate its clinical application.

SSQ12-02 Molecular Lumbar Intervertebral Disc Alterations in Patients with Leg Length Discrepancy Before and After Therapy

Thursday, Nov. 29 10:40AM - 10:50AM Room: S504CD

christoph.schleich@med.uni-duesseldorf.de

PURPOSE

Leg length discrepancy (LLD) is a frequent incidental finding during orthopedic physical examination and can be found in about two-thirds of the population without any physical complaints. According to recent studies, LLD greater than 10 mm could be a predisposing factor for early degenerations of lumbar intervertebral discs or vertebral facet joints. However, the need of its treatment is still controversial. Previous findings suggest that degeneration of the lumbar disc correlates with a decrease of glycosaminoglycan content (GAG). The purpose of this study was to elucidate the effect of LLD on GAG content in lumbar discs and to show therapy effects after the usage of shoe inserts and physical therapy.

METHOD AND MATERIALS

11 patients (25.6 ± 4.3 years) with LLD greater than 10 mm and 14 control subjects (23.9 ± 3.5 years) without LLD were examined using a 3T MR scanner. 8 patients were re-examined 6 months after physical therapy and the usage of shoe inserts. Morphological T2-weighted sequences in sagittal and transversal orientation and Glycosaminoglycan chemical exchange saturation transfer (gagCEST) sequence were performed. Subjects with bulged or herniated discs were excluded.

RESULTS

Nucleus pulposus-gagCEST values of L5/S1 disc were significantly lower in patients with LLD compared to control group ($p = 0.0008$). For all other disc levels, no significant difference was found. At follow-up, no significant difference of NP-gagCEST values at baseline and 6 months after therapy could be found ($p > 0.05$).

CONCLUSION

This study supports the hypothesis that LLD greater than 10 mm could be a predisposing factor for early molecular alterations of lumbar discs of L5/S1. Remarkably, we observed lower gagCEST values of the lumbar disc of L5/S1 caused by LLD even before any morphological pathology could be found. Biochemical disc alterations of patients with LDD could be stopped under therapy.

CLINICAL RELEVANCE/APPLICATION

This study supports the hypothesis that LLD could be a predisposing factor for early molecular alterations of the lumbar disc of L5/S1. Furthermore, lower gagCEST values of the lumbar disc of L5/S1 caused by LLD were observed before any morphological pathologies were detectable. This molecular alterations of L5/S1 of patients with LLD could be delayed under the effect of shoe inserts and physical therapy.

SSQ12-03 Blood Oxygen Level-Dependent MRI Can Evaluate the Oxygenation of Visceral Adipose Tissue in Zucker Diabetic Fatty Rats

Thursday, Nov. 29 10:50AM - 11:00AM Room: S504CD

PURPOSE

Visceral adipose tissue (VAT) hypoxia is associated with insulin resistance and obesity-related chronic low-grade inflammation (metaflammation). Its evaluation is then of great importance for prevention and therapy, but current methods are invasive and focus on subcutaneous fat rather than VAT. The purpose of this study is to investigate the feasibility of evaluating VAT hypoxia with Blood Oxygen Level-Dependent (BOLD) MRI, which is sensitive to hemoglobin oxygenation, in Zucker Diabetic Fatty (ZDF) rats.

METHOD AND MATERIALS

Seven-week old ZDF rats (n=18) were provided with water and high-fat diet ad libitum; their body weight and blood glucose were monitored. At 13 weeks of age they were divided into two subgroups, receiving a daily dose of pioglitazone (ZDF-PGZ, n=9) or saline (ZDF-VE, n=9) respectively. BOLD MRI was performed at 13 and 23 weeks of age using a multi-echo spoiled gradient-echo sequence (5 echo times from 3.75 to 29.07 ms with 6.33 ms echo spacing, TR = 408 ms, voxel size = 0.47x0.38x3 mm3). R2* values were measured in the perirenal VAT. The trygliceride, cholesterol and insulin levels were measured by blood biochemistry analysis, and insulin resistance was calculated by HOMA-IR = insulin[mU/L] x glucose[mmol/L] / 22.5. Immunofluorescence was used to evaluate hypoxia by pimonidazole adduct-positive area. The proportion of Th17 and Treg cells, CD34+ and CD34++ monocytes were evaluated by flow cytometry.

RESULTS

The ZDF-VE group had hyperlipidemia ($p < 0.01$) and hyperinsulinemia ($p < 0.001$) and higher HOMA-IR ($p < 0.001$) compared to the ZDF-PGZ group. There was a significant R2* increase between the two scans for ZDF-VE (20.14 ± 0.23 vs. 21.53 ± 0.20, $p = 0.012$) but not for ZDF-PGZ (figure 1A). VAT R2* values showed a positive correlation with pimonidazole adduct-positive area, HOMA-IR, the percentage of Th17 cells and CD43+ monocytes, and a negative correlation with the percentage of Treg cells and CD43++ monocytes (figure 1B).

CONCLUSION

This study showed the feasibility of VAT oxygenation by BOLD MRI in ZDF rats with obesity induced by high-fat diet. The R2*

values obtained by BOLD MRI are also associated with insulin resistance and metaflammation.

CLINICAL RELEVANCE/APPLICATION

BOLD-MRI can be a non-invasive tool for the evaluation of visceral adipose tissue hypoxia and obesity-related insulin resistance and systemic inflammation

PURPOSE

Whole-pancreatic transplant and islet cells transplantation are currently available strategies aiming towards diabetes cure. Beta cell specific non-invasive functional imaging using novel PET radiotracers are now available.68Ga-DOTA-Exendin-4 PET/CT is used for detecting localised Insulinomas. However this tracer can also be used for beta cell imaging and quantification. We have attempted in this study to recognise the pattern of uptake by this tracer in patients with pancreatic transplants.

METHOD AND MATERIALS

8 patients who had undergone pancreatic transplant for Diabetes Mellitus were included in the study. After obtaining informed consent from the patients 4-5 mCi of 68Ga-DOTA-Exendin-4 was injected intravenously. One hour after injection whole body PET CT was performed and the images were analysed.

RESULTS

Among the 8 patients who had pancreatic transplant, 4 patients had Type I Diabetes Mellitus and 4 patients had Type II Diabetes Mellitus. The mean age of the patients were 36 yrs. All the 8 patients were male patients. One of the patient had undergone simultaneous pancreatic and renal transplant. Anterior and lateral MIP images demonstrated diffuse heterogeneous GLP-1R expression in vertically oriented transplanted pancreas in 7 out of 8 patients. Three dimensional PET CT imaging along revealed increase tracer uptake in the transplanted pancreas. There was no uptake in the native pancreas in 6 out of the 8 patients. There was atrophy and calcification of the native pancreatic tissue in these 6 patients. Mild tracer uptake was noted in 2 out of the 8 patients. In one patient there was very low tracer uptake in the transplanted pancreas. Fat stranding was noted surrounding the transplant tissue with areas of necrosis within. This patient was later confirmed to have transplant rejection.

CONCLUSION

In our initial study of 8 patients we conclude Exendin-4 PET/CT is very sensitive tracer for beta cell imaging. It can be used for baseline and flow up of graft imaging. Currently biopsy is the only method to prove graft rejection. However with the use of Exendin-4 PET/CT early graft rejection can be detected non invasively. We further hypothesize the future use of Exendin-4 PET/CT for quantification of beta cell mass using volumetric analysis.

CLINICAL RELEVANCE/APPLICATION

68Ga-DOTA-Exendin-4 PET/CT can be used as baseline and for follow up pancreatic transplant patients for analysis of beta cell mass.

SSQ12-05 In Vivo Bioluminescence Imaging of Transplanted Mesenchymal Stromal Cells and Their Rejection Mediated by Intrahepatic NK Cells

Thursday, Nov. 29 11:10AM - 11:20AM Room: S504CD

Participants
Jingjing Liu, Zhengzhou, China (*Presenter*) Nothing to Disclose

liujingjing198631@126.com

PURPOSE

Mesenchymal stromal cells (MSCs) hold promise in the treatment of liver disease.However, short survival time of MSCs after intrahepatic transplantation limits their value; therefore,understanding the basis of MSCs survival and rejection may increase their utility. This study was aimed at determining the role of intrahepatic natural killer (NK) cells on MSCs survival and their retention in the liver shortly after transplant.

METHOD AND MATERIALS

Human MSCs were labeled with the Luc2-mKate2 dual-fusion reporter gene (MSCs-R), and the residence time and survival of MSCs-R xenografts after intrahepatic transplantation were evaluated by in vivo bioluminescence imaging (BLI). Coculture of MSCs and NK cells was performed to assess cytotoxicity. To evaluate the role of NK cells in rejection of the xenografted cells, the fates of transplanted MSCs-R were then assessed in vivo by BLI after activation of intrahepatic NK cells.

RESULTS

We observed a linear correlation between luciferase activity from live MSCs-R and cell number in vitro (R2 = 0.9956). In vivo, we observed a gradual decline in bioluminescent signals from transplanted MSCs-R over a region corresponding to the liver in both the control group and the NK-activated group.However, the survival time and retention of intrahepatic MSCs-R decreased more rapidly in the NKactivated group of mice compared to the control group. This indicated that activated NK cells accelerate the elimination of transplanted MSCs. Also, we found that the number of hepatic NK cells and the expression of NK activation markers significantly increased after intrahepatic delivery of MSCs. This suggested that resident NK cells, in a resting state, were activated by intrahepatic transplantation of human MSCs. Taken together, the data suggests that activated hepatic NK cells mediate, in part, rejection of the MSCs xenografts. Cytotoxicity assays showed that activated NK cells may inhibit the proliferation of MSCs and, to a certain extent, induce MSCs death.

CONCLUSION

Human MSCs could be followed dynamically in vivo by BLI, and the role of murine hepatic NK cells, especially activated NK cells, could be inferred from the loss of signals from MSCs.

CLINICAL RELEVANCE/APPLICATION

This finding may have practical clinical implications in MSCs transplantation in treating liver disease.

SSQ12-06 Assessment for NASH-Related Hepatocarcinogenesis Inhibition of Shikonin in a Murine Model Using DW-MRI

PURPOSE

Nonalcoholic steatohepatitis (NASH) is a major risk factor for hepatic carcinogenesis. This study was assess the effect of shikonin using diffusion-weighted magnetic resonance imaging (DW-MRI) in an NASH-related hepatocarcinogenesis murine model.

METHOD AND MATERIALS

On the second day after birth, male pups were subjected to a single subcutaneous injection of 200 μg streptozotocin (STZ) and fed high-fat (45% kcal from fat) diet from the age of 4 weeks. The mice were randomly divided into groups when the tumor area was about > 0.5 mm² as follows: STZ + high-fat diet (SH; n=6) and STZ + high-fat diet + shikonin (SHS; n=7). For the experimental group, shikonin (2.0 mg/kg) was injected intraperitoneally daily for 14 days (with diluted PBS). DW-MRI was performed to assess effects of shikonin at pre-and post-treatment. Aspartate aminotransferase (AST) and alanine aminotransferase (ALT), glucose, cholesterol, and triglyceride were determined in plasma. The liver tissues were collected at 14 day post-treatment for hematoxylin and eosin staining.

RESULTS

The mean area of tumors were 2.56 ± 2.12 mm² at the SH and SHS groups, before treatment initiation. The tumor area changes of the SH and SHS groups were 326.28 ± 320.81% and 91.58 ± 78.22% after post-treatment. The tumor area change in the SHS group significantly lower compared to the SH group ($p < 0.05$). The mean ADC changes of the SH and SHS groups were 41.97 ± 50.48% and -9.24 ± 30.46% after post-treatment. The ADC change in the SHS group significantly decreased compared to the SH group ($p < 0.01$). AST and ALT levels were significantly lower in the SHS group than in the SH group after post-treatment. Plasma glucose, total cholesterol and triglyceride levels were not significantly different between SH and SHS groups. The SH group exhibited numerous tumors on the liver surface, whereas the SHS group exhibited fewer and smaller liver tumors. The histological findings at SH and SHS groups revealed that the tumors were hepatocellular carcinoma.

CONCLUSION

In this study, we found that the cancer inhibition effects of shikonin in a NASH-related hepatocarcinogenesis murine model by using DW-MRI.

CLINICAL RELEVANCE/APPLICATION

Shinkonin might be considered a novel preventive or therapeutic approach for NASH-related hepatocarcinogenesis.

SSQ12-07 Management of Complex Regional Pain Syndrome (CRPS) with Sigma-1 Receptor Radioligand and PET/MRI

Thursday, Nov. 29 11:30AM - 11:40AM Room: S504CD

biswal@stanford.edu

PURPOSE

Complex regional pain syndrome (CRPS) is a severe chronic pain condition affecting millions worldwide. Unfortunately, there is no specific diagnostic test to identify the pain generators in CRPS, leading to poor pain management of this disease. Given sigma-1 receptors (S1Rs) specific association for pro-nociceptive processes, we determine the clinical impact of a more pain-specific PET/MRI approach for CRPS, adopting a novel high affinity sigma-1 receptor (S1R) PET radioligand ([18F]FTC-146; Ki = 0.0025 nM).

METHOD AND MATERIALS

IRB and FDA approval were obtained. Fifteen patients suffering from CRPS were referred directly from specialists in pain medicine. Whole-body (head-to-toe) PET/MR (time-of-flight PET; 3.0T MR bore; GE Healthcare) imaging was perfmored following 10 mCi IV injection of [18F]FTC-146. MR sequences included 3D axial LAVA-FLEX, high-resolution 3D axial DESS and 2D axial T2-weighted FSE scans. ROI analysis was performed (OsiriX v.6.0 64-bit). Findings from the PET/MR scans were discussed with the referring pain specialists, subsequent alterations in the pain management plan were recorded and, in a subset of cases, new treatments were applied to which outcomes were measured.

RESULTS

Fourteen out of 15 patients showed unexpected findings on [18F]FTC-146 PET/MRI, which lead to a change in the patients' pain management plans. In one specific case, a CRPS patient had severe (8-10/10) unilateral knee pain despite 2 previous unsuccessful surgeries. [18F]FTC-146 PET/MRI showed a high, focal [18F]FTC-146 PET uptake of a lesion which co-localized to an abnormal mass-like lesion in the intercondylar notch on the MRI. Subsequent arthroscopic surgery removed the [18F]FTC-146-avid lesion, which completely relieved the knee pain (0/10 pain). A separate CRPS patient with severe bilateral foreleg pain showed increased uptake of [18F]FTC-146 in the anterior compartment of both forelegs. Botulinum toxin injection in the areas of high [18F]FTC-146 uptake resulted in significant improvement in pain score (9-10/10 down to 2/10). We continue to follow the other patients to further evaluate our image findings.

CONCLUSION

A whole-body PET/MRI approach with a novel S1R PET tracer, [18F]FTC-146, can potentially identify pain generators in CRPS and improves treatment outcomes.

CLINICAL RELEVANCE/APPLICATION

The proposed whole body PET/MRI approach could alter the pain management for CRPS patients to achieve better pain-relief outcome.

SSQ12-08 Inflammation Focus Search with 18F-FDG-PET/MRI: Comparative or Additive Value of PET and MRI

Thursday, Nov. 29 11:40AM - 11:50AM Room: S504CD

ahmet.oernek@uk-essen.de

PURPOSE

To evaluate the comparative or additive value of 18F-FDG PET and MRI for identifying the etiology of inflammation of unknown origin.

METHOD AND MATERIALS

A total of 24 patients (13 m, 11 w, age 42±23 [8-82] y) with suspicion of an inflammation focus due to laboratory inflammation markers (increased CRP, leukocytes) or fever and up to now non-leading conventional imaging underwent a whole-body PET/MRI. Image analyses included the detection and localization of pathologically (focal) increased tracer uptake in PET including determination of SUVmax using VOI technique and evaluation of the contrast enhancement and diffusion restriction (ADC values) of abnormal lesions in MRI. Descriptive analysis included mean values, standard deviation and range. PET/CT, clinical, and radiological follow-up as well as histopathology served as standards of reference.

RESULTS

In 17/24 patients the PET/MRI contributed to the diagnosis of a (focal) pathological etiology of the inflammatory disease (vasculitis n=5, inflammatory bowel disease n=4, pneumonia n=1, infected vascular prosthesis n=2, (active) retroperitoneal fibrosis n=1,

peritonitis and cholecystitis n=1, synovitis n=1, mycotic infection (hepatic candidosis) n=1, bone marrow activation n=1). In PET all pathological foci showed a moderately to significantly increased FDG uptake (SUVmax 5.3 ± 3.5, range 1.4-14.2). The MRI satisfactorily allows the localization of the findings, but only in 12/17 a corresponding contrast-enhancement and in 13/17 a corresponding diffusion restriction could be found. 3/17 patients showed neither a contrast-enhancement nor a diffusion restriction, but only an increased FDG uptake.

CONCLUSION

Integrated 18F-FDG-PET/MRI shows high potential in identifying the etiology of inflammation of unknown origin. The MRI satisfactorily allows the localization of the findings, but a significant higher detection rate could be found in PET compared to MRI. Considering the significantly lower dose of ionizing radiation, PET/MRI may serve as a powerful alternative to PET/CT.

CLINICAL RELEVANCE/APPLICATION

Inflammation focus search with 18F-FDG-PET/MRI

SSQ12-09 Early Detection and Measurement of Disease Activity in Experimental, Inflammatory Bowel Disease Using Target-Specific Molecular Imaging and Fluorescence Colonoscopy

eisenblaetter@uni-muenster.de

PURPOSE

Pro-inflammatory monocytes comprise the majority of the early inflammatory infiltrate in inflammatory bowel disease (IBD). In mice, these cells are characterised by high expression of Ly6C. Purpose of this study was to evaluate Ly6C-specific imaging for visualisation and measurement of IBD activity in comparison to perfusion-type contrast agents and assess the performance in fluorescence mediated tomography (FMT) and fluorescence colonoscopy (FC) for whole body and local application respectively.

METHOD AND MATERIALS

IBD was induced in 10 female Balb/c wild type mice by application of DSS with the drinking water. The weight was monitored as a marker of disease activity. FMT was performed before and 5 and 10 days after IBD induction. Mice received a Cy5.5-labelled Ly6C antibody (2nmol dye) or an equivalently labelled, unspecific IgG to reflect perfusion effects. In parallel, all mice underwent FC for detection and scoring of local disease activity. Histology served for correlation and validation of in vivo imaging.

RESULTS

On day 5 after IBD induction, weight loss did not allow for safe identification of IBD activity and was only significantly increased at day 10 (2% vs. 15%). Perfusion was elevated on day 5 as compared to baseline already but did not increase significantly towards day 10 as reflected by the IgG-driven signal (192 vs. 328 vs. 342 pmol tracer). Ly6C-specific tracer accumulation was, in contrast, significantly elevated on day 5 already; a further increase towards day 10 reflected the growing disease activity (110 vs. 700 vs. 1166 pmol; $p<0.001$). In vivo colonoscopy allowed for safe identification of inflammatory foci based on the specific probe accumulation but not the unspecific control. FC-based disease scoring was clearly reflected by Ly6C-specific imaging.

CONCLUSION

Target-specific imaging of Ly6C as a marker for early infiltrating, pro-inflammatory monocytes allows for sensitive and specific measurement of IBD activity in vivo by non-invasive and endoscopic approaches. It is superior over clinical examination and perfusion type contrast.

CLINICAL RELEVANCE/APPLICATION

In IBD, monitoring of disease activity and sub-clinical inflammation e.g. under therapy is a relevant challenge. Specific imaging can aid research and potentially improve multi-modal clinical imaging.

PURPOSE

Our aim was to systematically analyze longitudinal MRI findings during the development of accelerated knee osteoarthritis (AKOA) to identify patients that may benefit from an intervention.

METHOD AND MATERIALS

Knees progressing from no radiographic osteoarthritis (OA, KL 0/1) to advanced-stage OA (KL 3/4) within 4 years (AKOA definition) at any time point within the Osteoarthritis Initiative were selected. OA risk factors including knee injury or surgery were noted. MRIs were graded using the modified Whole-Organ Magnetic Resonance Imaging Score (WORMS) at baseline, 2 and 4 years. Additional findings such as root tears and meniscal extrusion were noted. Presence or absence of features associated with KL 3/4 onset within 2 years compared to 4 years were assessed using Pearson's chi-square test for OA risk factors and multivariable logistic regression models for baseline imaging parameters.

RESULTS

AKOA was present in 162 knees in 149 subjects (age 63.25±8.3 years; 103 females; BMI 29.4±3.9). Knee injury was documented in 22% (36/162), meniscal resection in 27% (43/162). Moderate to severe meniscal lesions WORMS >= grade 3 were present in 25% (41/162) at baseline, 65% (105/162) at 2 years and in 94% (152/162) at 4 years. Meniscal extrusion was the most prevalent finding associated with AKOA (18% bl; 45% 2y; 94% 4y). Root tears were the most common types of meniscal tears (9% bl; 22% 2y; 38% 4y). Risk factors associated with KL 3/4 onset within 2 years (n=116) compared to 4 years (n=46), included higher baseline maximum scores of the weight-bearing cartilage (adjusted odds ratio [OR], 1.22; 95% confidence interval [CI]: 1.02, 1.46; p=0.033), presence of root tears at baseline (adjusted OR, 2.82; 95% CI: 1.33, 6.00; p=0.007) and presence of knee injury during the observation period (42%, 49/116 vs. 24%, 11/46, p = 0.032).

CONCLUSION

Meniscal abnormalities were the most prevalent morphological feature associated with AKOA and are likely responsible for rapid cartilage loss. Knee injury and meniscal resection were frequently present in our cohort and probable risk factors for AKOA. Root tears were associated with substantial increased risk for progression of radiographic joint space loss.

CLINICAL RELEVANCE/APPLICATION

Meniscal pathology/damage was associated with accelerated radiographic progression with joint space loss and identifies a subgroup of patients that may benefit from an intervention.

SSQ13-02 Amount of Partial Meniscectomy Impacts Severity and Worsening of Knee Osteoarthritis: Data from the Osteoarthritis Initiative

aprilsundong@163.com

PURPOSE

Previous studies have suggested that meniscectomy is a significant risk factor for osteoarthritis (OA), but it is not known how the amount of meniscal resection impacts disease burden and progression. The goal of this study was therefore to develop a MRI-based semi-quantitative scoring technique for postoperative assessment of the amount of meniscal resection, to test its reproducibility and to investigate how the meniscal resection scores correlate with the severity and worsening of degenerative changes.

METHOD AND MATERIALS

The right knees of 135 participants from the Osteoarthritis Initiative were selected, who underwent meniscal resection. Using a newly developed semi-quantitative meniscal resection score (MenRS) the extent of meniscal resection was assessed on baseline 3.0T MRIs. Dividing the meniscus into radial and circumferential zones amount of meniscal resection was scored from 0 (none) to 18 (complete resection). In addition knee osteoarthritic abnormalities at baseline and 48-month were graded using a modified Whole-Organ Magnetic Resonance Imaging Score (WORMS). Statistical analysis included linear and logistic regression to correlate MenRS with baseline and change in WORMS grades as well as intra-class correlation coefficient (ICC) to determine reproducibility.

RESULTS

Using the new MenRS system high ICC values for both intra- and inter-observer reproducibility of 0.980 and 0.977, respectively were found. Most importantly the amount of meniscal resection was significantly correlated with baseline WORMS grades throughout the knee: higher MenRS were associated with higher total WORMS grades ($p=0.004$) as well as cartilage ($p=0.004$), and ligament ($p<0.001$) subscores. Correlations were higher when analyzing the associations between WORMS abnormalities in the index compartment separately ($p<0.001$). There were no significant correlations of MenRS and change in WORMS grades over 4 years.

CONCLUSION

Using MenRS to assess the amount of meniscal resection showed excellent reproducibility and significant correlations with the amount of cartilage and ligamentous abnormalities, with the strongest association in the index compartment.

CLINICAL RELEVANCE/APPLICATION

The new meniscal resection score allows to analyze the amount of meniscal resection with high reproducibility and is directly correlated with the severity of degenerative knee abnormalities.

SSQ13-03 Three Tesla Multiparametric Combined Imaging Evaluation of Axial Spondyloarthritis And Pelvic Enthesopathy

PURPOSE

To evaluate patients with suspected axial spondyloarthritis (SpA) to determine technical success of multiparametric rheumatology lumbosacral MR imaging (MRLI) protocol, disease distribution, inter-reader reliability, and effect on patient management.

METHOD AND MATERIALS

41 consecutive patients with suspected axial SpA reffered by rheumaologists were included. Two rheumatologists recorded the clinical and lab findings as well as the disease activity based on a confidence scale before and after imaging results of 3T MRLI. Two radiologists interpreted the studies to record the findings of SpA and its activity. Prevalence-adjusted and bias-adjusted kappa (PABAK) was used for reader agreement. Changes in diagnostic confidence, treatment and patient response were evaluated using the sign rank test and the Fisher's exact test. P value less than 0.05 was considered statistically significant.

RESULTS

There were 41 patients; 31 females and 10 males with ages of 41+/-10 and 41+/-12 (mean+/- SD), respectively. The spine T2W

imaging received highest quality scores followed by whole abdomen-pelvis 3DT2W imaging, 3DCEMR, and DWI, respectively. On T2W, acute and chronic lesions of LS spine and SIJ were seen in 4/41, 18/41, 6/41, and 27/41 of the patients, respectively. Many enthesopathy lesions were seen in abdomen and pelvis. In the abnormal area of the bones, ADC measured 0.95+/-0.23 (mean+/-SD) versus normal bone (0.20+/-0.1). In synovial linings, there was overlap of ADC. PABAK for acute and chronic findings were 0.70-1.0 and 0.41-0.51, respectively. Clinical confidence scale after imaging changed in 20 out of 41 patients, however, with the change was not statistically significant. The changes in diagnosis occurred in 17/41 and no association existed with respect to change in treatment (p=1) or patient response (p= 0.2).

CONCLUSION

The study validates the whole abdomen and pelvis multiparametric imaging approach for axial spondyloarthritis with successful assessment of multiple regional enthesopathy sites in the same setting.

CLINICAL RELEVANCE/APPLICATION

High field multiparametric MRLI is technically successful and identifies multiple active SpA sites in the same setting. Larger scale studies can be performed using this novel protocol to evaluate the effect on patient outcomes.

SSQ13-04 Monosodium Urate Burden Assessed with Dual-Energy Computed Tomography Predicts the Risk of Flares in Gout: A 12-Month Observational Study

Thursday, Nov. 29 11:00AM - 11:10AM Room: E451A

Participants
Jean-Francois Budzik, MD, PhD, Lille, France (*Abstract Co-Author*) Nothing to Disclose
Julie Legrand, MD, Rouen, France (*Presenter*) Nothing to Disclose
Laurene Norberciak, Lille, France (*Abstract Co-Author*) Nothing to Disclose

Tristan Pascart, MD,PhD, Lille, France (*Abstract Co-Author*) Research Grant, Horizon Pharmaceuticals

For information about this presentation, contact:

budzik.jean-francois@ghicl.net

PURPOSE

To determine if the extent of urate burden measured with dual-energy computed tomography (DECT) and ultrasonography (US) is predictive of the risk of gout flares.

METHOD AND MATERIALS

This prospective observational study recruited gout patients to undergo monosodium urate (MSU) burden assessment with DECT (volume of deposits) and US (double contour sign) scans of knees and feet. Patients attended follow-up visits at 3, 6 and 12 months. Patients having presented with at least one flare at 6 months were compared versus those who did not flare. Odds-ratios (ORs) [95% confidence interval] were calculated on relevant data stored by the automatic selection procedure applied on the binary logistic regression model.

RESULTS

Overall, 64/78 included patients attended at least one follow-up visit. In bivariate analysis, the number of joints with the double contour sign was not associated with risk of flare (p=0.67). Multivariate analysis retained a unique variable: DECT MSU volume of the feet. For each 1cm3 increase in DECT MSU volume in feet deposits, the risk of flaring increased 2.03-fold during the first 6 months after initial assessment (OR 2.03 [1.15 - 4.38]) and 1.57-fold during the first 12 months (OR 1.57 [1.01 - 2.86]). The threshold volume best discriminating flarers from non-flarers was 0.81 cm3 (specificity 61%, sensitivity 77%).

CONCLUSION

This is the first study showing the usefulness of DECT for the management of gout patients beyond diagnosis by demonstrating that the extent of MSU burden measured with DECT but not US is predictive of the risk of flares.

CLINICAL RELEVANCE/APPLICATION

This is the first study to show the predictive value of DECT for gout flares.

SSQ13-05 Association Between Gout and Longitudinal 3T MRI-Based Knee Osteoarthritis (OA) Worsening: Initial Observation and Preliminary Analysis from the FNIH OA Biomarkers Consortium

Thursday, Nov. 29 11:10AM - 11:20AM Room: E451A

PURPOSE

To determine whether the presence of gout is associated with increased odds of knee osteoarthritis (OA) worsening in participants

of the Foundation for the National Institute of Health (FNIH) study.

METHOD AND MATERIALS

Using 1:3 propensity score matching method, 25 subjects with positive history of physician confirmed gout (symptomatic and/or subclinical gout in any joints) and 75 controls who were matched for OA and gout confounding variables (age, sex, BMI, and race) were included in this IRB approved HIPAA compliant study. Baseline and follow-up knee radiographic measurements and MRI Osteoarthritis Knee Score (MOAKS) variables for cartilage damage, bone marrow lesions (BMLs), osteophytes, effusion-synovitis, and Hoffa-synovitis were extracted. The association between gout and 48-months radiographic OA progression (>0.7mm reduction in medial tibiofemoral joint space width) was evaluated using conditional regression model. The relationship between gout and 24-months change in MOAKS measurements was determined using conditional regression. A mediation effect analysis was utilized to explore the variable mediating the association between gout and knee OA.

RESULTS

There was no significant association between gout and 48-months radiographic OA progression (OR 95%CI: 1.21 (0.66-2.21)). However, in comparison with matched controls, subjects with gout showed higher odds of worsening tibial cartilage damage (OR 95%CI: 2.02 (1.01-4.04)) and Hoffa-synovitis (OR 95%CI: 5.20 (0.89-30.48)), but not for osteophyte or BML worsening, over 24-months. Mediation analyses suggested a non-significant trend for the mediatory role of Hoffa-synovitis for the association between gout and tibial cartilage damage worsening (Sobel's test p-value: 0.086; indirect effect 95%CI: -0.084-2.087).

CONCLUSION

Positive medical history of gout is associated with longitudinal MRI-based OA-related structural damage worsening including tibial cartilage defect and Hoffa-synovitis.

CLINICAL RELEVANCE/APPLICATION

Presence of symptomatic or subclinical gout in any joints can be considered as a potential risk factor for future tibiofemoral OA progression.

Mike Notohamiprodjo, Munich, Germany (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The purpose of the study was to assess the effects of the metabolic syndrome on osteoarthritis of the hip joint.

METHOD AND MATERIALS

Included were 356 patients of the KORA cohort (Cooperative Health Research in the Augsburg Region) with metabolic syndrome and a healthy control group. All subjects underwent a detailed assessment for the waist circumference as well as the presence of diabetes mellitus (fasting glucose), hypertension (systolic and diastolic), elevated triglycerides as well as an MR scan. MR measurements were performed on a 3 Tesla scanner (Magnetom Skyra, Siemens Healthcare, Erlangen, Germany) using a dual-echo Dixon and a T2 Haste sequence for anatomical structures. In order to quantify osteoarthritis of the hip, assessment was performed by two experienced radiologists for joint gap narrowing, osteophytes and subchondral sclerosis according to the Kellgren-Lawrence classification. Statistical analysis was performed using odds ratios from univariate and multivariate logistic regressions.

RESULTS

Age was found the only parameter in univariate and multivariate analysis to be significantly influencing on osteoarthritis of the hip joint. There was no correlation in univariate and multivariate analysis shown for any parameter of the metabolic syndrome as the waist circumference (OR left hip: 1.00, p= 0.933 ; OR right hip: 1.00, p= 0.833), triglyceride (OR left hip: 1.00, p= 0.925; OR right hip: 1.00, p= 0.209), HDL (OR left hip: 1.01, p= 0.084; OR right hip: 1.01, p= 0.111), systolic (OR left hip: 1.01, p= 0.469; OR right hip: 1.01, p= 0.404) or diastolic (OR left hip: 1.01, p= 0.407; OR right hip: 1.00, p= 0.736) blood pressure and fasting glucose (OR left hip: 1.00, p= 0.573; OR right hip: 1.02, p= 0.102) in comparison to osteoarthritis of the hip joint. Neither did the complex of metabolic syndrome in total show any significant correlation (OR left hip: 1.69, p= 0.104; OR right hip: 1.35, p= 0.313) to osteoarthritis of the hip joint.

CONCLUSION

Despite the strong influence of the metabolic syndrome on a wide range of inter alia cardiovascular diseases, we were able to show that metabolic syndrome does not affect osteoarthritis of the hip joint.

CLINICAL RELEVANCE/APPLICATION

Since a pathological mechanism has not yet been confirmed, growing research tries to associate osteoarthritis with the metabolic syndrome. This study wants to assess which subgroup of the metabolic syndrome is associated with osteoarthritis.

SSQ13-07 Association Between Patellofemoral Cartilage Damage and Frequency of Kneeling Activity in Subjects with/without Patella Alta: An FNIH OA Biomarkers Consortium Study

sdemehr1@jhmi.edu

PURPOSE

It has been suggested that kneeling in occupational/sport activities is associated with knee OA. Studies suggested the association between kneeling and tibiofemoral joint cartilage damage, but reports of patellofemoral joint (PFJ) involvement are controversial. We aimed to investigate whether kneeling activity is associated with the worsening of MRI measures of PFJ cartilage damage in subjects with/without patella alta (PA) using the Foundation for the National Institute of Health (FNIH) study participants.

METHOD AND MATERIALS

The study was IRB-approved and HIPAA-compliant. Baseline and 24-month follow-up semi-quantitative MRI Osteoarthritis Knee Score (MOAKS) measures of PFJ of 600 subjects from the FNIH study were extracted. At the baseline visit, subjects were asked how many days per week they participated in activities with kneeling activity >=30 minutes. Insall-Salvati ratio (ISR) (patellar tendon/patellar height) was measured by a musculoskeletal radiologist using the baseline MRIs; knees with ISR>=1.3 were considered as PA. Logistic regression adjusted for age, sex and BMI, Chi-square test and Breslow-Day Homogeneity test were used to assess the impact of kneeling on worsening of MOAKS cartilage scores over 24-months in subjects with/without PA.

RESULTS

Worsening in MOAKS cartilage scores was seen in subjects with >=6 days/week of kneeling activity compared to subjects with less kneeling activity (adjusted OR(95%CI): 2.95(1.08-8.07)). However, despite the trend, 2-5 days/week kneeling was not associated with worsening of PFJ cartilage damages compared to less kneeling activity (<2 days/week). Stratifying analysis showed that only PA+ subjects, not PA-, had significant association between the kneeling and worsening of PFJ cartilage damage, especially in surface cartilage score (OR: 45.01(1.40-1444.2)) and medial side (OR:44.0(4.55-425.7)). Homogeneity test demonstrated significant difference between PA+ and PA- groups (P-value: 0.005).

CONCLUSION

Kneeling activity in >=6 days/week is associated with the worsening of PFJ MRI cartilage scores compared to less kneeling activity, especially in subjects with underlying PA.

CLINICAL RELEVANCE/APPLICATION

Frequent daily kneeling activity is associated with the higher risk of PFJ cartilage damage resulting in PF OA, especially in subjects with associated patella alta.

PURPOSE

Although commonly used for quantitative imaging of hip cartilage, 3D dual flip angle techniques are highly sensitive to flip angle

Although commonly used for quantitative imaging of hip cartilage, 3D dual flip angle techniques are highly sensitive to flip angle variation (B1 inhomogenities) which is even more pronounced at 3 T. To compare precontrast T1 values of (1) hip cartilage and (2) periarticular musculature using a new inversion-recovery based method with conventional dual-flip angle acquisition in asymptomatic volunteers.

METHOD AND MATERIALS

IRB-approved study of 18 asymptomatic hips (9 volunteers; mean age 27 ± 2 years, 60% female). All subjects underwent non-contrast, quantitative T1 imaging of hip cartilage at 3T with two different methods: (1) 3D dual-flip angle GRE-based technique (0.9 mm3 isotropic T1 VIBE; acquisition time 8:30 min) including a prescan for B1 correction. (2) 3D dual inversion-recovery approach that has been recently introduced in brain imaging (0.9 mm3 isotropic T1 MP2RAGE; acquisition time 7:30 min) in which T1 values are calculated based on two different inversion pulses. Radial images were reformatted for both T1 techniques. Regions of interest were placed manually, based on anatomic landmarks within the (1) cartilage at each hour position of the clockface. (2) At the 3/9 o`clock position 2 quotients (%) of the peri-articular musculature were calculated as a measure for antero-posterior (T1 psoas /gluteus maximus muscle) and medio-lateral (T1 iliacus/gluteus medius muscle) flip-angle variations over the field of view.

RESULTS

(1) MeanT1 values and standard deviations of overall (1488±174ms vs 1036±41ms), anterior (1533±219ms vs 1026±45ms) and posterior (1444±157ms vs 1047±43ms) hip cartilage were higher for the dual-flip angle compared to the inversion-recovery based method (all p<0.001). (2) T1 psoas/gluteus maximus muscle quotient (105±11% vs 97±4%, p=0.01) and T1 iliacus/gluteus medius muscle quotient (131±16% vs 98±2%, p<0.001) were higher for the dual-flip angle compared to the inversion-recovery based method.

CONCLUSION

Despite the used B1 prescan inter-individual differences (= standard deviation) in T1 values of cartilage were greater with the dual-flip angle method compared to the inversion-recovery method due to the greater flip-angle variations at 3 T.

CLINICAL RELEVANCE/APPLICATION

A more robust method for acquisition of 3D maps of hip cartilage could help in defining thresholds to differentiate intact from biochemical cartilage degeneration at 3 T.

SSQ13-09 Evaluating Variability in Knee CartiGram MRI - A Quantitative Study

Thursday, Nov. 29 11:50AM - 12:00PM Room: E451A

vidur@mahajanimaging.com

PURPOSE

MRI cartilage assessment using CartiGram is a widely used T2 mapping sequence to non-invasively detect changes in cartilage. We tested the robustness of the technique by quantitatively measuring intra- and inter-scanner variability of T2 values.

METHOD AND MATERIALS

Our study had two parts. First, a phantom containing NaCl, GdCl3 and Agarose was created to mimic human meniscus, muscles, cartilage and synovium. A T2 CartiGram (test) and T1w IR-TSE (gold standard) were performed on a 3.0T (750W, GE Healthcare) and 1.5T (HDxt, GE Healthcare) MRI scanners. A phantom integrity test was performed at the end. Obtained data was evaluated by creating T2 maps and calculation of T2 mean±SD. Second, in two healthy volunteers, a T2 CartiGram was performed twice, at an interval of 10 minutes with subject lying still in the scanner, each on both the scanners on the same day. T2 maps were created and mean±SD and Relative Percentage Difference (RPD) calculated. Additional 2-D wear maps were created to check for anatomical variability.

RESULTS

Phantom: 3.0T MRI showed T2 values of 26.5±1.4 in meniscus, 61±3.5 in muscles and 56±2.9, 71.4±3.8 and 78±5.5 in three cartilage samples. The 1.5T MRI showed T2 values of 28±1.2 in meniscus, 62.3±3.4 in muscles and 52.9±2.9, 77.5±5.4 and 89±7.3 in the three cartilage samples. Healthy Volunteers: The RPDs on the same scanner for subject 1 were 3.5% (on 3.0T) and 3.8% (on 1.5T) on the medial femoral cartilage and -1.7% (on 3.0T) and -1% (on 1.5T) on the lateral, and for subject 2, they were -0.4% (on 3.0T) and 4.8% (on 1.5T) on the medial and 1.2% (on 3.0T) and 5.5% (on 1.5T) on the lateral. The 1.5T scanner reported a lower overall T2 value than the 3.0T, in contrast to the phantom results. Visual inspection of the 2D wear maps by a musculoskeletal radiologist revealed variability of T2 signal with no observable pattern.

CONCLUSION

There exists variability in T2 values of CartiGram when performed in healthy volunteers across both, different time points and different field-strengths. Further studies are needed to re-evaluate the threshold of 40ms for cartilage pathology and define MRI machine-specific guidelines.

CLINICAL RELEVANCE/APPLICATION

Significant differences in T2 values on CartiGram can lead to difficulty in diagnoses of borderline cases in clinical practice.

PURPOSE

Positron Emission Tomography (PET) offers the most sensitive method for *in vivo* imaging assays of physiologically important compounds, but it is fundamentally limited by low signal and/or high radiation dose to the subject, which negatively impacts image quality, scan times and the kinds of diseases that may be investigated. PET also has the capacity to dynamically track the fate of biomolecules *in vivo*, allowing for pharmacokinetic analysis. However, standard clinical scanners have an axial field of view (AFOV) of 15-30 cm, which limits such analysis to single organs. This research program aims to address all these limitations by building extended AFOV scanners. Here we report initial results from a 194 cm long device - the first medical tomograph capable of simultaneously imaging the entire human body.

METHOD AND MATERIALS

The scanner consists of 8 rings of 24 PET detector modules, each containing 5 x 14 detector blocks. Blocks consist of 6 x 7 LYSO crystals of size 2.76 x 2.76 x 18.1 mm3 (total ~560 kg of LYSO), read out by silicon photomultipliers. The PET component is paired with an 80-channel CT scanner. PET detector performance has been characterized and system construction and integration has been completed. Static data from a 200 cm phantom has been acquired and reconstructed to investigate detector response uniformity. A 30-second dynamic scan of activity moving through a tube has also been acquired to verify dynamic frame generation.

RESULTS

Detector time-of-flight resolution is 409±39 ps and energy resolution is 11.7%±1.5% at 511 keV. Detector dead-time of 3.5% was found at count-rates similar to those expected in clinical operation. Images of the 200 cm phantom show reasonable uniformity even though not all corrections have been implemented yet. The dynamic dataset shows that frame creation is working as expected.

CONCLUSION

The world's first total-body PET/CT scanner has been built. Detector performance is in line with expectations. The system is operational and producing images. Implementation and validation of corrections for accurate quantification is under way. Further performance characterization is planned.

CLINICAL RELEVANCE/APPLICATION

Total-body PET aims to improve all clinical PET through ultra-fast (<1min) scans; ultra-low-dose (<0.35mSv) scans; improved image quality; and total-body kinetic modeling for precision medicine.

SSQ14-02 The Effect of a Novel Bayesian Penalised Likelihood (BPL) PET Reconstruction on the Herder Risk Prediction Model of Malignancy in Solitary Pulmonary Nodules Undergoing Assessment with 18F-FDG PET-CT

murphy.84@gmail.com

PURPOSE

The British Thoracic Society (BTS) guidelines recommend using 18F-FDG PET-CT with the Herder model to assess the risk of malignancy in solitary pulmonary nodules (SPNs). Qualitative assessment of FDG uptake in SPNs, using an ordinal scale, integral to the Herder model, is based on analysis of standard Ordered Subset Expected Maximisation (OSEM) reconstruction PET images. Novel PET reconstructions improve image quality by increasing signal-noise ratio and suppressing image noise. Our aim was to assess the impact of a novel Bayesian Penalised Likelihood (BPL) PET reconstruction on the Herder risk prediction model of malignancy in SPNs in comparison with standard OSEM images.

METHOD AND MATERIALS

Subjects with a SPN who underwent 18F-FDG PET-CT between 2014-2017, with assessable OSEM and BPL reconstructions, and either histological confirmation of malignancy or histological and/or imaging follow-up confirmation of benignity were included. Two readers independently and blindly classified FDG uptake in each SPN on both OSEM and BPL images (BTS score; 1=none; 2=MBP but <2x liver; 4=>2x liver). The BTS score in combination with other clinico-radiological features was used to calculate the Herder risk score (%) for both OSEM and BPL images.

RESULTS

97 subjects (age 69±10 years, 52% male, 84% current/former smokers, mean nodule size 16±6mm) with 75 (77%) malignant SPNs were included. There was very good inter-observer agreement for the BTS score for both OSEM (κ=0.85) and BPL images (κ=0.87). BPL images increased the BTS score in 25 (26%) SPNs (20 malignant & 5 benign); 9 SPNs (7 malignant) increased from a BTS score 2 to 3, and 16 (13 malignant) from a BTS score 3 to 4, with a mean increase of 18±22% in Herder risk score. The mean Herder score using BPL images was significantly higher than OSEM for all SPNs (73±29 vs 68±32% respectively, p=0.001), and for malignant SPNs (83±19 vs 78±25%, p=0.004), but not for benign SPNs (42±35 vs 37±34%, p=0.07).

CONCLUSION

The use of BPL PET reconstruction increases the Herder score in approximately 25% of SPNs compared to standard OSEM datasets with the potential to affect subsequent management decisions.

CLINICAL RELEVANCE/APPLICATION

Novel BPL PET reconstruction, compared to standard reconstruction, may increase the estimated risk of malignancy in a SPN, using the Herder model, thus potentially affecting management decisions.

SSQ14-03 Impact of Point Spread Function Reconstruction on 68Ga DOTATATE PET/CT Quantitative Imaging Parameters

Thursday, Nov. 29 10:50AM - 11:00AM Room: S505AB

Awards
Trainee Research Prize - Medical Student

Participants
Helena You, Dallas, TX (*Presenter*) Nothing to Disclose
Yasemin Sanli, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose
Rathan M. Subramaniam, MD,PhD, Dallas, TX (*Abstract Co-Author*) Consultant, Blue Earth Diagnostics Ltd; Speaker, Blue Earth Diagnostics Ltd

PURPOSE

68Ga DOTATATE PET/CT has been increasingly used for diagnosis and therapy response assessment of patients with neuroendocrine tumors (NETs). We investigated the impact of point spread function (PSF) reconstruction and lesion size on 68Ga DOTATATE PET/CT quantitative parameters.

METHOD AND MATERIALS

A total of 38 patients with 42 68Ga DOTATATE PET/CT scans and 125 lesions were included. Scans were reconstructed with and without PSF modulation. For each lesion, one reader measured the maximum and peak standardized uptake value (SUVmax and SUVpeak), metabolic tumor volume (MTV), total lesion somatostatin avidity (TLS), and tumor somatostatin receptor expression heterogeneity (TH) using area under the curve method. Intraclass correlation coefficient (ICC) and Bland-Altman analyses were used to compare PSF and non-PSF values. Subgroup analysis was performed to determine the impact of lesion size.

RESULTS

Mean age of the patients was 55 ± 15 years. 21 patients were male and 17 were female. Of the 42 scans, 11 were baseline scans and 31 were follow-up scans. Of the 125 lesions, 51 were located in the liver, 31 in lymph nodes, 17 in bone, 8 in pancreas, 4 in lung, and 14 in other sites. Correlation coefficients between PSF and non-PSF values were excellent for SUVmax (ICC=0.97), SUVpeak (ICC=0.99), MTV (ICC=0.98), and TLS (ICC=0.99), and was good for TH (ICC=0.81). Comparison of PSF with non-PSF values showed a bias (mean percent change ± SD) of +27.5 ± 14.7% for SUVmax, +15.5 ± 9.5% for SUVpeak, -18.6 ± 37.6% for MTV, +0.8 ± 28.1% for TLS, and -7.1 ± 11.0% for TH. For lesions less than 2 cm in size (n=75), comparison of PSF with non-PSF values showed a bias of +32.7 ± 15.8% for SUVmax, +19.3 ± 9.3% for SUVpeak, -27.9 ± 45.4% for MTV, -1.7 ± 35.4% for TLS, and -5.0 ± 12.2% for TH. For lesions 2 cm or more in size (n=50), comparison of PSF with non-PSF values showed a bias of +19.7 ± 8.0% for SUVmax, +9.8 ± 6.2% for SUVpeak, +0.01 ± 23.1% for MTV, +4.6 ± 8.8% for TLS, and -10.4 ± 7.9% for TH.

CONCLUSION

PSF and non-PSF values for 68Ga DOTATATE PET/CT quantitative parameters were highly correlated. PSF reconstruction increased SUVmax and SUVpeak, decreased TH, and had a variable effect on MTV and TLS depending on lesion size.

CLINICAL RELEVANCE/APPLICATION

PSF reconstruction increases SUVmax and SUVpeak and should be considered in evaluating 68Ga DOTATATE PET/CT quantitative parameters for diagnosis and therapy response assessment of NETs.

SSQ14-04 Value of CT Iterative Metal Artifact Reduction in PET/CT: Clinical Evaluation in 103 Patients

PURPOSE

To assess the technical feasibility and diagnostic benefit of CT iterative metal artifact reduction (iMAR) in patients with metal implants undergoing PET/CT.

METHOD AND MATERIALS

PET/CT examinations of 103 consecutive patients with metal implants in different localization performed between 10/2017 and 03/2018 using a state-of-the-art clinical PET/CT scanner (Siemens Biograph mCT) were included. As PET tracers 18F-FDG (75/103), 68Ga-PSMA (25/103) and 68Ga-DOMITATE (3/103) were used. Diagnostic CT data were reconstructed with iMAR and without iMAR (noMAR) and used in comparison for PET attenuation correction, generating iMAR-corrected and noMAR-corrected PET data. The effect of iMAR on quantitative CT and PET analysis was assessed by HU and SUV measurements in predefined normal anatomical structures and pathological lesions in the vicinity of metal implants. Qualitative diagnostic confidence for lesion delineation was assessed by 2 radiologists using a 3-point Likert Scale (1=not delineated; 2= fair delineated; 3=good delineated).

RESULTS

For artifact-affected anatomical structures, mean HU of iMAR CT images were significantly different compared to noMAR CT and respective standard deviations were significantly lower (e.g., M. masseter in case of dental fillings/implants: 105.1 HU, SD 43 [noMAR] vs. 72.2 HU, SD 14 [iMAR] P<.01; M. gluteus maximus in case of hip endoprostheses: 79.4 HU, SD 23 vs. 50.0 HU, SD 15; P<.01). However, SUVs did not differ significantly in these artifact-affected anatomical structures (SUVmean 0.90 [iMAR] vs. 0.91 [noMAR]; P>.05) and pathological findings (SUVmean 10.65 [iMAR] vs. 10.67 [noMAR]; P>.05) between the iMAR and noMAR PET data. In the qualitative analysis, a significantly improved delineation of pathologic findings was observed using iMAR in CT for both the interpretation of physiological (score: 1.23 [noMAR] vs. 2.26 [iMAR]; P<.01) and pathological structures (score: 2.31 [noMAR] to 2.80 [iMAR]; P<.01).

CONCLUSION

The use of iMAR in PET/CT significantly improves delineation of both physiological and pathological structures in the vicinity of metal implants in CT. The PET quantification and image quality are not significantly affected by the use of iMAR based attenuation correction.

CLINICAL RELEVANCE/APPLICATION

Metal related artifacts impair image quality and increase the risk of missing pathological findings in PET/CT. Lesion delineation is quantitatively and qualitatively improvable by iMAR.

SSQ14-05 PET/CT versus PET/MR: Quantitative Accuracy in Y-90 Dosimetry Analysis

PURPOSE

The purpose of this study is to compare Y-90 dosimetry estimates based on PET/MR versus PET/CT, identify errors in PET/MR dosimetry related to MR-based attenuation correction (AC) and PET detector equipment, and offer methods to avoid these errors.

METHOD AND MATERIALS

An IRB-approved prospective study was performed on eight patients receiving Y-90 radioembolization for liver malignancies. Following the intervention, patients were scanned by PET/CT (Siemens Biograph mCT) and PET/MR (Siemens Biograph mMR). PET/CT scans were performed arms-up, while the PET/MR scans were performed either arms-up, arms-down, or both. AC for PET/CT was derived from a low-dose CT scan. AC for PET/MR was performed with three class segmentation using the Dixon technique. Dosimetry calculations were performed using MIMs 6.5 software (MIM Software Inc.). PET/CT dosimetry was used as the standard to compare PET/MR dosimetry analysis. Accuracy of PET/MR dosimetry was analyzed in relation to injected activity, background liver and tumor dose, and PET/MR arm location.

RESULTS

PET/MR dosimetry provided accurate dosimetry estimates (within 20% of PET/CT) in the majority of cases. Inaccuracies in PET/MR dosimetry estimates were most pronounced in studies having segmentation errors or truncation errors in the PET/MR AC map, causing inappropriate attenuation correction. Inaccurate PET/MR dosimetry also occurred in cases with high Y-90 injected activity (>3 GBq). Such errors were attributed to the slow characteristics of the Biograph mMR's PET detectors given the high singles rate arising from bremsstrahlung x-rays, leading to inaccurate dead-time correction and increased noise and inaccurate corrections for random coincidences. These causes for error can be avoided by ensuring the AC map is accurate, checking for truncation errors, and using Y-90 doses less than 3 GBq.

CONCLUSION

PET/MR can provide accurate Y-90 dosimetry estimates as compared to PET/CT, provided that the injected activity is not excessive and the MR-based AC map has no major errors. Newer technologies, namely high-speed PET detectors using silicon photomultipliers and new atlas-based methods for PET/MR AC, are expected to improve accuracy of PET/MR Y-90 dosimetry.

CLINICAL RELEVANCE/APPLICATION

PET/MR can provide accurate Y-90 dosimetry estimates as compared to PET/CT, provided that the injected activity is not excessive and the MR-based AC map has no major errors.

SSQ14-06 Evolution of PET/MR Protocols Since 2011: A Single-Center Observational Study Including 1797 Examinations

PURPOSE

PET/MR is a versatile hybrid imaging modality especially used for oncologic imaging. Since the introduction of combined PET/MR systems in 2011 this relatively new technology has undergone significant developmental stages and has evolved into a robust clinical modality. The purpose of this study was to record and evaluate the development of clinical PET/MR examinations in our institution with respect to acquisition times, protocol complexity and tracer dosage.

METHOD AND MATERIALS

Essential parameters of 1797 clinical PET/MR examinations were recorded in an institutional database between 01/2013 and 12/2017 including total examination time, PET acquisition time, number of PET bed positions, number of generated images, injected tracer dose and administration of MR contrast agent. All examinations were conducted on a clinical PET/MR system (Siemens Biograph

mMR, 3 T). PET/MR protocols were iteratively adjusted according to available optimal settings over the observation period. We evaluated the recorded PET/MR parameters with respect to their development over time and with respect to their variation among different examination groups (adult patients, pediatric patients and brain studies).

RESULTS

The 1797 examinations included in the final database consisted of 1004 adult patient studies, 278 pediatric patient studies, and 515 brain studies. Average examination time decreased significantly between 01/2013 and 12/2017 from 75.7±26.7 to 66.6±23.4 min ($P < 0.5$). Compared to adult patients, the average pediatric examination time was longer but also significantly shortened between 01/2013 and 12/2017 (from 96.8±21.2 min to 84±23.0 min ($P < 0.5$)). In the same period however, overall examination complexity measued by the number of acquired images significantly increased from 2697 to 3696 acquired images per examination ($P < 0.01$).

CONCLUSION

PET/MR is a complex and time-consuming imaging modality producing a large number of complex image data. Despite increasing protocol complexity however, examination times were significantly reduced by the introduction of accelerated MR imaging techniques and protocol optimization.

CLINICAL RELEVANCE/APPLICATION

By optimizing examination protocols PET/MR scan times can be reduced, potentially increasing patient comfort and patient compliance, which is particularly important when examining children.

SSQ14-07 Feasibility of "Low Dose MR" Dixon Technique for Imaging FDG PET-MR Lymphoma

Thursday, Nov. 29 11:30AM - 11:40AM Room: S505AB

Dinko Franceschi, MD, Stony Brook, NY (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Clinical whole body PET-MR imaging has wrestled with the problem of acquiring high quality multiplanar MR sequences compared to lower resolution fast MR sequences. "Low dose MRI" is a term used in the nuclear medicine community to describe fast acquired PET-MR scan protocols that relied heavily on PET images for diagnosis. In this study, we sought to determine if the Dixon sequences obtained for attenuation correction could be used as a diagnostic sequence for interpreting PET-MRI lymphoma cases.

METHOD AND MATERIALS

We retrospectively identified 40 patients who underwent 88 FDG PET-MR body imaging studies for staging or restaging lymphoma. Brain images were not reviewed. A radiologist and nuclear medicine physician blindly reviewed PET images, attenuation correction coronal Dixon MRI, PET-MR fusion with Dixon, and multisequence (ms) MR, and ms PET-MR images. Lesions were characterized based on location, imaging characteristics, size, max SUV, and malignant potency.

RESULTS

All patients were adults with average study age 43.8 y. Studies consisted of 40 females and 48 males with 7 for staging and 81 for restaging. All patients had systemic lymphoma with 29 being diffuse large B-cell lymphoma. 37 studies had active lymph nodes (LN) on Dixon PET-MR that agreed with ms PET-MR in 33 positive cases (89.1%) having avg SUV 10.2 +/-7.74 SD. 4 Dixon PET-MR cases did not detect lesions, avg SUV 2.3 +/-0.55 SD, read as minimal residual activity. ms MR identified 11 patients with enlarged LN without FDG uptake, not seen on Dixon. All 5 studies with bones lesions were detected by Dixon PET-MR as well as 2 soft tissue organ lesions. ms MR identified 1 patient with nonactive healed bone lesions. 55 true negative. Compared to ms PET-MR, Dixon had 89.2% sensitivity, 100% specificity with no false positive studies.

CONCLUSION

In this retrospective study, Dixon PET-MR was shown to be sensitive and specific compared to ms PET-MR in the detection of lymphoma. Low number of cases not detected had minimally active LN that resolved on subsequent imaging and probably were not clinically important.

CLINICAL RELEVANCE/APPLICATION

Low dose MRI sequences using the Dixon technique for interpretation may a play role in PET-MR imaging when scan time becomes important. This may be necessary in patients with comorbidity, claustrophobia, or when multiplanar MR of particular areas be necessary.

SSQ14-08 An Unsupervised Dixon-Based Five-Tissue 18F-Sodium Fluoride Synthetic CT Generation for PET/MR Attenuation Correction

raymond.muzic@case.edu

PURPOSE

To create accurate voxel-wise attenuation correction (AC) maps for PET/MR using Na18F images and obviate the need for both specialized MR pulse sequences and conventional methods that typically lack bone information.

METHOD AND MATERIALS

Sixteen breast cancer patients received research PET/MRI exams (Philips Ingenuity TF) following clinical Na18F PET/CT exams. Free-breathing 3D T1-weighted (T1W), breath-holding mDixon, and (clinical) low-dose CT images were acquired. Rigid-body registration and local-phase deformable registration were used to transform CT, Dixon-water (Water), and Dixon-fat (Fat) to match free-breathing T1W images. A bone feature image was segmented from the non-AC Na18F image. Water, Fat, and bone features were classified into five tissue types using fuzzy c-means clustering. CT numbers of -1000, -741, -98, 40, 380 HU were assigned to estimated air, lung, fat, soft tissue, and bone classes, respectively. Synthetic CT (sCT) was generated as a linear combination of these. Mean error (ME) and mean absolute error (MAE) were estimated to evaluate the accuracy of the sCT generated by water-filled (WF), three-class T1W-based (3C-T1W), four-class Dixon-based (4C-Dx), four-class deformed Dixon-based (4C-defDx) and five-class deformed Dixon-Na18F (5C-DxBone) methods. A threshold-based CT bone mask was used to assess the accuracy of the sCT in bone regions.

RESULTS

The MAE of the sCT from WF, 3C-T1W, 4C-Dx, 4C-defDx, 5C-DxBone were 135±8, 133±19, 111±14, 105±11, 103±10 HU, respectively. The 4C-defDx group showed better agreement to measured CT than the conventional 4C-Dx. The ME in the bone mask (MEbone) of the 4C-defDx and 5C-DxBone were -351±27 and -225±29 UH. The 5C-DxBone group presented robust Na18F-derived bone information especially in spine and pelvis; it reduced by 33-37% the MEbone when compared with the other AC methods and resulted in the lowest ME and MAE.

CONCLUSION

The deformable registration mitigated the mismatch between Na18F and Dixon due to different breathing conditions. The results suggest that the Dixon-based sCT can be improved by having a Na18F-derived bone feature to increase the accuracy of PET/MR Na18F quantification.

CLINICAL RELEVANCE/APPLICATION

PET/MR Na18F for bone metastasis detection is not well-established as the lack of bone information for attenuation correction (AC). We propose a feasible five-tissue method for PET/MR Na18F AC.

SSQ14-09 Investigation on PET/MR Image Fusion Mismatch Due to Expanding Bladder: A Pilot Study

Thursday, Nov. 29 11:50AM - 12:00PM Room: S505AB

Participants
Pengcheng Hu, Shanghai, China (*Presenter*) Nothing to Disclose
Zheng Zhang, MD, Shanghai, China (*Abstract Co-Author*) Employee, Healthcare Device Manufactor
Tuoyu Cao, PhD, Houston, TX (*Abstract Co-Author*) Employee, Medical Device Manufactor

Hongcheng Shi, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

A considerable change of the urinary bladder shape between consecutive bed positions poses a unique challenge on a multi-bed simultaneous PET/MR scan. Our aim is to report our initial experience on the fusion error caused by expanding bladder.

METHOD AND MATERIALS

120 patients (63 males and 57 females, average age = 51.3 years, range 22-70 years) who had been diagnosed with cancer or had previous history of cancer were recruited. Each patients were scanned on a simultaneous whole-body PET/MR system with 5 bed positions (feet in first, 4 bed positions for body and 1 for head). All PET/MR images were visually examined by two independent experts to evaluate the pelvis fusion accuracy with a Likert scale scoring system (1-5, 5 as the best quality).

RESULTS

The mean and standard deviation of the score is 4.57 and 0.75 correspondingly. 14 patients(11.7%) were rated less or equal to 3 by both readers all because of mismatch in the bladder area. This is due to the fact that the bladder area is in the overlap region of PET images from two consecutive bed positions, so the image of the bladder area is a weighted sum of these two PET images based on the sensitivity curve. Because the bladder expanded significantly between these two bed positions, the average of the two very different bladder images cannot match the MRI image from either bed position. This effect is magnified with PET/MR scanning because the scan duration for each bed position is usually significantly longer than that of a PET/CT system due to the limitation of MRI.

CONCLUSION

Our initial clinical results shows that, in most scenarios PET/MRI can achieve very good image fusion accuracy in the pelvis area. However, it is important to know that expanding bladder might cause mismatch between PET and MRI images when the bladder area is in the PET overlap region of two bed positions. Special care might be needed if there is diagnostic interests of the area near bladder. This effect can be avoided by arranging bed position accordingly so that bladder is close to the center of one bed position.

CLINICAL RELEVANCE/APPLICATION

This study provides a guideline for simultaneous PET/MR scan protocol to avoid the fusion error in pelvis area due to expanding bladder.

PURPOSE

Abnormal structural brain networks are believed to be an important cause of serious mental illness. Detailed studies of brain networks using advances neuroimaging approaches continues to advance understanding of these network disturbances. In the present study, we used a relatively novel approach for identifying atypical gray matter network organization in a large cohort of patients with serious mental illness and their first degree relatives, and examine their genetic associations.

METHOD AND MATERIALS

N=854 subjects (330 probands with psychotic disorders, 320 of their nonpsychotic relatives and 204 healthy controls) were recruited. Single-subject gray matter networks were extracted from structural MRI scans using a recently developed automated and data-driven method. In gray matter graphs, nodes represent small cortical areas whereas edges represent statistical similarities in regional gray matter morphology between nodes. Small-world properties and nodal centrality metrics were calculated and compared among participant groups. Genetic associations of abnormal network metrics were examined using GWAS.

RESULTS

Psychotic probands showed decreased nodal degree and nodal efficiency mainly in right superior frontal gyrus and bilateral superior temporal regions relative to healthy controls. The connectivity matrix analysis showed that the impaired connections between frontal and temporal regions were found highly replicated for each abnormal node. Genome-wide significant association with nodal degree of right frontal cortex was observed with SNPs in the cell proliferation regulating inhibitor of protein phosphatase 2A gene (CIP2A) at chromosome 3q13.13, while temporal nodal metric changes were associated with psychotic symptomatology. The network metrics of nonpsychotic relatives did not differ from healthy controls.

CONCLUSION

By investigating single-subject gray matter graphs to define neuroanatomic networks in a large group of individuals with psychotic disorders, our findings provide novel evidence indicating disorganizations of anatomical gray matter network mainly involving the fronto-temporal circuit that were related to genetic and clinical factors, which may underpine the neuropathology of psychotic disorders.

CLINICAL RELEVANCE/APPLICATION

Our study provide novel evidence indicating gray matter disorganizations in fronto-temporal circuit that are related to the genetic origin and severity of psychotic symptomology.

SSQ15-02 Synthetic MRI in 3D

marcel.warntjes@syntheticmr.com

PURPOSE

Synthetic MRI is based on absolute quantification of R1 and R2 relaxation rates and proton density PD, where image contrast is synthesized as a post-processing step. A limitation thus far has been the lack of a 3D sequence with a clinically relevant image quality and scan time. The aim of this work was to assess a new 3D quantification method, QALAS, for high-resolution brain imaging in 6 minutes scan time.

METHOD AND MATERIALS

The 3D QALAS sequence is a segmented spoiled gradient echo sequence with 5 parallel acquisitions, interleaved with a T2 preparation and inversion pulse. The 2D QRAPMASTER sequence (MDME or MAGiC) is a saturation recovery multi-slice TSE sequence with multi-echo read-out. Twenty-four phantoms with various combinations of R1 and R2 relaxation rates were scanned with an inversion recovery (IR) sequence with 6 inversion delay times at 100, 200, 500, 1000, 2000 and 5000 and a multi-echo (ME) TSE sequence with 20 echoes. Additionally, a group of 10 volunteers was acquired with the two quantification methods to correlate automatically segmented brain volumes of white matter, grey matter, cerebrospinal fluid and myelin. Post-processing was performed by a prototype SyMRI 12 (SyntheticMR, Sweden). The scanner was a patched Philips Ingenia 3T.

RESULTS

Linear regression showed a slope of 0.97 and an intercept of 0.01 of QALAS R1 and IR. A slope of 1.02 and an intercept of 0.01 was observed for QALAS R2 and ME. The Pearson correlation coefficient was >0.99 for R1, R2, PD and for the synthetic T1W, T2W and FLAIR. The observed mean brain volume for QALAS was 1337 ml, the mean intracranial volume was 1493 ml, a difference of -36 ml and -34 ml, respectively, compared to QRAPMASTER. WM volume was 552 ml, GM 744 ml, CSF 157 ml and myelin 176 ml, a difference -9, -45, -1, -11 ml, respectively. Normalized for ICV, no significant differences were observed, the brain fraction BPF was 89.5%, WM fraction 36.9%, GM fraction 49.8%, CSF fraction 10.5% and myelin fraction 11.8%.

CONCLUSION

Absolute quantification in 3D isotropic resolution using QALAS provides very similar values for R1, R2 and PD, synthetic T1W, T2W, FLAIR and automatic brain segmentation in comparison to a known 2D quantification method in the brain.

CLINICAL RELEVANCE/APPLICATION

Synthetic MRI provides many image contrast in a short scanning time. Being based on quantitative maps it also provides robust input to automatic brain segmentation.

SSQ15-03 Abnormal Cerebellar-Default Mode Network Connectivity in Unmedicated Bipolar II Depression

Thursday, Nov. 29 10:50AM - 11:00AM Room: S503AB

Participants
Guanmao Chen, Guangzhou, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

1659565780mao@sina.com

PURPOSE

Objective: Bipolar disorder (BD) is a common psychiatric disease. Previous studies have found abnormalities in structural and functional brain connectivity in BD patients. However, few studies have focused on the functional connectivity (FC) of the cerebellum and its sub-region in patients with BD. The present study aimed to examine the FC of cerebellar subregion-default mode network (DMN) in patients with BD II.

METHOD AND MATERIALS

Materials and Methods: All patients met Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (known as DSM-V) criteria for BD II according to the diagnostic assessment by the Structured Clinical Interview for DSM-V Patient Edition (SCID-P). And they were diagnosed with total YMRS score<7 and HDRS-24 score>21. In total, 92 patients with unmedicated BD II depression and 100 healthy controls (HCs) were recruited, and they underwent the resting-state functional magnetic resonance imaging. Three pair subregions of the cerebellum the DMN-related had been selected as seed regions (bilateral Crus I, Crus II, and lobule IX) and calculate the whole brain FC for each subregion. The two-sample t test was performed to assess the significant differences of the FC for each subregion between BD II and HCs. Age, gender and the mean framewise displacement were included as nuisance covariates. Statistical maps were thresholded using permutation tests (1000 trials). The threshold-free cluster enhancement and voxel-wise correction with permutation tests were tested at two-tailed $p<0.05$ for multiple comparisons.

RESULTS

Results: Compared with HCs, the patients with BD II depression showed increased FC in the right Crus I-bilateral precuneus, decreased FC in the left Crus II-right medial prefrontal cortex (mPFC), -bilateral medial frontal gyrus (MFG) and the right Crus II-left MFG. There were no significant difference in the whole FC of the left Crus I and bilateral lobule IX between the BD II depression group and the HCs group.

CONCLUSION

Conclusions: The findings showed impaired FC between the cerebellum and the DMN in BD, partially FC of the Crus I-precuneus, the Crus II-prefrontal cortex, suggest the importance of abnormal cerebellum-DMN FC in the pathophysiology of BD.

CLINICAL RELEVANCE/APPLICATION

The work described has not been submitted elsewhere for publication, and all the authors have approved the manuscript that is

enclosed. The authors do not have any possible conflicts of interest.

SSQ15-04 Denoising fMRI Data Using Random Matrix Theory Improves Language Mapping Sensitivity in Brain Tumor Patients

Thursday, Nov. 29 11:00AM - 11:10AM Room: S503AB

Participants

PURPOSE

Functional MRI improves preoperative planning in brain tumor patients, however BOLD signal changes for task-based 3T fMRI are only 2-3% and the tumor often compromises patient performance. This study tested the hypothesis that Marchenko-Pastur Principle Component Analysis (MP-PCA) denoising significantly improves statistical power for pre-operative fMRI language mapping.

METHOD AND MATERIALS

This IRB-approved, HIPAA-compliant study retrospectively identified 22 brain tumor patients (13 female; 42.5±18.1yrs, all left language dominant) that successfully performed verb generation, sentence completion and listening comprehension language fMRI paradigms. Original and MP-PCA denoised volumes for the 3 language tasks were processed using FSL-FEAT. For each task, we created histograms of z scores for original and MP-PCA denoised data within the left frontal operculum (LFO) and left parieto-temporal junction of the contralateral homologous region. Mean Z-scores were compared using paired 2-sided t-tests and their distributions compared with Kolmogorov-Smirnov tests.

RESULTS

MP-PCA denoising resulted in increased volume and magnitude of fMRI activation for all 3 language tasks. In the LFO during sentence completion, MP-PCA denoised statistic maps showed 12% average greater volume of voxels with $Z>3$ ($p=0.0002$) and mean z-score increased from 4.9±1.1 to 5.7±1.5 ($p<0.0001$) (almost an order of magnitude increase in statistical power). Mean z-scores did not increase after MP-PCA denoising in contralateral regions not involved in language. Histogram of z-scores in cortical language regions shifted to stronger statistical correlations to the task (KS test; $p<0.0001$) and appeared less Gaussian than typically observed with fMRI, which may better reflect known widespread cortical recruitment during language performance.

CONCLUSION

MP-PCA denoising demonstrated increased sensitivity for cortical regions recruited during language task-based fMRI paradigms in brain tumor patients. This could improve the clinical value and practical utility of performing preoperative fMRI in more brain tumor patients.

CLINICAL RELEVANCE/APPLICATION

A recently described denoising approach can significantly increase the statistical power of task-based fMRI to improve language mapping sensitivity in patients with brain tumors.

SSQ15-05 Assessment of Zygomatic Bones Symmetry through 3D Segmentation and Mirroring Procedure on CT Scans (MFCT) for Reconstructive Maxillofacial Surgery Work-Up

PURPOSE

Zygomatic bones contribute to overall facial morphology: their integrity and symmetry is of pivotal interest in reconstructive maxillofacial surgery. Our aim was to prove the feasibility of a new technique for zygomatic bones symmetry assessment through registration and calculation of point-to-point distances between the mirrored 3D models.

METHOD AND MATERIALS

100 patients (50 male, 50 females), divided in 2 groups (18-49 years ; 50-95 years) were randomly selected from our CT-scans

database. CT acquisition parameters were: 150 mAs, 120 kV, collimation: 128 x 0.6 mm, pitch: 0.55, recon. thickness: 1 x 0.8 mm, recon.algorithm: H60 sharp. 1 operator performed a 2 -step semi-automatic segmentation of bone volumes through ITK-SNAP software; first the bone surface from zygomatic, maxillary, frontal and temporal areas was acquired; then the obtained 3D model was elaborated with a 3D-elaboration software (VAM© software) to manually select the zygomatic bone according to sutures. Once the 2 zygomatic bones are acquired, the left bone is automatically mirrored and registered on the right one according to the least point-to-point distance between the 2 models by the VAM© software, which provides point-to-point mean and root mean square (RMS) distance and a graphical representation of constant and variable areas between the 2 surfaces.

RESULTS

According to Bland-Altman test, repeatability of RMS measurements performed by the same operator and by a different observer was 79% for both. TEM for intra- and inter-observer error was respectively 4.3% and 3.5%. No statistically significant differences were found according to sex, neither for mean point-to-point distance ($F = 0.15$, $p = 0.670$) nor for RMS value ($F = 0.4$, $p = 0.529$). No statistically significant difference was found according to age groups, neither for mean point-to-point distance ($F = 0.58$, $p = 0.448$) or RMS value ($F = 0.05$, $p = 824$). Interaction between sex and age was negligible for both the parameters ($F = 0.38$, $p = 0.539$; $F = 0.82$, $p = 0.367$, respectively). Effect size for sex and age groups was respectively 0.15 and 0.00: in the former case the value corresponds to a small effect, whereas in the latter one to no effect.

CONCLUSION

We confirmed the feasability of this new 3D method for assessing zygomatic symmetry.

CLINICAL RELEVANCE/APPLICATION

The use of this technique can help a precise planning for surgical reconstruction of zygomatic bones fractures.

SSQ15-06 Which Standardized T1-Weighted Brain MRI Template to Use in Studies on Older Adults?

Thursday, Nov. 29 11:20AM - 11:30AM Room: S503AB

PURPOSE

Atlas-based MRI investigations on older adults typically utilize young adult standardized structural templates, such as those of the ICBM. In addition, a quantitative assessment of how different available standardized structural templates perform in an aging population has not yet been performed. Here, a new standardized T1-weighted template designed specifically for studies on older adults was developed and compared to 15 other standardized templates in terms of image quality and inter-subject spatial normalization accuracy.

METHOD AND MATERIALS

T1-weighted brain MRI data from 222 non-demented older adults (65-95 age-range, male: female=1:1) participating in the Memory and Aging Project were included in this work. A template was constructed from these data based on ANTs registration and is referred to in the following as the IIT-Aging template. The IIT-Aging template and 15 other standardized templates were compared in terms of image sharpness by means of the normalized power-spectral density. All templates were also compared in terms of the inter-subject spatial normalization accuracy achieved when used as references for normalization of T1-weighted data from 222 non-demented ADNI participants. Normalization accuracy was assessed for each template by means of the average pair-wise normalized cross-correlation, standard deviation, and average absolute log-Jacobian determinant in gray matter of ADNI participants.

RESULTS

The IIT-Aging template has higher image sharpness compared to other templates, also demonstrated as higher energy at high spatial frequencies in the normalized power spectra Fig (A, B). Inter-subject spatial normalization accuracy was higher when using the IIT-Aging compared to all other templates Fig (C, D). The IIT-Aging and MCALT templates required lower spatial deformation for spatially normalizing ADNI datasets Fig (E).

CONCLUSION

The new IIT-Aging T1-weighted template is characterized by superior image quality and allows higher inter-subject spatial normalization accuracy for studies on older adults, compared to other available standardized templates.

CLINICAL RELEVANCE/APPLICATION

Evaluate older adult templates for use in aging population

SSQ15-07 Three Dimensional Deep Neural Network Based Multi-Modality and Multi-Organ Automatic Segmentation for Brain Radiosurgery

PURPOSE

Tumor and critical organ delineation is the most critical step in automatic stereotactic radiosurgery (SRS) treatment planning workflow for brain metastases. Recent progress in 3D convolutional neural networks has made it feasible to produce voxel-wise predictions of volumetric images and provide a powerful tool for automatic segmentation. The present study aims to develop a 3D convolutional networks algorithm for tumor and multi-organ segmentation on multi-modality imaging including contrast-enhanced computed tomography (CTc) and contrast-enhanced T1-weighted magnetic resonance imaging (MRI-T1c).

METHOD AND MATERIALS

Our training and testing dataset are acquired from one brain metastases cohort (n=95) treated with SRS using CyberKnife system. Each data included volume mask for brain tumors, brain stem, optic chiasm, bilateral eyes and optic nerves with associated CTc and MRI-T1c. We develop a workflow to organize the raw data, perform image preprocessing including data augmentation and registration, construct 3D U-Net models containing 19 million parameters, train and test the models then visualize the results. The workflow was developed by using Python 3.5 programming language and Google TensorFlow framework. All models were trained on NVIDIA Tesla P100 or V100 GPUs.

RESULTS

Our preliminary results of DICE scores for tumors and multi-organs ranged around 0.72-0.76 and 0.58-0.64 in the training set for CTc and MRI-T1c images, respectively. The DICE scores for the testing set for multi-organs ranged from 0.53-0.61 for CTc and 0.46-0.51 for MRI-T1c images.

CONCLUSION

The present work demonstrated the feasibility of simultaneous tumor and multi-organ segmentation using 3D neural network based on multi-modality imaging. Further work to elaborate the algorithm and incorporate it into SRS planning process is warranted and will shed light on future automated radiation therapy workflow.

CLINICAL RELEVANCE/APPLICATION

Simultaneous tumor and multi-organ segmentation is the very first step in automatic radiotherapy treatment planning, and multi-modality imaging schemes will help the precise delineation of the target region. The combined approaches will possess the key position in comprehensive automatic radiotherapy workflow.

SSQ15-08 Deep Learning Segmentation for Detection of Brain Metastases in the Small Data Regime

PURPOSE

Detecting brain metastases can be a tedious and time-consuming task for many radiologists, particularly with the routine use of 3D imaging. By leveraging a fully CNN's ability to learn from the detailed pixel-wise labels of segmentation data, we have trained a network that can scalably detect brain metastases on MRI.

METHOD AND MATERIALS

In this retrospective cohort study at a single academic institution, we included 48 pre-surgical patients who had brain metastases from several primary malignancies. MRIs, all of which included a contrast-enhanced axial IR-prepped FSPGR T1-weighted images, were performed on a combination of 1.5T (n=8) and 3T (n=40) scanners. 42 patients were used for training, and 6 patients were used for testing. The input to our segmentation network is a 2D image slice from the aforementioned sequence. Manual segmentation was performed by an experienced neuroradiologist using OsiriX software by drawing region of interests around each enhancing metastatic lesion. We used a GoogLe net architecture modified for segmentation.

RESULTS

The mean age of patients was 63.7 yrs (range: 29-90 yrs). Primary malignancies included 29 lung, 13 breast, 3 melanoma, 1 esophageal, 1 renal, and 1 multiple cancers in the setting of Li Fraumeni syndrome. The test set of 6 patients had a total of 38 lesions. Our segmentation IoU (averaged per scan) was 0.46. We detected brain metastases at a sensitivity of 0.89 with a false positive rate of 5 lesions per scan. Similar experiments were done with a variety of different network architectures with very similar results. Adding additional slices as input channels (i.e., 2.5D) yielded similar results.

CONCLUSION

Even training with as few as 48 patients, our network could learn and provide usable results and ultimately yielded high sensitivity for the detection of brain metastases. By leveraging pixel-data, our network could learn from richer pixel-wise target labels rather

than construct robust features from scan-wise class labels.

CLINICAL RELEVANCE/APPLICATION

Our study provides proof of concept for the application of a widely available deep learning network to detect brain metastases on contrast-enhanced MRI with high sensitivity and illustrates the potential use of this technique in a clinically relevant setting.

SSQ15-09 Dictionary Based T1 Mapping Algorithm for the Tri-TSE Pulse Sequence

Thursday, Nov. 29 11:50AM - 12:00PM Room: S503AB

Participants
Ning Hua, PhD, Boston, MA (*Presenter*) Nothing to Disclose
Hernan Jara, PhD, Boston, MA (*Abstract Co-Author*) Inventor, Boston University

For information about this presentation, contact:

huaning@bu.edu

PURPOSE

Quantitative T1 mapping provides absolute measures of tissue hydration and integrity. In addition it facilitate cross-platform comparison. Traditional T1 mapping can be slow, thus it has not been adopted in clinical settings by radiological community. Most qT1 methods require solving steady-state Bloch equations for each voxel, which is time consuming and generates numeric solution. Here, we propose using two standard clinical sequences, T1-weighted single echo (SE) and dual echo (DE), as well as an adaptive T1 dictionary, to efficiently and accurately access T1 relaxation in addition to T2 map generated from DE.

METHOD AND MATERIALS

Theory and data analysis scheme is illustrated. Briefly, instead of solving the non-linear equation, we establish a dictionary for each T1 values in the 0 to 5000ms (interval=0.01ms) range, by calculating the corresponding PVRdictionary (the signal ratio of SSE and SDE1)using the Bloch equation. To generate T1 map, the minimal absolute difference between obtained PVRvoxel and PVRdictionary was used to quickly identify the matching T1. The algorithm was tested on 20 clinical subjects without radiological findings or exposure to Gd, using a 3T system (Ingenia, Philips, Best, The Netherlands). The key parameters were: TRSE/DE=500/2129ms, FA= 90, ES=10ms, ETLSE/DE=7/14. The study was approved by our IRB. Data was analyzed in Matlab (Mathworks, MA). Histogram of T1/T2 values for each subject was also generated.

RESULTS

Representative T1/T2 maps from a subject were shown. The corresponding T1/T2 histograms of the whole brain were shown. The average of all patients, the peak value of gray matter was 1267.036.4ms, white matter 771.438.8ms. The averaging processing time for T1 map is 78.8±4.4s.

CONCLUSION

The combination of clinical available SE/DE sequence and dictionary searching method provides an accurate and efficient T1 mapping in addition to T2 maps provided by DE, hence, have the potential for facilitating the adaption of quantitative MRI in the clinical setting.

CLINICAL RELEVANCE/APPLICATION

The triFSE sequence are commonly available and could provide T1/T2-weighted images that match diagnostic standards. Our method creates additional relaxometry measures without extra time burden in clinics, which would have an impact on cross-platform researches, and also provide a better quantitative tool to understand diseases.

PURPOSE

To retrospectively assess, in a large and diverse clinical population, the feasibility, safety and tolerance of cerebrovasuclar reactivity (CVR) mapping with a well-controlled CO2 stimulus protocol. Images were obtained using blood oxygen level-dependent (BOLD) magnetic resonance (MR) imaging during the CO2 protocol.

METHOD AND MATERIALS

We performed a retrospective chart review of all CVR studies at a tertiary care hospital between Jan 1, 2006 and March 19, 2018. The CO2 protocol included elevations in CO2 over resting baselines between 10 and 15 mmHg. Demographic data, past medical history, incidence of adverse events and reasons for failed examinations were collected in addition to study parameters. The diagnostic quality of CVR mapping was conducted by two independent and blinded observers. Studies were graded as good, diagnostic but suboptimal, non-diagnostic, requiring reassessment or failed/missing. Data are presented as raw values using descriptive statistics (means +/- standard deviations), and inter-observer variability was evaluated using the intra-class correlation coefficient.

RESULTS

One thousand fifty consecutive CVR examinations from 597 patients (47.5% male patients) were studied. Patient age ranged from 9 to 88 years (mean age, 55.0; median 46.8). There were no cerebrovascular accidents, myocardial infarctions, or other major complications. The success rate of generating diagnostic scans was 70.0% (735 of 1050) and those requiring reassessment was 17.4% (183 of 1050). Among the 735 diagnostic examinations, good quality CVR maps were obtained in 672 (64.0%) and diagnostic but suboptimal in 63 (6.0%). Of the 315 non-diagnostic and failed scans, 67 (24.0%) were due to discomfort, 27 (8.6%) due to head motion, 8 (2.9%) due to inability to cooperate, 19 (6.8%) due to technical difficulties, and 158 (55.6%) due to unknown or unspecified conditions. Factors that influenced the successful completion of these scans included patient characteristics such as anxiety, claustrophobia or a pre-existing medical condition.

CONCLUSION

Prospectively targeted CO2 stimulus for CVR mapping with BOLD MR imaging is technically feasible and well tolerated. Importantly, in this large and diverse clinical cohort, patient safety was maintained.

CLINICAL RELEVANCE/APPLICATION

Prospectively targeted CO2 stimulus with BOLD MR imaging is a safe and effective technique for imaging cerebral vascular activity in a diverse clinical population.

SSQ16-02 Visualizing Wall Enhancement Over Time in Unruptured Intracranial Aneurysms Using 3D Vessel Wall Imaging

Thursday, Nov. 29 10:40AM - 10:50AM Room: S504AB

Participants
Bing Tian, MD, Shanghai, China (*Abstract Co-Author*) Nothing to Disclose
Laura B. Eisenmenger, MD, Salt Lake City, UT (*Abstract Co-Author*) Nothing to Disclose
Christopher P. Hess, MD, PhD, Mill Valley, CA (*Abstract Co-Author*) Nothing to Disclose
David A. Saloner, PhD, San Francisco, CA (*Abstract Co-Author*) Nothing to Disclose
Luguang Chen, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

High resolution MRI vessel wall imaging provides important capabilities in assessment of intracranial vascular disease including intracranial aneurysms. This study aims to compare the aneurysm wall visualization on pre- and post- 3D isotropic T1-weighted SPACE images and to explore whether there is a change in wall enhancement at follow up.

METHOD AND MATERIALS

Twenty-nine patients with thirty-five unruptured intracranial aneurysms were scanned on a 3T Siemens Skyra scanner with pre- and post-contrast 3D T1-weighted SPACE (0.5mm isotropic). Follow up studies were performed on all patients. Aneurysm wall visibility and enhancement scores were assigned by three neuroradiologists on pre- and post-contrast SPACE respectively. The aneurysm wall visibility between pre- and post-contrast images as well as the wall enhancement between follow up and baseline studies were compared. Differences in wall visibility and enhancement were also investigated as a function of aneurysm diameter and location.

RESULTS

Agreement among three reviewers in grading wall visibility and enhancement was excellent. Post-contrast images had significantly higher wall visibility. A wall enhancement score >=2 was found on 71% (25/35) of the aneurysms. Changes in levels of wall enhancement were found on 17% (6/35) of the aneurysms at follow up studies, but those changes were small. Wall visibility and enhancement scores of large aneurysms were significantly higher than that of small aneurysms.

CONCLUSION

3D T1-weighted high resolution SPACE can be used to assess changes in enhancement at follow up studies. Contrast SPACE image provides better aneurysm wall visibility and improves diagnostic confidence.

CLINICAL RELEVANCE/APPLICATION

Advances in vessel wall imaging techniques using high-resolution MR sequences now allow for improved visualization of the walls of intracranial vessels. In this study, we present results obtained with a 3D variable flip angle fast spin echo sequence (SPACE) to visualize the walls of intracranial aneurysms and to grade the extent of aneurysm wall enhancement in subjects whose aneurysms were monitored over time. Our studies showed that visualization of the aneurysm wall is significantly better on post-contrast images than on pre-contrast images, and the majority of unruptured aneurysms show wall enhancement. Furthermore, we found the wall enhancement scores to remain essentially unchanged on follow up studies.

SSQ16-03 Branching Pattern of Lenticulostriate Arteries in Moyamoya Disease and Atherosclerotic Moyamoya Syndrome by Whole-Brain Vessel Wall Imaging

Thursday, Nov. 29 10:50AM - 11:00AM Room: S504AB

Participants

Zhiwen Liu, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

fang_1989.127@163.com

PURPOSE

Moyamoya disease (MMD) and atherosclerotic moyamoya syndrome (A-MMS) have a great overlap in luminal imaging, which brings difficulties to differential diagnosis. Whole-brain (WB) magnetic resonance vessel wall imaging (VWI) enables visualization of vessel wall structure and lenticulostriate arteries (LSAs) in one image setting, allowing distinguishing different vasculopathies. We hypothesized that the pattern of branching of the LSAs and vessel wall characteristics is different between the two diseases. For the purpose of the study, we made a comparative analysis of the pattern of branching of the LSAs and vessel wall characteristics using WB-VWI between MMD and A-MMS.

METHOD AND MATERIALS

WB-VWI was performed on 19 adult patients with clinically defined MMD and 21 adult patients with A-MMS. The pattern of branching of the LSAs (pattern 1=no dilation or proliferation, pattern 2=mild dilation and proliferation, pattern 3=dense dilation and proliferation), wall thickening pattern (eccentric and concentric), morphology of occluded middle cerebral artery (MCA) (plugged and vanishing), and intraluminal thrombosis (absent and present) were evaluated.

RESULTS

A total of 80 involved hemispheres were analyzed (38 in MMD and 42 in A-MMS). The pattern of branching of the LSAs was

different (P=0.004) between MMD (pattern 1=55.3%; pattern 2=31.6%; pattern 3=13.2%) and A-MMS (pattern 1=88.1%; pattern 2=7.1%; pattern 3=4.8%). Concentric wall thickening was more frequently observed in MMD than A-MMS (78.9% versus 21.4%, P < 0.001). Morphology of occluded MCA and intraluminal thrombosis were not statistically different between the two groups (P < 0.05 for both).

CONCLUSION

MMD has a distinct vascular pathophysiology in terms of the pattern of branching of the LSAs and wall thickening characteristics compared with A-MMS. WB-VWI enables the combination of vessel wall and LSA imaging, which together may improve the differentiation of MMD and A-MMS.

CLINICAL RELEVANCE/APPLICATION

(dealing with whole-brain MR vessel wall imaging) whole-brain MR vessel wall imaging detects distinct pattern of branching of the LSAs and wall thickening characteristics in patients with MMD and is recommended in the differential diagnosis of moyamoya disease and atherosclerotic moyamoya syndrome.

SSQ16-04 Strain Discontinuities in Carotid Atherosclerotic Plaques - A Novel Marker for Plaque Vulnerability?

PURPOSE

We aim to develop and validate a novel method using ultrasound radiofrequency (RF) measurements to determine intraplaque inhomogeneities in the strain distribution with a high axial resolution.

METHOD AND MATERIALS

Ultrasound examinations were performed on common (CCA) and internal carotid arteries (ICA) of 22 patients, 17 with recent ischemic stroke / transient ischemic attack and 5 asymptomatic patients (39 CCAs and ICAs). The strain distribution was computed from RF data with a depth resolution <0.5mm using a custom MATLAB algorithm. In the plaque-free CCA, the radial wall strain was compared with the relative diameter change to validate the strain computation. Two observers analyzed the data for intra-observer variation analysis. In the ICAs, strain inhomogeneities in symptomatic and asymptomatic plaque were studied.

RESULTS

Within the CCA wall, the strain (observer 1: -7.4±2.7%, observer 2: -6.4±2.6%) had reasonably good intra-subject precision (1.6%) and accuracy (correlation with relative distension, observer 1: r=0.69; p<0.0001, observer 2: r=0.68; p<0.0001). Intra-observer variability had an ICC of 0.681 (two-way mixed, single measure). In the ICA, strain inhomogeneities had an elongated shape (mean: 0.7x11mm) and demarcated in 58% of the cases the plaque-adventitia boundary. The percentage of ICAs with 1 or more strain inhomogeneities was increasing with the degree of stenosis (p=0.03, 95%-CI). Strain inhomogeneities were more frequent in ICAs at the symptomatic side of stroke/TIA patients as compared to the contralateral arteries and both carotid arteries of the asymptomatic subjects combined (odd's-ratio=4.7; p=0.07). In contrast to the average strain, strain in the deviating strain regions was higher at the symptomatic compared to the asymptomatic side (p=0.02).

CONCLUSION

The proposed method to assess local radial strain distribution proved to be accurate and precise in the CCA. In the ICA, areas with high strain inhomogeneities were more frequent in symptomatic plaques as compared to asymptomatic plaques. These strain inhomogeneities could be a promising novel marker for plaque vulnerability.

CLINICAL RELEVANCE/APPLICATION

Rupture of atherosclerotic plaques is an important underlying cause of stroke and is ultimately a biomechanical event. Local ultrasound strain measurements may identify vulnerable plaques.

SSQ16-05 Quantitative Susceptibility Mapping Analysis of Carotid Intraplaque Hemorrhage

PURPOSE

Intraplaque hemorrhage is considered an important factor in carotid plaque vulnerability. We investigated whether quantitative susceptibility mapping (QSM) can be used to characterize the composition of carotid plaques and to detect intraplaque hemorrhage.

METHOD AND MATERIALS

We obtained 3T MR data on 9 carotid plaque specimens from 9 patients who had undergone carotid endarterectomy. QSM images were generated using the morphology-enabled dipole inversion method. One radiologist measured the susceptibility values (SVs) on QSM images by using a region-of-interest (ROI) method. Pathologists performed histo- and immunopathologic analyses for tissue characterization and the identification of intraplaque hemorrhage. Areas immunopositive for glycophorin A, a sialoglycoprotein of the red blood cell membrane, were semi-quantified using color image analysis software. These areas were expressed as the ratio of positively-stained areas per ROI area (PSA/RA). The relationship between the mean SVs and the PSA/RAs was assessed using the Spearman rank correlation coefficient.

RESULTS

We examined 24 areas (intraplaque hemorrhage, n=7; lipid-rich necrotic core, n=7; calcification, n=10). The average SV for intraplaque hemorrhage, lipid-rich necrotic core, and calcification was 201 ± 115 parts per billion (ppb), -10.8 ± 17.3 ppb, and -157.7 ± 78.1 ppb, respectively. The difference in the mean SV among the three tissue components was statistically significant ($p < 0.05$). The PSA/RA was positively correlated with the mean SV ($r=0.65$, $p<0.0001$).

CONCLUSION

Our preliminary study suggests that QSM can be used to characterize the carotid plaque composition and to detect intraplaque hemorrhage.

CLINICAL RELEVANCE/APPLICATION

QSM is useful for evaluating the presence of carotid intraplaque hemorrhage.

SSQ16-07 Deep Learning based Computer-Aided Detection of Unruptured Cerebral Aneurysms

PURPOSE

To demonstrate the usefulness of deep learning based Computer-Aided Detection (CAD) for reader performance in detecting unruptured cerebral aneurysms from the data of MR Angiography (MRA).

METHOD AND MATERIALS

100 head MRA datasets (39 men and 61 women; mean age, 63.8 years ± 12.3; mean aneurysm size, 3.5 mm ± 1.3), 40 with one or more unruptured cerebral aneurysms and 60 without, were retrospectively evaluated. Twenty doctors (10 expert radiologists, and 10 non-specialists) were asked to detect cerebral aneurysms on MRA scans with associated projection images. The readers indicated their confidence level rating on a visual analog scale for each detected lesion, first without and then with CAD output. Our CAD algorithm consisted in the following steps: (1) volume reconstruction from MRA images; (2) vessel segmentation using a threshold-based method; (3) key point extraction based on principal curvature method; (4) ranking of key points using a deep learning method (convolutional neural network composed of 39 convolutional, one average pooling, and one fully connected layers); (5) clustering of the key points with score higher than 0.5. The observers' performance was evaluated using receiver operating characteristic (ROC) and jackknife free-response ROC curves.

RESULTS

For the cases used in this study, the sensitivity of the CAD software was 90.5% (57/63) with an average of 1.6 false-positive detections per case. Using the software, the area under the inferred ROC curve (AUC) improved on average from 0.850 to 0.888 across all readers ($P = 0.0002$). The AUC for non-specialists improved from 0.794 to 0.855 ($P = 0.0006$) and from 0.910 to 0.926 for expert radiologists ($P = 0.0236$). The figure-of-merit values computed using the jackknife free-response ROC program improved from 0.735 to 0.810 for non-specialists ($P = 0.0001$) and from 0.884 to 0.908 for expert radiologists ($P = 0.0064$). Whereas the average sensitivity increase from 90.3% to 93.1% for expert radiologists was not statistically significant, average sensitivity significantly improved from 67.9% to 80.1% for non-specialists.

CONCLUSION

The diagnostic accuracy of cerebral aneurysms improved among all readers with the use of CAD.

CLINICAL RELEVANCE/APPLICATION

In the detection of unruptured cerebral aneurysms, the use of CAD can reduce the oversight of radiologists, and enable non-

in the detection of unruptured cerebral aneurysms, the use of CAD can reduce the oversight of radiologists, and enable non-specialists to improve their reading performance as an educational tool.

SSQ16-08 4D Flow MRI Analysis of Cerebral Blood Flow before and After Extracranial-Intracranial Bypass Surgery for Atherosclerotic Disease

PURPOSE

The purpose of this study was to clarify the change in the hemodynamics after superficial temporal artery to middle cerebral artery (STA-MCA) bypass surgery for atherosclerotic steno-occlusive disease by using time-resolved 3D-phase contrast (4D Flow) MRI.

METHOD AND MATERIALS

We retrospectively enrolled 20 patients (14 men; mean age 63.9) undergoing STA-MCA bypass surgery for internal carotid artery (ICA) stenosis (10 pt.) and MCA stenosis (10 pt.). We excluded moyamoya disease. All patients underwent 4D Flow MRI preoperatively and 3 weeks after surgery. The imaging parameters; 3.0-T MRI (Achieva, Philips), TR/TE = 8.4/5.4, VENC = 100cm/sec, voxel size = 0.82X0.82X1.4mm, heart phase = 15, scan time = approx. 6 min. We measured blood flow volume (BFV) of bilateral ICAs, basilar artery (BA), and bilateral STAs using GT Flow (Gyro Tools). The BFV of each vessel and total brain BFV (total-BFV = bilateral ICAs + BA + ipsilateral STA (after surgery)) was compared between before and after surgery with the paired t-test. We evaluated postoperative hyperperfusion syndrome based on the clinical chart.

RESULTS

4D Flow MRI data were successfully generated in all patients. Hyperperfusion syndrome occurred in 1 case. BFV of ipsilateral STA significantly increased after surgery (0.53 ± 0.22 vs. 1.78 ± 0.54 ml/sec ($p < 0.001$)). BFV of ipsilateral ICA significantly decreased after surgery (2.37 ± 5.09 vs. 1.82 ± 3.42 ml/sec ($p = 0.03$)). While, no significant difference was observed in total-BFV (12.40 ± 5.55 vs. 12.94 ± 6.71 ml/sec ($p = 0.24$)) or BFV of contralateral ICA (5.14 ±5.87 vs. 4.72 ± 4.60 ml/sec ($p = 0.06$)), BA (4.89 ± 2.89 vs. 4.61 ±2.48 ml/sec ($p = 0.11$)), and contralateral STA (0.33 ± 0.06 vs. 0.40 ±0.06 ml/sec ($p = 0.07$)) between before and after surgery.

CONCLUSION

BFV of ipsilateral STA significantly increased after surgery. While, there was no significant difference in total-BFV between before and after surgery. It may indicate that ipsilateral STA and native intracranial arteries (i.e., bilateral ICAs and BA) supply blood flow complementarily after surgery.

CLINICAL RELEVANCE/APPLICATION

4D Flow MRI can quantify the change of hemodynamics after EC-IC bypass surgery for intracranial atherosclerotic steno-occlusive disease.

SSQ16-09 Imaging Characterization and Differentiation of Intracranial Vasculopathies Using 3T MR Vessel-Wall Imaging

PURPOSE

The purpose of this study is to evaluate the ability of MR VWI to differentiate between various types of intracranial vasculopathies.

METHOD AND MATERIALS

Patients who presented with new non-traumatic intracranial hemorrhage and/or MRI-confirmed ischemic stroke and who also demonstrated vascular abnormalities suggestive of underlying intracranial vasculopathy on initial CT, MR or catheter angiography were identified between January 1, 2013 and July 1, 2017. All patients received our institution's MR VWI protocol (high-resolution multiplanar T1W pre- and post-contrast and 3D SPACE T2W sequences) and underwent CSF collection with or without image-guided brain biopsy. An expert clinical neurologist panel retrospectively evaluated each patient's history, imaging, labs, and

pathology in order to produce a consensus diagnosis of the underlying vasculopathy. A radiologist, blinded to patient identity and diagnosis, evaluated each MR VWI study. The distribution and severity of intracranial vascular stenoses, vessel wall thickening, and vessel wall enhancement were assessed. Statistical analysis was performed in order to identify the correlation between these imaging features and the specific underlying vasculopathy.

RESULTS

Thirty-eight patients (22F, 16M) were included in the final analysis. Reversible cerebral vasoconstriction syndrome (RCVS) presented with an average of 5 stenoses per patient which was the largest number of stenoses per patient amongst all of the vasculopathy types evaluated. RCVS was 4.6 times more likely to demonstrate moderate-to-severe stenoses than infectious vasculopathies (p=9.73E-05). Infectious vasculopathies presented with the greatest number of enhancing lesions per patient, with varicella zoster virus (VZV) vasculitis and miscellaneous infectious vasculopathies presenting with on average 4.7 and 4.3 enhancing lesions per patient, respectively. Overall, these infectious vasculopathies were 2.3 and 2.7 times more likely to show enhancing lesions relative to RCVS (p=0.045).

CONCLUSION

MR VWI can aid in differentiating intracranial vasculopathies based on imaging features. Infectious vasculopathies are more likely to demonstrate abnormal vessel-wall enhancement whereas RCVS is more likely to demonstrate high grade multifocal stenoses.

CLINICAL RELEVANCE/APPLICATION

Pertinent MR VWI findings may be used to both guide therapy decisions and monitor patient response as well as to direct surgical biopsy.

PURPOSE

To develop methods for 3D printing realistic anthropomorphic phantoms of individual patients for simulation of patient exposure in computed tomography and radiation therapy.

METHOD AND MATERIALS

In a first step, patient CT images are printed with inkjet technology and radiopaque ink on paper. In a second step, the printed paper sheets are processed with paper based 3D printing methods to mechanically stable phantoms with the attenuation properties and the external contour of the patient. The resulting patient phantoms are examined in the CT scanner (Canon Aquilion One and Aquilion Prime). Acquisition parameters (tube voltage, tube current, acquisition mode, pitch, reconstruction technique) are systematically combined and dose and image quality are analyzed.

RESULTS

Radiopaque 3D printing achieves detailed patient phantoms with individual anatomy and pathology. Phantom Hounsfield units correlate linearly with patient Hounsfield units ($r = 0.9925$) and phantom attenuation values correspond to patient values for different radiation energy levels. Systematic analysis of 72 combinations of acquisition and reconstruction parameters on patient phantoms yields a dose optimum with automated tube potential selection in combination with automated tube current modulation, volume acquisition and iterative reconstruction. Dose reduction potential of iterative reconstruction is >60% in comparison with filtered back projection.

CONCLUSION

Radiopaque 3D printed patient phantoms provide a detailed simulation of patient exposure and allow systematic investigation of dose and image quality.

CLINICAL RELEVANCE/APPLICATION

Realistic patient phantoms allow systematic development and analysis of dose reduction, optimization and imaging techniques.

SSQ17-02 Rapid Measurement of Low Contrast Detectability

Thursday, Nov. 29 10:40AM - 10:50AM Room: N229

Participants
Scott S. Hsieh, MS, Los Angeles, CA (*Presenter*) Nothing to Disclose
Akinyinka O. Omigbodun, PhD, Los Angeles, CA (*Abstract Co-Author*) Nothing to Disclose
John M. Hoffman, PhD, Los Angeles, CA (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Low contrast detectability (LCD) is a metric of fundamental importance in CT imaging, but cannot easily be measured with nonlinear reconstruction methods because concepts such as contrast-noise ratio (CNR), modulation transfer function (MTF) and noise power spectrum (NPS) do not directly apply. We introduce a new framework for rapidly measuring LCD using model observers with a single scan.

METHOD AND MATERIALS

We place a large number of low-contrast markers into the field of view and assess their detectability using a model observer. In this work, we used a non-prewhitening (NPW) observer that searches the image for candidate marker locations by subtracting an estimate of the local background signal, convolving with a template disk image, and then identifying local maxima above a response threshold. More sophisticated alternatives to NPW could also be used. By varying the threshold, we can produce free-response ROC curves. We used this framework to compare iterative reconstruction (IR) with filtered backprojection (FBP) in simulations. We also tested the framework on experimental data, fabricating a phantom consisting of small polycarbonate spheres interspersed in acrylic spheres and placed in 13.5% sugar solution. The sugar solution was iso-attenuating with acrylic, leading to a dispersion of low-contrast polycarbonate bead markers of about 20 HU.

RESULTS

In simulations with anisotropic noise, IR+NPW showed consistently better performance than FBP+NPW, with sensitivity at one false positive (FP) of 80% compared to 57%. With uniform noise, the difference disappeared and the sensitivities at 1 FP were 70% and 67% for IR+NPW and FBP+NPW, respectively. Experimental scans demonstrated the feasibility of low-contrast automated detection (of polycarbonate spheres) with an easily constructed phantom.

CONCLUSION

An objective metric for LCD can be produced by scanning a specialized, target-rich phantom and using model observer software. This framework holds equally well for iterative or analytic reconstruction algorithms, and could be used for comparison of scanners, assessment of new reconstruction algorithms, or routine quality assurance.

CLINICAL RELEVANCE/APPLICATION

Automatic detection of LCD could be used in routine quality assurance and could also be used to elucidate conditions (for example, non-uniform statistics) that affect detectability.

SSQ17-03 Diagnostic Accuracy of Sub-Millisievert Coronary CT Angiography on 16cm Wide-Detector CT Using 70kVp for Patients with High Heart Rate: Comparison with Digital Subtracted Angiography

Thursday, Nov. 29 10:50AM - 11:00AM Room: N229

Awards
Student Travel Stipend Award

chenyuhuan0528@163.com

PURPOSE

To investigate the image quality and diagnostic accuracy of coronary CT angiography (CCTA) on a 16cm wide-detector CT using 70kVp for patients with high heart rate using Digital Subtracted Angiography (DSA) as reference standard.

METHOD AND MATERIALS

Forty-three patients with heart rates higher than 80 bpm underwent both CCTA on a 256-row, 16cm wide-detector CT (Revolution CT) and DSA. All CCTA scans were acquired in one heart beat with bolus-tracking technique using 70 kVp and automatic tube current modulation for noise index of 36HU at 0.625mm image thickness, and at weight-dependent contrast dose rate of 16mgI/kg/s for 8s injection. Images were reconstructed at the best cardiac phase with the least motion with 80%ASIR-V and with Snapshot Freeze Motion Correction in all patients. Two experienced cardiovascular radiologists and two cardiovascular specialists evaluated the subjective and objective image quality of CCTA study and the DSA results, separately and independently . CCTA performance for diagnosing >=50% stenosis was analyzed against the DSA results. The sensitivity and accuracy of CCTA were calculated. The volumetric CT dose index (CTDIvol), dose length product (DLP) were recorded to calculate the effective dose.

RESULTS

The mean heart rate was 96.2±17.1bpm (range: 81-156bpm). The mean effective radiation dose was 0.46?±?0.21 mSv. All CCTA images were deemed to have diagnostic quality, and 94.2% (650/690) of the coronary segments were analyzed for stenosis. Using DSA as the reference standard, sensitivity and accuracy for diagnosing >=50% stenosis with CCTA were 100% and 90.7% on a per-patient basis. These values were 92.3% and 89.0% on the per-vessel basis and 77.6% and 87.2% on the per-segment basis.

CONCLUSION

CCTA on a 16cm wide-detector CT using low tube voltage of 70kVp provides high quality images and high accuracy for diagnosing stenosis at sub-millisievert radiation dose even for patients with high heart rates.

CLINICAL RELEVANCE/APPLICATION

CCTA with 70kVp on 16cm wide-detector CT that enables 1-beat imaging at sub-mSv radiation may be used to provide high image quality and diagnostic accuracy for cardiac patients with heart rates.

SSQ17-04 Low Contrast Detectability Observer Study For Four Different Reconstruction Algorithms in CT

Thursday, Nov. 29 11:00AM - 11:10AM Room: N229

Participants
Stanislav Zabic, PhD, Mayfield Village, OH (*Presenter*) Employee, UIH America, Inc
Min Ji, Shanghai, China (*Abstract Co-Author*) Employee, Shanghai United Imaging Healthcare Co, Ltd
Wenjing Cao, Shanghai, China (*Abstract Co-Author*) Employee, Shanghai United Imaging Healthcare Co, Ltd
Guotao Quan, PhD , Shanghai, China (*Abstract Co-Author*) Employee, Shanghai United Imaging Healthcare Co, Ltd
Yuan Bao, Shanghai, China (*Abstract Co-Author*) Employee, Shanghai United Imaging Healthcare Co, Ltd

PURPOSE

This report performs a comparative human and model observer study for low contrast detectability, following the MITA recommendations. Standard filtered backprojection (FBP) is compared to model based iterative reconstruction (MBIR) and two different methods for noise reduction in image space: edge preserving denoising and deep learning algorithm.

METHOD AND MATERIALS

Data was scanned 50 times at 3 different dose levels each using MITA low contrast module phantom and subsequently reconstructed with the aforementioned four reconstruction methods. We used 120kV scans with 50, 40 and 30 mAs. Dose levels were chosen to be low enough to make the signals seemingly saturated with noise, making the detectability task difficult in standard FBP for a human observer. Eight human observers were asked to review obtained images using 4-alternative-forced-choice method with 3 signal-absent images and 1 signal-present image. The objective was to understand the capability of advanced image reconstruction methods to improve the low contrast detection over the standard FBP reconstruction. The same images were also fed into a publically available model observer tool to understand whether a model observer can be used in place of human observers in the future examinations.

RESULTS

Human observers consistently performed with approximately two times higher detectability indices in images reconstructed using MBIR when compared to the standard FBP. A similar result was also repeated in detectability indices for images denoised by the deep learning method. An edge preserving denoising used in this study had relatively same detectability index as the standard FBP (between 0.8 and 1.2). Model observer technique for low contrast detectability task performed with similar trends as the human observers, but absolute values for the detectability indices were higher by a factor of 1.5.

CONCLUSION

Advanced reconstruction and noise reduction methods can improve the low contrast detectability indices in CT imaging, but not all methods perform the same way. One has to perform tuning when attempting to replace human observers with the model observers.

CLINICAL RELEVANCE/APPLICATION

Low contrast detectability tests with MITA phantom and diagnostic tasks in liver and brain studies are closely related. Clinical users should expect an improved performance in imaging with MBIR and deep learning algorithms, when compared to the standard reconstruction methods.

SSQ17-05 The Weight of ASiR-V in Low Radiation Dose Craniocerebral CT Scan

Thursday, Nov. 29 11:10AM - 11:20AM Room: N229

For information about this presentation, contact:

147690660@qq.com

PURPOSE

To explore the weight of ASiR-V under low radiation dose craniocerebral CT scan that was comparable that obtained in conventional scanning

METHOD AND MATERIALS

60 Patients who underwent craniocerebral CT scan were prospectively and randomly divided into two groups. Group A (n=30) use conventional 120kVp scanning protocol while group B (n=30) use 100kVp scanning protocol.The data in Group A were reconstructed with ASiR-V 50% images while the data in Group B were reconstructed with ASiR-V weights of 60%, 80% and 100% images. Three slices were selected in each group of patients. The CT values of bilateral frontal gray matter, parietal gray matter and centrum ovale white matter were measured at the centrum ovale slice. The CT values of bilateral frontal gray matter, temporal lobe gray matter, occipital lobe gray matter, lenticular and white matter were measured at the basilar nucleus slice. The CT values of bilateral cerebellum gray matter, temporal lobe gray matter, and white matter were measured at the cerebellum slice. The ROI were drawn in the front of the forehead to measure the air standard deviations (SD). SD of air is used as the background noise. Three slices of gray/white matter SNR were calculated and the CNR of gray-white matter were calculated. The subjective noise, contrast of gray-white matter and posterior fossa artifacts score was evaluated blindly by two radiologists independently using a 5-point scoring system.

RESULTS

The effective dose in group B (1.02mSv) decreased by 34.3% compared to group A (0.67mSv). Group B with ASiR-V 60% was only higher than group A ($p<0.01$), and the other was similar to group A (all $p>0.05$). Gray/white matter SNR with ASiR-V 100% was

higher than group A in the three slices (all p<0.05), and the other was similar to group A (all p>0.05). the gray-white matter-CNR with ASiR-V 80% and 100% was higher than group A in the basilar nucleus slice (all p<0.05), and the other was similar to group A (all p>0.05). There were no significant difference in noise, contrast of gray-white matter and posterior fossa between the Group B with ASiR-V 60% and Group A (all Adjust-p>0.05).

CONCLUSION

The image quality of ASiR-V 60% in group B was similar to group A in objective parameters and subjective evaluation in craniocerebral CT scan.

CLINICAL RELEVANCE/APPLICATION

In craniocerebral CT scan, low radiation dose scan combined with the increased ASiR-V weight could ensure adequate image quality.

SSQ17-06 Low-Contrast Detectability of Clinical CT Images in 3D Reformatted Planes

Thursday, Nov. 29 11:20AM - 11:30AM Room: N229

Participants
Jayse Weaver, Rochester, MN (*Presenter*) Nothing to Disclose
Lifeng Yu, PhD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose
Cynthia H. McCollough, PhD, Rochester, MN (*Abstract Co-Author*) Research Grant, Siemens AG

For information about this presentation, contact:

Weaver.Jayse@mayo.edu

PURPOSE

3D reformatted images are frequently generated in clinical CT for diagnostic purposes. Due to the difference between axial and 3D-reformatted images in terms of spatial resolution and noise correlation, it is unknown if the low-contrast detectability of 3D-reformatted images is comparable to that of axial images from the same data. The purpose of this work was to use a Channelized Hotelling Observer (CHO) to evaluate the index of detectability for low-contrast objects of various sizes in the coronal plane compared to in the axial plane.

METHOD AND MATERIALS

A 3D-printed phantom with embedded spheres of various sizes and contrast levels was scanned 50 times on a 192-slice scanner (Force, Siemens) to provide an ensemble dataset for CHO calculation. Images were reconstructed in the axial and coronal planes using filtered backprojection (FBP) with a Br40 kernel and an iterative reconstruction (IR) method (ADMIRE, Siemens) with the same Br40 kernel but two strength settings, Br40-3 and Br40-5. The reconstruction planes were across the center of the spheres. Pixel size was kept the same between reconstructions. A CHO with 12 Gabor channels (previously validated against human observer performance) was used to calculate the index of detectability, d', for two low contrast spheres (3 and 9 mm in diameter, both with a contrast of -36 HU from background) in the axial and coronal planes.

RESULTS

For FBP, d' in the coronal plane was similar to that in the axial plane for both size spheres (9 mm: 5.78±0.58 in coronal vs. 5.87±0.61 in axial; 3 mm: 2.15±0.24 in coronal vs. 1.96±0.25 in axial). When IR was applied, d' improved over FBP for the large sphere in both planes, but the improvement in the coronal plane was less than that in the axial plane. For the smaller sphere, applying IR appeared to have no effect on d'.

CONCLUSION

Given the same slice thickness and reconstruction kernel, the low-contrast detectability was similar in the axial and coronal planes using the FBP reconstruction. When IR was used, the low-contrast detectability in coronal planes appeared to improve less than that in axial planes, especially for large objects.

CLINICAL RELEVANCE/APPLICATION

Low-contrast detectability in 3D-reformatted planes appears to be similar to that in routine axial planes using FBP reconstruction method. The performance may differ when IR is used.

SSQ17-07 Assessment of Beam-Hardening Artifact Reduction Effect on CT

Thursday, Nov. 29 11:30AM - 11:40AM Room: N229

Participants

niu-niupy@163.com

PURPOSE

To evaluate the effect of beam-hardening artifacts reduction technologies on 256 Multi-Detector wide-coverage CT and high-definition gemstone spectral CT(HDCT) by comparing the two CT models.

METHOD AND MATERIALS

A cylindrical plastic phantom with 9 hard plastic tubes which were filled with different concentrations(20, 10, 0 mgI/ml) of iodine

solution was used in phantom(The diameter is 18mm), the highest concentration (20mg/ml) is the center of the plastic phantoms , and the other 8 tubes were located clockwise in outer circle. The phantom was scanned using three different modes respectively: 1) a 256 Multi-Detector CT (Revolution CT) scanner equipped with Multi-Material Artifact Reduction (MMAR) technology and Volume High Definition (VHD) image reconstruction technology, which scans by axial mode(Group A),2) HDCT(Discovery CT)scans with conventional 120kvp mode(Group B) and GSI mode (Group C) were respectively performed. In each of the three groups, ROIs with the same area were placed on regions that were most significantly affected by beam-hardening artifact (between tubes with 20 and 10 mgI, 20 and 10 mgI, 20 and 0 mgI iodine solution). Image noise (SD) in these ROIs were measured and artifact index (AI) was calculated as AI2=SD2-SDb2 (SDb was the background noise).

RESULTS

The average image noise in the three groups (Group A, Group B and Group C) were 6.4±0.6,8.7±2.1 and 2.7±0.2, and the AI were 8.3±0.5,10.3±1.8 and 6.8±0.1 respectively. Compared with conventional 120kvp mode of HDCT, Revolution CT with VHD technology and MMAR technology, and GSI mode of HDCT can reduce image noise and AI, the effect of GSI mode is better than Revolution CT.

CONCLUSION

Revolution CT scan with VHD technology and MMAR technology, and HDCT-GSI mode can reduce hard-artifact index (AI), and improve image quality, but the effect of HDCT-GSI mode is best.

CLINICAL RELEVANCE/APPLICATION

256 Multi-Detector CT (Revolution CT) with 16 cm wide body detector, by one rotation can complete a single organ (such as the heart, brain, substantial / hollow organs) imaging .It return to the origin of CT scan- axial scan equipped with Multi-Material Artifact Reduction (MMAR) technology and Volume High Definition (VHD) image reconstruction technology for better image quality.

SSQ17-08 Evaluation of CT Image Quality and Liver Lesion Detectability with Different Dose Levels and Different Levels of the Iterative Reconstruction Algorithm ASiR-V

Thursday, Nov. 29 11:40AM - 11:50AM Room: N229

Participants

Anne C. Martinsen, Oslo, Norway (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

ekir@ous-hf.no

PURPOSE

The aim of this study was to optimize image quality and dose levels with different levels of ASiR-V.

METHOD AND MATERIALS

A novel anthropomorphic liver phantom customized for quantitative and qualitative image analysis (Phantom Laboratory, NY US) was scanned at three different dose levels (CTDIvol 15, 10, and 5 mGy) and 120 kVp on a GE Revolution 16 CT scanner (GE Healthcare, Milwaukee, WI US). Images were reconstructed using a standard abdominal kernel and different levels of the iterative reconstruction (IR) algorithm ASiR-V (0-100%). Mean CT values, noise, signal to noise ratio (SNR), contrast to noise ratio (CNR), low contrast detectability and noise power spectrum (NPS) was analyzed. Noise texture deviation (NTD) was evaluated to look at IR specific artifacts. Lesion detectability was assessed on a 5-point scale by 5 readers. The areas under the receiver operating characteristic (ROC) curve were calculated.

RESULTS

Mean CT-values and low contrast detectability did not change with increasing level of ASiR-V. Compared to filtered back projection the noise was reduced while SNR and CNR increased for ASiR-V levels 10-100%. The NTD analysis showed that the mean NTD was not different from NTD calculated for FBP for ASiR-V 10-40 % for CTDI 15 mGy and ASiR-V 10-50 % for CTDI 10 and 5 mGy ($p>0.05$). Mean NTD increased to be different from FBP for ASiR-V 50-100% for CTDI 15 mGy and ASiR-V 60-100 % for CTDI 10 and 5 mGy ($p<0.05$). The area under the ROC curve increased with increasing level of ASiR-V. For the CTDIvol 15, 10 and 5 mGy reconstructing with 90%, 80 % and 100% ASiR-V gave the highest area under the ROC curve respectively. Lower dose levels reduced the lesion detectability, low contrast detectability, SNR and CNR. Preliminary analysis of the NPS showed that the peak frequency decreased slightly as the level of ASiR-V increased.

CONCLUSION

This study showed that increasing the level of ASiR-V improved liver lesion detectability when using a standard abdominal kernel. SNR and CNR increased at increasing level of ASiR-V while low contrast detectability remained constant. Noise texture deviation analysis showed that IR artifacts increased for higher levels of ASiR-V (above level 40%).

CLINICAL RELEVANCE/APPLICATION

Iterative reconstruction aims to reduce patient dose in CT. Lesion detectability and image quality need to be assessed to ensure satisfactory examination quality, which was the purpose in this study.

SSQ17-09 Technical Assessment of a Mobile CT Scanner for Image-Guided Brachytherapy: Image Quality, Dose, and Technique Protocols

PURPOSE

A technical assessment of imaging performance and radiation dose is reported for a recently introduced mobile CT scanner (Airo, Brainlab, Munich, Germany), with application to image-guided brachytherapy. Such quantitative assessment guides selection of technique protocols for pertinent imaging tasks and facilitates translation to new applications.

METHOD AND MATERIALS

Four studies were performed to assess 3D image quality and dose of the system: (1) Objective measures of uniformity and noise (20 cm diameter water phantom), HU accuracy and contrast (tissue-simulating materials (Gammex RMI)), and spatial resolution (modulation transfer function, MTF); (2) Visual image quality using anthropomorphic phantoms with realistic bone and soft-tissue anatomy of the head, chest, abdomen, and pelvis; (3) Image quality and artifacts measured using custom phantoms emulating transvaginal brachytherapy via cylindrical or tandem-and-ring applicators adjacent to soft-tissue; and (4) Radiation dose (CTDI) measured in 16 cm (head) and 32 cm (body) cylinders. Image quality and dose were assessed for manufacturer-specified techniques as well as custom protocols spanning a wide range of kV, mA, scan mode (axial or helical), smoothing kernel, and (optional) metal artifact reduction (MAR).

RESULTS

The technical assessment provided quantitative insight on system performance and limitations. Image uniformity and HU accuracy were within 5%, supporting dose calculation in brachytherapy. Helical scans (1.4 pitch) reduced dose and scan time compared to axial scans, but also reduced z-direction MTF and introduced windmill artifacts about high-contrast structures and instrumentation, diminishing soft-tissue visibility. Contrast and noise performance were sufficient for soft-tissue visualization in brachytherapy of the cervix and uterus. The MAR algorithm greatly improved soft-tissue visualization in the presence of needles and applicators.

CONCLUSION

The imaging system provided excellent accuracy and uniformity with sufficient contrast and spatial resolution for application in transvaginal brachytherapy. The technical assessment identified opportunities for dose reduction (lower kV protocols) and artifact reduction in helical scan mode.

CLINICAL RELEVANCE/APPLICATION

New mobile CT systems can improve precision and safety of image-guided interventions. Rigorous assessment of image quality and dose helps guide adoption and future application of such technology.

SSQ18-01 Estimating Embryo and Fetal Dose from Abdomen/Pelvis CT Scans That Use Tube Current Modulation

Thursday, Nov. 29 10:30AM - 10:40AM Room: N228

Participants
Anthony Hardy, MS, Los Angeles, CA (*Presenter*) Nothing to Disclose
Maryam Bostani, PhD, Los Angeles, CA (*Abstract Co-Author*) Nothing to Disclose

Michael F. McNitt-Gray, PhD, Los Angeles, CA (*Abstract Co-Author*) Institutional research agreement, Siemens AG; ; ; ; ;

PURPOSE

Estimates of embryo and fetal dose have previously been limited to fixed tube current exams. However, tube current modulation (TCM) is used routinely in clinical practice. Therefore, the purpose of this work is to develop patient size-specific CTDIvol-to-fetal-dose conversion coefficients from TCM abdomen/pelvis (A/P) CT exams of pregnant patients of various gestational ages.

METHOD AND MATERIALS

Twenty-four publicly available voxelized pregnant patient models were used in Monte Carlo (MC) simulations of A/P CT scans using TCM. The models represent a range of gestational ages from less than 5 to 36 weeks and have maternal and fetal anatomy identified from image data. Attenuation characteristics were estimated from simulated topograms of each voxelized patient model. Predicted TCM schemes were then generated for each patient model using a validated method that accounts for both patient attenuation and scanner model characteristics. Embryo and fetal doses were obtained by incorporating each TCM scheme into an MC source model of a 64-slice MDCT scanner, simulating the A/P exam and tallying dose to the fetus. If the fetus was not visible (i.e. early gestational age) then dose to the gestational sac or uterus was used to estimate embryo dose. Water equivalent diameter (Dw) was used as the size metric and was calculated at the image containing the three-dimensional geometric centroid of either the fetus or the gestational sac. All embryo and fetal doses were normalized by scan-specific 32 cm CTDIvol values based upon the average tube current across the entire simulated scan. Normalized embryo and fetal doses were then parameterized as a function of Dw using an exponential function similar to SSDE.

RESULTS

Embryo and fetal doses from the 24 simulated CT A/P exams using TCM demonstrate an exponential relationship between normalized dose and Dw which has a coefficient of determination of 0.79. This relationship is slightly different from that of SSDE, which is not an explicit representation of organ or fetal dose.

CONCLUSION

A method to estimate embryo and fetal dose that account for patient size (through Dw) and TCM has been developed which uses an exponential function similar to SSDE.

CLINICAL RELEVANCE/APPLICATION

Using this methodology, embryo and fetal dose at various gestational ages can be reasonably estimated with the scanner-reported CTDIvol and a metric of patient size such as Dw.

SSQ18-02 Web-Platform for Fast and Accurate Assessment of Radiation Dose Received by Conceptus in Clinical CT

Thursday, Nov. 29 10:40AM - 10:50AM Room: N228

Participants
Natalia Saltybaeva, PhD, Zurich, Switzerland (*Presenter*) Nothing to Disclose
Hatem Alkadhi, MD, Zurich, Switzerland (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

Natalia.Saltybaeva@usz.ch

PURPOSE

Computed tomography (CT) is sometimes required during pregnancy. In this case the radiation dose received by conceptus should be evaluated. Existing methods are either limited in their accuracy or require complicated measurements and calculations. The aim of this study is to develop a web-based tool for radiation dose assessment received by conceptus in CT; validate this tool and implement it in clinical routine.

METHOD AND MATERIALS

The tool is based on the doses derived from Monte Carlo (MC) simulations performed for generic CT system on virtual phantoms, representing a range of various patient sizes and gestational ages. For validation, the values calculated by the online tool were compared against dose values calculated by detailed MC simulations performed on real patients' data. The data for 30 pregnant patients, underwent clinically indicated examinations on CT scanner of two different vendors (Siemens, GE) were collected. Detailed MC simulations took individual patient geometry and scan parameters into account. After the validation the software framework was designed in order to provide the free of charge access to the tool for multiple clients, without installing the software locally. The feedbacks from the users have been collected.

RESULTS

The validation of the tool has shown that the average error of the dose values calculated by the online tool was 23%, with the overestimation of about 41% in case of obese patients. The biggest error of 56% was found in patient when additional hardware (i.e. fixation device) was applied and visible in the reconstructed image, resulting in the higher current values applied by the CT system, and thus higher fetal dose values estimated by the program. The users have found the program convenient and intuitive for use in clinical routine. The average time required for calculating single patient case is less than 2 minutes.

CONCLUSION

The online platform provides fast and reliable evaluation of the radiation dose, received by conceptus from CT examination.

CLINICAL RELEVANCE/APPLICATION

This tool can be used by physicians for fetal dose assessment and performing risk-benefit analysis. It can be also used for training purposes.

SSQ18-03 The Impact of Scanning Heads Within a Dedicated Head Holder Versus the Table Top on Effective Mas, Image Quality, and CTDI

tszczykutowicz@uwhealth.org

PURPOSE

Often, especially in the CT trauma setting, heads must be placed on the table top instead of in a head holder. A head holder attenuates the beam less than the table top requiring less effective mAs to obtain the same image quality. The purpose of this study is to quantify this difference.

METHOD AND MATERIALS

264 adult head (193 head holder, 71 table top) head data was collected under IRB approval. The effective mAs and CTDIvol were recorded for each case. Phantom scans were performed with a 16 cm CTDI phantom placed on the table top and in the head holder. Regional (center, top, bottom of the phantom) noise values and regional (center, top hole, bottom hole) CTDI100 values were measured. The use of AEC, which allowed the scanner to account for the extra attenuation of the table versus the head holder, and manual mA were used to scan the phantom. For the human scans, we also documented the presence or absence of patient transport "slider boards" and dental amalgam to evaluate their impact on scanner output.

RESULTS

The mean effective mAs for the clinical scans increased by a factor of 1.7 times for heads imaged on the table top relative to the head holder. Statistically significant differences in image noise were observed from the phantom scans for table top versus head holder positioning in manual mA mode. A statistically significant difference in image noise between the top and bottom of the CTDI phantom was observed for table top imaging, but not for head holder imaging indicating noise is more uniform for head holder scans. The presence of dental amalgam and "slider boards" did not cause a statistically significant difference in CTDIvol. Head holder and table top positioning produced statistically significant differences (6% versus 23% respectively) between top and bottom hole CTDI100 measurements.

CONCLUSION

This study demonstrates the superiority of using AEC versus a manual technique for head. Using a manual technique inhibits one's scanner from being able to compensate for the attenuation differences between the table and head holder.

CLINICAL RELEVANCE/APPLICATION

Using manual mA for head imaging does not account for attenuation differences between table top and head holder patient positioning leading to poorer image quality for the latter.

SSQ18-04 Clinical Study of Measurement of Mammary Gland Dose Using Organ-Based AEC

Thursday, Nov. 29 11:00AM - 11:10AM Room: N228

j.ohta@chiba-u.jp

j.ohta@chiba-u.jp

CONCLUSION

For plain chest CT of Japanese women, Organ-Based AEC reduces the exposure dose to mammary glands by 14.6%. Earlier studies, conducted using phantoms, overestimated the reduction effect of Organ-Based AEC.

Background

Chest CT requires suppression of exposure to mammary glands. Many reports of earlier studies have described that Organ-Based AEC can reduce the exposure dose by 25-60%. In a report that analyzed CT images retrospectively, it is considered that most of the mammary glands are not included in the dose reduction area. However, these phantom data and simulation studies did not actually measure patients. Therefore, the effect of Organ-Based AEC exposure dose reduction in clinical research has not been clarified. This clinical study measured mammary gland doses using Organ-Based AEC in chest CT. Furthermore, the properties of Organ-Based AEC were examined by phantom study.

Evaluation

This observational study study examined plain chest CT scans of female patients: 30 using Organ-Based AEC, and 30 not using Organ-Based AEC. Subjects were randomly extracted. Their mammary gland doses were measured. An OSL dosimeter was affixed to 12 patients' breasts. The equipment used was Aquilion ONE® (Toshiba Medical systems). Organ-Based AEC used OEM (Organ Effective Modulation). In the Organ-Based AEC, as the size of the subject became smaller, the reduction effect was also lower. The Organ-Based AEC had the greatest reduction effect in the anterior side of the subject, the reduction effect got lower as approaching the lateral side. In clinical study, results show that 9.18 ± 1.96 mGy doses were received when Organ-Based AEC was used, but 10.76 ± 2.58 mGy doses were received when Organ-Based AEC was not used. The radiation dose reduction ratio of mammary glands was therefore 14.6%.

Discussion

The results of phantom studies of earlier studies have a greater dose reduction effect than our clinical studies. The reason is that in the earlier study, part of the mammary gland is out of the dose reduction zone, and it is not considered that the physique affects the reduction ratio of Organ-Based AEC.

SSQ18-05 How Much Does Low kV Imaging Increase Skin Radiation Dose in Contrast-Enhanced CT? - A Simulation Study on a Virtual Population of Patient Models

Thursday, Nov. 29 11:10AM - 11:20AM Room: N228

Participants
Shobhit Sharma, BEng,MSc, Durham, NC (*Presenter*) Nothing to Disclose
Justin B. Solomon, PhD, Durham, NC (*Abstract Co-Author*) License agreement, Sun Nuclear Corporation; License agreement, 12 Sigma Technologies
Ehsan Samei, PhD, Durham, NC (*Abstract Co-Author*) Research Grant, General Electric Company; Research Grant, Siemens AG; Advisory Board, medInt Holdings, LLC; License agreement, 12 Sigma Technologies; License agreement, Gammex, Inc

For information about this presentation, contact:

ss715@duke.edu

PURPOSE

To compare the effect of utilizing a lower kV setting over a standard high kV setting (70 vs 120 kV) on skin dose in contrast enhanced CT.

METHOD AND MATERIALS

The scanner-specific geometry was modeled for a state of the art CT scanner (Revolution CT, GE Healthcare) on a GPU-based Monte Carlo tool based on the MC-GPU framework. This tool was utilized in association with a virtual population of 58 anthropomorphic XCAT patient models (age, 18-78 y.o.; BMI, 18.21-38.81 kg/m2; sex #(M/F), (34/24)) to estimate organ doses for the abdominopelvic protocol (1.375 pitch, 80 mm collimation) at tube voltages of 70 and 120 kV. The organ dose values for both tube voltages were then normalized to a volumetric CTDI value of 12, to make them representative of a typical abdominopelvic scan. In addition to tabulating an average skin dose value for each tube voltage, the ratio of the skin dose to the effective dose (reff) and cumulative dose (rcum) was also computed as additional metrics of dose comparison. The standard deviation for each metric was calculated to represent the dose variability over the virtual patient population.

RESULTS

The absorbed dose values for skin were estimated to be 1.49±0.16 and 1.36±0.14 mGy for 70 and 120 kV tube voltages,

respectively. The corresponding values for reff were 0.80±0.12 and 0.59±0.06 respectively. For the same pair of tube voltages, the rcum value were 0.030±0.004 and 0.023±0.002. Lowering tube voltage from 120 to 70 kV didn't translate to a statistically significant increase in the absorbed skin dose as observed over a virtual population of 58 XCAT patients.

CONCLUSION

The lowering of kV setting from 120 to 70 kV did not lead to a significant increase in skin dose for the virtual patient population, thereby mitigating potential concerns related to the detrimental effects of low kV on skin dose.

CLINICAL RELEVANCE/APPLICATION

CT imaging at lower kV potentially leads to greater dose efficiency and increased image quality, especially for contrast enhanced CT. Concerns about drastic increases in skin radiation dose seem to be overstated with only marginal increases in skin dose.

SSQ18-06 Retrospective Assessment of Radiation Dose in Abdominopelvic CT: Inter- and Intra-Scanner Variability

Thursday, Nov. 29 11:20AM - 11:30AM Room: N228

Participants
Aiping Ding, Durham, NC (*Presenter*) Nothing to Disclose
Yakun Zhang, MS, Durham, NC (*Abstract Co-Author*) Nothing to Disclose
Justin B. Solomon, PhD, Durham, NC (*Abstract Co-Author*) License agreement, Sun Nuclear Corporation; License agreement, 12 Sigma Technologies

Ehsan Samei, PhD, Durham, NC (*Abstract Co-Author*) Research Grant, General Electric Company; Research Grant, Siemens AG; Advisory Board, medInt Holdings, LLC; License agreement, 12 Sigma Technologies; License agreement, Gammex, Inc

For information about this presentation, contact:

aiping.ding@duke.edu

PURPOSE

To develop a practical data-crunching solution for retrospectively assessing inter- and intra-scanner variabilities and inconsistencies in abdominopelvic CT dose using clinical patient data.

METHOD AND MATERIALS

This IRB-exempt study evaluated CT abdominopelvic (AP)-related examinations performed in 2016 and 2017 from 12 scanners (4 GE 750 HD,2 GE VCT, 4 Siemens Flash, and 2 Siemens Definition AS) in 3 site hospitals in an enterprise. An in-house developed informatics system automatically extracted protocol information, patient size (cross-sectional diameter), radiation dose, and *in vivo* noise magnitude within images. Protocol nomenclature categorization was performed using a decision-tree machine learning algorithm. Dose reference and fit lines were defined for each scanner by using machine learning logistic regression algorithms between dose and patient size. For a predefined reference patient size, Reference dose (RfD: intersect point of dose fit line and reference patient size) and dose deviation index (DDI: a ratio of received dose and ideal dose minus one) were then calculated.

RESULTS

17,000 (Data2016) and 17,000 (Data2017) AP studies for patients ages 0-70 and sizes 13-48 cm were identified. 12 dose reference lines with slopes 0.03-0.1 from Data2016 and 24 dose fitting lines (1th and 99th) from Data2017 were constructed. RfDs were calculated using a reference size of 31 cm and ranged from 466-568 mGy-cm for GE 750 HD, 630-674 mGy-cm for GE VCT, 401-428 mGy-cm for Siemens Flash, and 220-306 mGy-cm for Siemens Definition AS. DDIs ranged from 0.15-0.55. A multi-dimensional metrics compositing the above results was then established and visualized for system performance evaluation across systems.

CONCLUSION

This study offers the first even data-crunching solution for assessing inter- and intra-scanner variabilities in CT dose with clinical patient data. High dimensional metrics built upon patient data are essential for quantitatively assess protocol- and system-inconsistencies as well as optimize the quality, patient safety, and clinical operation.

CLINICAL RELEVANCE/APPLICATION

This study fulfilled an unmet need for quantitative assessment of system-inconsistencies, along with device performance assessment and optimization, to ensure rigorous patient safety and consistent image quality.

SSQ18-07 Explore the Feasibility of 'Four-Low' Scanning Protocol in Coronary Imaging Using Wide-Detector Revolution CT

PURPOSE

To investigate the feasibility of low-kvp, low-contrast medium, low-flow rate, low-dose 'four-low'scans for coronary artery imaging using wide-detector Revolution CT.

METHOD AND MATERIALS

60 patients underwent coronary artery CT imaging with coronary heart disease diagnosed in our hospital were divided into two groups. Group A use 100 kVp and group B use 80 kVp with 30 cases in each group. Contrast agent iopamidol (370 mgI/mL), both use standard (25 mgI/kg/s) iodine flow rate, dose and flow rate calculation formula. Scanning parameters: cardiac axial scan, Smart mA (200-650 mA), NI=26, fixed collimator width 140mm, Auto gating ECG, Pre-Asir-V=70%, Post-Asir-V=80. The CT values and SD standard deviations of aortic root, coronary artery RCA, LAD, LCX proximal lumen and surrounding adipose tissue were measured, SNR, CNR were calculated, CTDI, DLP were recorded, and the effective radiation dose ED was calculated. Subjective evaluations were conducted using a 4-point grading system by two senior-level physicians by double-blind method according to the American Heart Association (AHA) coronary 13 segments. The radiation dose, image quality, contrast agent dosage, and flow rate were statistically analyzed.

RESULTS

Age and heart rate in the two groups have no statistical significance (P> 0.05). The two groups of contrast agents were: (41.52±5.14) ml, (22.64±2.70) ml, and group B contrast was 45.5% less than that of group A. The flow rates in the two groups were: (3.45±0.43)ml/s, (1.90±0.21)ml/s, and group B was 44.9% lower than that of group A. ED was: (41.52±5.14) mSv in group A and (22.64±2.70) mSv in group B, group B dose was 41.0% lower than that of group A with statistical significant difference (P<0.05). There was no statistically significant difference in image quality subjective scores at the distal end (P>0.05).

CONCLUSION

Low-kVp, low-contrast, low-flow rate, low-dose, CT coronary artery imaging in wide-detectors is feasible. Image quality was not affected and the contrast agent dosage was reduced by 45.5%, the effective radiation dose was reduced by 41.0%, and the flow rate was reduced by 44.9%.

CLINICAL RELEVANCE/APPLICATION

The"four-low"scan scheme is feasible in coronary imaging without affecting the image quality. At the same time, the radiation dose, the contrast agent dose, and the injection rate of the contrast agent are greatly optimized and is recommended for clinical promotion.

SSQ18-08 A Comparison of Lung and Breast Doses from CT Scans Using Organ-Based Tube Current Modulation (TCM) vs. Conventional Attenuation-Based TCM Using Monte Carlo Simulations

Thursday, Nov. 29 11:40AM - 11:50AM Room: N228

PURPOSE

Organ-based Tube Current Modulation (TCM) was designed to reduce organ dose to anteriorly-located, radiosensitive organs such as the breast in CT exams. The purpose of this work was use Monte Carlo simulation techniques to compare lung and breast doses from chest CT exams using organ-based (TCM) to those using conventional TCM.

METHOD AND MATERIALS

Under IRB approval, raw projection and image data were collected from thirty-four patients (17 females, 17 males) who underwent CT chest/abdomen/pelvis (CAP) examinations employing organ-based TCM (XCARE + CAREDose4D, Siemens Healthineers). The actual organ based TCM schemes for the chest portion were extracted from the raw projection data for each patient. Lung and glandular breast tissue were semi-automatically segmented from patient image data for each case to create voxelized models of patient anatomy for use in a validated Monte Carlo (MC) transport code. Additionally, for these patients, TCM schemes from conventional, attenuation-based modulation only (CAREDose4D) were also estimated using a recently developed method that accounts for patient attenuation characteristics and scanner design. Absolute lung and breast doses for each TCM scenario were estimated for each patient model using MDCT source models in Monte Carlo simulations. The resulting lung and breast doses from each scheme were compared using within-patient percent difference using the from conventional TCM as the reference.

RESULTS

The differences of lung and breast dose from organ-based TCM across patients ranged from -35% to 73% and -53% to 45%, respectively. The mean female lung and breast dose differences were -11% and -21%, respectively. The average male lung dose difference was -21%. When pooled, on average, organ-based TCM reduces breast dose by 21% while dose lung dose remained nearly constant with a 5% increase.

CONCLUSION

Organ-based TCM may reduce breast dose while not incurring a substantial lung dose penalty when compared to conventional TCM. However, there can be some patients in which this may not be the case and may increase lung dose for men.

CLINICAL RELEVANCE/APPLICATION

On average, organ-based TCM may reduce breast dose relative to conventional TCM without increasing lung dose, but some patients may receive higher lung or breast from organ-based TCM.

SSQ18-09 Coronary CT Angiography Using a 70 kVp Protocol on 16cm Wide-Detector CT: Improved Vascular Enhancement with Reduction of Both Radiation and Contrast Agent Doses

Thursday, Nov. 29 11:50AM - 12:00PM Room: N228

PURPOSE

To investigate image quality, radiation dose, and diagnostic efficiency of prospectively ECG-triggered coronary CT angiography (CCTA) on 16cm wide-detector scanner using 70 kVp with low contrast dose compared with routine 100 kVp CCTA protocol.

METHOD AND MATERIALS

Forty patients (29 men and11 women; mean age, 55±14 years) received CCTA using either 70 kVp, noise index (NI) of 36HU, and at weight-dependent contrast dose of 16mgI/kg/s rate for 9s injection (Group A, n=20) or the conventional 100kVp, NI of 28HU, and at 25mgI/kg/s rate for 10s injection (Group B, n=20). Adaptive statistical iterative reconstruction (ASIR-V) was used with 80% strength for the 70 kV group and 60% strength for the 100 kV group. All CCTA image quality was evaluated by two experienced cardiovascular radiologists using a 5-point scale (5: best, 1: worst, >=3 scores diagnosable) and signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated and compared. The volumetric CT dose index (CTDIvol) in mGy, dose-length-product (DLP) in mGy-cm of CT scan were recorded. The Mann-Whitney U-test was used to compare the subject image quality scores and the unpaired t-test was used to compare the continuous variables including CT value, SNR, CNR and radiation dose and contrast dose.

RESULTS

There was no significant difference in age, heart rate and body mass index (21.18±2.08kg/m2 vs. 22.00±2.33kg/m2) between the two groups (all P>0.05); Mean CT values, SNR and CNR of the two groups were statistically the same(all P > 0.05). Subjective image quality showed no difference between the two groups (P=0.458) with good interobserver agreement (k=0.820). However, there was a significant difference in CTDIvol between Group A (2.20±1.0mGy) and Group B (9.03±5.50mGy) (P<0.05), resulting in 76.1% effective dose reduction for the 70kVp group (Group A) (0.43±0.20mSv vs. 1.80±1.28mSv, p<0.001). Moreover, the contrast dose for Group A was significantly lower than for Group B (22.01±3.11ml vs. 38.21±5.40ml) (P<0.001), a reduction of 42.4%.

CONCLUSION

Our proposed 70kVp CCTA protocol provides diagnostic information with substantial reduction in both radiation and contrast agent doses compared to the routine CCTA at 100 kVp.

CLINICAL RELEVANCE/APPLICATION

CCTA with 70kVp on a 16cm wide-detector CT that reduces both radiation and contrast agent doses while maintaining image quality compared with the routine 100 kVp CCTA protocol.

dgshen@med.unc.edu

PURPOSE

Early brain functional development studies using resting-state functional MRI (rs-fMRI) has been recently emerging. However, little is known whether the development of brain functional connectome can be embedded in the high dimensional connectome space and, if so, how such embedding looks like in the context of developmental neuroscience. This study is to explore the large-scale neuromechanism that encode the developmental functional connectome.

METHOD AND MATERIALS

Whole-brain region-wise functional connectome was built for each infant from a longitudinal rs-fMRI dataset with a large sample size (# subjects = 87, # scans = 302, natural sleeping from neonate to 2 years old, while passive movie watching for older subjects up to 6 years old). Principal component analysis (PCA) was conducted on the multi-subject, multi-scan functional connectome and each component was examined with age information. Based on a pure data-driven method, a 2-D embedding of the functional connectomes was adopted to unravel any development-related gradient(s).

RESULTS

Different age groups show clear clustered patterns with the first two principal components used even they accounted ~10% variance across subjects/scans. Two intriguing gradients were identified, one encoding development (span from younger to older ages), the other encoding brain states during the rs-fMRI scan ('natural sleeping' or 'awakening while movie watching'). The developmental gradient shows dominant inter-modular connections, with several hubs in auditory and spatial attention-related regions, and the thalamus. The state-related gradient shows prominent connections within visual, default mode, and executive control networks, with hubs in high-order cognitive function-related regions.

CONCLUSION

This is the first developmental study on 0-to-6-year-old functional connectome. The pure data-driven method could reveal changes in functional connectome due to early development and different brain states. The functional connectome gradients could be informative for better understanding brain functional development in the first years of life, a previously less investigated period.

CLINICAL RELEVANCE/APPLICATION

Reveal brain functional changes in the first years of life by detecting two 'gradients' and highlight regions and links that are most important to the rapid, dynamic development in this pivotal stage.

SSQ19-02 Longitudinal Strain Measures of White Matter Tracts in Youth Football Players

Thursday, Nov. 29 10:40AM - 10:50AM Room: S402AB

PURPOSE

We characterized longitudinal strain of the white matter in youth football players compared to non-contact sport control athletes and tested the hypothesis that axial and radial shape changes of fiber bundles would be associated with participation in contact sports and serve as a new neuroimaging biomarker of subconcussive head impact exposure.

METHOD AND MATERIALS

Twenty-three male youth football players (Age=12.1±1.2 yrs) and 13 male non-contact sports control participants (Age=10.6±1.7 yrs) were recruited for this IRB approved study. Longitudinal brain MRI data, including diffusion tensor imaging (DTI) were acquired before and after a single sports season (approximately 3-months) . Longitudinal registration was performed between pre-season and post-season T1-weighted images. DTI processing included geometric distortion correction, eddy-current correction, fitting of diffusion parameters, and co-registration to T1-weighted images. The voxel-wise fiber-specific deformations (axial and radial strains) were estimated by aligning 3D deformation tensor derived from longitudinal T1-weighted images to the co-registered eigenvectors from DWI. Parameter maps for axial and radial strains were registered to the study-specific template. We compared total and voxel-wise white matter volume change rates between football players and control participants using a linear regression and multiple comparison correction.

RESULTS

There was greater axial strain (contraction) among football players compared to controls in the body and right splenium of the corpus callosum ($p < 0.01$, 340 vox) (upper panel of figure). There was greater radial strain (expansion) in the splenium of the corpus callosum among controls compared to football players ($p < 0.01$, 219 vox) (lower panel of figure).

CONCLUSION

Axial and radial strain data demonstrated more directional contraction and less expansion, respectively, in the football group compared to non-contact sports controls. These tract-specific strains in white matter tracts may reflect changes associated with repetitive sub-concussive head impact exposure.

CLINICAL RELEVANCE/APPLICATION

There is growing concern regarding the long-term consequences of repetitive sports-related subconcussive head impact exposure on the developing brain. We propose a novel white matter tract-specific morphometry method to analyze the effects of repetitive subconcussive impacts on brain developmental trajectory.

SSQ19-03 White Matter Microstructural Correlates of Sensory Processing Disorder (SPD) on Connectome Edge Density Imaging and Probabilistic Tractography: Potentials of Machine Learning Models for Devising New Imaging Biomarkers

PURPOSE

SPD - affecting up to 16% of children - is associated with Autism Spectrum Disorders, and ADHD. We aimed to evaluate white matter microstructure of children with SPD, and apply machine-learning models for devising image-based diagnostic biomarkers.

METHOD AND MATERIALS

Children (aged 8 to 12 years) were prospectively recruited via our 'Sensory Neurodevelopment and Autism Program'. The connectome Edge Density (ED) and probabilistic Tract Density (TD) maps were developed using DTI and high-resolution T1 scans. Tract-Based Spatial Statistics (TBSS) was used for voxel-wise analysis. Stepwise penalized logistic regression was used to identify independent tract-based ED/TD variable(s) distinguishing children with SPD. Five different machine-learning models were used for identification of SPD: random forest, neural network, naïve bayes, and support vector machines with 'linear' and 'polynomial' kernels. Cross-validation of models was performed applying stratified random sampling of cohort into training and validation datasets (x500), preserving SPD-to-TDC ratio.

RESULTS

44 children with SPD and 41 typically developing children (TDC) were included. There was no significant difference in average age ($p=0.191$) and gender ratio ($p=0.338$) between SPD and TDC groups. On voxel-wise analysis, children with SPD had lower ED and TD in body and splenium of corpus callosum, posterior corona radiata, posterior thalamic radiation, and tapetum. On stepwise penalized logistic regression analysis, the average TD of splenium was the only independent variable differentiating SPD from TDC ($p<0.001$). Among different machine learning models, the random forest algorithm using ED had the best test characteristics NPV for identification of SPD with 75.6% accuracy, 79.4% sensitivity, 71.3% specificity, 77.5% PPV, and 75.1% among validation datasets.

CONCLUSION

Children with SPD have lower density of connectome edges and probabilistic tracts in body/splenium of corpus callosum and posterior white matter pathways, with 'lower splenium TD' as the most distinctive pattern. Machine learning models - particularly random forest algorithm using tract-based ED - can help identify children with SPD.

CLINICAL RELEVANCE/APPLICATION

Edge density imaging and probabilistic tractography can be used to identify white matter microstructural abnormalities in children with SPD, and to devise imaging biomarkers for SPD based on machine-learning models.

SSQ19-04 The Brain Network Architecture Classification of Pediatric Patients with Autism

zdchu@texaschildrens.org

PURPOSE

Although many cases are genetic in etiology, no clinical method exists to diagnose autism before its syndrome appears. Earlier diagnosis could allow intervention before the brain network fully developed. Brain imaging is a promising method to probe brain network organization without requirement for patient cooperation. In this study, we measured morphologic and diffusion-based brain network metrics in terms of their capacity to differentiate autism patients from controls. Those metrics can be measured individually and have the potential to be used as one of biomarkers for autistic diagnosis and prediction.

METHOD AND MATERIALS

17 age-matched pairs of autistic-control sibling were selected in this HIPAA-compliant study. The T1-weighted structural data was processed using FreeSurfer 5.3 resulting in 148 cortical parcels. Further division results in around 600 fine parcels with roughly equal size. We transformed parcels from anatomical space to diffusion space. First, cortical thickness was measured over the whole brain. Next, probabilistic tracking (FSL) on 32 directional diffusion data generated a connectivity matrix where the connection between each pair of network nodes was defined as the probability that a white matter connection exists between nodes. Based on the connection matrix, we computed five topologic properties of network organization (table 1) using the Brain Connectivity Toolbox. Univariate comparison between groups were performed for age and all measured metrics. A machine learning algorithm was used to measure the importance of each metric to autism classification after adjusting for the contribution of all other metrics.

RESULTS

The cortical thickness and brain network modularity are metrics showing significant group differences (Table 1). Further, the machine learning analysis demonstrated that the cortical thickness and modularity stand out as most important metrics in autism classification (figure 1).

CONCLUSION

In this cohort of pediatric autistic patients cortical thickness and brain network modularity were important discriminators between autistic patients and normal subjects.

CLINICAL RELEVANCE/APPLICATION

MR imaging provides a potential tool to predict/diagnose brain network disorder in early age. We investigates the importance of imaging-based brain network architecture in autism classification.

SSQ19-05 Integrating U-Net and Dilated Dense Network for Infant Hippocampus Subfield Segmentation

dgshen@med.unc.edu

PURPOSE

Accurate and automatic segmentation of hippocampus (HC) subfields from magnetic resonance (MR) brain images is important for studying both normal and abnormal early brain development. The goal of this study is to develop an automatic HC subfield segmentation method for infant MR brain images.

METHOD AND MATERIALS

Image Dataset: We used infant MR brain images of ten subjects, each with T1w and T2w images acquired at age of 12 months. Five HC subfields were manually labeled for each subject by the consensus of two neuroradiologists, including cornu ammonis sector

1 (CA1), CA2/3, subiculum (SUB), CA4/dentate gyrus (DG), Uncus. Methods: We propose a novel deep neural network for HC subfield segmentation. It is based on U-net, consisting of a contracting path to extract abstract features and an expansive path to recover spatial resolution. However, the contracting-expansive process in U-net can often miss detailed image information, thus affecting the accurate segmentation of small structures, such as HC subfields. To overcome this limitation, we embed the dilated dense network in the U-net to obtain a new network (DUnet). In the DUnet, the embedded dilated dense network can provide multi-scale features with relatively high spatial resolution. To further improve the performance, we group every two convolutional layers with one residual connection in the DUnet, and obtain the Residual DUnet (ResDUnet).

RESULTS

Our proposed methods were compared with U-net, using Dice ratio. The results show that our proposed DUnet outperforms the U-net in all subfields. Our proposed ResDUnet can further improve the segmentation performance by introducing residual connections. In particular, ResDUnet increases Dice ratios: 0.024 for CA1, 0.031 for CA2/3, 0.026 for SUB, 0.020 for CA4/DG and 0.024 for Uncus, compared with U-net.

CONCLUSION

We propose a new network for infant hippocampal subfield segmentation by integrating U-net and dilated dense network. Our proposed network can avoid losing detailed image information in the successive down-sampling steps, and effectively extract multi-scale features, which are important for image voxel localization and classification.

CLINICAL RELEVANCE/APPLICATION

Our proposed method for automatic segmentation of infant hippocampal subfields from MR brain images can be used for studying neurodegenerative diseases.

SSQ19-06 Alterations of Structural and Functional Connectivity in Bilateral Severe-to-Profound Sensorineural Hearing Loss Infants within an Early Sensitive Period: A Combined fMRI and DTI Study

Thursday, Nov. 29 11:20AM - 11:30AM Room: S402AB

jelly_66@126.com

PURPOSE

The development of central auditory system has a sensitive period during the first few years of life. This study was aimed to characterize the patterns of whole-brain structural and functional connectivity change in infants with bilateral severe-to-profound sensorineural hearing loss (SNHL) within an early sensitive period.

METHOD AND MATERIALS

36 infants with bilateral severe-to-profound SNHL (mean age = 16 months, range 6-35 months) and 33 age and sex matched healthy controls were recruited for the present study based on referral for clinical MRI and other inclusion criteria. All subjects underwent 3.0T anatomical and functional MRI included DTI and resting-state fMRI. DTI data were processed using Tract-Based Spatial Statistics (TBSS) to describe white matter (WM) impairment across the whole brain. fMRI data were analyzed to map functional connectivity (FC) feature related to left/right primary auditory cortex (A1) using a seed-based correlation method with the voxels in the whole-brain.

RESULTS

In comparison to controls, SNHL infants showed pronounced and wide-spread WM abnormalities, including the cortico-cortical WM tracts (SLF, ILF, UF and inferior fronto-occipital fasciculus), the cortico-fugal WM tracts (CST, external capsule, corona radiata, as well as thalamic radiation) and the interhemispheric connections of corpus callosum. In addition, SNHL infants exhibited enhanced functional connectivity between left A1 with right insula and right superior temporal gyrus, right A1 with right superior temporal gyrus.

CONCLUSION

Using DTI-TBSS in conjunction with rs-fcMRI analysis, the present study provides new evidences in support of the disconnection hypothesis caused by hearing loss, revealing the characteristics of early brain reorganization and compensatory activation changes in congenital severe-to-profound SNHL infants within early sensitive period.

CLINICAL RELEVANCE/APPLICATION

Improvements in our understanding of early brain development after auditory deprivation can promote individually customized rehabilitation programs targeted at improving clinical outcomes for cochlear implanted children.

SSQ19-07 Brain Language Network Architecture and Verbal Intelligence in Children with Focal Epilepsy

Golriz@bcm.edu

PURPOSE

Higher order functions of the human brain depend on the efficient integration of information across a functionally specialized brain network. The aim of this study is to examine the relationship between verbal intelligence and language network architecture in the pediatric, epileptic brain.

METHOD AND MATERIALS

Patients were retrospectively identified with the following criteria: 1) localization-related epilepsy; 2) brain MRI imaging at 3T, including resting-state fMRI sequence; and 3) Full-scale IQ subscales, including verbal comprehension index (VCI) measured by a pediatric neuropsychologist. The cerebral cortex was subdivided into approximately 1500 gray matter network nodes. Language network map was generated based on the automated Neurosynth meta-analysis. The strength of a connection between each pair of nodes within the language network was defined as the correlation between their resting BOLD time-series. The following network architecture metrics were calculated: clustering coefficient, global efficiency, modularity, transitivity, and path length. A machine-learning algorithm was used to measure the independent contribution of each metric to the verbal comprehension index while adjusting for age, gender and seizure duration.

RESULTS

Forty-six patients met the criteria with mean age 12.9 years (age range: 3 - 18). The male: female ratio was 28/18. After accounting for age, sex, and seizure duration, all five metrics including clustering coefficient, global efficiency, transitivity, modularity and path length were shown to be independently associated with verbal comprehension index. Clustering coefficient was the strongest predictor of verbal comprehension index.

CONCLUSION

These findings show that the topology of the constructed language network in children with focal epilepsy is associated with a core aspect of the brain function.

CLINICAL RELEVANCE/APPLICATION

Quantification of specific functional networks is an important step toward the clinical utility of network-based biomarkers.

SSQ19-08 Brain Structural Damage and Atrophy Correlates of Impaired Processing Speed in Pediatric Onset Multiple Sclerosis

PURPOSE

Brain atrophy (anatomical imaging), and structural damage (diffusion imaging), are commonly used to quantify neurodegeneration in multiple sclerosis (MS) and its impact on neurocognitive impairment. However, very few studies have investigated such relationships in pediatric onset MS (POMS) patients. The goal of this study was to investigate atrophy and diffusivity changes in pediatric onset MS patients and to correlate them with cognitive impairment.

METHOD AND MATERIALS

T1-weighted and diffusion tensor imaging (DTI) at 3T, and neuropsychological tests - symbol digits modality test (SDMT), brief visuospatial memory test (BVMT), Rey's audio verbal memory test (RAVLT), wide range achievement test (WRAT) and CogState brief battery - were performed on N=25 POMS patients (14F, 20.8 ± 4.5 years, age at onset = 15 ± 3.7 years, EDSS= 1.1 ± 1.26, mild disability) and N=24 age/sex-matched healthy controls (HC) (14F, 20.3 ± 3.7 years). Normalized total gray (GM), white matter (WM) and deep gray matter structures (DGM) volumes were quantified from T1-w images. Mean diffusivity (MD) was mapped across WM from DTI images, and normalized to standard space for voxelwise analyses. Volumetric and diffusivity metrics were analyzed for group differences, and correlated with age-adjusted neuropsychological test scores.

RESULTS

POMS showed decreased total WM, Thalamus (Thal), Putamen (Put) and Pallidum (Pall) volumes when compared to HC. In POMS group only, significant association was found between Put and Thal volumes and SDMT ($p<0.01$), Hippocampus volume and RAVLT ($p<0.05$), and total GM and Put volumes and WRAT ($p<0.05$). Voxelwise analyses showed widespread increases in MD in POMS when compared to controls. SDMT (processing speed) correlated negatively and CogState (processing time) scores correlated positively with increased MD in the corpus callosum, L/R superior and posterior corona radiata, and L/R superior longitudinal fasciculus ($p<0.05$, corrected). There were no significant correlations of MD with other neuropsychological scores.

CONCLUSION

In our mildly disabled POMS cohort, processing speed impairment was significantly associated with reduced DGM volumes and increased MD indicative of tissue loss and structural damage, respectively.

CLINICAL RELEVANCE/APPLICATION

Improved understanding of MS pathophysiology and progression in patients with pediatric disease onset could help develop strategies for early detection and treatment.

SSQ19-09 Effects of Repetitive Non-Concussive Head Impact Exposure on Default Mode Network Connectivity among Youth Football Players

Thursday, Nov. 29 11:50AM - 12:00PM Room: S402AB

Christopher T. Whitlow, MD, PhD, Winston-Salem, NC (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The purpose of this investigation was to determine if repetitive sports-related head impact exposure alters default mode network (DMN) connectivity in a cohort of youth football players compared to a non-contact sport control group.

METHOD AND MATERIALS

Twenty-nine male football players (mean±SD; 11.62±0.78 yrs; age range 10-13 yrs) and 19 age-matched male non-contact sports controls (mean±SD; 11.64±0.8 yrs; age range 10-13 yrs) were recruited for this IRB approved study. None of the participants had a history of concussion before or during the sports season. Participants received pre- and post-season MRI, including resting-state BOLD imaging. Pre-processed BOLD data were coregistered to structural T1-weighted images. A DMN seed was created from the orthogonal slices of spatial cross-correlation of the ICA spatial maps and used to extract individual DMNs for pre- and post-season data. A delta metric was computed by subtracting pre- and post-season DMN data for each individual to estimate changes in DMN connectivity strength. Voxel-wise linear regression with covariate (age) was conducted to examine between-group differences in longitudinal DMN connectivity strength. Lastly, we estimated the size of false positive clusters and applied this threshold to remove noise-only clusters.

RESULTS

Four clusters demonstrated between-group differences in DMN connectivity strength: 1. right middle/superior temporal cortex and right angular gyrus, 2. left middle temporal and left angular gyrus, 3. right superior/middle frontal gyrus, and 4. left middle/superior gyrus and left anterior cingulate cortex. Regression analyses demonstrated statistical significant differences in DMN connectivity strength between these regions ($P<0.05$). Overall, DMN connectivity strength increased among non-contact-sport controls, but decreased for footballers.

CONCLUSION

A single season of youth football was associated with decreases in DMN connectivity strength among football players compared to controls. These changes were not associated with clinically diagnosed concussion, and more work is necessary to determine potential functional significance among youth athletes with repetitive non-concussive sports-related head impact exposure.

CLINICAL RELEVANCE/APPLICATION

Decreased resting-state DMN connectivity strength could reflect disruption of related functions in youth athletes with repetitive sports related non-concussive head impact exposure.

SSQ20-01 Utility of Microcatheter for Adrenal Venous Sampling in Primary Aldosteronism

Thursday, Nov. 29 10:30AM - 10:40AM Room: S403A

Participants
Yoshifumi Noda, MD,PhD, Gifu, Japan (*Abstract Co-Author*) Nothing to Disclose
Satoshi Goshima, MD, PhD, Gifu, Japan (*Abstract Co-Author*) Nothing to Disclose

Nobuyuki Kawai, MD, Gifu, Japan (*Abstract Co-Author*) Nothing to Disclose
Masayuki Matsuo, Gifu, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To evaluate the utility of using microcatheter for the assessment of aldosterone hypersecretion and the laterality in adrenal venous sampling (AVS) for patients with primary aldosteronism.

METHOD AND MATERIALS

This prospective study was approved by our institutional review board and written informed consent was obtained. Thirty-seven consecutive patients with primary aldosteronism underwent AVS. A microcatheter was inserted in right adrenal central vein (RCV), left adrenal central vein (LCV), and left adrenal common trunk (CT). Aldosterone hypersecretion was diagnosed if the plasma aldosterone level after cosyntropin injection was >= 14,000 pg/mL. Laterality of aldosterone hypersecretion was determined based on the lateralized ratio and contralateral ratio. The diagnosis of aldosterone hypersecretion and laterality were compared between the results with 5-French (5-Fr) catheter and microcatheter.

RESULTS

The plasma aldosterone levels were significantly higher in RCV, LCV, and CT selected with microcatheter than in the right and left adrenal vein selected with 5-Fr catheter (*P < 0.0001-0.029). Five and twenty-two patients for right and left AVS were diagnosed aldosterone hypersecretion only with microcatheter. The diagnosis of aldosterone hypersecretion from left adrenal gland was statistically more accurate with microcatheter than with 5-Fr catheter (P < 0.0001). Diagnostic change of the laterality from unilateral to bilateral was found in 3 patients (8%) with microcatheter.*

CONCLUSION

The microcatheter was useful for the assessment of aldosterone hypersecretion and the laterality, especially in the left adrenal vein.

CLINICAL RELEVANCE/APPLICATION

The clinical diagnosis and treatment options potentially are changed on the basis of the results in AVS with microcatheter.

SSQ20-02 *Fluoroscopic Gastrojejunostomy with Lumen-Apposing Metal Stent: Feasibility and Safety in Swine*

Thursday, Nov. 29 10:40AM - 10:50AM Room: S403A

Participants
Jingui Li, Beijing, China (Presenter) Nothing to Disclose
Jiaywei Tsauo, Beijing, China (Abstract Co-Author) Nothing to Disclose
Xiaowu Zhang, Beijing, China (Abstract Co-Author) Nothing to Disclose
He Zhao, Beijing, China (Abstract Co-Author) Nothing to Disclose
Tao Gong, Beijing, China (Abstract Co-Author) Nothing to Disclose
Xiao Li, PhD, Chengdu, China (Abstract Co-Author) Nothing to Disclose

For information about this presentation, contact:

ljg_intervention@163.com

PURPOSE

To evaluate the feasibility and safety of fluoroscopic gastrojejunostomy (GJ) with lumen-apposing metal stent (LAMS) in a miniature swine model.

METHOD AND MATERIALS

The animal experiments were approved by the institutional animal care and use committee. Six female miniature swine (range, 2.5-3.0 kg) were included in this study. With the animals under general anesthesia, a pigtail catheter was inserted through the mouth and negotiated into the proximal jejunum with a hydrophilic guidewire under fluoroscopic guidance as the puncture target. A Rösch-Uchida liver access set was introduced into the stomach over a separate hydrophilic guidewire, and the proximal jejunum was punctured under continuous fluoroscopic monitoring. A 16-mm-diameter and 20-mm-length LAMS was placed between the stomach and the proximal jejunum, and contrast medium was injected to confirm the stent position.

RESULTS

Technical success was achieved in all animals. The number of needle puncture ranged from 1 to 2. All procedures were completed within 45 minutes. One animal had vomiting for 3 days after the procedure. No other procedure-related complications were observed. All animals were alive and well at 1 month after the procedure, with no signs of stent malfunction.

CONCLUSION

Fluoroscopic GJ with LAMS is feasible and safe in a miniature swine model.

CLINICAL RELEVANCE/APPLICATION

(dealing with gastric outlet obstruction(GOO)) 'Fluoroscopic GJ is an alternative to surgical bypass for the palliation of GOO with simple operation and minimal invasion.'

SSQ20-03 Biodegradable Magnesium Stent Insertion for the Treatment of Benign Esophageal Stricture in a Rabbit Model

Thursday, Nov. 29 10:50AM - 11:00AM Room: S403A

Participants
Yingsheng Cheng, MD, Shanghai, China (Presenter) Nothing to Disclose
Yueqi Zhu, MD, Shanghai, China (Abstract Co-Author) Nothing to Disclose

PURPOSE

To determine the technique feasibility, therapeutic effect and tissue response to silicone-covered biodegradable magnesium stent insertion into the benign esophageal stricture in rabbits.

METHOD AND MATERIALS

Benign esophageal stricture was surgically created in 12 rabbits. Twelve silicone-covered biodegradable magnesium stents were inserted to treat benign esophageal stricture in rabbit models under fluoroscopic guidance. Esophagography was performed at 1, 2 and 3 weeks. Four rabbits in each group were euthanized at each time point for histological examination

RESULTS

All stent insertions were well tolerated. The esophageal diameters at immediate,1, 2 and 3 weeks were 9.8 ± 0.3mm, 9.7 ± 0.7mm, 9.4 ± 0.8mm and 9.2 ± 0.5 mm, respectively (vs. 4.9 ± 0.3 mm before stent insertion; $P < 0.05$). Magnesium stents migrated rate was 9.3% (1/12) at 1 week, 25% (2/8) at 2 weeks and 100% (4/4) at three weeks respectively. Esophageal wall remodeling (thinner epithelial and smooth muscle layers) was found more significant in the stent groups than in the normal esophageal wall ($P < 0.05$). Esophageal injury and collagen deposition following stent insertion were similar and did not differ to the normal esophageal wall ($P > 0.05$).

CONCLUSION

Esophageal silicone-covered biodegradable magnesium stent insertion was feasible for the treatment of benign esophageal stricture, without causing severe injury or tissue reaction.

CLINICAL RELEVANCE/APPLICATION

Biodegradable magnesium stent can further be applied for the treatment of benign esophageal stricture in clinical.

SSQ20-04 Adhesive Embolization of Truncal Varicosities: Can It Be an Alternative to Thermal Ablation of Varicose Veins?

Thursday, Nov. 29 11:00AM - 11:10AM Room: S403A

Participants
Venkatesh Kasi Arunachalam, MBBS, DMRD, Coimbatore, India (Presenter) Nothing to Disclose

For information about this presentation, contact:

drkasivenkatesh@yahoo.co.in

PURPOSE

1. To evaluate the success rate of Glue embolisation using N Butyl 2 Cyanoacrylate. 2. To compare the occlusion rate with thermal ablation (we are comparing with Radiofrequency ablation as it is performed in our hopital) for varicose veins(Truncal veins) 3. To compare the cost of adhesive embolisation and RFA.

METHOD AND MATERIALS

Study period: October 2017 to August 2018. Inclusion criteria: Patients with symptomatic SFJ incompetence Exclusion criteria:

Deep vein thrombosis Glue embolisation of great saphenous vein(GSV) is planned atleast for thirty patients with N Butyl 2 cyanoacrylate. The great saphenous vein in thigh was punctered directly with 21 G needle atleast at 7 - 10 sites with a gap of 5cms and 0.1-0.2ml of glue is injected at each sites. After injection, compression is done with ultrasound probe for 45 seconds at that site. The injection is started from the caudal to cranial direction. The cranial most site of injection is 3cm distal to SFJ. The procedure is performed without perivenous tumescence. The patients are followed with ultrasound at one week, one month and six months intervals. The Patients will be evaluted for occlusion of GSV as well as complications associated with it. The results are compared with the results of RFA of varicose veins in literature. The cost of the procedure is also calculated and compared with the cost of the RFA in our hospital.

RESULTS

Till now 15 cases were performed with glue embolisation. We are planning to perform atleast 30 cases with glue and follow them atleast for 6 months. The cost of glue embolisation in our institution is about 15000 INR and RFA is about 60000 INR. If we are able to acheive the results of RFA with glue embolisation , the expenditure for the patient will be 1/4th of RFA.. The complications associted with glue embolisation including Inflammation , soft tissue necrosis and ulcer will be assesed and has to be compared with complictions assocaited with RFA.

CONCLUSION

The hypothesis of this exhibit is that efficacy of glue embolisation of varicose veins done with direct puncture is similar to RFA and it can be done with decreased cost (<1/4th of RFA).

CLINICAL RELEVANCE/APPLICATION

In a developing country like India, if we have a procedure which can give an acceptable rate of occlusion of varicose veins with decreased cost , it will be the procedure of choice and many patients will be benefitted.

SSQ20-05 Neutropenia in Adults at the Time of Subcutaneous Chest Port Insertion is a Risk Factor for Early Infection-Related Port Removal

Thursday, Nov. 29 11:10AM - 11:20AM Room: S403A

Participants
Andrew Perez, BS, Nashville, TN (Presenter) Nothing to Disclose
Jennifer M. Watchmaker, PhD, Nashville, TN (Abstract Co-Author) Nothing to Disclose
Filip Banovac, MD, Navshville, TN (Abstract Co-Author) Nothing to Disclose

PURPOSE

To determine if neutropenia at the time of subcutaneous, implantable chest port placement in adults confers an increased risk for early, infection-related removal.

METHOD AND MATERIALS

This retrospective cohort study was approved by the institutional review board and compliant with the Health Insurance Portability and Accountability Act. It included 2580 ports placed at a single tertiary medical center between June of 2007 and July of 2017. A total of 159 of these ports were placed in neutropenic patients. Neutropenia was defined as an absolute neutrophil count (ANC) <1500 cells/mm3. Electronic medical record follow-up was conducted for 30 days following port placement. Absolute percentages were calculated for port removal within 30 days in neutropenic and non-neutropenic groups. A chi-squared test was used to compare categorical data between the groups, and a t-test was used to compare continuous variables. Infection-related port removal was defined as a port removed due to a confirmed port infection. Port infection included central line-associated bloodstream infections (CLABSI) or local infections evidenced by either deep erythema, induration and/or tenderness overlying the catheter tunnel and port, or superficial erythema and induration overlying the port.

RESULTS

Within 30 days of port placement, ports placed in neutropenic patients had a significantly greater incidence (P = 0.01) of infection-related removal (3.8%, 6/159) compared to ports placed in nonneutropenic patients (1.1%, 27/2421). There was no significant difference between the neutropenic and nonneutropenic groups in gender or age (P = 0.31 and P = 0.77, respectively). Neutropenic patients had a greater, but not statistically significant, incidence of death related to port infection within the first 30 days (0.63%, 1/159) compared to the nonneutropenic group (0.12%, 3/2421; P = 0.22).

CONCLUSION

Neutropenia at the time of implantable, subcutaneous port placement is associated with an increased risk for early infection-related port removal. Incidence of death related to port infection, while increased in the neutropenic population, is not significantly higher than in the nonneutropenic population.

CLINICAL RELEVANCE/APPLICATION

Neutropenia in adults at the time of subcutaneous, implantable chest port placement confers an increased, although still low, risk for early infection-related port removal and should be taken into account when considering port placement.

SSQ20-06 Point of Care Ultrasound by Nonradiologist Physicians: Do the Trends Indicate a Shift Away from Radiologists?

Thursday, Nov. 29 11:20AM - 11:30AM Room: S403A

sarah.kamel@jefferson.edu

PURPOSE

"Point of care" ultrasound (POC US) is defined as US performed at the patient's bedside in real-time by a nonradiologist provider (NRP) versus formal ultrasound interpreted by a radiologist. Given the continued encouragement and development of POC US specialty based guidelines, our purpose was to assess the trends in use of POC US to determine if there has been a shift from radiologists to NRPs.

METHOD AND MATERIALS

The nationwide Medicare Part B fee-for-service databases for 2004-2016 were searched. All noninvasive noncardiac US CPT codes were selected. The databases indicate procedure volume which were used to calculate utilization rates per 1000 Medicare beneficiaries. Medicare place-of-service codes showed where the exams were interpreted and specialty codes indicated the specialty of the interpreting physicians. Sample statistics are not required in full populations like this.

RESULTS

POC US performed by NRPs peaked in 2010 at 211 studies per 1000 Medicare beneficiaries and has since declined to 192 studies in 2016 (-9%). POC US by NRPs is predominantly performed in private offices where peak utilization was seen in 2010 at 159 studies per 1000, declining to 140 in 2016 (-12%). The 2004-2016 interval changes in the remaining places-of service where NRP POC US is performed are as follows: (1) EDs: 1 to 3 (+136%); (2) hospital inpatients: 21 to 14 (-31%); hospital outpatient departments (HOPDs): 21 to 26 (+23%). The top NRP specialties in noncardiac POC US in 2016 and their rates were: vascular surgeons 38, cardiologists 37, other surgeons 31, primary care physicians 20. US use by radiologists peaked in 2011 at 238 studies and has since fluctuated between 234-238 without a significant trend. Over the period of the study, US use by radiologists has grown in the following places-of-service: (1) ED: 10 to 23 (+133%); (2) HOPD: 83 to 101 (+21%); (3) private offices: 39 to 56 (+44%). Inpatient US by radiologists has declined recently.

CONCLUSION

Despite the increased advocacy of POC US in recent years, NRPs have demonstrated a 9% decline in its utilization since 2010, particularly with decreasing use in private offices. There is no evidence of a recent shift away from radiologists. Radiologists demonstrated growth in use of POC US in EDs, HOPDs and private offices.

CLINICAL RELEVANCE/APPLICATION

There is no significant growth in use of point of care ultrasound by nonradiologist physicians.

SSQ20-07 Primary Percutaneous Placement of Low-Profile versus Traditional Pigtail and Standard Balloon-Retention Gastrostomy Catheters in Adults: A Retrospective Review

Thursday, Nov. 29 11:30AM - 11:40AM Room: S403A

Awards
Student Travel Stipend Award

For information about this presentation, contact:

iftigto@gmail.com

PURPOSE

De novo percutaneous placement of low-profile or button-type gastrostomy catheters (LP) is infrequently reported in adults. This study compares the safety and clinical outcomes of primary percutaneous placement of LP catheters and traditional (pigtail and balloon-retention) gastrostomy catheters (TG) at a single institution.

METHOD AND MATERIALS

This was an institutional review board-approved retrospective, single-institution review comparing initial LP and TG catheter placements in a 24-month time period. The age, gender, indication, catheter type, catheter French size, and method of anesthesia of 139 consecutive initial gastrostomy placement procedures were recorded. Total catheter days without intervention, major and minor complications, reasons for re-intervention, and procedure fluoroscopy times were compared.

RESULTS

During the 24 month study period, 61 LP and 78 TG catheters were placed. Technical success for both methods was 100%. Mean total catheter days prior to intervention was 137 days in the LP group and 128 days in the TG group ($p = 0.70$). Minor complications including cellulitis, peri-catheter leakage and early catheter occlusion occurred in 4.9% (3/61) in the LP group and 9% (7/78) in the TG group ($p = 0.51$). Major complications including early catheter dislodgement and bleeding requiring transfusion (in one patient) occurred in 4.9% (3/61) in the LP group and 7.7% (6/78) in the TG group ($p = 0.73$). Procedure fluoroscopy time was lower in the LP group (2.56 minutes) compared to the TG group (4.21 minutes) ($p < 0.005$).

CONCLUSION

Primary placement of low-profile or button-type gastrostomy catheters is technically feasible with a low complication rate similar to that of traditional gastrostomy catheters.

CLINICAL RELEVANCE/APPLICATION

De novo placement of low-profile gastrostomy catheters is technically feasible with a comparable safety profile to traditional

pigtail and balloon-retention gastrostomy catheters.

SSQ20-08 Comparison of Treatment Outcomes in Thermal Ablation for T1a Renal Cell Carcinoma: Does Treatment Modality Matter?

Thursday, Nov. 29 11:40AM - 11:50AM Room: S403A

Awards
Student Travel Stipend Award

Participants

wenhui.zhou@tufts.edu

PURPOSE

To compare the clinical outcomes of radiofrequency ablation (RFA), cryoablation (CA) and microwave ablation (MWA) for treatment o fT1a renal cell carcinoma (RCC).

METHOD AND MATERIALS

A retrospective analyis was performed of 320 patients (mean age = 71 ys., range = 22-90 yrs.) between October 2006 and December 2017. Mena R.E.N.A.L., P.A.D.U.A. and centrality index scores were 6., 8.1, and 2.9, respectively. Treatment response, residual disease and survival outcome were compared among the three groups. Local recurrence-free, metastatic-free,and overall surival rates were tabulated using Kaplan-Meier methods and compared with log-rank tests.

RESULTS

365 T1a biopsy-proven RCC measuring 1.2 to 4. cm were treated with CT-guided MWA (n= 40, 11%), RFA (n=291, 80%), or CA (n=34, 9%). There were no significant differences in patient demographics or tumor characteristics betwen the three cohorts. Technical success rate, complication rate and rsidual disease rate were similar among the three groups (p=0.91, p=0.14, p=0.46, respectively). At two-years follow-up, analysis of the local disease free-, metastatic free-, andoverall survial rate showed that MWA is non-inferior to RFA and CA (p=0,60, p=0.93, p=0.75, respectively).

CONCLUSION

CT-guided percutaneous MWA is an effective thermal ablation option for treatmen of T1a renal cell carcinoma.

CLINICAL RELEVANCE/APPLICATION

Microwave ablation has comparable therapeutic efficacay and oncologic outcomes when compared to RFA and CA.

SSQ20-09 Role of Dynamic Contrast-Enhanced MRI (DCE-MRI) in Treatment Response Evaluation of Metastatic Bone Disease

PURPOSE

To correlate perfusional features in skeletal metastases treated with MR-guided Focused Ultrasound (MRgFUS) with clinical outcomes assessed by visual analogue scale (VAS).

METHOD AND MATERIALS

53 patients with symptomatic skeletal metastases, suitable for MRgFUS, were enrolled. Dynamic Contrast-Enhanced MR exam (3T Discovery 750 scanner, GE; Gd-BOPTA, Bracco) was performed before and 3 months after the ablative procedure. As perfusional parameters, DCE transfer rate (Ktrans) and extravascular volume fraction (ve) were calculated by dedicated analysis software. Clinical outcomes were evaluated over the following three months using VAS scale.

RESULTS

42 of 53 treated subjects (79.2%) demonstrated a clinical complete response (CR), with a VAS score mean reduction of 4,5 (48,2%. p<0,001), whereas five patients showed a partial clinical response (PR) with residual pain, according to VAS scale. Perfusional analysis demonstrated in CR population significant decrease of Gadolinium extraction (mean Ktrans reduction 2,18/min, ΔKt=52,72%. p<0,01) and ve increase (5,6%. p<0,01). Partial Responders showed no substantial modification in Ktrans value (ΔKt=+0,044/min, +11,39%. p>0,05) or increase in extravascular volume (1.3%. p<0,01). Spearman test revealed a significant relationship between Ktrans quantitative parameters and pain relief evaluated by VAS scale (p<0,001) in both CR and PR patients.

CONCLUSION

K trans value reduction positively correlates to clinical outcomes, probably for a decreased neoplastic cells' metabolism after ultrasound ablation procedure.

CLINICAL RELEVANCE/APPLICATION

DCE-MRI has an important role in treatment response evaluation. Perfusional parameters may be routinely included in the imaging evaluation of patients affected by metastatic bone disease.

PURPOSE

Tumor perfusion has varying effects on cancer therapy depending on the nature of the treatment used. While drug delivery and radiation therapy require increased tumoral perfusion for a better response, non invasive ischemic therapy and hyperthermia models require reduced blood flow. The purpose of this study is to investigate the dose-dependent effects of novel antivascular ultrasound therapy (AVUS) on hepatocellular carcinoma (HCC) tumoral blood flow.

METHOD AND MATERIALS

HCC was induced in 15 Wistar rats by ingestion of diethylnitrosamine (DEN) for 12 weeks. Rats received AVUS treatment at low and high doses. Low dose group (n=6) received 1 watt/cm2 ultrasound for 1 min with 0.2 mL microbubbles injected IV. High dose group (n=9) received 2 watts/cm2 for 2 min with 0.7 mL microbubbles IV. Tumoral perfusion was measured before and after AVUS with contrast-enhanced ultrasound (CE-US) and power Doppler (PD-US). Quantitative measures: perfusion index (PI) and peak enhancement (PE) were obtained from each AVUS dose. Histology samples were evaluated for percent area of hemorrhage and findings of tissue injury and repair including inflammation, necrosis, and fibrosis. Histology results were compared with pre- and post-AVUS ultrasound imaging findings.

RESULTS

With high dose AVUS, PE and PI of CE-US decreased from baseline by an average of 29.3% and 28.8%, respectively. Histology showed extensive tissue injury (hemorrhage, necrosis, fibrosis) in 58% of tumor cross-sectional area. Conversely, low dose therapy led to an increase in PE and PI of CE-US by an average of 39.3% and 67.8%, respectively. Histology showed smaller areas of microhemorrhage versus large pools of hemorrhage (only 17% area). PD-US changes were similar to CE-US.

CONCLUSION

Low-dose therapy increased tumoral perfusion, which may improve drug delivery or radiation therapy. Conversely, high-dose therapy decreased tumoral perfusion, an effect that could be used for noninvasive ischemic therapy. This tunable modulation of blood flow in tumors could provide multiple roles for AVUS in cancer therapy.

CLINICAL RELEVANCE/APPLICATION

Increasing availability of ultrasound in developing world could enable AVUS as an inexpensive & less resource-intensive tool for HCC therapy. Titrating the dose of AVUS could allow selective use to enahnce radiation therapy, drug delivery, or for ischemic therapy.

SSQ21-02 Radiofrequency Ablation Using a Separable Clustered Electrode for Treatment of HCCs: Randomized Controlled Trial of a Dual Switching Monopolar Mode versus a Single Switching Monopolar Mode

djc0105@gmail.com

PURPOSE

To prospectively compare the efficacy, safety and mid-term outcomes of dual-switching monopolar (DSM) radiofrequency ablation (RFA) with those of conventional single-switching monopolar (SSM) RFA in the treatment of hepatocellular carcinoma (HCC)

METHOD AND MATERIALS

This prospective study was performed with approval of the institutional review board, and written informed consent was obtained for all enrolled patients. From January 2015 to May 2016, 80 patients with 94 HCC nodules were enrolled and randomly treated with either DSM-RFA or SSM-RFA, using a separable clustered electrode and a three-channel dual-generator unit. Technical parameters, procedure-related complications, and technical efficacy were assessed at the post-procedural imaging studies. For a mean follow-up of 23.9 months ± 9.2, the patients were observed for local tumor recurrence as well as overall disease progression. Survival analysis was performed with the Kaplan-Meier method, and differences between the survival curves were evaluated with the log-rank test.

RESULTS

Significantly higher ablation energy per given time was delivered in the DSM-RFA group than in the SSM-RFA group (1.61 ± 0.28 kcal/min vs. 1.17 ± 0.28 kcal/min, respectively; P < .0001). Major complications were observed in two (4.9%) of 41 patients in the DSM-RFA group and in one (2.6%) of 39 patients in the SSM-RFA group (P=1.0000). A patient in the DSM-RFA group experienced intercostal arterial bleeding that required embolization. Pleural effusion developed in one patient in each group. Rates of local tumor recurrence in HCC nodules treated with DSM-RFA and SSM-RFA were 8.5% and 4.7%, respectively, at 2 years (P = .3160). The 2-year local recurrence-free survival rates in the DSM-RFA group and the SSM-RFA group were 90% and 94.4%, respectively (P = .3312). The 2-year event-free survival rates in the DSM-RFA group and the SSM-RFA group were 54.9% and 75.7%, respectively (P = .2649).

CONCLUSION

Although dual-switching monopolar radiofrequency ablation using a separable clustered electrode delivers higher ablation energy per given time than the SSM-RFA, it failed to show superior effectiveness to the SSM-RFA in the treatment of HCCs.

CLINICAL RELEVANCE/APPLICATION

Dual-switching monopolar radiofrequency ablation may be considered as a technically more efficient alternative with non-inferior clinical effectiveness to the SSM-RFA.

SSQ21-03 Utility of Change in Volumetric ADC and Enhancement Post TACE in Predicting Histologic Grade of HCC, with Pathologic Correlation

Thursday, Nov. 29 10:50AM - 11:00AM Room: S403B

PURPOSE

To investigate the role of change in ADC and enhancement after trans- arterial chemoembolization (TACE) in predicting histological grade of hepatocellular carcinoma (HCC).

METHOD AND MATERIALS

This HIPPA compliant retrospective study was approved by our institutional review board. The study population included 104 HCC patients (128 index lesions) with MR imaging within 6 months before and 6 months after TACE who presented at our institution between 2001 and 2015. All cases had pathologic report of the HCC tumor by biopsy or liver transplantation. Volumetric measurements of venous enhancement (VE) and apparent diffusion coefficient (ADC) were performed on baseline and post TACE MRI. Based on pathology report, the tumors were histologically classified into two groups: Low grade HCC (n=42) and intermediate/high grade HCC (n=86). In case of tumors with mixed differentiation, the worst differentiation grade was considered. The mean ADC (mm2/s) and enhancement (%) of two groups were compared at two-time points. P value<0.05 was considered statistically significant.

RESULTS

Mean ADC increased by (363.88±529.07 x 10 -6 mm2/s) in low grade vs. (136.20±503.73 x 10 -6 mm2/s) in high grade HCC post TACE. ADC change in low grade tumors was higher than in intermediate/high grade tumors (P=0.02). Setting the cutoff of 148.4 x

10 -6 mm2/s or more in ADC change had a sensitivity and specificity of 62% and 55%, respectively in differentiating between the 2 groups. Enhancement decreased by (46 ± 34%) in low grade vs. (28± 36%) in high grade tumors post TACE. Enhancement change was significantly higher in low grade HCC as compared to intermediate/high grade tumors (P=0.011). Setting the cutoff of 39% or more decrease in enhancement had sensitivity and specificity of 65% and 55%, respectively in differentiating between the 2 groups.

CONCLUSION

Low grade tumors demonstrate a greater change in ADC and enhancement post TACE as compared to intermediate/ high grade tumors.

CLINICAL RELEVANCE/APPLICATION

The change in ADC and enhancement in HCC after TACE could potentially be utilized to predict tumor differentiation and can help the clinicians to plan future treatment in these patients.

speidel@wisc.edu

PURPOSE

To evaluate the quantitative accuracy and precision of flow measurements derived from 4D digital subtraction angiography (4D DSA) and to evaluate 4D DSA flow values in a model of hepatic transarterial embolization (TAE).

METHOD AND MATERIALS

4D DSA generates a time-resolved 3D angiogram using a conventional C-arm acquisition consisting of a mask rotation followed by a contrast-enhanced rotation. Methods of quantifying flow in vessel segments of the 4D data are under development. In this work, flow was derived from a Fourier phase analysis of the pulsatile contrast waveform that arises when a constant-rate intra-arterial iodine injection mixes with pulsatile blood flow. 4D DSA flow was compared to reference standard flow measured by an ultrasonic flow probe (Transonic) in a vascular phantom study (range of flow rates 5-20 mL/s). In a porcine model, 4D DSA flow was evaluated before and after selective left or right hepatic TAE with 100-300 m microspheres. Iodinated contrast medium was injected at 2 mL/s during 4D DSA imaging.

RESULTS

4D DSA flow was linearly proportional to reference standard flow in the vessel phantom (R2 = 0.96) with a slope of 1.33 +/- 0.06 and an intercept of -0.2 +/- 0.77 mL/s. The slope was consistent with a flow state between the extremal cases of plug flow and parabolic flow, and the intercept was consistent with zero bias. The standard deviation in the 4D-DSA flow measurement averaged 1.2 mL/s in the phantom. In the porcine study (4 subjects), the mean reductions in 4D DSA flow following embolization were -0.2, -1.3, -2.2, and -1.0 mL/s ($p <= 0.04$). In repeat measurements performed in the same in vivo flow state, the average change in 4D DSA flow was 0.7 mL/s.

CONCLUSION

4D DSA can provide quantitative measurements of pulsatile flow through a vessel. These measurements are sensitive to changes in flow that occur during hepatic transarterial embolization.

CLINICAL RELEVANCE/APPLICATION

4D DSA flow measurements may be used to quantify treatment-related changes in arterial blood flow in the interventional suite, yielding a new, quantitative endpoint for procedures.

SSQ21-06 Radiofrequency Ablation of Primary Parathyroid Adenoma: Preliminary Results for Patients Ineligible for Surgery

Thursday, Nov. 29 11:20AM - 11:30AM Room: S403B

Participants
Eun Ju Ha, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose
Jung Hwan Baek, Seoul, Korea, Republic Of (*Abstract Co-Author*) Consultant, STARmed; Consultant, RF Medical

PURPOSE

The purpose of this study was to retrospectively evaluate the outcomes of ultrasonography (US)-guided radiofrequency ablation (RFA) of parathyroid adenoma in patients who were ineligible for surgery

METHOD AND MATERIALS

Between October 2010 and June 2016, six parathyroid adenomas (mean diameter, 2.0 cm; range, 1.2-3.8 cm) in six patients with primary hyperparathyroidism were treated with US-guided RFA by two radiologists in two hospitals. The inclusion criteria for this study were (1) primary hyperparathyroidism, (2) pathologically confirmed parathyroid adenoma on US-guided fine-needle aspiration, and (3) refusal- or ineligibility- for surgery. RFA was performed using a RF generator and 19-gauge internally cooled electrode. The hydrodissection technique using the 5% dextrose water was applied in all patients. The medical records were reviewed and analysed, focusing on the procedural profiles of RFA, symptoms and complications during and after RFA, and changes in hormone levels on follow-up US.

RESULTS

Before RFA, the mean nodule volume was 1.0 ± 0.5 mL. The mean parathyroid hormone (PTH) level was 210.4 ± 283.9 pg/mL and calcium level was 10.4 ± 0.9 mg/dL. At 1- and 6- month follow-up after RFA, a significant reduction in the mean volume (78.4 ± 3.7% and 89.1 ± 8.4 %, respectively) was noted and five ablation zones (5/6, 83.3%) near completely disappeared (<=0.1mL). The mean PTH level was decreased to the normal range (50.9 ± 6.5 pg/mL) at 1-month follow-up and were progressively decreased at 6-month follow-up in 5 patients (40.1 ± 7.3 pg/mL). The PTH level in one patient was re-increased from 48 pg/mL to the 241 pg/mL at 6-month follow-up. The mean calcium level was decreased to 9.3 ± 0.8 mg/dL at 6-month follow-up. There was no immediate complication during- and after- the procedure.

CONCLUSION

RFA might represent an effective and a safe alternative for managing parathyroid adenomas, especialy in patients ineligible for surgery

CLINICAL RELEVANCE/APPLICATION

RFA might be an alternative treatment option for managing parathyroid adenomas in patients with primary hyperparathyroidism.

SSQ21-07 Conventional versus Drug-Eluting Beads Chemoembolization for Infiltrative Hepatocellular Carcinoma: Comparison of Efficacy and Safety

Thursday, Nov. 29 11:30AM - 11:40AM Room: S403B

Participants
Yu-dong Xiao, Changsha, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

xiaoyudong222@csu.edu.cn

PURPOSE

To compare the early tumor response and the toxicity in patients with infiltrative hepatocellular carcinoma (iHCC) treated with conventional or drug-eluting beads transarterial chemoembolization (TACE).

METHOD AND MATERIALS

A total of 89 iHCC patients who were treated with either cTACE(n=33) or DEB-TACE(n=56) were included in this retrospective study between April 2016 and September 2017. Tumor response was measured one month after the procedure using Modified Response Evaluation Criteria in Solid Tumors (mRECIST). Toxicity was graded by Common Terminology Criteria for Adverse Events v5.0 (CTCAE v5.0). The difference of tumor response and toxicity were compared between cTACE group and DEB-TACE group using Chi-square test or Fisher's exact test (if appropriate).

RESULTS

There was no difference in objective response rate between cTACE group and DEB-TACE group (12.1% vs. 10.7%, P=0.839). However, disease control rate is significantly higher in DEB-TACE group than cTACE group (85.7% vs. 66.7%, P=0.034). In some advanced disease, such as bilobar lesions, ECOG 1-2, and presence of portal venous tumor thrombus, DEB-TACE showed higher disease control than which cTACE showed (all P<0.05). For side-effect analysis, abdominal pain (P=0.034) and fever (P=0.009) are more frequent in cTACE group, and there was no difference in serious liver toxicity between two groups.

CONCLUSION

DEB-TACE offers more benefits of efficacy and tolerability in iHCC than cTACE, particularly for patients with more advanced disease.

CLINICAL RELEVANCE/APPLICATION

For iHCC patients, especially with ECOG 1-2, bilobular or portal venous tumor thrombus, DEB-TACE is recommended due to the low toxicity and well tolerability.

SSQ21-08 A Matched Study Comparing Right Portal Vein Embolization with and Without Segment 4 Portal Vein Embolization for Right Hepatic Trisectionectomy

Thursday, Nov. 29 11:40AM - 11:50AM Room: S403B

PURPOSE

Portal vein embolization (PVE) is widely used before major hepatectomy. However, the necessity of segment 4 (S4) portal veins embolization in addition to embolization of the right portal vein before right hepatic trisectionectomy is controversial. Thus, we examined the effect of S4 PVE on hypertrophy of segments 2 and 3 (S2+3) in a matched retrospective cohort study.

METHOD AND MATERIALS

We retrospectively reviewed patients with biliary carcinoma who underwent preoperative PVE using gelatin sponge and coils between January 2010 and November 2017. Totally, 28 patients underwent right and S4 portal veins embolization (RPVE+4) for right hepatic trisectionectomy, and 100 patients underwent right PVE (RPVE) for right hepatectomy. We measured the liver volumes by CT using the workstation before and after embolization, and 22 patients from each group respectively were matched for the ratio of S2+3 volume to total liver volume (%S2+3 volume) before embolization. Volume changes in S2+3 after embolization were compared among the two groups.

RESULTS

There was no statistically significant difference between the two groups in the time between PVE and volumetric CT (mean, RPVE+4, 26.5days vs RPVE, 23.4days; P = .349). The absolute S2+3 volume increase was significantly more in RPVE+4 group than RPVE (RPVE+4, 129.5±79.5ml vs RPVE, 70.5±29.9ml; P = .002). The %S2+3 volume increased in both groups: from 23.7±4.5% before PVE to 33.0±4.7% after PVE in RPVE+4, and from 23.6±4.4% to 29.6±4.6% in RPVE. The increase of the %S2+3 volume (9.3±3.2% vs 5.9%±1.3; P < .001) and the increase rate of the %S2+3 volume (41.7±22.1% vs 26.3±8.6%; P = .004) were significantly higher in the RPVE+4 group. In multiple regression analysis, the absolute S2+3 volume increase (P = .002) and the increase rate of the %S2+3 volume (P = .003) were also significantly higher in the RPVE+4 group.

CONCLUSION

S4 PVE in addition to right PVE significantly improves S2+3 hypertrophy and increases the proportion of the future liver remnant compared with right PVE alone.

CLINICAL RELEVANCE/APPLICATION

S4 PVE added to right PVE is more effective in preparation for right hepatic trisectionectomy and may make the operation safer.

SSQ21-09 Multicentric Assessment of the Hong Kong Liver Cancer Staging System in Chinese Patients following Transarterial Chemoembolization

Thursday, Nov. 29 11:50AM - 12:00PM Room: S403B

byzhongir@sina.com

PURPOSE

Recently, the hepatitis B-based Hong Kong Liver Cancer (HKLC) staging system was reported to guide treatment options. We aimed to validate the performance of the HKLC compared with the Barcelona Clinic Liver Cancer (BCLC) staging system in Chinese hepatocellular carcinoma (HCC) patients treated with conventional transarterial chemoembolization (cTACE) as initial treatment.

METHOD AND MATERIALS

This retrospective study included patients with HCC who underwent cTACE between January 2008 and December 2016 at three Chinese institutions. All of the patients were calculated HCC stage using 5-substage HKLC (HKLC-5), 9-substage HKLC (HKLC-9), and the BCLC system. Based on overall survival (OS), these three staging systems' performance on treatment outcome prediction were compared using C statistic, Akaike information criterion (AIC), area under the receiver operating characteristic curve (AUC), linear trend chi-square, likelihood ratio chi-square, and calibration plots, respectively.

RESULTS

A total of 715 patients were included. The median OS was 10.1 months. Compared with the BCLC system, the HKLC system, especially HKLC-9 showed better performance on survival prediction (HKLC-9: C=0.689, AIC=6646.162; HKLC-5: C=0.683, AIC=6662.663; BCLC: C=0.680, AIC=6654.146), homogeneity (likelihood ratio chi-square: HKLC-9=232.38, HKLC-5=215.87, and BCLC=224.39, p <0.001) and calibration (R2: HKLC-9=0.923, HKLC-5=0.916, and BCLC=0.914). HKLC-9 outperformed on AUC at 6, 12, and 24 months' survival prediction than HKLC-5 and BCLC. BCLC showed better performance on monotonicity (linear trend chi-square: HKLC-9=121.641, HKLC-5=117.389, and BCLC=125.752; p <0.001).

CONCLUSION

Combining survival prediction, discrimination, and calibration, the HKLC, especially HKLC-9 system performed better for Chinese patients treated with cTACE than the BCLC system.

CLINICAL RELEVANCE/APPLICATION

HKLC outperforms BCLC when regarding patients with HCC treated with conventional TACE as initial treatment.

182389433@qq.com

PURPOSE

To compare the average glandular dose (AGD) between single-view digital breast tomosynthesis (DBT) and single-view full-field digital mammography (FFDM), and to evaluate the correlation of AGD with breast thickness and density.

METHOD AND MATERIALS

A total of 318 female patients who underwent both DBT and FFDM (DBT and FFDM were performed in the same compression thickness in each breast) were included. 636 DBT images of unilateral breast mediolateral oblique (MLO) view and 636 FFDM images of unilateral breast mediolateral oblique (MLO) view were analyzed. Mammographic breast density was determined according to BI-RADS breast density grading, and breast thickness and AGD per exposure in MLO views retrieved from DICOM headers were recorded. Breast thickness were divided into the following four groups: <= 30cm, 31 ~ 45cm, 46 ~ 60cm and > 60cm. The statistical analyses used variance analysis and Pearson's correlation for parametric tests.

RESULTS

(1) The AGD of DBT had a weak negative correlation with breast density (correlation coefficient =-0.305, P<0.001), decreased as the breast density increased. The AGD of FFDM did not change significantly with breast density increased (correlation coefficient =-0.027, P=0.501). (2) Breast thickness was significantly associated with AGDs, and both AGDs of FFDM and DBT increased with increased breast thickness (correlation coefficient =0.771 and 0.935, respectively, all P<0.001). (3) When breast density was >75% and breast thickness was >60cm, the AGD of DBT was lower than that of FFDM, and the difference was statistical significant (P = 0.031).

CONCLUSION

The AGD of DBT increased with breast thickness increased and decreased with breast density. For thick and dense breast, the radiation dose of DBT was lower than that of FFDM.

CLINICAL RELEVANCE/APPLICATION

In this study, we evaluated the AGD of MLO FFDM and DBT according to breast density and thickness.

SST01-02 Accuracy of Molecular Breast Imaging in Patients with Suspicious Calcifications

Friday, Nov. 30 10:40AM - 10:50AM Room: E353B

Dietlind Wahner-Roedler, MD, Rochester, MN (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Molecular breast imaging (MBI), which shows uptake of Tc-99m sestamibi in metabolically-active tissue, has been proposed as a tool for determining whether biopsy of mammographically-detected lesions is necessary. Here, our goal was to evaluate the diagnostic accuracy of MBI in patients with suspicious calcifications on mammography.

METHOD AND MATERIALS

Women scheduled to undergo stereotactic biopsy of calcifications detected on 2D mammography were prospectively enrolled to undergo MBI prior to biopsy. MBI was performed with injection of Tc-99m sestamibi and a dedicated gamma camera. A breast radiologist interpreted MBI in conjunction with mammography.

RESULTS

In 71 women studied, 76 discrete areas of calcifications were identified for biopsy, of which pre-biopsy MBI was positive in 17/76 (22%). Of 76 calcification lesions, 24 (32%) were malignant, including 20 DCIS and 4 invasive ductal cancer; MBI was positive in 10/20 (50%) DCIS and 2/4 (50%) invasive cancers. In 21 cancers with calcification morphology of amorphous, coarse heterogeneous, or fine pleomorphic (BI-RADS 4B), MBI was positive in 12/21 (57%), while in three cancers with fine linear or fine linear branching calcifications (BI-RADS 4C), MBI was negative in all 3 (p=0.06). Calcification distribution was more varied for the MBI-positive cancers (0 regional, 7 grouped, 1 linear, 4 segmental) than for the MBI-negative cancers (1 regional, 10 grouped, 1 linear, 0 segmental) (p=0.14). The median pathologic size for MBI-positive cancers was 1.5 cm (range=0.5-3.2 cm) compared to 0.9 cm (range=0.1-2.0 cm) for MBI-negative cancers (p=0.09). Beyond calcification lesions, detection of non-mass focal areas of uptake on MBI led to additional biopsies of 6 sites, of which 2 were malignant (DCIS). The overall positive and negative predictive values of MBI were 61% (14/23) and 81% (48/59), respectively.

CONCLUSION

MBI has insufficient negative predictive value to be used for identifying calcifications in which biopsy could be avoided. However, MBI can reveal additional sites of mammographically-occult disease.

CLINICAL RELEVANCE/APPLICATION

Negative findings on MBI should not be used to avoid biopsy of suspicious calcifications on mammography.

SST01-03 Staging Early Breast Cancer with Simultaneous PET/ MRI: Impact on Management

Friday, Nov. 30 10:50AM - 11:00AM Room: E353B

s_tanejaa@yahoo.com

PURPOSE

Breast cancer is a biologically heterogenous disease with certain clinical subtypes having a greater propensity to develop metastasis even at an early stage. In its present state, NCCN recommends 18-F FDG PET CT in patients above clinical stage III disease. There have been reports on PET CT in altering clinical stage in early breast cancer. DCE (Dynamic Contrast-Enhanced) MRI has been shown to detect additional disease in the ipsilateral & contralateral breast. Simultaneous PET/MRI combines 18F-FDG PET & MRI of the whole body & DCE-MRI of the breast in a single examination. This retrospective study evaluates the impact of simultaneous 18F-FDG PET/MRI in pretreatment staging of early breast cancer (Stage I-IIIA).

METHOD AND MATERIALS

The study was approved by institutional ethics committee. 101 patients with histologically proven breast cancer (clinical stage I, IIA, IIB, IIIA) who underwent simultaneous PET/MRI (including DCE MRI breast) were included. Breast lesions, nodes & metastases were evaluated on PET, MRI & PET-MRI for lesion count & diagnostic confidence (DC).

RESULTS

101 index breast lesions were identified on MRI, PET/MRI (Mean DC 4.96) & 99 on PET (Mean DC >=4). MRI detected multifocality in 15 (14.8%), multicentricity in 10 (9.90%) & contralateral unsuspected cancer in 2 patients. PET detected axillary nodal metastases in 12/18 (DC>=4), MRI in 15/18 (DC>=4) and PET/MRI in 15/18 patients. Distant metastases were found in 18 /101 (18 %) on PET (Mean DC score 4.1), MRI (Mean DC score=3.7) & PET/MRI (Mean DC score =4.7) with bone (n =11), lymph nodes (mediastinal; n=2), liver (n=4), brain (n=1) & lung (n=5). The mean metastatic lesion size on MRI was 1.52 ± 0.25 cm (Range: 0.5-5.7cm). PET MRI changed the overall stage in 66 patients (65%, upstaging: 62, downstaging:4) & overall change in management in 29 % of early stage breast cancer patients including 18 patients who were upstaged to stage IV.

CONCLUSION

Simultaneous18F-FDG PET/MRI has the potential to impact the initial staging in early breast cancer for an overall improved patient management.

CLINICAL RELEVANCE/APPLICATION

Simultaneous PET/MRI has the potential to alter the stage and hence the clinical management in patients with early breast cancer thus reducing the morbidity and cost due to inappropriate therapies.

SST01-04 The Gambler's Fallacy in Screening Mammography

PURPOSE

It has been documented in multiple settings that the sequence of decisions already made affects future decision-making. One component of this phenomenon is known as the gambler's fallacy: the tendency to underestimate the likelihood of 'streaks' (successive identical decisions) occurring by chance. The purpose of this study was to determine if the gambler's fallacy affects radiologists interpreting screening mammography.

METHOD AND MATERIALS

This was a retrospective, HIPPA compliant IRB approved study. Patients who underwent routine screening mammography in 2014 at our institution were included, with 8,543 total exams, which was sufficient to detect a 1% change in recall rate based on an 80% power calculation with a two-sided 0.05 significance level, for our recall rate of 7%. Data were collected from log books containing the BI-RADS assessments of routine screening mammograms, the order in which the examinations were interpreted, and the number of preceding BI-RADS 0 and BI-RADS 1 or 2 assessments for each exam. If recalled (BI-RADS-0), subsequent diagnostic exam BI-RADS assessment also was recorded. Analysis was performed using Fishers exact test to evaluate whether an increasing number of preceding decisions to not recall (BI-RADS-1 or 2) resulted in an increased number of recalls that did not lead to a cancer diagnosis. False positive was defined as a BI-RADS 0 assessment at screening, followed by a BI-RADS 1, 2 or 3 at diagnostic breast imaging. A true positive was defined as a BI-RADS 0 assessment at screening, followed by a BI-RADS 4 or 5 assessment at diagnostic breast imaging.

RESULTS

Data on 8,543 routine screening exams was collected for the year 2014. An average of 20.9 exams were batch read in each session. 700 exams (8%) were assessed as BI-RADS 0. Of those, 231 (33%) were assigned either BIRADS-4 or 5 at the time of diagnostic imaging. True and false positives were compared, stratified by the number of preceding BI-RADS 1 or 2 assessments in that batch-read session. Exams with a higher number of preceding negative assessments did not have a higher false positive rate.

CONCLUSION

At our academic institution, we did not observe a statistically significant effect of the gambler's fallacy in one year's worth of screening mammography.

CLINICAL RELEVANCE/APPLICATION

We did not detect an effect of the gambler's fallacy in one year's worth of screening mammography at an academic institution.

SST01-05 Outcomes of Ductal Carcinoma in Situ According to Detection Modality: A Multicenter Study Comparing Recurrences Between Mammography and Breast US

Friday, Nov. 30 11:10AM - 11:20AM Room: E353B

PURPOSE

To determine whether if disease recurrence and intrinsic characteristics of ductal carcinoma in situ (DCIS) is associated to the imaging method of detection in asymptomatic women who are diagnosed with DCIS.

METHOD AND MATERIALS

This retrospective, multicenter study was conducted at 8 institutions including 844 women who were treated for asymptomatic, pure DCIS who had preoperative mammography and breast ultrasonography (US) available for review. Mean follow up interval after treatment of the 844 women was 91.2 months (standard deviation: 533.3, range: 6.4-180.9 months). Medical records and breast images were reviewed by 8 breast-imaging dedicated radiologists for clinicopathologic information and image analysis. Kaplan-Meier analysis and univariable/multivariable Cox proportion hazard model was used to analyze the recurrence-free survival rates and factors associated with recurrence after DCIS treatment.

RESULTS

Of the 844 women who were treated for DCIS, 25 (3.0%) had developed recurrences. Patients with US-detected DCIS had significantly lower 5- and 10-year recurrence-free survival rates compared to patients with mammography-detected ones (P=0.011). US-detected DCIS had significantly lower 5- and 10-year recurrence-free survival rates compared to mammography-detected ones in patients <50years or with mammographically-dense breasts (P=0.002, and 0.002, respectively). Multivariable analysis showed that US for detection modality (HR: 4.451, 95% CI: 1.530, 12.950, P=0.006) and HER2 positivity (HR: 4.036, 95% CI: 1.438, 11.330, P=0.008) showed significant association to recurrences.

CONCLUSION

US for detection modality and HER2 positivity were factors significantly associated to recurrences in patients treated for asymptomatic DCIS.

CLINICAL RELEVANCE/APPLICATION

Supplementary screening US may enable detection of clinically important DCIS, especially in younger women or mammographically-dense breasts in which mammography has suboptimal performances in detection of DCIS or small invasive cancers.

SST01-06 Do Triple Negative Breast Cancers Have Characteristic Imaging Features According to Androgen Receptor and Vimentin Status?

PURPOSE

Lehmann et al (Journal of Clinical Investigation, 2011) previously identified six molecular subtypes of triple negative breast cancer (TNBC) through analysis of gene expression profiles; the luminal androgen receptor (LAR) subtype has been shown to have a higher percentage of regional spread to lymph nodes and the mesenchymal (M) subtype, a lower percentage. The purpose of this study is to determine if TNBCs have characteristic imaging features based on androgen receptor (AR) and vimentin (VM) status, which are surrogate immunohistochemical markers for the LAR and M subtypes of TNBC, respectively.

METHOD AND MATERIALS

This study is part of a clinical trial of stage I-III TNBC patients, which is being conducted at a single quaternary care center. A total of 144 patients, who were randomized to the intervention arm of being informed of the results of their molecular characterization including androgen receptor and vimentin status prior to receiving neoadjuvant chemotherapy, were included in this interim imaging analysis. Androgen-receptor-positive tumors (AR+) were defined as having >=15% staining. Vimentin-positive (VM+) tumors were defined as having >=50% staining. Two experienced, fellowship-trained breast radiologists used BIRADS (Breast Imaging Reporting and Data System) lexicon to review and reach consensus on all imaging studies (i.e., mammogram, ultrasound, and breast magnetic resonance imaging) while blinded to the immunohistochemical results. Fisher's exact test was used to assess the association of AR or VM status with imaging features. P values less than 0.05 was considered statistically significant.

RESULTS

Androgen-receptor-positive TNBC was significantly associated with scattered and heterogeneous breast composition on mammography (p=0.04), presenting as a mass with calcifications on mammography (p=0.04), having an irregular shape on ultrasound (p=0.005), and having an irregular margin on MRI (p=0.04). However, vimentin expression in TNBC was not significantly associated with any specific imaging features.

CONCLUSION

TNBCs have characteristic imaging features based on androgen receptor status but not based on vimentin status.

CLINICAL RELEVANCE/APPLICATION

Multimodality breast imaging may help identify LAR TNBC, which has been shown to be a subtype with a higher rate of regional nodal disease and with decreased response to neoadjuvant chemotherapy.

SST01-07 Usefulness of Surveillance MR for Early and Late Recurrent Breast Cancer in Women after Breast-Conservation Therapy

Friday, Nov. 30 11:30AM - 11:40AM Room: E353B

Participants
Jeong Min Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

jmlee328@gmail.com

PURPOSE

To investigate the diagnostic performance of mammography, ultrasonography, and breast magnetic resonance imaging (MRI) for early and late recurrences in patients who underwent breast-conservation therapy (BCT) for breast cancer.

METHOD AND MATERIALS

This retrospective study was approved by our institutional review board. Between January 2014 and February 2018, 1312 women with 1951 surveillance breast MR examinations after BCT were studied. We assessed the cancer detection rate of each surveillance MR, mammography and ultrasound.

RESULTS

Of 1951 cases of surveillance postoperative MRI, 59 cases were confirmed as cancer recurrence through biopsy. Nineteen cases of recurrences within 12 months post-BCT were defined as early recurrences while other 40 cases of recurring after 13 months post-BCT were defined as late recurrences. There were no statistically significant differences in patients' demographics between two groups with $p > 0.05$; age at cancer diagnosis, age at recurrence, symptoms, laterality of recurred cancer and intense surveillance. Among 19 patients with early recurrence, 7 cases were detected on mammography (36.8%), 10 on ultrasound (52.6%), and 17 on MRI (89.5%). Of 40 patients with late recurrence, 24 were detected on mammography (60%), 29 on ultrasound (72.5%) and 39 on MRI (97.5%). In both groups, MRI showed significantly higher cancer detection rate than mammography or ultrasound ($p < 0.01$).

CONCLUSION

In breast cancer patients with BCT, regardless of early or late, postoperative MR surveillance showed a significantly higher detection rate for cancer recurrence than mammography or ultrasound.

CLINICAL RELEVANCE/APPLICATION

Postoperative surveillance MR is useful tool for screening early or late cancer recurrence in breast cancer patients with breast conserving therapy.

SST01-08 The Role of Digital Breast Tomosynthesis (DBT) versrus Automated Breast Ultrasound (ABUS) in the Detection and Characterization of the Different Breast Lesions

Friday, Nov. 30 11:40AM - 11:50AM Room: E353B

dr.mahahelal@yahoo.com

PURPOSE

DBT and ABUS are advanced applications of digital mammography and breast ultrasound respectively. We aimed to evaluate the role of DBT versus ABUS in the detection and characterization of breast lesions

METHOD AND MATERIALS

Institutional review board approval was obtained for this prospective study that included 80 patients with 87 breast lesions. Methods of evaluation were digital breast tomosynthesis and automated breast ultrasound. For mammogram acquisition the system acquires a traditional digital mammogram and a tomosynthesis scanning in the same compression in the MLO and CC views. 3D ABUS were done for anteroposterior; lateral and medial acquisitions. Included breast lesions were analyzed regarding size, shape, margin, extension, calcifications and multiplicity. Operative data was the gold standard reference

RESULTS

ABUS showed more accurate measurements of the size of the breast lesions as DBT overestimated 18.8% of masses, on the other hand ABUS over estimated 25% of masses. No size under estimation by both modalities. ABUS was superior to DBT in estimation of the shape of the lesions 87% versus 69.6% for DBT, but both displayed similar values in the evaluation of the margins (65.2%).Tomosynthesis was far better in the detection of calcification in 40 lesions; while automated ultrasound was able to detect calcifications in only 11 lesions of them. Multiplicity was better demonstrated by ABUS that showed an accuracy of 100% compared to 80% by DBT. We found out that the sensitivity of tomosynthesis in detection and characterization of breast masses was 100 %, the specificity was 81.25%, the positive predictive value was 87.5% and the negative predictive value was 100%. On the other hand the sensitivity of automated ultrasound was 100%, the specificity was 75%, the positive predictive value was 84% and the negative predictive value was 100%.

CONCLUSION

DBT and ABUS, both showed near estimation in the detection and characterization of breast lesions. DBT is the modality for calcifications and ABUS is more accurate in the detection of multiplicity.

CLINICAL RELEVANCE/APPLICATION

DBT is considered as an adjunct to digital mammogram to increase the conspicuity of the different breast lesions. ABUS is a revolution in the ultrasound scanning of the breast that can be used as a non-invasive, fast and easy tool of breast imaging in early detection (i.e. screening) and differentiation of breast lesions.

SST01-09 First Description of Molecular Imaging Heterogeneity Profiles for Breast Tumors and Its Clinical Utility

PURPOSE

The concept of tumor heterogeneity, also called in Radiology as Tumor Texture, is based on the different areas of tumor uptake, which correspond to different levels of expression, cellularity, hypoxia or other parameters interested in being measured. We want to know if the description of the tumor heterogeneity uses in Radiology has its relation with PET parameters and if any biological characteristics of the breast tumors have a structure-function correlation.

METHOD AND MATERIALS

We have analyzed 1000 consecutive patients with breast cancer in a dedicated breast PET (dbPET). Different parameters have been defined that allow us to find a pattern of Texture and Heterogeneity (TeHe), for this, and following the rules of the radiological descriptions we defined a series of structural templates that cover practically all tumors, a mathematical formula has been defined for this correlation, and a assisted software for tumor shape description has been used to perform 3D categories.

RESULTS

7 different patterns divided into 5 groups for TeHe are described, and classified as: 1: Homogeneous-diffuse, 2: Lobular, 3: Annular and Spindle, 4: Eccentric and Focused; and 5: Speckled. A numerical value has been assigned between 1 and 5 for this classification with 1 being the most homogeneous and 5 being the most heterogeneous. This value is achieved through a mathematical relationship: medSUV/maxSUV: values close to 1 denote a high homogeneity and those close to 0 indicate a high heterogeneity. Process is complicated when tumor geometry becomes part of this heterogeneity. In those cases, some geometric patterns may explain similar values. We have analyzed the clinical utility of this classification and we have found two major uses: i) in the description of the efficiency of neoadjuvant therapy, where changes in TeHe pattern define responders of non-responders and ii) we have found, for the FIRST TIME, a correlation between TeHe patterns and the molecular subtype, crucial fact in the future of imaging based breast cancer diagnosis.

CONCLUSION

Studies of tumor heterogeneity based on metabolism show us different patterns that correlate with molecular subtypes and predict response to treatments.

CLINICAL RELEVANCE/APPLICATION

Tumor Texture and Heterogeneity are becoming, like in conventional radiology, in a new tool for prediction of response to the treatment and in molecular subtype characterization.

PURPOSE

Based on pathological size TNM8 introduced additional T-descriptor size cutpoints at 1cm intervals impacting stage groups. Our aim was to determine whether radiological staging by different radiologists consistently classifies lesion size within this more detailed staging.

METHOD AND MATERIALS

4 thoracic radiologists (4-17yr experience) staged 180 consecutive new lung cancers, recording multiple parameters blinded to the study aim. Readers were provided with axial 2.5mm, 1mm, coronal and sagittal 3mm images and asked to stage the primary as per clinical practice. Readers recorded the solid component for subsolid lesions. 2 observers covertly recorded the image series used for review and measurement. Inter-rater consistency of primary lesion size and T-size determination was evaluated. The impact of reader recorded lesion characteristics on consistency was assessed.

RESULTS

Readers recorded lesions as solid in 78-87% of cases, part-solid in 11-17% and pure ground glass in 1-2% with a moderate mean inter-rater kappa (0.71). 176 lesions were considered measurable by at least 3 readers (median 38mm, 7-113mm), 95% evaluated by all 4 readers. Readers varied widely in measurement plane (2.5mm:20-90%, 1mm:2-54%, coronal:7-24%, sagittal:0-26%) and mean number of planes reviewed (1.1-3.0). For lesions the mean range of measurement about the consensus median size was 31% (3-175%). Increased reader range of measurement about the median size was associated with part solid (mean 43% v 29% solid, $p<0.01$ Mann Whitney U) and cavitary lesions (32 v 19%, $p<0.05$). Atelectasis and spiculation were not significant. Using median size to determine T-descriptors, only 42% of cases had 100% reader concordance (74% concordance for at least 67% of readers). Complete concordance was significantly lower for groups T1c-T3 (20-35%) and higher in the remaining groups (42-67%). Mean inter-rater T assignment kappa was 0.57 (moderate), but higher with weighted kappa (0.80, good).

CONCLUSION

There is considerable variation in tumor size determination by thoracic radiologists, influenced by lesion perceived morphology, and measurement choices that result in lower inter-reader concordance for the narrower range TNM8 T-size criteria.

CLINICAL RELEVANCE/APPLICATION

Pathological size data informed increased numbers of cutpoints in TNM8 to better predict survival but increases radiological stage uncertainty and inter-reader variance in clinical practice.

PURPOSE

To develop an differentiation algorithm in patents with multiple lung cancers, using clinical and imaging variables.

METHOD AND MATERIALS

We retrospectively included 112 lesions in 55 patients (57 pairs) with multiple lung cancers who received at least two separate surgeries between January 2007 and December 2016. Each pair of multiple lung cancers was classified into two categories with histopathologic findings as the standard reference: multiple primary lung cancer (MPLC) and intrapulmonary metastasis (IPM). We established five serial questions for differentiation; 'Is either nodule pure ground-glass nodule on CT?' or 'Are both of the two lesions ground-glass dominant nodules?' (Step1), 'Does either nodule harbor air-bronchogram or irregular shape?' (Step2), 'Do both of the two nodules have the same or different grade of maximal standardized uptake values (SUVmax) on PET/CT?' (Step3), and 'Does either case harbor mediastinal LN or distant metastasis on preoperative work-up?' (Step4). The SUVmax values were classified into grade 1(<2.5), grade 2(2.5-5.0), and grade 3(>5.0). At each decision step, each pair was classified as MPLC or IPM. The sensitivity, specificity, and accuracy of the differentiation algorithm were analyzed.

RESULTS

Among 57 pairs, 36 pairs (63.2%) were classified as MPLCs, and the other 21 pairs (26.8%) as IPMs of standard reference. In step1, 14 pairs were classified as MPLC. In step2, 10 pairs with absence of air-bronchogram or irregular contour on both lesions were classified as IPM. In step3, 8 pairs showing two grades of separate SUV were classified as MPLC. In step4, 3 pairs with mediastinal LN or distant organ metastasis were classified as IPMs and 22 pairs were considered MPLC. The sensitivity for MPLC (specificity for IPM), specificity for MPLC (sensitivity for IPM), and accuracy were 94.4%, 52.4%, and 78.9%, respectively. Accuracy for each step was 100% for step 1, 90% for step 2, 62.5% for step 3 and 68% for step 4, respectively.

CONCLUSION

Approach algorithm using comprehensive information of clinical and imaging variables can allow differentiation between MPLCs and IPMs in a substantial number of cases of multiple lung cancers with multiple pulmonary sites of involvement.

CLINICAL RELEVANCE/APPLICATION

Our approach algorithm using clinical and imaging information can help differentiation between MPLCs and IPMs in multiple lung cancers.

SST02-03 Risk of Occult Mediastinal Disease in Non-Small Cell Lung Cancer Patients with Radiographic N0 Disease according to Tumor Location

Friday, Nov. 30 10:50AM - 11:00AM Room: E350

dongyoung.jeong@samsung.com

PURPOSE

Lung cancer guidelines recommend invasive mediastinal staging for patients with centrally located tumors without evidence of nodal disease on imaging studies. However, there is no uniform definition of central tumor. This study aims to evaluate the risk of occult mediastinal disease in non-small cell lung cancer (NSCLC) patients with radiographic N0 disease according using several different definitions for central tumor.

METHOD AND MATERIALS

Of the patients who underwent curative-intent surgical resection or endobronchial ultrasound-guided transbronchial needle

aspiration between January 2014 and December 2015, 1,337 consecutive patients with radiographic N0 disease were identified. Based on the most proximal part of the tumor in computed tomography (CT) image, tumors were categorized using five different definitions; contact with hilar structure, located within inner one-third or two-thirds of hemithorax according to concentric or sagittal lines.

RESULTS

About 7% (93/1337) of patients had occult N2 disease and they had significantly larger tumor size and more solid tumors in CT image. All but inner two-thirds of hemithorax by sagittal line were associated with N2 disease. However, only inner one-third of hemithorax by concentric line remained significant after adjustment for tumor size and density in CT (adjusted odds ratio [95% confidence interval], 2.29 [1.28-4.11]).

CONCLUSION

We suggest using inner one-third of hemithorax by concentric line as indication of EBUS-TBNA in NSCLC with radiographic N0 disease.

CLINICAL RELEVANCE/APPLICATION

Using inner one-third of hemithorax by concentric line as indication of EBUS-TBNA in NSCLC with radiographic N0 disease.

SST02-04 Comparison of Computed Tomography and Clinical Findings Between Immune-Related Pneumonitis and Pneumonia by Pathogen in Patients Treated with Anti-Programmed Death-1 (PD-1)/Programmed Death Ligand 1 (PD-L1) Therapy

Friday, Nov. 30 11:00AM - 11:10AM Room: E350

Participants
Cherry Kim, MD, Ansan, Korea, Republic Of (*Presenter*) Nothing to Disclose
Mi Young Kim, MD, PhD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Chang-Min Choi, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Yeon Joo Kim, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Immune-related pneumonitis (IRP) is an uncommon but potentially fatal toxicity of anti-programmed death-1 (PD-1)/programmed death ligand 1 (PD-L1) therapy for intrathoracic malignancy including non-small cell lung cancer. The purpose of study was to compare CT and clinical findings between IRP and pneumonia by pathogen.

METHOD AND MATERIALS

A total of 154 patients who received anti-PD-1/PD-L1 therapy were identified from 2014 to 2017. Among these patients, IRP developed in 9 (5.8%) and pneumonia in 30 (19.5%), which were confirmed through multidisciplinary approach. CT findings (reticulation, consolidation, ground glass opacity [GGO], interlobular septal thickening, micro- [<10mm] and macro-nodules [>=10mm], bronchial wall thickening, bronchiectasis, pleural effusion, and lesion distribution/bilaterality) and clinical features (symptom, smoking history, cancer staging, laboratory findings, underlying disease, prior radiotherapy history) were compared between IRP and pneumonia. Grade and outcome of IRP were also investigated.

RESULTS

In chest CT, diffuse reticulation (44.4% vs.0%, P=0.02), patchy/diffuse GGO (100% vs. 50%, P=0.01), and interlobular septal thickening (66.7% vs. 10%, P=0.002) were significantly more frequent in IRP than in pneumonia, whereas macronodule (0 vs. 36.7%, P=0.033) was significantly more common in pneumonia than IRP. IRP significantly showed peripheral location (77.8% vs. 16.7%, P=0.001) and bilateral distribution (44.4% vs. 3.3%, P=0.007). However, there were no significant differences in clinical findings between IRP and pneumonia. Among the IRP patients, 66.7% (6 of 9) of cases were grade 3, and 66.7% improved with drug holding/steroid therapy. The median onset duration of IRP from the first prescription was 126 days (range, 40-669), the median time for improvement was 43 days (range, 21-45), and the median time to death due to IRP was 18 days (range, 11-55).

CONCLUSION

Several CT findings including diffuse reticulation, patchy/diffuse GGO, and interlobular septal thickening with bilateral and peripheral distribution were more frequent in IRP than pneumonia by pathogen. Clinical findings were overlapped.

CLINICAL RELEVANCE/APPLICATION

It is crucial to suspect IRP as opposed to pneumonia in routine practice. Radiologists should be familiar with those findings of IRP to avoid delayed diagnosis and serious drug related complication.

SST02-06 Growth Rates of Thymic Epithelial Tumor and Thymic Cyst: Is Differentiation Feasible?

Friday, Nov. 30 11:20AM - 11:30AM Room: E350

Participants

PURPOSE

To investigate the growth rate of thymic epithelial tumors (TETs) and thymic cysts to determine whether they can be differentiated, and to identify clinico-radiological predictors of interval growth and their differential implications.

METHOD AND MATERIALS

This retrospective study included 122 patients (male:female=64:58; mean age, 57.2 years) with pathologically proven thymic cysts (n=56) or TETs (n=66) who underwent 2 serial chest CT scans at least 8 weeks apart. Average diameters were measured, and volume-doubling times (VDTs) were calculated. Attenuation was also measured and clinical characteristics were recorded. VDTs were compared between the thymic cysts and TETs using the log-rank test. Predictors of growth were analyzed using the log-rank test and Cox regression analysis.

RESULTS

The frequency of growth did not significantly differ between TETs and thymic cysts (P=0.279). The VDT of the thymic cysts (median, 324 days) was not significantly different from that of the TETs (median, 475 days; P=0.808). Water attenuation (<=20 Hounsfield Unit) predicted growth in thymic cysts (P=0.016; HR, 13.2 [95% CI, 1.6-107.3]) and lesion size (>17.2 mm) predicted growth in TETs (P=0.008 for size and P=0.029 for size*time; HR=e^(-0.001×time+1.654)). Among the growing lesions, positive and negative predictive values of water attenuation for the thymic cysts was 93% and 80%, respectively.

CONCLUSION

The frequencies of interval growth and VDTs were indistinguishable between TETs and thymic cysts. Water attenuation and lesion size predicted growth in thymic cysts and TETs, respectively. Among the growing lesions, the water attenuation was a differential feature of thymic cysts.

CLINICAL RELEVANCE/APPLICATION

Water attenuation (<=20 HU) indicates thymic cysts for the growing thymic lesions. Thus, CT follow-up, instead of surgical resection, can be recommended for the obvious cysts even if they show interval growth.

SST02-07 Cut-Off Value of MR Enhancement for Differentiating Benign Cysts from Solid Anterior Mediastinal Lesion: A Preliminary Observation

Friday, Nov. 30 11:30AM - 11:40AM Room: E350

ken921004@hotmail.com

PURPOSE

To determine the optimal cut-off value of MR enhancement for the differentiation of benign cysts from solid lesions in the anterior mediastinum.

METHOD AND MATERIALS

The derivation dataset consisted of 19 consecutive patients with pathologically proven benign cysts (n=7) and solid lesions (n=12) in the anterior mediastinum who underwent a diagnostic contrast-enhanced MR from two institutions. We measured maximum diameters, T1 and T2 signal intensities (SI), apparent diffusion coefficients (ADCs) from diffusion-weighted images, and relative enhancement ratios (RERs). T1 and T2 SIs were normalized by SI of cerebrospinal fluid. RERs were obtained from the subtraction of axial pre- and post-contrast T1-weighted fat-suppressed images after the precise non-rigid image registration of the two images using a dedicated WIP software (MRI Arithmetics, Siemens Healthcare, Erlangen, Germany). After comparison of image variables between cysts and solid masses, the cutoff value of the most differential MR variable was determined based on a receiver operating characteristic curve. For validation, two separate datasets were utilized: 1) 15 patients with 8 cysts and 7 solid lesions from another institution (validation dataset 1); 2) 11 patients with MR-proven stable benign cysts more than 2 years (validation dataset 2). Diagnostic accuracies were calculated from validation datasets.

RESULTS

Normalized T2 SI (0.21-0.92 vs. 0.12-0.58; *P*=.013), ADC (1.76-4.09 vs. 0.66-2.93 10-3 mm2/s; *P*=.013), and RER (0.41-24.1% vs. 28.1-771.7%; *P*<.001) significantly differed between cysts and solid masses. RER of 26% or less was determined as the cutoff value for differentiation of cysts from solid masses. In validation dataset 1, the cutoff value showed sensitivity of 87.5% and specificity of 100%, the sensitivity of 90.9% was observed in validation dataset 2.

CONCLUSION

The assessment of RER with the cutoff value of 26% can appropriately differentiate benign cysts from solid anterior mediastinal masses.

CLINICAL RELEVANCE/APPLICATION

The differentiation of benign cysts from solid anterior mediastinal masses can be supported by quantitative measurement of RER, potentially reducing a futile thymectomy.

SST02-08 Primary Tumor Standardized Uptake Value (SUVmax) as Powerful Prognostic Factor for Early

Esophageal Squamous Cell Carcinoma

Friday, Nov. 30 11:40AM - 11:50AM Room: E350

PURPOSE

We have previously shown that initial PET-SUVmax(Standardized uptake value) of early esophageal cancer helps both discriminating T1a and T1b stage esophageal squamous cell carcinoma(eSCC) from other eSCCs. In this study, we analyze the impact of PET-SUVmax for patient's survival.

METHOD AND MATERIALS

This retrospective study was based on 435 patients with a surgically proven early T- (Tis or T1a [< T1a], T1b and T2) stage eSCC. We performed survival analysis by the Kaplan-Meier method and comparisons of survival using log-rank test.

RESULTS

131 < T1a, 234 T1b, and 70 T2 eSCCs were enrolled. Mean SUVmax value were 2.53 for < T1a eSCCs, 4.02 for T1b eSCCs and 9.69 for T2 eSCCs. With ROC curve analysis, cut off value of SUVmax 3.05 (AUC: 0.757; 95% CI, 0.710-0.803; P < .001) at PET provided sensitivity 74.8% (98/131), specificity 70.1% (213/304), respectively, for differentiating < T1a eSCCs from other cancers. Cut off value of SUVmax 5.65 (AUC: 0.897; 95% CI, 0.857-0.937; P < .001) provided sensitivity 77.1% (54/70), specificity 87.7% (320/365), respectively, for differentiating T1 (< T1b) eSCCs from T2 eSCCs. In multivariate analysis, both SUVmax and pathologic staging including tumor size and node involvement were significant predictors of survival (p < 0.01). Survival analysis and log-rank test showed significant difference for overall survival among groups based on proposed cut-off SUVmax values (p =0.008 for cut off value 3.05, p <0.001 for cut off value 5.65)

CONCLUSION

In early esophageal squamous cell carcinomas, SUVmax gives us powerful predictor of overall survival after resection.

CLINICAL RELEVANCE/APPLICATION

Pretreatment SUVmax of primary esophageal cancer shows powerful predictive values which can be comparable to pathologic T stage.

SST02-09 Surgically Resected T1- and T2-Stage Esophageal Squamous Cell Carcinoma: T and N Staging Performance of EUS- and PET/CT

Friday, Nov. 30 11:50AM - 12:00PM Room: E350

dongyoung.jeong@samsung.com

PURPOSE

To demonstrate the frequency of nodal metastases and to disclose the diagnostic performance of endoscopic ultrasonography (EUS) and PET/CT in T and N staging in surgically resected early-stage esophageal squamous cell carcinomas (eSCCs).

METHOD AND MATERIALS

IRB approved this retrospective study with waiver of informed consent for reviewing medical record. We included 435 patients with an early T-stage (Tis or T1a [< T1a], T1b and T2) eSCC. The rates of metastatic lymphadenopathy were calculated. Then, the performance of EUS and PET/CT in subdividing T and N stages was assessed.

RESULTS

131 < T1a, 234 T1b, and 70 T2 eSCCs were identified. In discriminating < T1a from other cancers, the sensitivity, specificity and accuracy of EUS were 60.3% (79/131), 80.3% (244/304), and 74.3% (323/435), respectively. With ROC curve analysis, cutoff value of SUVmax 3.05 at PET provided sensitivity 73.3% (96/131), specificity 70.4% (214/304), and accuracy 71.3% (310/435) for differentiating < T1a eSCCs from others. Ten (7.6%) of 131 < T1a cancers had nodal metastasis. In discriminating N0 from node-positive disease, sensitivity, specificity and accuracy of EUS were 89.6% (267/298), 41.6% (57/137) and 74.5% (324/435), respectively, whereas those of PET/CT were 88.9% (265/298), 38.7% (53/137), and 73.1% (318/435), respectively.

CONCLUSION

In > 70% of patients with < T1a eSCCs, the tumor stage can be discriminated from higher stage cancers by using EUS or PET/CT, and substantial percentage (7.6%) of < T1a eSCC patients have nodal metastases, but the nodes are missed in more than half of the patients in clinical staging.

CLINICAL RELEVANCE/APPLICATION

Substantial percentage (7.6%) of < T1a eSCC patients have nodal metastases, and nodal metastasis rates increase as T stage increases (T1b [37.6%] and T2 [55.7%]). Moreover, more than half of nodal metastases were missed on PET/CT or EUS. Thus, after endoscopic surgery or even after curative surgical resection of < T1a eSCCs, adjuvant therapy is needed for those having nodal metastasis.

SST03-01 Efficacy of Gadoxetic Acid-Enhanced MRI for Evaluating Biliary Anatomy in Living Donor Liver Transplantation

Friday, Nov. 30 10:30AM - 10:40AM Room: E352

Participants
Sang Hyun Choi, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose
Kyoung Won Kim, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Jin Sil Kim, MD, Seoul, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose
Hye Young Jang, Daejeon, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To determine the added value of combined T2-magnetic resonance cholangiography (MRC) and hepatobiliary phase-MRC (T2+HBP-MRC) for evaluating the biliary anatomy in living liver donors by comparing it with T2-MRC alone, and evaluate the clinical usefulness of T2+HBP-MRC for surgical planning

METHOD AND MATERIALS

Our institutional review board approved this study and waived the requirement for informed consent. Between January and December 2016, we included 276 donors who underwent T2 and gadoxetic acid-enhanced MRI before right hemihepatectomy for living donor liver transplantation. Two reviewers evaluated the biliary anatomy classification using T2-MRC in the first session and T2+HBP-MRC in the second session. The sensitivity, specificity and confidence level (5-point scale) of T2-MRC and T2+HBP-MRC for variant biliary anatomy were evaluated using McNemar's test or paired t-test. The agreement rates of each biliary anatomy classification between MRC and operative cholangiography and the underestimated rates of multiple BDO for each MRC were evaluated using McNemar's test.

RESULTS

Of the 276 donors, variant biliary anatomy was observed in 36.2% (100/276). T2+HBP-MRC showed a significantly higher sensitivity for diagnosing variant biliary anatomy than T2-MRC alone (99.0% [99/100] vs. 89.0% [87/100], p = 0.006) with better confidence level (4.9±0.3 vs. 4.6±0.7, p<0.001), and inter-observer agreement (kappa, 0.902 vs. 0.730). A significantly higher agreement of biliary anatomy classification with operative cholangiography (98.6% [272/276] vs. 89.9% [248/276], p<0.001) and a significantly decreased the underestimation rate of multiple BDO (5.8% [16/276] vs. 9.4% [26/276], p=0.002) were obtained by T2+HBP-MRC than T2-MRC alone.

CONCLUSION

T2+HBP-MRC can be more useful than T2-MRC alone by improving diagnostic performance of variant biliary anatomy and giving information to make accurate surgical plans.

CLINICAL RELEVANCE/APPLICATION

T2+HBP-MRC can be clinically more useful than T2-MRC alone for evaluating biliary anatomy in living donor liver transplantation.

SST03-02 In Vivo Imaging of Hepatocellular Carcinoma Using Hyperpolarized Water

sebastian.fischer@kgu.de

PURPOSE

Besides the risk of allergic reactions and a nephrogenic systemic fibrosis, research showed remnants of Gadolinium based MR contrast agents (GBCA) in the brain - with unknown long-term effects. Purpose is to examine dynamic nuclear polarization (DNP) of water as a method to generate MR contrast and to prove it can be used for imaging of hepatocellular cancer (HCC) in vivo.

METHOD AND MATERIALS

Liquid-state Overhauser DNP hyperpolarizes water molecules by temporarily coupling their nuclear spin to the electron spin of irradiated radicals under resonance conditions. Microwave irradiation takes place in a resonator chamber containing immobilized TEMPO radicals, passed by a NaCl solution at a flow rate of 800µl/min within the bore of a 1.5T scanner. After catheterization of iliac vessels hyperpolarized water was administered directly at the celiac trunk of transgenic TGFa/c-myc mice that develop HCC. The aorta, its hepatic branches and the liver were visualized at 2 fps with dynamic GRE sequences (TR 6.4ms, TE 2.8ms, FoV 58x78x5mm, Matrix 128x77px) for 10 sec. Temporal DNP signal intensities, SNR and CNR values were measured in the aorta, hepatic artery, HCC and liver parenchyma. Anatomic sections und IHC staining confirmed the lesions as HCCs.

RESULTS

Magnitude imaging featured mainly a negative signal due to short relaxation time and fast signal decay during repetitive GRE pulses. In phase imaging signal intensities increased by factor 2.1 in the aorta, 1.6 in the hepatic artery and 1.2 in HCC and liver parenchyma. These changes were subsequently visible at the following periods after application: sec. 1-4 in the aorta, sec. 3-7 in the hepatic artery, sec. 4-8 in HCC and only slowly in the liver parenchyma, illustrating the HCC's typical early arterial enhancement. SNR increased up to 1.7 times and CNR up to 10.8 times. After stopping microwave power no contrast resides.

CONCLUSION

The in-bore DNP setup continuously creates hyperpolarized water, featuring high T1 signal enhancements in MR imaging and a short relaxation time. The strong contrast enhancement made a dynamic visualization of the supplying vessels and the typical contrast dynamics of HCCs possible - even using a standard clinical 1.5T scanner.

CLINICAL RELEVANCE/APPLICATION

Hyperpolarized water might be a promising future alternative to GBCA in MR angiographies and liver imaging without risking the potential adverse effects or intracorporal remnants.

SST03-03 Modified Breath-Hold Compressed-Sensing 3D Magnetic Resonance Cholangiopancreatograph: Clinical Feasibility in Biliary and Pancreatic Disorders

Friday, Nov. 30 10:50AM - 11:00AM Room: E352

PURPOSE

To prospectively evaluate the clinical feasibility of a modified 3D breath-hold (BH) compressed-sensing (CS) MRCP prototype protocol with small field-of-view (FOV) and high spatial resolution (modified BH-CS-MRCP), and to compare its performance with respect to the original BH-CS-MRCP and navigator-triggered (NT)-CS-MRCP.

METHOD AND MATERIALS

In this prospective IRB approved study, a total of 82 patients (46 male, median age, 55 years, range, 16-79 years) underwent 3D CS-MRCP on a 3T MR scanner. Three protocols (modified BH-CS-MRCP, original BH-CS-MRCP and NT-CS-MRCP) were performed in random order. Acquisition time of each protocol was recorded. Image quality, background suppression, duct visibility and diagnostic confidence with duct anatomic variations and duct-related pathologies were rated on a 5-point scale by two blinded radiologists independently. The diagnostic performance of each protocol was calculated using receiver operating characteristic curves.

RESULTS

Acquisition time was 17 seconds for both BH-CS-MRCP protocols, and 127.5±36.9 seconds for NT-CS-MRCP. In 75 cooperative patients, the incidence of major artifacts was low for all protocols (5.3%-8.0%). Background suppression was similar with the two BH-CS-MRCP protocols, both inferior to the NT-CS-MRCP protocol. Modified BH-CS-MRCP and NT-CS-MRCP depicted pancreatic duct and second-level branches of biliary duct better than original BH-CS-MRCP (all $p<0.01$). The diagnostic performance for detecting bile duct abnormalities was similar for all protocols(all $p>0.05$), whereas for detecting pancreatic duct abnormalities, modified BH-CS-MRCP and NT-CS-MRCP had significantly better performance(both $p<0.01$). In 7 non-cooperative patients, NT-CS-MRCP had superior image quality than both BH protocols (both $p<0.01$).

CONCLUSION

Modified BH-CS-MRCP is clinically feasible for pancreatic and biliary disorders. NT-CS-MRCP is useful in non-cooperative patients.

CLINICAL RELEVANCE/APPLICATION

The general image quality with CS-MRCP was reported to be similar or even superior compared to the conventional navigator-triggered (NT) protocol. However, according to previous reports, the visibility of the pancreatic duct with the original BH-CS-MRCPwas lower, and the diagnostic yield was lower. We found that the modified BH-CS-MRCP is feasible in clinical patients, with image quality and diagnostic performance equally good or better than NT-CS-MRCP.

SST03-04 Assessment of Liver Stiffness with Free-Breathing MR Elastography in Patients and Volunteers

PURPOSE

Liver MR elastography (MRE), as a quantitative imaging biomarker for hepatic fibrosis, is often performed during breath hold at end-expiration to avoid the changes due to respiratory motion. However, some patients have limited ability to perform adequate breath holds (e.g., pediatric and sedated patients). Our study purpose is to evaluate the technical feasibility and measurement variation of a rapid, free-breathing MRE technology for assessing liver stiffness (LS) with a comparison of standard breath-held MRE.

METHOD AND MATERIALS

We have recruited 32 patients with chronic liver diseases, and 8 controls. A standard breath-held multi-slice 2D GRE-MRE was performed to calculate the baseline liver stiffness (LSB). A view-sharing based reconstruction strategy for a free-breathing single-shot multi-slice 2D EPI-MRE was performed to calculate median liver stiffness (LSM) within anatomically co-registered ROIs, and its temporal variation ΔLS (defined in FigB). We performed Bland-Altman and intraclass correlation (ICC) analyses to analyze variance statistics and method accuracy, and Spearman correlation analyses to evaluate the relationships between LSB, LSM and ΔLS in non-cirrhotic (LSB<5kPa) and cirrhotic (LSB>=5kPa) livers respectively, with a 0.05 significance level.

RESULTS

FigA shows two example LSB and LSM images of a healthy liver and a cirrhotic liver, respectively. FigB shows an example of dynamic liver stiffness measurement in free-breathing MRE. Bland-Altman analysis shows mean difference of -0.18kPa between LSB and LSM with ICC of 0.96. FigC illustrates that LSM excellently agrees with LSB in all subjects (R^2=0.87, $p<0.0001^*$), highly accurate in 33 non-cirrhotic livers (LSM=1.03×LSB, $p<0.0001^*$), moderately underestimates LSB in 7 cirrhotic livers (LSM=0.79×LSB, $p<0.0001^*$). Measurement variation (FigC, shown as bubble size) increases with disease severity(R^2=0.40, $p<0.0001$).

CONCLUSION

Our preliminary results suggest that free-breathing MRE provides highly accurate liver stiffness value, especially for non-cirrhotic livers.

CLINICAL RELEVANCE/APPLICATION

The free-breathing MRE excellently agreeing to conventional breath-held liver stiffness will be beneficial for pediatric and sedated patients.

PURPOSE

To examine inter- and intra-observer reliability between different hepatobiliary phase (HBP) image scores on gadoxetic-acid (GA)-enhanced MRI and their correlation with clinical parameters and liver function in patients with diffuse chronic liver disease.

METHOD AND MATERIALS

This retrospective IRB-approved study included 353 patients (224 male, 129 female, mean age 53.4 ±13.8 years) with chronic liver disease who had undergone GA-enhanced MRI of the liver between 2010-2015. Relative liver enhancement (RLE), contrast uptake index (CUI), hepatic uptake index (HUI), and liver to spleen contrast ratio (LSC) were calculated by two radiologist independently using unenhanced and GA-enhanced HPB images (obtained 20 minutes after GA administration); 50 image sets were reviewed twice to assess intra-observer reliability. Albumin-bilirubin (ALBI) grade, Child-Pugh score and Model of End Stage Liver Disease (MELD) were calculated as markers of disease severity. Associations between HPB and disease severity markers were assessed (Spearman ´s correlation). Reader reliability was evaluated using intraclass correlation coefficient (ICC).

RESULTS

There was a significant correlation ($p<0.001$ for all) between five pairs of MR-derived parameters: RLE-CEI (R=0.947,), RLE-LSC (R=0.813,) RLE-HUI (R=0.767), CEI-LSC (R=0.818) and HUI-LSI (R=0.943). Depending on the MR parameter, MR-disease severity correlation coefficients ranged from 0.482-0.525 for ALBI-score, 0.371-0.430 for MELD, and 0.490-0.333 for Child-Pugh. Intra-observer ICCs ranged from 0.979 (0.963-0.989) for RLE to 0.816 (0.670-0.898) for LSI indicating excellent agreement. Inter-observer ICCs ranged from 0.979 (0.962.0.988) for RLE to 0.792 (0.629-833) for HUI.

CONCLUSION

Strong correlations were observed between different MR-derived HBP-based parameters with each other and between these parameters and disease severity markers. MR-derived parameters showed excellent inter- and intra-observer agreement.

CLINICAL RELEVANCE/APPLICATION

Qualitative MR-derived HBP imaging parameters have high observer releiability and show promise for evaluation of chronic liver disease severity.

SST03-06 Abbreviated Gadoxetic Acid-Enhanced MRI (AGAM) Including Second Shot Arterial Phase (SSAP) for Liver Metastasis Workup

PURPOSE

To evaluate feasibility of AGAM protocol including SSAP for liver metastasis workup

METHOD AND MATERIALS

This retrospective study was approved by our IRB and the requirement for informed consent was waived. 108 patients with hepatic metastasis who underwent gadoxetic acid-enhanced MRI using a modified injection protocol were included. Modified injection protocol included routine dynamic imaging after a first injection of 6-mL and SSAP after a second injection of 4-mL. Primary cancer sites consisted of colorectum (n=59), stomach (n=16), biliary trees (n=16), pancreas (n=7), and others (n=7).The image set 1 consisted of T2WI, chemical shift image, DWI, and T1-weighted dynamic image including hepatobiliary phase (HBP) [full original protocol]. The image set 2 consisted of T2WI, DWI, HBP, and SSAP [abbreviated protocol]. Acquisition time was measured in each image set. Visual assessment of vascularity was performed in the original arterial phase (AP), SSAP, and their subtraction images. After excluding patients with >=10 metastatic lesions, 149 lesions in 51 patients were included for detection and characterization analysis. The reference standard was a combination of pathologic result and follow-up image. Two radiologists independently reviewed two image sets regarding the presence and probability of liver metastasis with >6-week time interval. The diagnostic performance of each image set for each reader was compared by using a jackknife alternative free-response receiver operating characteristic (JAFROC) analysis. The sensitivity and positive predictive value (PPV) were also calculated.

RESULTS

Acquisition time was significantly shorter in img set 2 than in img set 1 (1118.3±128.3 vs. 372.8±30.5 sec, $p<0.0001$). Regarding the visual assessment of vascularity, 98.8% (85/86) hypervascular metastases (hyperintense on the original AP) showed hyperintensity on the SSAP and/or SS subtraction images. For both readers, average JAFROC figure-of-merit was not significantly different between img set 1 and 2 (0.998 vs. 0.997, $p=0.210$), and sensitivity and PPV did not show significant difference.

CONCLUSION

AGAM protocol including SSAP can provide faster image acquisition with preserving visual vascularity and diagnostic performance for liver metastasis workup.

CLINICAL RELEVANCE/APPLICATION

For liver metastasis workup, AGAM protocol can serve as a faster and more convenient alternative without compromising the diagnostic performance.

SST03-07 Magnetization Transfer Imaging Adds Information to Conventional MRIs to Differentiate Inflammatory and Fibrotic Intestinal Strictures in Crohn's Disease

Friday, Nov. 30 11:30AM - 11:40AM Room: E352

Participants
Zhuangnian Fang, Guangzhou, China (*Presenter*) Nothing to Disclose
Xuehua Li II, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose
Ren Mao, MD, Guang Zhou, China (*Abstract Co-Author*) Nothing to Disclose
Canhui Sun, MD, PhD, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose
Shiting Feng, MD, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose
Ziping Li, MD, PhD, Guangzhou, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Identifying inflammation- or fibrosis-predominant strictures in patients with Crohn's disease (CD) is crucial for developing treatment strategies. We evaluated the value of magnetization transfer (MT) with conventional MRI in characterizing CD stricture types using surgical histopathology as a reference standard.

METHOD AND MATERIALS

Forty patients with CD who underwent MRI scanning before surgery were enrolled. MRI parameters included: T2WI hyperintensity, bowel wall thickness, enhancement pattern changes over time, enhancement pattern and gain ratio in dynamic contrast-enhanced image phases, and MT ratios. Group and logistic regression analyses were performed to identify MRI variables for predicting inflammation and fibrosis, respectively.

RESULTS

Significant correlations with histological inflammation scores were shown for wall thickness ($r=0.361$, $P=0.001$) and T2WI hyperintensity ($r=0.396$, $P<0.001$), whereas histological fibrosis scores were significantly correlated with MT ratio ($r=0.681$, $P<0.001$) and wall thickness ($r=0.461$, $P<0.001$). Using T2WI hyperintensity as a predictor, conventional MRI could differentiate mild and moderate-to-severe inflammation with a sensitivity of 0.871 and a specificity of 0.800. The MT ratio could discriminate mild and moderate-to-severe fibrosis with a sensitivity and a specificity of 0.913 and 0.923, respectively. Combining MT ratios and T2WI hyperintensity, the MRI classification moderately agreed with the pathological stricture classification ($P<0.01$, $K=0.567$). The diagnostic accuracy of T2WI hyperintensity and MT ratio were 84% and 87%, with a moderate agreement between the MRI and the pathological classification ($P<0.01$, $K=0.576$).

CONCLUSION

The MT ratio in addition to conventional MRI improves the differentiation of fibrotic from inflammatory components of a small bowel stricture in patients with CD.

CLINICAL RELEVANCE/APPLICATION

Measuring the degree of bowel inflammation and fibrosis help optimize management strategies.

SST03-08 Transient Severe Motion in Gadoxetate Disodium Enhanced Liver MRI: A Multi-Center and Multi-Reader Trial in 1789 Patients

Friday, Nov. 30 11:40AM - 11:50AM Room: E352

PURPOSE

To determine the frequency of transient severe motion occurring in dynamic gadoxetate disodium enhanced liver MRI in a large multi-center setting.

METHOD AND MATERIALS

Institutional review board approval with a waiver for informed consent was obtained from all participating institutions from two different countries for this retrospective study. 1789 gadoxetate disodium enhanced liver MR examinations (1069 male and 720 female patients) acquired after intravenous administration of 5-20 ml gadoxetate disodium were included. 7156 dynamic data sets (pre-contrast, arterial phase, portal venous phase, late venous phase; each acquired during a single breath-hold) were reviewed by 10 radiologists with a minimum of 5 years after board certification. To determine interrater agreement and reliability all radiologists were obliged to review 40 selected additional data sets as a pre-requisite. Image evaluation was performed on a 5-point scale (1, no respiratory motion artifacts; 5, extensive respiratory motion artifacts, non-diagnostic study). Transient severe motion (TSM) was defined as a pre-contrast score of <=2, arterial score of >=4 and a portal and late venous score of <=3. Statistical tests included intraclass correlation coefficient (ICC), Kendall coefficient of concordance (W), normality test, and paired t-test.

RESULTS

ICC for interrater agreement and reliability were 0.983 (CI 0.973 - 0.990) and 0.985 (CI 0.978 - 0.991), respectively (both p<0.001), indicating excellent agreement and reliability. 874 (48.6%), 453 (25.2%), 346 (19.2%), 91 (5.1%), and 25 (1.4%) of all arterial phases were rated with a score of 1-5, respectively. Transient severe motion was detected in 51 of 1789 (2.9%) examinations. Mean motion scores for the pre-contrast scan, arterial phase, portal venous phase, late venous phase were 1.37±0.68, 1.85±0.99, 1.51±0.80, 1.38±0.66, respectively. Arterial phase motion scores were rated significantly worse than all other phases (p<0.001, respectively).

CONCLUSION

Although arterial phase imaging is significantly more often affected by motion artifacts than all other phases, the frequency of transient severe motion in gadoxetate enhanced dynamic liver MRI is only 2.9%.

CLINICAL RELEVANCE/APPLICATION

With only 2.9% the rate of transient severe motion in gadoxetate enhanced liver MRI is substantially lower than reported in previous single and dual center studies.

SST03-09 Role of Quantitative Parameters from Dynamic Contrast-Enhanced MRI in Evaluating Regional Lymph Nodes with Short-Axis Diameter Less Than 5 Millimeters in Rectal Cancer

Friday, Nov. 30 11:50AM - 12:00PM Room: E352

Participants

xiaoxj90@126.com

PURPOSE

It is still a challenge for radiologists to evaluate lymph nodes (LNs) metastatic status in rectal cancer with morphology when LNs are too small. However, there are about 50% metastatic LNs in rectal cancer which are less than 5 millimeters in size. The aim of this study was to investigate whether it was feasible to differentiate metastatic from non-metastatic LNs with short-axis diameter less than 5mm in rectal cancer using quantitative parameters derived from dynamic contrast-enhanced (DCE)-MRI.

METHOD AND MATERIALS

Sixty-five LNs with short-axis diameter less than 5mm from 122 patients were evaluated, including malignant LNs (n=27) and benign LNs (n=38). DCE-MR examinations were performed on a 3.0 Tesla MRI system (Magnetom Verio, Siemens, Germany). The following parameters were assessed: volume transfer constant (Ktrans), rate constant (kep), fractional extravascular extracellular space (EES) volume (ve), short-axis diameter (S), long-axis diameter (L) and short-to-long-axis diameter ratio (S/L). Receiver operating characteristic (ROC) curves were applied for analyzing significant parameters.

RESULTS

The metastatic LNs exhibited lower Ktrans than the non-metastatic LNs (P<0.001), but other parameters had no statistical differences in two groups. The AUC of Ktrans was 0.732 with the 95% CI being 0.610-0.854, and the diagnostic cutoff value was 0.088 min-1 (sensitivity, 60.5%; specificity, 81.5%).

CONCLUSION

Ktrans had moderate diagnostic performance in assessing small regional LNs in rectal cancer, making it a supplementary predictor when it is hard to distinguish malignant LNs from benign ones only by morphology.

CLINICAL RELEVANCE/APPLICATION

LN status plays a pivotal role in the treatment strategy of rectal cancer and has an influence on the prognosis of the colorectal cancer patients. Therefore, accurate LN evaluation is a necessary before treatment.

PURPOSE

To evaluate the correlation of "placental bulge sign" with the depth of invasion in patients with placenta accreta spectrum. Placental bulge sign is defined as deviation of uterine serosa from expected plane caused by abnormal outward bulge of placental tissue. Uterine serosa may appear intact but outline shape is distorted.

METHOD AND MATERIALS

In this HIPAA- compliant, IRB-approved, retrospective study, patients undergoing MR Imaging for evaluation of placenta accreta spectrum between March 2015 to 2018 were included. Patients who delivered elsewhere were excluded. Evaluation for placental bulge was performed by 2 independent readers and its presence or absence was recorded. Surgical pathology from cesarean hysterectomy or pathology of the delivered placenta was used as a reference standard. Statistical significance was calculated using Chi square test and inter-reader agreement was evaluated with kappa analysis.

RESULTS

61 patients underwent MRI for invasive placenta over 3 years. 2 patients delivered elsewhere and were excluded. 17 cases were normal placenta. At surgical pathology from cesarean hysterectomy, there were 8 cases of placenta accreta, 29 increta & 4 percreta. Placental bulge was present in 32 of 33 increta & percreta cases (True positive= 96.9%). Placental bulge was absent in 25 of 26 cases of normal placenta or placenta accreta without myometrial invasion(True negative=96.2%). Positive & negative predictive values were 96.9% and 96.2%,respectively. The results were statistically significant($p<0.01$). Estimated Kappa of 0.87 signified excellent inter reader concordance. In 1 false positive, placenta itself was normal but the bulge was present. On surgical pathology, this patient has markedly thinned, fibrotic myometrium without accreta. 1 false negative case was imaged at 16 weeks and may have been too early to diagnose the placental bulge sign.

CONCLUSION

Presence of uterine bulge can be confidently used to diagnose myometrial invasion and signifies at least placenta increta. In conjunction with other findings of invasive placenta, placental bulge was 100% predicitve of myometrial invasion. Using the bulge alone without other signs can be fraught with pitfalls and false positive results.

CLINICAL RELEVANCE/APPLICATION

Till date,no diagnostic finding for placenta increta is recognized. This diagnosis has surgical implications i.e. increased hemorrhage.Adjunct measures to control post-partum bleeding become necessary

SST04-02 ADC and IVIM: The New Perspective to Diagnose Placenta Accreta by MRI

Friday, Nov. 30 10:40AM - 10:50AM Room: E260

byw2271564204@163.com

PURPOSE

To investigate the diagnostic value of single b value (ADC) and multiple b value (IVIM) model for placenta accreta in pregnant women by MRI in functional perspective. We evaluate the differences of tissue characters between placenta accreta and normal placenta quantitatively, aimed to provide the basis for the functional diagnosis of placenta accreta by MRI.

METHOD AND MATERIALS

61 pregnant women were enrolled in our retrospective study. Among them, 24 cases were confirmed for placenta accreta by operation or pathology. The remaining 37 cases were normal placenta. Gestational weeks were 23 weeks to 36 weeks. All patients underwent DWI scanning which including 7 b values (0, 50, 100, 150, 400, 700 , 1000s / mm²) and the 2 b values(0, 800 mm²). The perfusion percentage (f%), diffusion coefficient (D), pseudo-diffusion coefficient (D *) and apparent diffusion coefficient (ADC) were measured by DKI tool and Siemens workstation respectively. The enrolled cases were divided into accreta group and control group. The accreta group were divided into two groups according to implanted part and non-implanted part. And the differences between the groups were tested by the Kruskal-Wallis test.

RESULTS

The average values of f%, D * and D in normal group were (29.66±7.0)%, (11.02±3.5) and (1.45±0.27) respectively, and those in the implanted part of accreta group were (52.18±7.8)% , (12.99±2.99) and (1.41±0.3) respectively. Those in non-implanted part of accreta group were (38.18±7.29)%,(11.04±3.23) and (1.40±0.17) respectively. ADC was (1.87±0.15) mm2 / s in the normal group, (2.32±0.17) mm2 / s in implanted part and (1.99±0.12) mm2 / s in non-implanted part of accreta group. The above comparison groups were statistically significant except for the D value.

CONCLUSION

f% and D * ADC provide information about perfusion and diffusion of placental tissue. Placenta accreta is significantly higher than the normal one. Implanted part is also higher than the non-implanted part in the accreta cases. IVIM and DWI (ADC) can be used as a potentially functional technique for placenta accreta's diagnosis by Magnetic Resonance Imaging.

CLINICAL RELEVANCE/APPLICATION

IVIM and ADC are recommended as new fMRI sequences which provide the perfusion and diffusion imformation to diagnosis the placenta accreta

SST04-03 Predictive Parameters of the Morbidly Adherent Placenta on MRI

Friday, Nov. 30 10:50AM - 11:00AM Room: E260

Participants
Timothy W. Ng, MD, Dallas, TX (*Presenter*) Nothing to Disclose
Ambereen A. Khan, MD, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose
Yin Xi, PhD, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose
Christine M. Dang, BA,BS, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose
Diane M. Twickler, MD, Dallas, TX (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To assess predictive indicators of morbidly adherent placenta in 2nd and 3rd trimester MRI.

METHOD AND MATERIALS

This is a retrospective study of 2nd and 3rd trimester pregnancies assessed by MR from 2007 to present. Women were included if there was suspicion for placental invasion based on surgical history and suspicion of placenta previa on ultrasound. MR was performed on 1.5 T Signa (GE Healthcare) or Magnetom (Siemens) magnet. Studies were anonymized on OsiriX (Pixmeo SARL). The MRIs were then reviewed by an experienced radiologist, specialized in OBGYN imaging, who was blinded to clinical outcomes. Twenty qualitative and quantitative parameters were assessed and compared to four clinical outcome measurements: need for cesarean hysterectomy, pathology report, impression at time of surgery, and intraoperative blood transfusions. Univariate logistic regression analysis was performed. P-values less than 0.05 were considered significant. Analyses were performed using SAS (SAS Institute Inc).

RESULTS

Of 41 women, 29 required a cesarean hysterectomy, 11 had cesarean delivery, and 1 delivered vaginally. Twenty-five of 41 required blood transfusion. On pathological assessment, 22 had evidence of invasion. Twenty-five of 41 women were deemed clinically invaded by the surgeon during delivery. Eleven out of the twenty MRI parameters assessed demonstrated statistical significance (see table). Of particular note, the greatest linear dimension of invasion, inhomogeneity, fibrin deposition, radiologist impression and assessment of degree of invasion had the greatest predictive value.

CONCLUSION

Multiple MR parameters can predict placental invasion and correlate with the need for cesarean hysterectomy, as well as pathological and surgical impressions of invasion. These defined MRI parameters provide a systematic method for assessing placental invasion. Future work should combine these and clinical variables in a larger series with multiparamteric analysis to design a standardized index.

CLINICAL RELEVANCE/APPLICATION

Quantitative outcomes based assessment of MR parameters can be used to predict placental invasion and reduce diagnostic uncertainty.

SST04-04 Feasibility and Reliability of a Novel Low Cost 3D Ultrasound System in 2nd Trimester Fetal Imaging

PURPOSE

The clinical utility of ultrasound (US) is limited by operator dependence and restricted planar image capture. We have developed a novel, low cost technology to enable 3D volumetric image acquisition and automatic orientation using existing 2DUS platforms. We demonstrate its feasibility and reliability in 2nd trimester fetal imaging.

METHOD AND MATERIALS

The research device (orientation sensor, screen capture device, and computer) plus 2DUS machine (GE Voluson E8, 2D C1-5 probe) were used to capture 2 image volumes for each of 10 2nd trimester fetuses. Source images were obtained by a student with minimal US experience by sweeping the US transducer continuously across the region of interest. Acquisition and reconstruction times were automatically recorded. Volumes were reconstructed using a voxel-based algorithm designed by the research team. 3DSlicer was used for image analysis. Blinded measurements of biparietal diameter (BPD), femur, and humerus were made by the student during image review and compared to those reported by expert sonographers during routine anatomy scans performed on the same day. Inter-rater reliability was assessed using the intraclass correlation coefficient (ICC).

RESULTS

Gestational ages ranged from 16 to 23 weeks. BMI ranged from 23.2 to 30.9. Image acquisition (sweep time) and volume reconstruction required mean 29.9s and 72.9s, respectively. Fetal orientation, BPD, femur, and humerus could be identified in multiplanar and volumetric images. ICCs demonstrated strong inter-rater reliability between the student and expert report for each measurement (BPD ICC 0.88 CI95% 0.53-0.97; femur ICC 0.91 CI95% 0.63-0.98; humerus ICC 0.81 CI95% 0.22-0.95).

CONCLUSION

Comprehensive fetal image volumes were rapidly acquired by a novice and reconstructed for interactive visualization without restriction to planar images. Orientation, BPD, femur, and humerus could be identified for each fetus during image review despite no attempt at identification during scan acquisition. Measurements were highly reliable. This low cost technology could advance the clinical utility of US in obstetric imaging, especially in low resource settings.

CLINICAL RELEVANCE/APPLICATION

A novel, low cost device enabled capture of comprehensive, oriented fetal image volumes by a novice and may enhance the clinical utility of US in obstetrics, particularly in low resource settings.

SST04-05 Utility of High Resolution Images in MR Evaluation of Placenta Accreta Spectrum

Friday, Nov. 30 11:10AM - 11:20AM Room: E260

Participants
Priyanka Jha, MBBS, San Francisco, CA (*Presenter*) Nothing to Disclose
Liina Poder, MD, Mill Valley, CA (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

priyanka.jha@ucsf.edu

PURPOSE

To assess the utility of high resolution (HR) images in management of placenta accreta spectrum (PAS).

METHOD AND MATERIALS

In this HIPAA- compliant, IRB-approved, retrospective study, patients undergoing 3T MR Imaging for evaluation of placenta accreta spectrum between March 2015 to 2018 were included. The images were analyzed by 2 independent readers with 5 and 15 years of experience and expertise in placental imaging. First, the large field of view (FOV) images, which include the entire uterus were analyzed for diagnostic quality and the presence or absence of findings of PAS. Additional pertinent observations included location of invasion, depth of invasion/myometrial thinning, presence of cervical invasion, bladder invasion and intra-placental hemorrhage. Next the HR, small FOV images were reviewed for diagnostic quality. These images were reviewed for any additional findings not previously identified on large FOV images. Intraoperative findings & surgical pathology were used as reference standard. Reader confidence for diagnosis was recorded on both large & small FOV images.

RESULTS

60 patients who underwent 3T MRI for invasive placenta were included in the study. Of these, HR images were found to be non-

diagnostic from respiratory motion artefact in 19 cases(32%). In remaining cases, HR images were not found to add any additional information to effect patient management in 37 cases(58%). In 2 cases, HR images were found to be helpful to exclude focal accreta. In additional 2 cases with placenta increta, HR images were helpful to exclude bladder invasion. However, when adequately performed, reader confidence for diagnosis of all accreta, increta and percreta was increased.

CONCLUSION

HR images are often degraded from artefact, probably related to their acquisition later in the protocol, reflecting increasing patient discomfort. Although HR images improve reader confidence, in most cases, no new findings or additional diagnostic information is acquired. If MRI is positive for invasive placenta, additional HR may rarely be necessary to evaluate for invasion of adjacent organs. In a negative examination, they may be helpful to exclude focal invasion. Live review of acquired images can guide need for HR aquisition.

CLINICAL RELEVANCE/APPLICATION

HR images can be omitted during MR for invasive placenta in many cases, reducing imaging time, associated cost and patient discomfort. Rarely, they are useful to assess focal invasion.

SST04-06 Estimation of Fetal Weight by Measurement of Fetal Thigh Soft-Tissue Thickness (STT) in the Late Third Trimester: Its Correlation with Hadlock's Method and Actual Birth Weight

Friday, Nov. 30 11:20AM - 11:30AM Room: E260

Participants
Chetankumar M. Mehta, MBBS,MD, Vadodara, India (*Presenter*) Nothing to Disclose
Ayaz J. Dabivala, MBBS, Vadodara, India (*Abstract Co-Author*) Nothing to Disclose
Arpita D. Fernandez, MD , Vadodara, India (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

drchetan_mehta@yahoo.com

PURPOSE

The purpose of this study is To assess the reliability of the linear measurement of mid-thigh soft-tissue thickness (STT). To prospectively evaluate the Formula derived by Scioscia et al using Fetal STT for estimating fetal EFW. To assess its correlation with established method of Hadlock and finally compare the results with actual birth weight post delivery.

METHOD AND MATERIALS

This was a prospective study involving 325 singleton uncomplicated pregnancies presenting to emergency department. 300 of these, who delivered within 48 hours of measurement were considered for the analysis. Scioscia et al developed the equation for Estimated Fetal Weight using multiple stepwise regression analysis (EFW = -1687.47 + (54.1 × femur length) + (76.68 × STT)). This equation was utilised in following three consecutive phases: (1) Evaluation of the novel formula derived by Scioscia et al for EFW using femur length and STT , (2) Comparing the resulting EFW with existing Hadlock's equation and (3) To test the accuracy of the formula by comparison with actual birth weight.

RESULTS

The STT was significantly correlated with both abdominal circumference and birth weight ($r2 = 0.64$ and 0.34, respectively; $P < 0.001$).The correlation matrix of FL and STT with actual birth weight was higher ($r2 = 0.86$ and 0.80, respectively) as compared to their mutual correlation. However,among the studied estimates, the model using STT proposed herein was apparently more accurate compared with the hadlock's method owing to lower standard error and better stronger correlation with actual birth weight. Moreover, the differences between EFW and actual birth weight were more spread out using the estimates of Hadlock et al. than they were using ours.

CONCLUSION

Our findings confirm the potential of linear measurement of mid-thigh STT as a valuable parameter for the sonographic assessment of fetal growth and EFW. Scioscia's equation is apparently at least as reliable as the most widely used formulae for EFW, is easily reproducible and has a better correlation with actual birth weight.

CLINICAL RELEVANCE/APPLICATION

Accuracy of STT in estimating the estimatedd fetal weight (EFW) outperforms the routinely used formulas, so STT shall be measured in all obstetric sonograms in third trimester.

SST04-07 Predictive Accuracy of Trans-Cerebellar Diameter in the Determination of Gestational Age in Third Trimester of Pregnancy

Friday, Nov. 30 11:30AM - 11:40AM Room: E260

omololakinwunmi@gmail.com

PURPOSE

To determine the accuracy of trans-cerebellar diameter (TCD) measurement in sonographic assessment of gestational age in third trimester of pregnancy and its correlation with other conventional fetal biometric parameters

METHOD AND MATERIALS

A cross-sectional study was conducted on 500 pregnant women who fulfilled the inclusion criteria and were attending the hospital's antenatal clinic from January to October, 2015. Each participant underwent a transabdominal obstetric ultrasound examination for the measurement of trans-cerebellar diameter and other fetal biometric parameters using an Ultrasonix touch ultrasound machine version 5.6.4 with a 3,5MHz curvilinear probe

RESULTS

The average age of participants was 32 years. The average gestational age was 34 weeks and the mean trans-cerebellar diameter (TCD) estimation was 46.1 ± 6.1mm (corresponding to 34.7 ± 2.6 weeks). We observed a statistically significant correlation between gestational age and TCD at third trimester with correlation co-efficient of 0.97 and R2 of 0.931 ($p < 0.001$). From regression analysis, a strong significant association was observed between fetal TCD at third trimester and actual gestational age. The observed sensitivity of TCD in predicting gestational age was 95.6% with a positive predictive value of 98.3%. TCD was also significantly correlated with other fetal biometeric parameters including bipareital diameter (BPD), head circumference (HC), abdominal circumference (AC) and femur length (FL) with correlation co-efficient of 0.76, 0.90, 0.79 and 0.75 respectively.

CONCLUSION

The findings of this study have suggested trans-cerebellar diameter as a reliable sonographic tool in the estimation of gestational age in normal third trimester pregnancy.

CLINICAL RELEVANCE/APPLICATION

Tran-cerebellar diameter measurement can be reliably used to estimate gestatinal age for optimal obstetric management especially for pregnant women who are not sure of their last menstrual period, those who have had no antenatal records or those who present with obstetric emergency. It is therefore recommended as part of the baseline sonographic parameter in estimating gestational age

PURPOSE

We aimed to examine if the location of a first radiographic vertebral fracture (VF) determines the risk of future incident radiographic VFs.

METHOD AND MATERIALS

Prevalent radiographic VFs were scored in 3882 subjects aged 55 years or older at baseline and after a mean follow-up of four years, using two methods: SpineAnalyzer® Quantitative Morphology (QMSA) and Algorithm Based Qualitative (ABQ). We defined the location by a) three regions: T4-T8; T9-T12 and L1-L4, b) exact vertebral level from T4 to L4. The association between the location of first prevalent VF and occurrence of future incident VFs was examined using logistic regression models adjusted for age, sex, BMI, and FN- BMD.

RESULTS

At least one incident VF was observed in 3.9 % (QMSA) and 2.0% (ABQ) of the participants. As compared to participants without VFs, individuals with multiple fractures at baseline had three (OR= 2.7; 95%CI 1.7-4.2 for QM) to 12 (OR= 12.4; 95%CI 4.8-31.9 for ABQ) times increased likelihood of suffering incident VFs. A first QMSA VF at T4-T8 was associated with increased risk of incident VF (OR= 7.7; 95%CI 4.3; 13.8), at T9-T12 (OR=2.5; 95% CI 1.0; 6.1) and L1-L4 (OR= 3.5; 95% CI 1.2; 10.5). A first ABQ VF at T4-T8 was associated with increased risk of incident VF (OR= 17.2; 95%CI 4.8; 61.4), at T9-T12 (OR=4.2; 95% CI 1.3; 12.7) but not at L1-L4 (OR= 1.9; 95% CI 0.5; 6.5). Of all vertebral levels, subjects with VFs arising at T8 had (with both methods) the highest risk for incident VFs (OR= 16.0; 95%CI 2.5; 102.2) for ABQ and (OR=11.5; 95%CI 4.5; 29.1) for QMSA, as compared to participants without VFs. Fractures at T6 scored with QMSA (OR=16.8; 95%CI 5.3; 52.6), T7 (OR=5.5; 95%CI 1.9; 15.2), L1 (OR=7.3; 95%CI 2.3; 22.6) and at T12 scored with ABQ (OR=5.6; 95%CI 1.5-20.8) were also associated with incident VFs. No other vertebral body locations were significantly associated with future VFs risk.

CONCLUSION

A first radiographic VF located at the upper thoracic region (T4-T8) and specifically at T8, is strongly and robustly associated with increased risk for future VFs independent of age, sex and BMD according to two different scoring methods.

CLINICAL RELEVANCE/APPLICATION

Since VFs in the upper thoracic spine (T4-T8), and specifically at T8, are strongly associated with increased risk for future VFs, such fractures require special attention for radiologists and warrant referral for monitoring and appropriate treatment.

SST05-02 UTE MR Morphology of Disco Vertebral Junction: Correlation with Disc Grade and T2 Values

PURPOSE

We have previously reported unique capability of ultrashort echo time (UTE) MRI to image the morphology of the discovertebral junction (DVJ) in human lumbar spines. In this cadaveric study, we sought to determine if DVJ morphology correlates with disc Pfirrmann grades and T2 values.

METHOD AND MATERIALS

Lumbar spines from 37 cadavers (30 males, 60±10.1 yrs, mean±SD) were imaged at 3T using UTE (TR=300 ms, TEs=0.01 and 5.5 ms, FOV=16 cm, matrix=512x512) and spin echo T2 map (TR=2000 ms, 8 TEs=10 to 70 ms) sequences. UTE images were used to define morphology of the DVJ as being normal (distinct linear high signal intensity, Figure 1A, arrows) or abnormal with focal signal loss (Figure 1A, arrowhead) and/or irregularity (Figure 1A, curved arrow). Spin echo data was used to perform Pfirrmann grading of the disc (Figure 1B), and T2 mapping (Figure 1C). T2 values of nucleus pulposus was determined using an atlas-based automated region of interest. Using statistics, we compared proportion of disc grades (Figure 1D) and nucleus T2 values (Figure 1E) when the disc was adjacent to normal DVJs, 1 abnormal DVJ, or 2 opposing abnormal DVJs.

RESULTS

Out of 278 DVJs, 198 were normal, 45 had focal signal loss, and 35 were irregular. There was greater proportion of higher disc grades (Figure 1D; chi-square p=0.00004), as well as lower T2 values (Figure 1E; ANOVA p=0.18), in discs adjacent to 2 opposing abnormal DVJs, compared to discs adjacent to normal DVJs.

CONCLUSION

These results suggest that the prevalence of abnormal DVJs in human lumbar spines are quite high (~25%), and given the association between DVJ and disc degeneration, altered DVJs could be important for the etiology of disc degeneration.

CLINICAL RELEVANCE/APPLICATION

By direct assessment of the DVJ with UTE MRI early detection of beginning disc pathology in a preclinical stage is feasible. DVJ may play a biomechanical/metabolic role in support of healthy discs.

SST05-03 Feasibility of Zero Echo Time Sequence of the Cervical Spine MRI: Emphasis on Evaluation of Osseous Structures and Calcification

PURPOSE

To determine the availability of zero echo time (ZET) sequence for the evaluation of osseous foraminal stenosis (OFS) and presence of peridiscal osteophyte (PO), discal calcification (DC), and ossification of posterior longitudinal ligament (OPLL) by comparison with CT as reference standard.

METHOD AND MATERIALS

Twenty one patients (mean age, 67.7 years; 10 male, 11 female) who underwent cervical MRI including 3D ZET sequence and concomitant CT within 1 months (mean interval, 3.8 days; range, 0-27 days) were retrospectively enrolled from November 2017 to March 2018. Two independent musculoskeletal radiologists evaluated ZET images and CT in separate sessions for the followings at each level: 1) grading of OFS by a visual 4-point scale from 0-3 (0=none or minimal, 1=mild, 2=moderate, 3=severe) on oblique sagittal images from C2-3 to C7/T1 (total 252 foramina); 2) presence of PO and DC of central zone of central canal from C2-3 to C7/T1 (total 126 disc level); 3) presence of OPLL from C2 to C7 (total 126 vertebral body level). Intermodality agreement between ZET and CT, and intra- and interobserver agreements for ZET were measured with the kappa (κ) statistics.

RESULTS

Intermodality agreements for detecting PO, DC, and OPLL between ZET and CT were almost perfect by 2 readers (κ=0.943-1 by reader 1; κ=0.867-1 by reader 2, respectively). Substantial to almost perfect agreements (κ=0.826 by reader 1, κ=0.787 by reader

2) were found for grading of OFS between ZET and CT. Overall intra- and interobserver agreements were substantial to almost perfect for ZET (κ=0.788-1).

CONCLUSION

The results of our study shows strong intermodality agreement between ZET sequence of MRI and CT in the cervical spine for evaluation of osseous structures and calcification.

CLINICAL RELEVANCE/APPLICATION

ZET sequence of MRI can demonstrate 'CT-like' contrast for the evaluation of cervical spine.

SST05-04 Effect of Physical Activity on Thoracic and Lumbar Disc Degeneration - a MRI Based Analysis of 385 Healthy Controls from the KORA Cohort

Friday, Nov. 30 11:00AM - 11:10AM Room: E351

PURPOSE

Depending on the type and extent of physical activity, there isn´t always a health preventing and health promoting impact found. Less information is available on the impact of physical activity on vertebra disc degeneration. Therefore, the purpose was to evaluate the impact of physical activity on intervertebral disc degeneration of the thoracic and lumbar spine.

METHOD AND MATERIALS

A total of 385 patients of the KORA study (Cooperative Health Research in the Augsburg Region) were included in this study. All subjects underwent full body dual-echo Dixon and T2 Haste sequence MR scan performed on a 3T scanner (Magnetom Skyra, Siemens Healthcare). Furthermore, they were tested on the basis of a standardized assessment tool inter alia on anthropometric data such as age, weight and heights as well as on physical activity/work, daily bike rides and daily walks. In order to quantify thoracic and lumbar disc degeneration, assessment was performed by two experienced radiologists according to the Pfirrmann Score (Grade >2 = pathological). Statistical analysis was performed by univariate and multivariate analysis.

RESULTS

Age (BWS-Pfirrmann score:0.15; p<0.001, LWS Pfirrmann score:0.06; p<0.001 and Overall-Pfirrmann score:0.21, p<0.001), BMI (BWS-Pfirrmann score:0.11; p<0.05, LWS Pfirrmann score:0.05; p<0.01 and Overall-Pfirrmann score:0.16, p<0.01) as well as no physical activity (BWS-Pfirrmann score:1.96; p<0.01, LWS Pfirrmann score:0.99; p<0.001 and Overall-Pfirrmann score:2.95, p<0.001) lead to significant thoracic and lumbar disc degeneration when testing for univariate correlation. When testing on interdependency, we showed that age (BWS-Pfirrmann score:0.15; p<0.001, LWS Pfirrmann score:0.06; p<0.001 and Overall-Pfirrman score:0.21, p<0.001) and no physical activity (BWS-Pfirrmann score:1.85; p<0.01, LWS Pfirrmann score:0.97; p<0.001 and Overall-Pfirrmann score: 2.82, p<0.001) still correlate with disc degeneration in multivariate analysis. On the other hand, we found that much physical activity also leads to a thoracic and lumbar disc degeneration.

CONCLUSION

No or less physical activity as well as age and BMI correlate with thoracic and lumbar disc degeneration.

CLINICAL RELEVANCE/APPLICATION

According to the literature, high physical activity increases degeneration. In contrast research for no to little physical activity and degeneration is limited. We were able to show that no or less activity results in a similar outcome.

SST05-05 The Assessment of Disco-Ligamentous Complex Injury on Magnetic Resonance Imaging (MRI) and CT Scan After Acute Cervical Spine Trauma

Friday, Nov. 30 11:10AM - 11:20AM Room: E351

shangkmii@hanmail.net

PURPOSE

to investigate useful imaging findings to assess disco-ligamentous injury after acute cervical spine trauma

METHOD AND MATERIALS

Between January 2015 and December 2017, 96 patients (11women, 85 men, age range 20-83 years, mean age 58 years) performed cervical spine MRIs and CT scans after acute trauma. We evaluated pre-vertebral hematoma, edema of cervical back muscles, high signal intensity (SI) within the spinal cord (contusion), instability, discontinuity of anterior longitudinal ligament (ALL), abnormal high SI of disc, ossification of ALL or anterior spur formation, and fracture of posterior elements. The presence or absence of disco-

ligamentous complex injury confirmed by surgery were compared with imaging findings.

RESULTS

Disco-ligamentous complex injuries were identified in 58 patients (60%) at surgery. The instability of the bony structure associated with fracture was seen only 27 patients (28%). Prevertebral hematoma (mild;26, moderate;27, severe;34) were presented in 87 (91%), edema of cervical back muscles in 75 (78%), spinal cord contusion in 86 (90%), high SI of disc in 67 (70%), and OALL or spur formation in 44 (46%).The agreement between the imaging assessment of ALL discontinuity and the disco-ligamentous injury identified in surgery was very low (kappa value; 0.25). There was a high correlation between disco-ligamentous complex injuries identified in surgery and cord contusion, abnormal high SI of disc and fractures of posterior elements on the images.

CONCLUSION

The imaging findings of cord contusion, abnormal high SI of disc and fractures of posterior elements might be useful for assessment of disco-ligamentous complex injury while the imaging asessment of ALL discontinuity is less accurate.

CLINICAL RELEVANCE/APPLICATION

If instabilities or fractures are not well seen on the images, it is difficult to directly recognize ALL rupture including disc. Therefore these secdonary imaging findings might be useful to recognize disco-ligamentous complex injury before surgery and scoring subaxial cervical spine injury.

SST05-06 Prediction of Abnormal Bone Density and Osteoporosis from Lumbar Spine MR Using Modified Dixon Quant in 257 Subjects with QCT as Reference

Friday, Nov. 30 11:20AM - 11:30AM Room: E351

PURPOSE

To investigate the predictive value of using vertebral bone marrow fat fraction (BMFF) obtained from lumbar spine MRI to assess abnormal bone density and osteoporosis

METHOD AND MATERIALS

257 participants (181 females, and 76 males; age: 48.9+-14.7 years old; BMI: 22.9+-3.04 kg/m2) were recruited for the study with written consent and approved by local institutional review board (IRB). Exclusion criteria: history of known spinal tumor, trauma, dysplasia, spinal surgery and hormone therapy. All subjects underwent lumbar MRI (Ingenia 3.0T, Philips) including modified Dixon(mDixon) Quant for assessment of BMFF at L1, L2 and L3 by manually drawing ROI (region of interest) on the fat fraction map (InterlliSpace TM Portal, Philips). Quantitative computed tomography (QCT) was performed on all subjects for determination of bone mineral density (BMD). Partial correlation analysis between vertebral BMFF and BMD was first performed. Logistic regression analysis using independent training and validation data sets were performed to evaluate the performance of predicting abnormal BMD (osteopenia [80 to 120 mg/cm3] and osteoporosis [<80mg/cm3]) or osteoporosis using BMFF.

RESULTS

All participants were divided into three groups based on their BMD from QCT: normal bone density (>120mg/cm3, 135 subjects), osteopenia (82 subjects) and osteoporosis (40 subjects). Moderate inverse correlation was found between vertebral BMFF and BMD after controlling age, gender and BMI ($r = -0.529$, $p<0.001$). The logistic regressions were trained using 2/3 of the cases and the performance was evaluated using the independent validation set comprised of the rest 1/3 cases. The area under the curve, sensitivity, specificity of predicting abnormal bone density were 0.940, 0.902, and 0.867, respectively and 0.906, 0.929 and 0.764, respectively for predicting osteoporosis. Its positive predictive value was found to be 0.907, making it an excellent screening tool.

CONCLUSION

Our study demonstrates statistically significant moderate correlation between vertebral BMFF and BMD. mDixon Quant as a fast, simple, non-invasive and non-ionizing imaging method to access vertebral BMFF has a high predictive power for identifying abnormal bone density and osteoporosis.

CLINICAL RELEVANCE/APPLICATION

Lumbar spine MRI is one of the most commonly performed study in clinical practice, added value of prediction of abnormal BMD using mDixon Quant would greatly benefit the patients.

SST05-07 Quantitative Assessment of Fat Infiltration in Lumbar Multifidus Muscle using T2-Weighted Multipoint Dixon in Patients with Low Back Pain: Correlation with Herniated Nucleus Pulposus

[redacted]

PURPOSE

This study is to quantitatively assess fat infiltration in lumbar multifidus muscle using T2-weighted multipoint Dixon (T2 Dixon) and to reveal the relationship with herniated nucleus pulposus (HNP) in patients with low back pain (LBP).

METHOD AND MATERIALS

Among 241 patients who performed MRI of lumbar spines (L-spine) for LBP on 1.5T scanner, 114 patients (age, 42.7±1.4y; 58 females) were enrolled, excluding patients with prior spine surgery, malignancy, compression fracture, spondylolisthesis, spondylitis, and advanced spinal stenosis. The presence and level of HNP were recorded. Two readers independently measured multifidus sectional area from T2 Dixon of axial L3 level and coronal L-spine. Volumetric multifidus measurement was performed using Syngo.via. Fat fraction (Ff) of multifidus was calculated from signal intensity (SI) of in-phase (IP) and out-of-phase (OP) images by using the formula: '(SIIP-SIOP)/2SIIP x 100(%)'.

RESULTS

Inter-reader agreement of Ff for each method and inter-method agreement of Ff were excellent (ICCs: 0.81 to 0.98). 20 patients had no HNP (age, 39.3±15.7y; 9 females; BMI, 22.4±2.4) and 94 patients had HNP (age, 43.7±14.6y; 49 females; BMI, 25.3±3.4). Among positive HNP, 76 patients had HNP less than 3 levels (age, 40.8±13.9y; 38 females; BMI, 25.3±3.4) and 18 patients had multi-level (>=3 levels) HNP (age, 56.0±10.3y; 11 females; BMI, 25.4±3.7). In positive HNP, coronal Ff (20.1±2.8%) and volumetric Ff (19.8±2.6%) were significantly higher than those of negative HNP (18.0±3.8%, 17.6±3.2%; P=.005, .002, respectively). In multi-level HNP, axial-L3 Ff (22.1±2.9%) and coronal Ff (22.2±2.0%) were significantly higher than those of HNP less than 3 levels (19.0±3.3%, 19.6±2.7%; P<.001 for each). Multivariate logistic regression analysis adjusted for age, sex, and BMI showed that BMI is significantly associated with HNP (odds ratio [OR]: 1.376, P=.004), while age and coronal Ff are significantly associated with multi-level HNP (OR: 1.075, 1.524, P=.021, .015, respectively).

CONCLUSION

Coronal Ff from T2 Dixon of L-spine has the best discriminating power to quantify the fatty infiltration of lumbar multifidus in patients of HNP. Increased coronal Ff was significantly associated with multilevel HNP.

CLINICAL RELEVANCE/APPLICATION

The fat fraction of lumbar multifidus using coronal T2 Dixon is recommended method for patient of LBP to discriminate multi-level HNP from one or two level HNP.

SST05-08 Epidural Fibrosis and Nerve Root Changes on Magnetic Resonance Imaging (MRI) After Lumbar Disc Surgery: Correlation with Clinical Symptoms

Friday, Nov. 30 11:40AM - 11:50AM Room: E351

Participants

shangkmii@hanmail.net

PURPOSE

To investigate correlation between epidural fibrosis and nerve root changes on Magnetic resonance image (MRI) and clinical symptoms after lumbar disc surgery

METHOD AND MATERIALS

Between January 2010 and May 2017, 75 patients (32 women, 43 men, age range 30-87 years, mean age 60 years) who performed lumbar disc surgery at unilateral side of only one level examined follow-up lumbar spine MRI due to back pain or variable neurologic symptoms. We investigated size change, abnormally increased signal intensity, distinction in the epidural space, displacement and compression of nerve root and epidural fibrosis at operative site on mainly axial sequences. Also, the presence or absence of arachnoiditis was evaluated. The clinical symptoms were compared with MR imaging findings using statistical analysis.

RESULTS

Symptoms related with lumbar disc surgery were found in 31 patients (41.3%). The size change of nerve root was seen in 43 patients and high SI of nerve root in 44. The displacement of nerve root was presented in 11 patients and there were no patients showing definite nerve root compression. 51 patients showed epidural fibrosis and definite distinction of nerve root in the epidural space was seen in 45 patients. Arachnoiditis was seen in only 22 patients. The size change of nerve root at surgery site was the only significant MR finding correlating with symptom ($p < 0.05$).

CONCLUSION

The size change of nerve root at surgery site was significantly correlated with new or persistent symptoms after lumbar disc surgery.

CLINICAL RELEVANCE/APPLICATION

MR imaging findings of size change and abnormally high SI of nerve root, indistinction of nerve root in the epidural space and epidural fibrosis are common after lumbar disc surgery. However, these findings except size change of nerve root were post-operative changes unrelated to new or persistent symptoms.

SST05-09 Assessment of Osseous Cervical Foraminal Stenosis in Spinal Radiculopathy Using Susceptibility-Weighted MRI

guenther.engel@charite.de

PURPOSE

The aim of this study was to evaluate the diagnostic performance of susceptibility-weighted MRI for the evaluation of osseous foraminal stenosis of the cervical spine compared to conventional MR sequences, using CT as a reference standard.

METHOD AND MATERIALS

Twenty-one patients with suspected radiculopathy of the cervical spine were prospectively included. As standard of reference, 280 neuroforamen of the cervical spine, including 58 foraminal stenosis, were identified on sagittal CT images. T1, T2 and SW-MRI of the cervical spine were performed. For this study, the presence of foraminal stenosis was assessed on sagittal views on T1, T2 and SW-MR images. Sensitivity / specificity were calculated and differences in detection rate, severity scoring and sagittal diameter of spinal foraminal stenosis between the different sequences were tested. CT was used as reference standard for all analysis.

RESULTS

56 of 58 osseous foraminal stenosis could be correctly identified on SW-MR magnitude images. SW-MR imaging achieved a sensitivity of 96.6% and specificity of 99.5% for the identification of foraminal stenosis of the cervical spine. In comparison, conventional T1 spine MR sequences achieved a sensitivity and specificity of 43.1% and 100% respectively. Conventional T2 spine MR sequences achieved a sensitivity and specificity of 65.5% and 99.1%, respectively. The overall detection rate was significantly (p0.05) higher on SW-MR imaging and there was no significant difference (p>0.05) in severity scoring compared to CT imaging. T1/T2-weighted MR underestimated the degree of foraminal stenosis. Intermodality and interobserver agreement were highest for SW-MR sequences.

CONCLUSION

Susceptibility-weighted MRI enables the reliable detection of osseous foraminal stenosis of the cervical spine in patients with spinal radiculopathy with a higher sensitivity and specificity compared to conventional T1/T2 MR sequences, with CT as a reference standard.

CLINICAL RELEVANCE/APPLICATION

The main limitation of MRI, compared to CT, is limited value for the detection of osteophytic changes as a cause of foraminal stenosis. Standard MR T1 and T2-weighted sequences often do not allow a differentiation these changes. Therefore, CT or conventional radiographs are often required to detect and quantify these changes. SW-MRI may therefore replace additional tests and prevent radiation exposure for patients as well as speed up diagnostic work up.

PURPOSE

Cross sectional imaging of the abdomen on occasion can demonstrate incidental pancreatic/peri-pancreatic lesions of unknown etiology. Although these lesions sometimes have the appearance of splenic tissue, situation arise were metastasis and/or primary pancreatic etiology are also on the differential. Scintigraphy with Tc99m Sulfur colloid or heat damaged RBC can be a useful diagnostic tool in identifying the presence of splenic tissue, suggesting a benign etiology for these lesions although the accuracy is uncertain.

METHOD AND MATERIALS

Retrospective review of all non-PET nuclear medicine studies in which a lesion in the upper abdomen were the cause of imaging from 1/2000 to 7/2017. Studies performed for hepatic artery perfusion or liver parenchyma lesion were excluded. Patients charts were reviewed, the date/results of the index study, subsequent imaging, clinical management, along with the last recorded encounter in our electronic medical record to establish benignity in the absence of pathology.

RESULTS

Initial review obtained 623 studies performed, a majority (74%) for hepatic artery perfusion. Liver lesion evaluation was performed in 7% of the cases (hemangioma or FNH). The remainder of the cases were done for evaluating splenic tissue in ITP (~5% of cases), ectopic splenic tissue (~9% after trauma or splenectomy) or to evaluate incidental pancreatic/peri-pancreatic lesions with potential neoplastic etiology (~5% cases, 34 cases total). Of these 34 cases, pathology was obtained in 12/34 patients. Imaging was correct in identifying nonsplenic tissue in 11/12 cases (92%). One case was splenic tissue on path, but was not identified on imaging. For the patients that had imaging indicating splenic tissue without subsequent pathology (12/22), follow up of the patient occurred > 3-years.

CONCLUSION

Pancreatic/peri-pancreatic lesions of unknown etiology can present a diagnostic challenge with causes ranging from benign splenic tissue to a neoplastic process. Scintigraphy offers a unique ability to identify ectopic splenic tissue with a high degree of diagnostic accuracy, >90%, yielding a benign diagnosis and limiting the need of further workup.

CLINICAL RELEVANCE/APPLICATION

Liver/Spleen imaging with Tc99m Sulfur colloid or damaged RBC can accurately identify incidental pancreatic/peri-pancreatic lesions as ectopic splenic tissue not requiring further workup.

SST06-02 The Diagnostic Accuracy of Brain-Lung Uptake and Whole-Body Uptake Derived from Technetium-99m-Labeled Macroaggregated Albumin (MAA) Lung Perfusion Scan for the Diagnosis of Hepatopulmonary Syndrome

Friday, Nov. 30 10:40AM - 10:50AM Room: E261

hezhaoo@gmail.com

PURPOSE

Technetium-99m-labeled macroaggregated albumin (MAA) lung perfusion scan is considered as a complementary tool for detecting intrapulmonary vascular dilations (IPVD), which is an essential criterion for diagnosing hepatopulmonary syndrome (HPS). The purpose of this study was to compare the diagnostic accuracy of brain-lung uptake and whole-body uptake for detecting IPVD.

METHOD AND MATERIALS

From December 2014 to October 2015, all patients with chronic liver disease and/or portal hypertension, undergoing interventional radiological procedures at our institution were eligible for inclusion in this prospective study. The brain-lung uptake was calculated using the geometric mean (GMT) of technetium counts around the brain and lung in the following formula: (GMTbrain / 0.13) / (GMTbrain / 0.13 + GMTlung). The brain-lung uptake was regarded as positive when the MAA shunt fraction was > 6%. The whole-body uptake was calculated using the GMT of technetium counts around the lung and whole body in the following formula: (1 - GMTlung / GMTwhole-body)

RESULTS

A total of 69 patients were included, IPVD was detected in 32 (46%) patients by contrast-enhanced echocardiography. Of these patients, 26 (38%) patients with elevated AaO2 were diagnosed as HPS. The brain-lung uptake was similar between those with or without IPVD [median, 3.5 (interquartile range (IQR), 2.6-5.8) % vs. 3.1 (IQR, 2.5-4.9) %; P = 0.245]. However, the whole-body uptake was significantly higher in the patients with IPVD than those without IPVD (48.0 ± 6.1 % vs. 40.1 ± 8.1 %; P = 0.001). Multivariable logistic regression showed that whole-body uptake was the only independent predictor that associated with the presence of IPVD [odds ratio (OR), 1.29; 95% CI, 1.07-1.55; P = 0.008]. The AUC values of the whole-body uptake for detecting IPVD were 0.75 (95% CI, 0.60-0.86). The optimal cut-off values of whole-body uptake for detecting IPVD was 42.5%. The sensitivity, specificity, and accuracy for detecting IPVD were 100%, 52%, and 74%, respectively.

CONCLUSION

Whole-body uptake could be a useful alternative to CEE and brain-lung uptake for detecting IPVD, especially in patients with mild or moderate HPS.

CLINICAL RELEVANCE/APPLICATION

Whole-body uptake derived from MAA lung perfusion scan could be a useful alternative to contrast-enhanced echocardiography and brain-lung uptake for detecting intrapulmonary vascular dilations.

SST06-03 Diagnosing Hepatobiliary Disease during Myocardial Perfusion Imaging Using Tc99m Methoxy Isobutyl Isonitrile

Friday, Nov. 30 10:50AM - 11:00AM Room: E261

Participants
Haitham M. Elsamaloty, MD, Holland, OH (*Abstract Co-Author*) Nothing to Disclose
Mohamad F. Bazerbashi, MD, Ann Arbor, MI (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

haitham.elsamaloty@utoledo.edu

PURPOSE

Tc99m Methoxy Isobutyl Isonitrile (MIBI) has been used for myocardial perfusion imaging (MPI) for the detection of ischemia. This study aimed to investigate the feasibility of effectively evaluating cystic duct patency, during routine visual analysis of the raw MPI and/or with the 3-D reconstructed data.

METHOD AND MATERIALS

A retrospective study of 91 patients undergoing cardiac Sestamibi scan for acute chest pain, and HIDA scan (within no more than 3 months) for suspected gallbladder obstructive disease (GBD). Gallbladder visualization during either the rest or stress portion of the MIBI study was indicative of cystic duct patency. These results were compared to those by the HIDA studies.

RESULTS

Ten patients had the MIBI and HIDA studies 4 days apart, both studies agreed 100% with the diagnosis of cystic duct patency. Sixteen patients had both studies between 4 days and 3 weeks and had an agreement of 87.5% with cystic duct patency. Sixty-one patients had both studies 3 weeks to 3 months apart and had an agreement of 80% with cystic duct patency.

CONCLUSION

The initial results of this study indicate that MPI with Tc99m MIBI is useful in detecting a patent cystic duct and should help in eliminating unnecessary additional Gallbladder testing.

CLINICAL RELEVANCE/APPLICATION

If the interpreting physician was made aware of the benefits of being able to diagnose cystic duct obstruction and gallbladder disease when using the Tc-99m cardiac sestamibi to evaluate myocardial perfusion, it would lead to earlier diagnosis and more efficient patient care; thus, decreasing the amount of imaging that patients need to go through to reach a diagnosis of gallbladder obstruction, which will lead to decreased cost.

SST06-04 Qualitative and Quantitative Analysis of 68ga-DOTA-Peptide Uptake for Identifying Neuroendocrine Tumor in Uncinated Process of Pancreas

Friday, Nov. 30 11:00AM - 11:10AM Room: E261

Participants
Amrita Kasat, MBBS,MD, Mumbai, India (*Presenter*) Nothing to Disclose
Sachin K. Gawde, MD, Mumbai, India (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

amrita.lahotinm@gmail.com

PURPOSE

68Ga-DOTA-peptide is a somatostatin analogue used for imaging neuroendocrine tumors (NET). Various organs demonstrate physiological distribution of which uncinate process of pancreas is a particular concern because uncinate is a common site for NET and great variability of tracer distribution at this location is making the interpretation difficult. Thus aim is to characterize 68Ga-DOTA-peptide distribution in uncinate process and useful hints for distinguishing pathology from physiological distribution.

METHOD AND MATERIALS

83 68Ga-DOTApeptide PET CT scans of 25 patients done between May 2009 and Oct 2014 were reviewed retrospectively. 66 scans from 20 subjects tumor involvement of uncinate process was excluded based on pathological,clinical,radiological evaluation and atleast 1 year follow-up. 17 scans from 5 subjects neuroendocrine tumor involvement of the uncinate process was confirmed by histology and/or multimodality imaging. Statistical analyses univariable Generalized Estimating Equations was carried out for normal uncinate uptake features. Comparison of normal vs tumor uptake was carried out using Mann Whitley test.

RESULTS

There are 3 types of normal distribution in uncinate process diffuse,focal and multifocal. Average SUVmax for normal uncinate process is 5.88 +/-3.34 with highest to be 21.07. The average SUVmax for uncinate neuroendocrine tumor is 76.28 +/- 44.72 with lowest to be 27. Tumor/spleen ratio is significantly higher than uncinate/spleen ratio (8.98 +/- 3.83 with lowest 3.67 vs 0.36 +/- 0.41 with highest 1.44). Strong positive correlation between uptake in normal uncinate process to that in pituitary and spleen (both $P<0.0001$) and the uptake is negatively affected by dose of peptide ($p=0.0002$).

CONCLUSION

Distribution pattern and uptake intensity in uncinate process vary greatly between patients and between scans. Pituitary and spleen uptake serve as references in judging the nature of uptake in uncinate. Low grade NET in uncinate process demonstrate significantly higher than normal uptake and greater than normal uncinate/spleen ratio.

CLINICAL RELEVANCE/APPLICATION

SUVmax and uncinate/spleen ratio is useful for differentiating normal versus tumor. SUVmax of 25 and uncinate/spleen ratio of 1.5 are recommended reasonable cutoff values for this purpose. But tumor involvement in uncinate process should be made by not only by presentation on PET scan but correlating with other imaging findings and/or biopsy result.

SST06-05 Hepatobiliary Scintigraphy versus Ultrasound in the Evaluation of Acute Cholecystitis: An Institutional Review

Friday, Nov. 30 11:10AM - 11:20AM Room: E261

Participants
Timur Kotlyar, MD, New Hyde Park, NY (*Presenter*) Nothing to Disclose
Christopher Kyriakakos, MD, New Hyde Park, NY (*Abstract Co-Author*) Nothing to Disclose
Vincent Lau, MD, New Hyde Park, NY (*Abstract Co-Author*) Nothing to Disclose

Christopher J. Palestro, MD, New Hyde Park, NY (*Abstract Co-Author*) Nothing to Disclose
Meera Raghavan, MD, Tampa, FL (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Acute cholecystitis is a common entity. Hepatobiliary radionuclide scintigraphy (HIDA) is considered the gold standard for diagnosing cholecystitis, with sensitivity up to 97%. Ultrasound (US) is the preferred modality in the initial evaluation of acute cholecystitis, due to its availability, low cost, and short examination time, despite being less sensitive than HIDA. At our institution, US is the initial imaging study of choice, and a HIDA is subsequently obtained for equivocal studies. We aim to evaluate the concordance of US and HIDA, and to identify clinical and/or laboratory parameters which may correlate with equivocal US in order to better guide patient management.

METHOD AND MATERIALS

Following institutional IRB approval, MONTAGE was used to search our reporting database between October 2016 and October 2017. HIDA results were categorized as "positive" or "negative". US results were categorized as "negative", "positive", or "equivocal" for the assessment of acute cholecystitis. Clinical and laboratory data were also collected.

RESULTS

A total of 307 patients underwent both US and HIDA (n=307) with 43% (n=132) with an equivocal US. 35% (n=107) of these patients had discordant US and HIDA. Of the cases with an equivocal US, 43% (n=57) underwent cholecystectomy. At pathology,

51% (n=29) had acute cholecystitis with a positive HIDA and 4% (n=2) had acute cholecystitis with a negative HIDA. 14% (n=8) had chronic cholecystitis with a positive HIDA, and 32% (n=18) had chronic cholecystitis with a HIDA negative for acute cholecystitis. In patients with equivocal US, HIDA had a sensitivity of 93.6% and specificity of 69.2%.

CONCLUSION

Over one-third discordance between US and HIDA can have significant clinical implications. Given the high sensitivity of HIDA in patients with equivocal US, initial evaluation with HIDA may be more appropriate in patients in whom US is likely to be equivocal, possibly leading to decreased time to surgery and length of stay.

CLINICAL RELEVANCE/APPLICATION

Our results may elucidate factors influencing HIDA/US concordance, and whether US or HIDA is a more appropriate initial test. Imaging utilization may influence length of stay and time to surgery.

SST06-06 Identification and Characterization of Myocardial Metastases in Neuroendocrine Tumor Patients Using 68Ga-DOTATATE PET-CT

PURPOSE

Focal 68Ga-DOTATATE PET lesions within the myocardium of neuroendocrine tumor (NET) patients are observed in clinical practice. We determined the frequency and characteristics of lesions that are consistent with cardiac metastasis and assessed the lesion detection rate of conventional imaging.

METHOD AND MATERIALS

629 patients who underwent 68Ga-DOTATATE PET-CT at a supraregional comprehensive cancer center on NET were included from a consecutive registry. Inclusion criteria were: (1) focal 68Ga-DOTATATE tracer uptake within the myocardium in more than two sequential PET exams, and (2) contrast-enhanced CT. To determine the diagnostic accuracy of conventional CT imaging, a case-control cohort with a ratio of 1:3 was used. PET and CT were independently analyzed by two blinded readers. Cohen's k was assessed for interreader agreement. Descriptive statistics were applied for frequencies and characteristics and group comparisons were analyzed using the Fisher's exact test.

RESULTS

The prevalence of myocardial metastases related to the registry was 2.4% with 15/629 NET patients fulfilling the inclusion criteria and a total of 21 focal myocardial 68Ga-DOTATATE tracer uptakes detected. Myocardial lesions were most frequently located in the left ventricle (43%) and the septum (43%). No patient demonstrated a pericardial effusion. Patients with myocardial metastases did not differ in demographics, tumor grading, disease stage or circulating tumor markers compared to the overall registry (all $p>0.05$). The patient characteristics are shown in Table 1. Higher Ki67-Indices were observed ($p=0.049$) for patients with myocardial metastases. Interreader agreement for PET assessment was excellent (Cohen's =1.0). CT reading showed a sensitivity of 19% (95% confidence interval: 6%-43%) at a specificity of 100% (95% confidence interval: 90%-100%). A patient example with a CT-detected cardiac metastasis is provided in Figure 1.

CONCLUSION

68Ga-DOTATATE PET enables detection of myocardial metastatic lesions in NET patients. In contrast, standard morphologic CT imaging provides very limited sensitivity.

CLINICAL RELEVANCE/APPLICATION

68Ga-DOTATATE PET imaging provides added diagnostic value in the initial staging of NET patients with cardiac metastasis and may provide further guidance during patient follow-up.

SST06-07 Evaluation of [18F]-FDG PET/MR Enterography in the Assessment of Ileocolonic Inflammation in Crohn's Disease - Which Surrogate Marker is Better? MaRIA, Clermont, PET, or PET-MR index?

Friday, Nov. 30 11:30AM - 11:40AM Room: E261

Lale.Umutlu@uk-essen.de

PURPOSE

To define a PET-MR index as hybrid surrogate marker and evaluate the diagnostic performance of validated MR indices, PET and PET-MR index in detecting ileocolonic inflammation in Crohn's disease (CD) with an integrated whole-body PET/MR .

METHOD AND MATERIALS

53 CD patients with recurrent symptoms underwent ileocolonoscopy with biopsy (reference standard) and PET/MR enterography. 7 ileocolonic segments were divided. The endoscopic activity of inflammation was determined by Simplified Endoscopic Activity Score for CD (SES-CD) and categorized in absent, mild to moderate and severe. Receiver Operating Characteristic (ROC) curves were performed and tested against each other with DeLong' test. Correlations between surrogate markers and SES-CD were tested with Spearmann's rank correlation test.

RESULTS

303 ileocolonic segments were analyzed. A simplified PET-MR index was defined as 0.87*wall thickness + 1.97*edema + 0.83*ulceration + 0.55*SUVmax ratio + 1.14. In detecting active disease (defined as SES-CD >= 2), MaRIA, Clermont score and PET-MR Index as multiparametric indicies performed significantly better than monoparametric SUVmax ratio (areas under ROC: 0.916, 0.914, 0.924 and 0.857, $p < 0.05$). In predicting severe inflammation with ulcerations, among all the surrogate makers (areas under ROC fo MaRIA, Clermont, PET-MR index and PET: 0.962, 0.970, 0.971 and 0.935) only a slightly significant difference could be observed between MaRIA and Clermont score ($p = 0.02$) in their operating characteristics. All surrogate markers correlated moderately with SES-CD both on segmental basis and gobal level ($0.4 < \rho < 0.7$, all $p < 0.001$).

CONCLUSION

As hybrid surrogate marker comprised of MR parameters and PET component, PET-MR index yielded a significantly increased diagnostic performance compared to PET alone. However, neither in predicting active disease nor in detecting severe ulcerative inflammation, PET-MR index could outperform MaRIA or Clermont significantly. Nevertheless, PET-MR index showed the best operating characteristics among all the surrogate markers.

CLINICAL RELEVANCE/APPLICATION

PET/MR enterography provides valuable surrogate markers for assessment of active disease in Crohn´s disease.

SST06-08 Dynamic Study by PET/CT: Phantom Study and Clinical Trial on Sequential 26 Cases of Malignant Lesions of Uterus

Friday, Nov. 30 11:40AM - 11:50AM Room: E261

Participants
Eri O'Uchi, MD, Kamogawa City, Japan (*Presenter*) Nothing to Disclose
Toshihiro O'uchi, MD,PhD, Kamogawa, Japan (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

Dynamic study of PET/CT with 18F-FDG has not been reported up to now. The purpose of this study was to check the reliability of SUVmax on GE IQ PET/CT by phantom study, and to compare tumor 18F-FDG uptake between two phases of 30-second acquisition of dynamic deep-inspiration breath-hold PET/CT (BHPC) before and after 5 to 7 steps of 150-sec free-breathing PET/CT(FBPC).These sequence was named 'Dynamic study by PET/CT'.

METHOD AND MATERIALS

The PET/CT scanner was GE IQ with 26cm BGO crystal and PET images were reconstructed by patented new method of successive approximation (25-times). Before the clinical study, a phantom study was performed using an International Electrotechnical Commission body phantom set corresponding to the NU 2-2001 standard. The phantom set was consisted of a torso cavity and two spheres (inner diameters: 10, 13, 17, 22, 28, and 37 mm). The torso cavity was filled with water, and the 6 spheres were filled with 18F-FDG solutions of the same radioactivity concentration (25 kBq/mL). We studied sequential 26 patients, from 40 to 84 years old, with uterine malignant tumor including 11 cases of corpus carcinomas, 13 cases of cervical carcinomas, and 2 cases of uterus origin malignant lymphomas. On the basis of the phantom study, patients with uterine malignant tumors smaller than 13mm were excluded. Maximum tumor 18F-FDG SUV (SUVmax) was measured in FBPC and the two phases of BHPC.

RESULTS

Our phantom study revealed that BHPC was also reliable when the size of lesion was bigger than 13mm with the accuracy of one SD which was smaller than 2% of SUVmax. This reliability was markedly improved by one tenth in comparison with that of 10 years ago. On clinical study, the mean SUVmax was 18.56 with FBPC, 15.51 with the early phase of BHPC, whereas 18.15 with the delayed phase of BHPC. In dynamic study, 19.2% increase in SUVmax in delayed scan.

CONCLUSION

SUVmax obtained in the early and delayed phase of BHPC which had 15 minutes discrepancy showed a significant difference. BHPC before and after FBPC may contribute to distinguish benign lesions from malignant tumors, and this technique is feasible in the clinical setting with minimum increase in examination time.

CLINICAL RELEVANCE/APPLICATION

The new technique 'Dynamic study of PET/CT' may contribute to distinguish benign lesions from malignant tumors, and this technique is feasible in the clinical setting with minimum increase in examination time.

SST06-09 Multiparametric Evaluation by 18F-Fluorocholine PET-CT and MRI Examinations in Patients with Prostate Cancer

PURPOSE

To evaluate the relationship between metabolic 18F-fluorocholine (FCH) PET-CT and functional parameters derived by Magnetic Resonance Imaging (MRI) in patients with prostate cancer (PC).

METHOD AND MATERIALS

Patients with proven PC who underwent FCH PET/CT and 1.5 T multiparametric MRI were included. FCH PET/CT consisted in a dual phase: early and late whole-body acquisition. A 12x5' - 3x30' time sampling was reconstructed from the first 150 seconds of the early acquisition. A freehand FCH PET/CT volume-of-interest (VOI) with a threshold of 40% of the maximum signal intensity was drawn on the late acquisition and projected onto the early static frame of 10 min and each frame of the dynamic reconstruction. For the kinetic analysis, an imaging-derived plasma input function was estimated from VOI placed within the largest arterial blood-pool structures available on the early PET image. The pharmacokinetic modeling was the reversible one-tissue compartment model. Kinetic parameter (K1 as influx) and static parameters (early SUVmean, late SUVmean and SUVmean retention index) were extracted. Concerning multiparametric MRI, axial diffusion-weighted imaging was obtained using three b values: 0, 50 and 1300 s/mm2. Dynamic contrast-enhanced studies were obtained with intravenous administration of gadolinium-based contrast agent with a 11x13' dynamic time sampling. Using co-registration of diffusion-weighting MRI with late whole-body FCH PET/CT, a freehand VOI was drawn to obtain the mean Apparent Diffusion Coefficient (ADC). VOI was projected onto the perfusion parametric maps to extract the mean transfer constant (ktrans) and the mean volume of the extracellular space (Ve) using the Tofts pharmakinetic model. Spearman's correlation coefficients were calculated to compare imaging findings.

RESULTS

Thirteen patients were analysed. The median time interval between PET and MRI was 39 days. Concerning correlation analysis between PET and MRI parameters, K1 was significantly correlated with ktrans ($r=0.59$, $p=0.035$) and early SUVmean was significantly correlated with ADC ($r=-0.58$, $p=0.04$).

CONCLUSION

FCH influx using the reversible one-tissue compartment model is significantly correlated with the transfer constant of gadolinium-based contrast agent in prostate cancer.

CLINICAL RELEVANCE/APPLICATION

These results might be useful in the design of future clinical trials involving FCHOLINE-PET/DCE-MR for the assessment of prostate cancer.

huangchao09@zju.edu.cn

PURPOSE

To investigate whether radiogenomics can identify therapeutically relevant molecular phenotypes defined by genomics, epigenomics, and/or transcriptomics for head and neck squamous cell carcinoma (HNSCC).

METHOD AND MATERIALS

We included 113 HNSCC patients from The Cancer Genome Atlas Head-Neck Squamous Cell Carcinoma (TCGA-HNSC) project. Molecular phenotypes investigated were RNA-defined HPV infection, 5 epigenomic subtypes discovered by MethylMix, 4 mRNA subtypes by TCGA group, and 5 common somatic gene mutations. In total, 2,131 quantitative image features were extracted from pre-treatment CT scans. Discriminative features were selected using the Minimum Redundancy Maximum Relevance (mRMR) algorithm. Afterwards, we applied logistic regression model with the least absolute shrinkage and selection operator (LASSO) to build binary classifiers for predicting each molecular subtype. All classifiers were trained using nested stratified 10-fold cross-validation repeated 10 times and the performance metric was the average area under the Receiver Operator Characteristic (ROC) curve (AUC) of the outer loop of the nested cross-validation. Additionally, an HPV prediction model was developed using the entire TCGA-HNSC cohort, and was validated by an independent validation cohort (N = 53).

RESULTS

Our results showed that CT-based features were capable of distinguishing multiple molecular phenotypes in HNSCC. We obtained significant predictive performance for RNA-defined HPV+ vs. HPV- (AUC = 0.82), MethylMix HPV+ vs. other MethylMix subtypes (AUC = 0.85), CIMP-Atypical vs. other MethylMix subtypes (AUC = 0.73), atypical vs. other mRNA subtypes (AUC = 0.83), basal vs. other mRNA subtypes (AUC = 0.75). Furthermore, the HPV prediction model was successfully validated in the validation cohort (AUC = 0.84).

CONCLUSION

Our study demonstrates that CT-based radiogenomic analysis has the potential to predict multiple HNSCC subtypes defined by molecular biological characteristics.

CLINICAL RELEVANCE/APPLICATION

Radiogenomic analysis of CT images can enable automated non-invasive assessment of therapeutically relevant HNSCC molecular subtypes across diverse clinical settings.

SST07-02 Performance Analysis and Optimization of ACR-TIRADS Using a Genetic Algorithm: An Opportunity for Improvement?

Friday, Nov. 30 10:40AM - 10:50AM Room: E353A

PURPOSE

To use the computer science technique of genetic algorithm to create an optimized version of the American College of Radiology Thyroid Imaging and Reporting Data System (ACR TI-RADS), and to compare the performance of the optimized system to the current version.

METHOD AND MATERIALS

1425 thyroid nodules from 1264 consecutive patients were retrospectively reviewed in this IRB-approved, HIPAA compliant study. Each nodule had either fine needle aspiration (FNA) or surgical histologic correlation. An expert reader assigned ACR TI-RADS features to each nodule. A genetic algorithm then used the TI-RADS assignments and the histologic 'ground truth' as input for a training set of 1325 nodules to create new TI-RADS feature points, numbers optimized using area under the receiver operating characteristic (ROC) curves. The algorithm-derived, optimized TI-RADS risk categories were then calculated and compared to ACR TI-RADS using a test set of 100 nodules not yet used in the algorithm.

RESULTS

The genetic algorithm created a new set of point assignments for 21 different TI-RADS features. The algorithm assigned the same number of points (as ACR TI-RADS) for 13 of the features and ascribed a new point value for 8 features (Figure). Some of the features that had point values that differed from the ACR version included mixed solid and cystic nodules, solid nodules, macrocalcifications, and taller-than-wide shape. Using the test set, sensitivity and specificity for biopsy of malignant nodules were 93% and 47%, respectively, for ACR TI-RADS and 93% and 65%, respectively, for the genetic algorithm optimized TI-RADS.

CONCLUSION

An optimized version of ACR TI-RADS derived from a genetic algorithm has similar point allocation to ACR TI-RADS, which validates many of the ACR's designated point values. The genetic algorithm version has improved specificity while maintaining sensitivity. In addition, newly proposed point values of 0 for some features may simplify the model and eliminate the need to scrutinize potentially confusing features.

CLINICAL RELEVANCE/APPLICATION

Further refinement of ACR TI-RADS points allocation by a genetic algorithm can both improve performance and simplify its clinical application.

SST07-03 MRI Texture Analysis (MTA) in the Optic Nerve During Acute Optic Neuritis (ON): Can Be Considered an Indicator of Optic Nerve Pathology or a Predictor of Visual Recovery?

Friday, Nov. 30 10:50AM - 11:00AM Room: E353A

PURPOSE

Retinal nerve fiber layer (RNFL) thickness at Optical Coherence Tomography (OCT) is a biomarker of neuroaxonal loss and a reliable index of visual function in multiple sclerosis (MS). Our aim was to assess the correlation between MTA and RNFL thickness and between MTA and visual outcome (VO).

METHOD AND MATERIALS

We enrolled clinical 27 consecutive patients, who presented to our Emergency Department with a first episode of acute ON (15 female, 12 male; age range: 21-50 years; mean age: 34; 32 eyes: 5 bilateral ON; 10 left ON; 12 right ON) from January 2015 to January 2017. At their arrival all patients underwent a complete ophthalmological evaluation, including assessment of visual acuity and of RNFL thickness at OCT, blood tests to exclude infective or autoimmune ON, and neurological evaluation. Orbit MRI was executed within 7 days from ON onset (mean time: 3.5±3 days) including the following sequence: an axial T1 TSE performed 1 minute after contrast medium injection (gadobutrol, 1ml/10kg), slice thickness:3 mm, gap: 0.5 mm; SPIR fat saturation, FOV 18 cm, from occlusal plane to above orbits. Segmentation of the whole affected optic nerves was executed by the same experienced neuroradiologist through 3D slicer open software version 4.9.0-2017 to get texture analysis. All patients underwent a complete neuro-ophthalmological follow-up at 6 months to assess the VO, classified as: complete recovery, partial recovery, or deficit persistence/relapse.

RESULTS

At Kruskal-Wallis test, we observed a statistically significant correlation between RNFL and the following radiomics features: uniformity (p=.02), energy (p=.01), median (p=.002), 90°percentile (p=.003), 10°percentile (p=.003), gray level variance (p=.005). Analyzing the correlation between radiomics features and VO, we observed a statistically significant correlation only with kurtosis (p=.002).

CONCLUSION

Analysis of the texture in orbit MRI during the acute phase of a first episode of ON may be a potential measure of visual function in ON patients. Kurtosis proved to be correlated with VO.

CLINICAL RELEVANCE/APPLICATION

In patients affected by acute ON, radiomics features can be considered indicators of visual function and kurtosis can be used to predict VO.

SST07-04 3D-FLAIR Sequence with Delayed Acquisition After Intravenous Administration of Gadolinium Can Detect Intralabyrinthine Abnormalities in Patients Referred with Typical Vestibular Neuritis

Friday, Nov. 30 11:00AM - 11:10AM Room: E353A

Participants
Michael Eliezer, Paris, France (*Presenter*) Nothing to Disclose
Julien Horion, 76000, France (*Abstract Co-Author*) Nothing to Disclose
Guillaume Poillon, Rouen, France (*Abstract Co-Author*) Nothing to Disclose
Arnaud Attye, MEd, Grenoble, France (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

The origin of vestibular neuritis (also known as acute vestibular syndrome) remains unkown. The blood labyrinth barrier is similar to the blood-brain barrier yet requiring at least 4 hours after an intravenous administration of contrast media to be evaulated on 3D-FLAIR sequences. We assessed the enhancement of the vestibular nerve and of the semi circular canals on 3D FLAIR sequences in patients with typical acute vestibular syndrome.

METHOD AND MATERIALS

In this multicentric study, 28 patients with an acute vestibular syndrome diagnosed on the basis of typical clinical findings were included. We performed 3D T2 free-precession and 3D-FLAIR sequences 4 hours after contrast media administration. Two radiologists, blinded to the clinical data, independently performed a visual assessment in order to evaluate the perilymph enhancement.

RESULTS

We found a delayed enhancement of the semi circular canals in 24 out of 28 patients (84%). The superior and lateral semi circular canals were involved in 14/24 patients (58%) while the posterior semi circular canal was involved in 4/24 patients (16%). By contrast, an enhancement of the vestibular nerve was never displayed. We found a signal loss on T2 sequences in 11/24 patients (39%). The utricle was involved in 7 patients and the posterior semi circular canal in 4 patients.

CONCLUSION

We demonstrated a significant enhancement of the semi-circular canals on 3D FLAIR sequences performed 4 hours after administration of gadolinium.

CLINICAL RELEVANCE/APPLICATION

Intratympanic therapies such as corticosteroids could be performed depending on the results of imaging in order to reduce chronic dizziness.

SST07-05 Hyperintensity of the Optic Nerve on 3D-FLAIR Imaging is Effective for Identifying Clinically Significant Papilledema in Patients with Idiopathic Intracranial Hypertension

Friday, Nov. 30 11:10AM - 11:20AM Room: E353A

Participants

PURPOSE

Our group previously demonstrated the role of contrast-enhanced (CE) 3D-Fluid Attenuated Inversion Recovery (FLAIR) imaging in detecting papilledema in idiopathic intracranial hypertension (IIH). The purpose of this study is to determine if a correlation exists between the degree of hyperintensity of the optic nerve (ON) and optic nerve head (ONH) on CE 3D FLAIR imaging and the severity of papilledema on the ophthalmologic Frisén scale.

METHOD AND MATERIALS

In this IRB-approved study, a retrospective chart review was performed of consecutive patients with diagnosed IIH and concurrent magnetic resonance imaging (MRI) with CE 3D FLAIR sequences between 2012 and 2015; MRIs with CE 3D FLAIR sequences from age- and sex-matched control patients were also identified. Two blinded CAQ-neuroradiologists independently reviewed each MRI and graded each ON independently on a scale of 0-3: 0=normal;1=hyperintensity within the nerve without ONH involvement; 2=hyperintensity within the ON and mild inversion of the ONH; and 3=hyperintensity within the ON and significant inversion of the

ONH. To estimate the correlation between MR and Frisén scores, a non-parametric correlation coefficient (Kendall's τ) with the associated 95% BCa-bootstrapped confidence intervals (4,000 iterations) were calculated for both eyes (OS and OD) using R (3.4.3).

RESULTS

49 patients (3 males, 45 females, mean age 29.2 ±10.99) with IIH and 62 controls (5 males, 57 females, mean age 30.89 ±11.74) with normal MRIs were included in this study. For both eyes, there was moderate correlation between the two scales (OD: τ=0.48, 95%CI=(0.32,0.48),OS: τ=0.38, 95%CI= (0.24,0.50)). Inter-reader reliability for MR scores was assessed using weighted Cohen's kappa (OD: κ=0.76 95%CI= (0.55,0.88), OS: κ=0.87 95%CI= (0.78,0.94)).

CONCLUSION

CE 3D FLAIR imaging correlates with the Frisén scale for moderate to severe papilledema and less so for mild papilledema. CE 3D FLAIR sequences also allow for consistent image interpretation with excellent inter-reader reliability. These findings suggest that MRI is effective for identifying clinically significant papilledema, in a setting where prompt diagnosis is crucial and where an ophthalmology evaluation may not be readily available.

CLINICAL RELEVANCE/APPLICATION

CE 3D FLAIR is a feasible imaging technique for the detection of papilledema. Herein, we demonstrate its utility for identifying clinically significant papilledema.

SST07-06 Lacrimal Passage Diseases: Clinical Application of 3.0T MR Dacryocystography of Whole Lacrimal Passages

Friday, Nov. 30 11:20AM - 11:30AM Room: E353A

Participants
Xuejun Guo, MD, Shenzhen, China (*Abstract Co-Author*) Nothing to Disclose
Mingmei Li, MMed, Shenzhen, China (*Presenter*) Nothing to Disclose

For information about this presentation, contact:

marabout@139.com

PURPOSE

To analyze the causes of obstruction or stenosis of lacrimal passages, and to investigate the value of 3.0T MR dacryocystography of whole lacrimal passages in clinical application.

METHOD AND MATERIALS

Thirty-eight cases with lacrimal passage diseases underwent MR dacryocystography of whole lacrimal passages. Before the examination, the conjunctival sac was instilled into Sodium Hyaluronate Eye Drops after Racanisodamine Eye Drops was administrated, and 3D-SPC sequence of 2D-TSE sequence were used,which section thickness of 0.2-2.0mm,and Special Purpose Coil was employed. Each part of whole lacrimal passages included lacrimal canaliculitis was demonstrated clearly. The location and cause of obstruction and the degree of stenosis were determined in patients with lacrimal passage diseases.

RESULTS

Of 38 cases of lacrimal passage diseases, chronic inflammation of lacrimal passages(n=28 cases, 35 eyes) were found, included dacryocystitis(n=21 eyes), inflammation of nasolacrimal duct and dacryocyst(n=11 eyes) and lacrimal canaliculitis (n=2 eyes). One cases with lacrimal canaliculus and inner canthus ligament abruption was diagnosed, and congenital variation of defective lacrimal duct(n=6 cases) and stenosing lacrimal sac(n=1 cases) was diaplayed. In addition, inflammation(n=5 cases, 5 eyes) and abscess(n=2 cases) around lacrimal passage were estimated, which closed to lacrimal passages. Paracrymal tumors or tumor- like lesions include steatocystoma (n=3 cases), epidermoid cyst with rupture infection (n=1 case), mucosa-associated lymphoid tissue lymphoma involving nasolacrimal duct(n=1 case) were found. MR dacryocystography of whole lacrimal passages can accurately identified the obstructive location of lacrimal passage, respectively in the lacrimal canaliculus(n=3 cases), in the dacryocyst (n=21 eyes), and in the distal nasolacrimal duct(in=11 eyes).

CONCLUSION

MR dacryocystography of whole lacrimal passages is a absolute noninvasive examination method with higher clinical value in diagnosis of lacrimal passage and its surrounding lesions. It must be recommended as a preferred examination method of lacrimal passage lesions.

CLINICAL RELEVANCE/APPLICATION

MR dacryocystography of whole lacrimal passages can completely replace the commonly used invasive methods such as lacrimal radiography, fluorescein imaging and radionuclide imaging.

SST07-07 MR-Based Quantitative Texture and Shape Analysis: Can It Differentiate Benign and Malignant Solid Epithelial Neoplasms of the Lacrimal Gland?

Friday, Nov. 30 11:30AM - 11:40AM Room: E353A

Participants
Jian Guo, PhD, Beijing, China (*Presenter*) Nothing to Disclose
Xiaoxia Qu, Beijing, China (*Abstract Co-Author*) Nothing to Disclose
Junfang Xian, MD, Beijing, China (*Abstract Co-Author*) Nothing to Disclose

For information about this presentation, contact:

jiangjoojle@163.com

PURPOSE

To assess the performance of MR-based texture and shape features in the differentiation of benign and malignant solid epithelial neoplasms of the lacrimal gland.

METHOD AND MATERIALS

This retrospective study of consecutive patient data was approved by the institutional review board and informed consent was waived. 76 consecutive patients with histopathology-proven epithelial neoplasms of lacrimal gland were enrolled in the study. A total of 924 first-order histogram, grey-level co-occurrence matrix (GLCM) and gray level run-length matrix (GLRLM) textural features, as well as shape features, were extracted from T2-weighted images (T2WI) and fat-suppression post-enhanced T1-weighted images (FS post-enhanced T1WI) of these cases. The least absolute shrinkage and selection operator (LASSO) method and linear discriminant analysis were used to select imaging features and reduce data dimension to discriminate malignant lesions from benign ones. Diagnostic performance was assessed by receiver operating characteristic area under the curve (ROC-AUC) analysis and cross-validated with leave-one-out analysis. Combinations of features were also entered as classification model in logistic regression models and optimal threshold criteria were used to assess its diagnostic sensitivity, specificity and accuracy.

RESULTS

Thirty-five cases of malignant and forty-one cases of benign epithelial neoplasms were enrolled in this study. Four quantitative image features (gray level co-occurrence matrix-inverse difference moment normalized, first-order high-high mean deviation, mean radius and gray level run-length matrix high-high long run emphasis) were selected according to the LASSO logistic regression. AUC-ROC of these four features were 0.880, 0860, 0.882 and 0.857 respectively, with AUC-ROC of 0.930 for combination of all four features. Using optimum-threshold criteria, the combined features identified malignant lacrimal gland epithelial neoplasms from benign group with 92.7% sensitivity, 82.9% specificity and 88.2% accuracy.

CONCLUSION

MRI-based quantitative texture and shape analysis provided improved predictive ability in discriminating malignant epithelial neoplasms from benign ones of lacrimal gland.

CLINICAL RELEVANCE/APPLICATION

The quantitative texture and shape analysis can help lesion characterization of benign and malignant lacrimal gland tumors and allows an appropriate diagnosis and treatment strategy.

SST07-08 Deep Learning Model for Biopsy Recommendations of Thyroid Nodules on Ultrasound: Comparison of a Machine and Radiologists

mateusz.buda@duke.edu

PURPOSE

To develop a deep learning algorithm that uses thyroid ultrasound images to decide whether a thyroid nodule should undergo a biopsy, and to compare the performance of such algorithm to expert and non-expert radiologists based on ACR TI-RADS.

RESULTS

The proposed deep learning algorithm achieved 87% sensitivity, outperforming expert consensus using ACR TI-RADS (81%) as well as five non-expert radiologists. The specificity of the deep learning algorithm was 52% which was higher than expert consensus (51%) and six non-expert radiologists. The mean sensitivity and specificity for non-expert radiologists was 80% and 48%, respectively, both lower than for our deep learning algorithm.

CLINICAL RELEVANCE/APPLICATION

Deep learning may play a significant role in assisting less experienced radiologists in FNA recommendation of thyroid nodules and may improve their sensitivity and specificity.

SST07-09 Reducing Beam Hardening Artifacts in Thyroid CT Images with Model-Based Iterative Reconstruction

Friday, Nov. 30 11:50AM - 12:00PM Room: E353A

Participants

Taiping He, Xianyang, China (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To investigate the ability of a new model-based iterative reconstruction algorithm with either spatial and density resolution balance (MBIRSTND) or low-density resolution preference (MBIRNR40) to reduce the beam hardening artifacts in thyroid images, in comparison with the adaptive statistical iterative reconstruction (ASIR) algorithm.

METHOD AND MATERIALS

Twenty patients with thoracic nodules and underwent chest CT scans were retrospectively reviewed. Images at the 0.625mm slice thickness were retrospectively reconstructed with 40%ASIR, MBIRSTND and MBIRNR40 algorithms. Coronal images with the most obvious beam hardening artifacts in the thyroid were selected for comparison. The CT value and standard deviation (SD) value of the left and right thyroid lobes affected by beam hardening artifacts and the surrounding normal tissue were measured and SD values were used to calculate the artifact index (AI) in the thyroid: AI=sqrt(SDthyroid2-SDnormal tissue2). Two radiologists used a 4-point scoring system (with 4 being the best) evaluate the subjective image quality in terms of artifacts in the image and the clarity of displaying thyroids on the coronal images. ANOVA and paired t-test were used to compare the CT value difference between the normal and affected thyroid tissues and AI values of different reconstructions. Subjective score differences were tested using the Wilcoxon symbol scale.

RESULTS

MBIRSTND and MBIRNR40 images significantly reduced the CT value difference between the normal and affected thyroid tissues and the beam hardening artifacts in the left and right thyroid lobes: AI values from 2.27±0.52 and 2.52±0.85 for the left and right lobe with 40%ASIR to 1.64±0.79 and 1.75±0.80 with MBIRNR40, respectively ($P < 0.05$). MBIRSTND and MBIRNR40 had significantly higher subjective scores for thyroid and nodules than 40%ASIR, with MBIRNR40 being the highest ($P < 0.05$).

CONCLUSION

MBIR, especially the one with low-density resolution preference, can significantly reduce the impact of the beam hardening artifacts caused by clavicle on the thyroid and its nodules during CT scans.

CLINICAL RELEVANCE/APPLICATION

Beam hardening artifacts caused by clavicle affect the image quality at the entrance of the thorax and are not conducive to the quality of CT images of the thyroid and other cervical structures. MBIR can reduce this effect.

PURPOSE

To find the MRI appearance of neonatal intracranial hypertension and study the relationship between intracranial volume (including cerebral white matter, grey matter and cerebrospinal fluid) of neonatal and intracranial hypertension, and consequently offer help for the diagnosis and treatment.

METHOD AND MATERIALS

A total of 51 suspicious intracranial hypertensive patients from the neonatology department in our hospital were included. All patients had undergone MRI examination and all of them had the result of cerebrospinal fluid pressure measured by lumbar puncture. All of the data were collected by Siemens 3.0T PRISMA. The scanning sequences included conventional T1WI, T2WI, T2FLAIR, T1MP2RAGE and T2MAP. The SMP12 software was used to do the volumetric segmentation . As for T2MAP, we counted the T2 value of bilateral frontal lobes, temporal lobes, occipital lobes and basal ganglia regions. Statistical analysis was performed using Pearson correlation analysis and independent sample T-test.

RESULTS

Our study found that there was no significant correlation between the volume of white matter or grey matter and intracranial pressure. The proportion of CSF to intracranial volume was significantly negatively correlated with intracranial pressure at 0.01 level (bilateral). The proportion of CSF to intracranial volume in the intracranial pressure normal group is significantly different from that in intracranial hypertension group. There was a significant difference in basal ganglia T2 value between the two groups. No significant difference in the T2 value of white matter of bilateral temporal lobe, frontal lobe and occipital lobe was found.

CONCLUSION

We found that CSF can provide a certain compensative capacity, while the compensative capacity of brain tissue is relatively weaker. We also found out that T2 value of basal ganglia region significantly increased in intracranial hypertensive patients, suggesting that basal ganglia region may be most common involved in encephaledemia caused by intracranial hypertension. Our study proves that MRI T1MP2RAGE and T2MAP are noninvasive and convenient and can offer a strong help for the diagnosis and treatment of neonatal intracranial hypertension.

CLINICAL RELEVANCE/APPLICATION

Our study proves that MRI T1MP2RAGE and T2MAP are noninvasive and convenient and can offer a strong help for the diagnosis and treatment of neonatal intracranial hypertension.

SST08-03 Clinical Implications of the Punctate White Matter Lesion on Brain MRI in Preterm Infants

Friday, Nov. 30 10:50AM - 11:00AM Room: E263

Participants
Young Jin Ryu, MD, Seongnam, Korea, Republic Of (*Presenter*) Nothing to Disclose
Ji Young Kim, MD, Seongnam-Si, Korea, Republic Of (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

To investigate the association between punctate white matter lesions (PWML) on term-equivalent age brain MRI and neurodevelopment outcome in preterm infants.

METHOD AND MATERIALS

From March 2013 to March 2017, brain MRI performed around term-equivalent age in preterm infants (gestational age < 32 weeks) were retrospectively reviewed with focused on the presence of isolated PWML without other brain pathology such as cavitary white matter lesion (CWML). An analysis of the MR findings of PWML included evaluation of the number, pattern, laterality, presence of diffusion restriction and signal intensity on SWI, T2WI of PWML. The presence of combined abnormal MR findings including intraventricular hemorrhage (IVH), intraparenchymal hemorrhage (IPH), cerebellar hemorrhage, extra-axial hemorrhage and hydrocephalus were also analyzed. Clinical follow-up was performed and neurodevelopmental outcome was assessed by Bayley Scales of Infant Development scores.

RESULTS

213 infants were included in the study. Among them, 41(19.2%) of 348 have isolated PWML. Of 137 infants with neurodevelopmental outcome, 23(16.7%) infants have isolated PWML. The presence of CWML, grade III/IV IVH, IPH, and hydrocephalus were significantly associated with mental and psychomotor developmental delay (all p-values <.05). There was no significant difference of psychomotor developmental index(PDI) and mental developmental index(MDI) between infants with normal MR findings (n=71) and infants with isolated PWML (n=23) (PDI, 95.1±14.2 vs. 98.0±10.3, P=.372; MDI, 99.4±9.5 vs. 98.9±11.2, P=.604). Mental and psychomotor developmental delay was found in 8.7% and 8.7% of infants who had isolated PWML, respectively, while 4.2% and 18.3% of infants with normal MR findings showed mental and psychomotor developmental delay, without statistically significant difference between two groups (all p-values>.05). Developmental delay in infants with isolated PWML was not statistical association with number, pattern, and signal intensity on SWI, T2WI and DWI, and laterality of PWML lesions.

CONCLUSION

Isolated PWML were detected with high incidence (16.7-19.7%) on term-equivalent age MRI in preterm infants. Isolated PWML have no statistically significant association with neurodevelopmental outcome.

CLINICAL RELEVANCE/APPLICATION

Isolated punctate white matter lesion without other brain pathology in preterm infants around term-equivalent age is not correlated with an adverse neurologic outcome.

SST08-04 Abnormal Spontaneous Low-Frequency Brain Activity in Children with Repaired Tetralogy of Fallot: Resting-State Functional Magnetic Resonance Imaging Study

Friday, Nov. 30 11:00AM - 11:10AM Room: E263

Participants
Yuting Liu SR, MD, Nanjing, China (*Presenter*) Nothing to Disclose

liuytmonkey@sina.com

PURPOSE

The majority of previous neuroimaging studies have demonstrated both structural and functional abnormalities in children with congenital heart disease (CHD). However, few studies have focused on the regional intensity of spontaneous fluctuations during the resting state and the relationship between the abnormal properties clinical variables and the neurocognitive performances. We use the amplitude of low-frequency fluctuation (ALFF) method to explore the changes in spontaneous low-frequency brain activity in children with repaired Tetralogy of Fallot(TOF) relative to controls.

METHOD AND MATERIALS

In this study, ten repaired Tetralogy of Fallot (TOF) children and thirteen normal controls were recruited. The ALFF method was used to assess the local features of spontaneous brain activity in children with repaired TOF. The ALFF difference between repaired TOF children and normal controls was analyzed and the observed mean ALFF values of the different areas were correlated with clinical neurological assement.

RESULTS

Compared with normal controls, children with repaired TOF showed significantly lower ALFF in bilateral cerebellum, left occipital lobe, and higher ALFF in right parahippocampal cortex, left medial prefrontal cortex (MPFC), left posterior cingulate(PCC). In addition, significant, positive correlations were found between the Wechsler scale scores and the ALFF change coefficients in left occipital lobe (r = .728, P = .017; r = .818, P = .004; r = .719, P = .019; r = -.751, P = .012;), between the Wechsler scale scores and the ALFF change coefficients in left MPFC (r = .636, P = .048), and negative correlations were found between the Wechsler scale scores and the ALFF change coefficients in left cerebellum (r =-.636, P =- .048).

CONCLUSION

The significant regional spontaneous activity deficits was found in repaired TOF children, and the relation between clinical neurological assement and the ALFF change coefficients, which might offer new insights into the neural pathophysiology underlying TOF-related neurodevelopment impairments.

CLINICAL RELEVANCE/APPLICATION

Children withCHD after repaired surgery often along with neurodevelopment impairments ,including cognitive, verbal, behavioral and excution control dysfunction.This study showed correlations between the Wechsler scale scores and the ALFF change coefficients,which might provide powerful new insights into neurodevelopment impairments.

SST08-05 Classification of Seizure Onset Zones in Children with Focal Epilepsy

Friday, Nov. 30 11:10AM - 11:20AM Room: E263

Participants
Michael J. Paldino, MD, Houston, TX (*Abstract Co-Author*) Nothing to Disclose
Rasoul Hekmat, Houston, TX (*Abstract Co-Author*) Nothing to Disclose
Wei Zhang, PhD, Houston, TX (*Presenter*) Nothing to Disclose

Robert Azencott, PhD, Houston, TX (*Abstract Co-Author*) Nothing to Disclose

PURPOSE

In refractory epilepsy, surgical resection of epileptogenic tissue can significantly improve seizure control. Accurate identification of seizure onset zones is crucial for surgical planning as well as post-operative prognosis. iEEG, the current gold standard for seizure onset zone localization is invasive and can only provide a local assessment. Resting-state fMRI has been used to provide a systematic evaluation of whole brain network architecture. We therefore aimed to identify features of the cerebral network constructed from resting-state fMRI that are useful for seizure onset localization.

METHOD AND MATERIALS

Patients were retrospectively identified with: 1. Focal epilepsy; 2. Resting-state fMRI; 3. A single seizure onset zone identified in a multidisciplinary epilepsy conference. Brain network nodes were defined by cortical parcellation, resulting in networks containing 148 anatomic regions. We then sub-divided each region into network nodes of size 350 mm2. Edges (connections) between each pair of nodes were defined as the mutual information between BOLD time courses. Intra-region connections were summarized by the 75% quantiles of edges within a region. A machine learning algorithm, Multi-layer Perceptron, was then used to predict seizure onset lobes of each individual based on their intra-region connectivity. Classification accuracy was assessed with the leave-one-out algorithm. Each anatomic region was analyzed according to its discrimination power with respect to seizure onset localization.

RESULTS

Fifteen patients met criteria (age: 4-18 years), of which seizure onsets were identified as 5 right frontal, 3 left frontal, 3 right temporal and 4 left temporal lobes. Leave-one-out classification accuracy was 14/15 (93%). The anatomic regions with the maximum discrimination power are distributed throughout the brain consistent with the idea that focal epilepsy is associated with global network abnormalities (Figure 1).

CONCLUSION

Intra-region connectivity obtained from resting-state fMRI had a strong association to clinical diagnosis of seizure onset zone.

CLINICAL RELEVANCE/APPLICATION

Whole brain network approaches can detect features of the epileptogenic network; more complete mapping of this network could improve surgical outcomes.

SST08-06 Comparison of CT and 'Black Bone' MRI for Detection of Skull Fractures in Children with Suspected Abusive Head Trauma

Friday, Nov. 30 11:20AM - 11:30AM Room: E263

PURPOSE

The purpose of this research was to determine the accuracy of "black bone" MRI for detection of skull fractures in children with potential abusive head trauma.

METHOD AND MATERIALS

A prospective study was performed in 35 pediatric patients who were evaluated for potential abusive head trauma. All patients had both a noncontrast Head CT (HCT) with multiplanar reformats and/or 3D volumetric reformatted images and "Black Bone" MRI of the brain with multiplanar reformatted images and 3D volumetric images. "Black Bone" MRI was performed using an ultrashort TE pointwise encoding time reduction with radial acquisition (PETRA) sequence at 1.5 T or 3T. "Black Bone" MRI datasets were post-

processed and 3D images created using Fovia's High Definition Volume Rendering software. A board certified pediatric neuroradiologist independently reviewed the HCTs and MRIs blinded to the findings from the other modality. The interpretation of the "Black Bone" MRI was compared to gold standard HCT diagnosis for skull fracture. The sensitivity, specificity, and accuracy for "Black Bone" MRI was calculated.

RESULTS

Median patient age was 4 months (range 1.2-18 months). The incidence of skull fracture was 20%. MRI demonstrated 86% sensitivity, 100% specificity, 97% accuracy, positive predictive value 100%, negative predictive value 97% for identifying skull fracture.

CONCLUSION

A "Black Bone" MRI sequence provides high sensitivity and specificity for detection of skull fractures in pediatric patients with abusive head trauma.

CLINICAL RELEVANCE/APPLICATION

"Black Bone" MRI detection of skull fractures may result in decreased utilization of CT and reduce exposure to ionizing radiation.

SST08-08 A Deep Learning System for Predicting Pediatric Brain Age Using Multi-Parametric MRI

PURPOSE

The dynamically evolving architecture of the developing brain in early childhood through adolescence poses diagnostic challenges for pediatric brain MRI. We propose to develop and validate an accurate deep learning model predictive of pediatric age using MRI in a multi-institutional cohort.

METHOD AND MATERIALS

In this retrospective study, we examined a dataset of 1034 pediatric brain MRIs reviewed by expert pediatric neuroradiologists and determined diagnostically normal and within the normal range of neural development. For external validation cohort, we studied 111 pediatric patients from an independent institution, which were also confirmed to be normal based on signal intensity, morphology, and absence of pathologic lesions. Patient ages ranged from 0.1 to 200 months. For biological age prediction, we developed a deep learning model (PageNet) that incorporates 2D and 3D convolutional networks using multi-parametric T1-weighted, T2-weighted, and diffusion-weighted imaging (DWI) MRI sequences. We tested our model using 5-fold cross-validation on our internal cohort and, separately, on the independent external validation cohort. Pearson's r correlation between predicted and actual age and mean-average-error (MAE) were used to evaluate model predictive performance.

RESULTS

Using multi-parametric MRI, PageNet accurately predicted pediatric age (r =0.95) in our internal cohort with a MAE of 15.8 months. Similar strong predictive performance was demonstrated on external cohort validation (r = 0.92; MAE = 20 months). Model performance using single MRI sequences was r = 0.93 for T1-weighted, r = 0.93 for T2-weighted, and r = 0.94 for DWI.

CONCLUSION

Deep learning can accurately map brain development captured by MRI to pediatric chronological age. This may serve as a useful clinical tool in assessing age-appropriate brain development and identifying developmental deviations.

CLINICAL RELEVANCE/APPLICATION

A reliable tool predictive of brain maturation can aid clinical assessment of healthy brain development and help gauge deviations of development and associated disorders in children.

SST08-09 Thrombectomy in Childhood Strokes

PURPOSE

As ischemic stroke is a rare but potentially severe event in children we aimed to evaluate endovascular treatment by mechanical thrombectomy for acute ischemic stroke in a pediatric patient population.

METHOD AND MATERIALS

In this retrospective trial, approved by the local institutional review board, we analyzed all patients < 18 years who were admitted to three large tertiary care centers for thrombectomy of thromboembolic intracranial vessel occlusion (Carotid-T, MCA- main stem M1 to M2- segment) within the last 5 years. Criteria to perform thrombectomy we similar compared to adult patients with acute ischemic stroke: symptoms (NIH score), time frame (onset of symptoms <6h) and imaging criteria (no infarct signs on native CT scan, mismatch in CT perfusion study and M1 vessel occlusion on CT angiography guided the decision for invasive treatment. Endovascular thrombectomy was performed using stent-retrievers alone, or in combination with thrombus aspiration. Clinical and Imaging data were extracted from electronic patient records and the picture archiving and communication system.

RESULTS

Thrombectomy was performed in a total of 12 children with a median age of 14 years (Interquartile Range IQR 7.8 to 16 years). Children presented with a median ASPECT Score of 8.0 (IQR 7.0 to 8.8) and a median pediatric NIHSS of 12.5 (IQR 8.0 to 21.5). Endovascular thrombectomy was successful in all children with acute ischemic stroke, with a TICI 2b stage in n=6 and TICI III in n=6 patients. Median pediatric NIHSS 7 days post thrombectomy was 3.5 (IQR 1 to 8), Modified Ranking Scale Score at 3 months was 1.0 (IRQ 0 to 2.0). No major complications such as arterial dissection, vessel rupture or bleeding were observed.

CONCLUSION

Our data adds to the growing evidence that thrombectomy is effective and safe not only in adults but also in children. Hence, it can be a valuable therapeutic option in childhood stroke.

CLINICAL RELEVANCE/APPLICATION

Our study adds that thrombectomy should be evaluated as a valuable option in pediatric patients presenting with acute ischemic stroke.

Sumeet Virmani, MD, Chicago, IL (*Abstract Co-Author*) Nothing to Disclose

CONCLUSION

The measured performances demonstrated that the inSPira HD SPECT scanner has high sensitivity, high resolution, and acceptable image quality and, hence, is well suited for high resolution static and dynamic SPECT neuroimaging studies.

Background

High-resolution SPECT imaging is of great interest for studying neurological pathologies. The objective of this study is to characterize the performances of high resolution inSPira HD SPECT scanner for neuroimaging applications.

Evaluation

inSPira HD is a dedicated high resolution SPECT scanner based on a rotating dual clamshell design that acquires data in dual-spiral geometry. The performance characteristics were evaluated in terms of spatial resolution, sensitivity, uniformity, and contrast. The spatial resolution was measured from images of a line source. System volume sensitivity (SVS) was calculated using large flood phantom filled with Tc-99m. ACR Small SPECT Phantom was used to evaluate the image quality in terms of uniformity and contrast. Brain phantom and patients images were acquired to access the system more realistically.

Discussion

Spatial resolution in terms of FWHM was 4.1 mm, 4.2 mm, and 4.3 mm for X, Y, and, Z plane respectively. SVS was 9914.6 cts/sec/uci/ml. Integral uniformity for UFOV and CFOV were 4.8 % and 2.1 % respectively. Percent contrast for the five visible spheres with attenuation correction was 26%, 58%, 76%, 93%, and 99%. Brain phantom and patients images show fine details of brain regions.

SST09-02 A Novel Approach for Dosimetry of 90Y Radioembolization Based on Quantitative 99mTc-MAA SPECT/CT Imaging

PURPOSE

Radioembolization (RE) with 90Y-microspheres is a well-established treatment modality for treating liver malignancies. At a time of

increasing evidence for dose-effect relationships in RE with 90Y microspheres, the general consensus is that there is an urgent need for accurate dosimetry in patients undergoing RE treatment. This work aimed at estimating absorbed doses to lesions and normal liver in a novel anthropomorphic set-up.

CONCLUSION

In RE treatment planning the dose-kernel method proved to be more accurate with respect to deposition method based on full 3D dose distributions.

CLINICAL RELEVANCE/APPLICATION

Treatment planning in molecular radiotherapy is mandatory to obtain the most appropriate and effective treatment of patient. It is mandatory to validate dose quantification obtained by SPECT/CT imaging.

SST09-03 An Investigation Study of Deep Learning Convolutional Neural Network for Whole-Body PET Denoising

cchan@MRU.MEDICAL.CANON

PURPOSE

The goal of this study is to investigate the quantitative impact of deep residual convolutional neural network (DCNN) configurations for PET image denoising.

METHOD AND MATERIALS

We first compared deep residual networks constructed with different numbers of layers (5 vs 8 vs 10 layers). For the 8 layers network, we also compared two versions such that one has half the number of filters of the other. We trained our networks using 64 clinical datasets representing a range of acquisition and reconstruction protocols. We evaluated the performance of different networks on 4 different human 18F-FDG studies acquired for 4 minutes per bed position. Synthetic lung and liver lesions were generated using GATE simulation and inserted into the listmode data. The listmode data were further rebinned into 2-minute and 3-minute lists in order to test the robustness of networks against different noise levels. All images were reconstructed using OSEM with 3 iterations, 10 ordered subsets and applied with a Gaussian filter (GF) at 6 mm FWHM. Quantifications were assessed by measuring the lesion contrast recovery versus variability of the background liver uptake.

RESULTS

The 10 layers and 8 layers networks with the full number of filters resulted in comparable quantitative and qualitative performance. However, the 10 layers network used 2-fold the training time than the 8 layers network did. Reducing the layers to 5 resulted in reduced lesion contrast recovery and robustness to the noise levels in the input images. Reducing the number of filters in the 8 layers network also reduced quantitative performance compared to the full 8 layers network.

CONCLUSION

The network architecture plays an important role in the denoising performance of a DCNN network. While fewer layers fail to capture the full complexity of the noise distributions, too many layers result in over-parameterization and difficulties in training without substantial performance gain.

CLINICAL RELEVANCE/APPLICATION

A properly chosen denoising neural network architecture can significantly improve noise levels over alternative architectures and help improve clinical decisions made based on resulting images.

SST09-04 Large Scale Assessment of Detectability and Estimability Indices from ACR CT Accreditation Database: Report of an ACR-RSNA Collaboration

Friday, Nov. 30 11:00AM - 11:10AM Room: E264

yakun.zhang@duke.edu

PURPOSE

To assess the variability in a subset of image quality attributes of clinical CT systems using advanced task-based metrics, detectability and estimability, across the US through a collaboration between the ACR and the RSNA (QIBA).

METHOD AND MATERIALS

The ACR CT accreditation program requires institutions to submit images using the Gammex 464 phantom. Through a collaboration between the RSNA QIBA and ACR, a set of 804 randomly-selected de-identified phantom data sets were analyzed using an automated image quality estimator. These data were not filtered with regard to ACR phantom pass/fail outcome. Basic image quality metrics, including HU numbers, CNR, and noise magnitude, were automatically extracted, as well as task-specific resolution (TTF) and noise power spectra. Two advanced task-based metrics that incorporate all the aforementioned metrics were also computed: detectability index (d') and estimability index (e') for CT volumetry, both with demonstrated correlation with human and machine performance. Results from each image set were binned into specific protocols. The data were analyzed in terms of variability across protocols.

RESULTS

For task-specific resolution, despite the wide spread of the frequencies for 0.5 TTF (f50) within each protocol, the median value was largely consistent across protocols (0.40-0.41 1/mm). Noise magnitude and CNR values, related to radiation dose, were highly dependent on the protocol. The d' median values and distribution changed considerably with the task definition. Similar trends were also observed for e'. The d' and e' median values for polyethylene were 142.3, 168.1, 85.8, and 129.1; and 0.026, 0.035, 0.017, and 0.024 for adult abdomen, adult head, pediatric abdomen, and pediatric head, respectively.

CONCLUSION

Assessment of detectability and estimatiblity indices from the ACR CT accreditation database was feasible. Phantom images can be used as a surrogate to ascertain variability across clinical operations. Such data could eventually be used in the development of future conformance assessment procedures.

CLINICAL RELEVANCE/APPLICATION

Analysis of reference phantom datasets across systems and institutions through the ACR Accreditation process enables granular assessment of multi-parameter variability across our national healthcare system enabling the development of key performance indicators, qualification of quantitative performance, and potential nation-wide image quality registries.

SST09-05 A Comprehensive Platform for Automated Analysis and Reporting of QC of Medical Imaging Modalities

a.schilham@umcutrecht.nl

CONCLUSION

This QC platform provides a tested, comprehensive solution for analysis and reporting of QC for most medical imaging modalities.

Background

Periodic testing of image quality is part of Quality Control (QC) of medical imaging devices. Implementation of QC testing is modality and model specific. If vendor-supplied QC is available, the details are not disclosed and exporting QC results is rarely possible. Those results are needed to spot drifts in system performance and to inform all users about the time and outcome of the latest QC. To aid implementation of a department-wide multi-modality QC program, the Society for Medical Physics of the Netherlands (NVKF) devised a community-driven, open source platform for automated analysis of medical images for quality control. The platform comprises a PACS, analysis modules, a database, and web based front-ends for administration and reporting. Analysis modules are available for most modalities, including MR, CT, MG, US, DX, RF and NM. In a normal workflow a user performs a QC test and sends the images to the QC PACS. Based on DICOM metadata, the platform runs the appropriate analysis modules and stores the results in the database. The web-based interface allows immediate access to the QC results.

Evaluation

This platform has been used since 2013 in several Dutch hospitals, successfully analyzing tens of thousands of datasets. Easy access to recent reports and trend plots of QC metrics were found beneficial for successful implementation of a QC program. Due to the open-source nature of the project, analysis modules are reviewed and imporved continually.

Discussion

This platform is a community driven, open source project, with only open source third party software requirements. Its goal is a comprehensive solution for analysis and reporting of QC for all medical imaging modalities. Analysis modules were initially developed for specific models of modalities. Easy exchange of analysis modules and configurations between institutes resulted in a push from the user community towards generalizations to other models and brands. After extensive testing, the platform was publicly released.

SST09-06 An Embedded Pre-Screening Electrochemical Profile in Label-Free and Image-Free Quantified Tissue Behavioral Analysis

PURPOSE

To address the overcharging challenge of improving the efficiency of cancer screening programs, a label-free and image-free pre-screening tool to detect a frequency-dependent electrochemical profile (or features) of body tissues is developed and tested.

METHOD AND MATERIALS

The study reports the integration of a unique pre-screening tool to non-invasively detect and analyse electrochemical tissue attributes. This pre-screening tool consists of a unique probe configuration including 8-sub-regional probes that are symmetrical distributed in a mirror reflection. The tool uses a 4-active-probe sensing (4-AP sensing) technique through which electrochemical profile of body tissues are measured with high-contrast bioelectrical properties. Therefore, information regarding the extraction of local tissue distinguishability and quantify of tissue behaviour in the frequency domain during asymmetric pathways in the electrochemical profile can be readily assessed without the use of other invasive techniques. The pre-screening tool is also unique in that it utilizes the delivery and sensing channels in a single-probe electrochemical analytical measurement attached directly to external layers of the body (e.g., breast) skin thereby preventing irreproducibility of results.

RESULTS

The performance of the pre-screening tool has been verified by analysis of electrochemical profile using several breast tissue and phantom studies with different simulated tissue density levels at different sub-regions. The results indicated that the tool enabled to sensitively detect, quantify and distinguish the simulated breast tissue and local asymmetrical distribution. The testing results are also quite reproducible and can be offer as a personalized measurement analysis.

CONCLUSION

This research for the first time demonstrates a unique electrochemical sensing device coupled with a quantified behavioural analysis of breast tissue in an innovative pre-screening tool for label-free analysis of breast tissue bioelectrical features. In future human studies, it has potential to build a new low-cost and easy-to-use tool for pre-screening several types of cancers (i.e., breast cancer) to increase cancer detection yield and reduce false positive recalls in current screening methods.

CLINICAL RELEVANCE/APPLICATION

this is a pre-screening tool can be used to increase cancer detection yeild and reduce false-positive recalls (over-diagnosis) in current mammography screening

SST09-07 Development and Initial Evaluation of a DaTscan Digital Reference Object

Friday, Nov. 30 11:30AM - 11:40AM Room: E264

Participants
Robert Miyaoka, PhD, Seattle, WA (*Presenter*) Research Consultant, MIM Software Inc; Research Grant, Koninklijke Philips NV; Research Grant, General Electric Company
Larry Pierce, PhD, Seattle, WA (*Abstract Co-Author*) Nothing to Disclose
Robert L. Harrison, Ludwigsburg, Germany (*Abstract Co-Author*) Research Consultant, General Electric Company

For information about this presentation, contact:

rmiyaoka@uw.edu

PURPOSE

The goal of this work was to design and evaluate 123I-Ioflupane DaTscan digital reference objects (DROs) and to create realistic projection datasets from a DRO to allow testing of DaTscan image reconstruction methods.

METHOD AND MATERIALS

The initial striatal brain DRO was created from an MRI image of an age-appropriate patient. The MRI was segmented to delineate structures of interest. Each structure was assigned a value according to expected Ioflupane uptake: CSF : background : right putamen : left putamen : caudate => 0.33 : 1: 5.5 : 3.25 : 5.5. This corresponds to a specific binding ratio (SBR) of 4.5 for the caudate and right putamen and an SBR of 2.25 for the left putamen. The initial, noise-free DRO was then smoothed using 6 mm and 10 mm Gaussian filters. The three versions were analyzed by four analysis packages. Next Monte Carlo simulation was used to model SPECT acquisition of the 123I-Ioflupane DRO. The simulation included multiple energy emissions and collimator/detector response modeling. After creation of a high count projection sinogram, Poisson-resampling was used to generate sinograms of different noise levels. Projection sinograms were reconstructed on a vendor workstation. Images were then analyzed using DaTquant™ software.

RESULTS

An Ioflupane DRO developed for assessing DaTscan analysis software was tested. The SBR for the striatum varied from 2.53-3.19 (right, healthy) to 1.81-2.05 (left, diseased putamen) for the non-blurred DRO for the different analysis packages. The caudate SBRs varied from 2.4-3.6 (right) to 2.33-3.05 (left). The putamen SBRs varied from 2.56-2.7 (right) to 1.7-2.14 (left, diseased). There was similar variability for the blurred DRO images. The SBRs for the Monte Carlo simulated DRO projection images reconstructed on a vendor workstation were similar to SBRs from experimentally collected phantom data.

CONCLUSION

DROs with known 123I-Ioflupane activity distributions have been created from a patient MRI. Results reveal the variability in the

calculated SBR for different analysis software. Monte Carlo simulation data sets have been created with full models of collimator detector response for testing DaTscan analysis packages and image reconstruction methodologies.

CLINICAL RELEVANCE/APPLICATION

DROs can be used to test/compare vendor analysis packages. Further, Monte Carlo simulations of DROs can be used to test/validate enhanced image reconstruction methods for 123I-Ioflupane brain imaging.

SST09-08 Quantitative Iodine Maps from Spectral Detector Computed Tomography in Daily Practice: A Real World Study in 60 Patients

Friday, Nov. 30 11:40AM - 11:50AM Room: E264

For information about this presentation, contact:

nils.grosse-hokamp@uk-koeln.de

PURPOSE

Iodine maps are available from spectral detector computed tomography (SDCT). They visualize the distribution of iodinated contrast media and allow for its quantification. While the accuracy of such maps has been investigated ex vivo in phantoms under optimized conditions, this study aimed to evaluate their accuracy in routine examinations.

METHOD AND MATERIALS

We designed a reference object consisting of 5 tubes filled with potassium iodide solutions of different concentrations (0.0, 0.8, 1.6, 3.2, 4.8 mg/ml). In 60 patients (31 male, mean age 65.2±11.4 years) who underwent routine SDCT of the abdomen, the reference object was positioned within the scan region at random positions/orientations. Iodine maps (IM) were reconstructed using the vendor provided algorithm. Two circular regions of interest were drawn in each tube, mean and standard deviation within each ROI were determined and averaged. Difference between IM and known iodine concentration was calculated. We performed a confounder analysis for BMI and radiation dose. In addition, we developed a software that allows for automatic measurement of the anterior-posterior and left-right diameter of each patient and further, computes a three-compartment model of the examined tissue (fat, bone, lean); all parameters were considered as possible confounders in statistic assessment.

RESULTS

Overall, iodine maps had a high accuracy as indicated by an offset of -0.01±0.12 mg/ml despite their random placement. The offset was found greater in low concentrations (relative offset in 0.8 and 4.8 mg/ml tubes: +6.5% and +1%, respectively). While smaller BMI tended to overestimate iodine content, greater BMI tended to underestimate iodine concentrations. Besides BMI, volume of bone was found to be a strong confounder regarding iodine quantification accuracy.

CONCLUSION

Iodine quantification using iodine maps from SDCT is technically feasible in routine examinations. When considering estimated concentrations for clinical decision making, increased caution is recommended in low concentrations, in skinny and obese patients and in images with presence of large amount of bone.

CLINICAL RELEVANCE/APPLICATION

Iodine quantification in daily practice is feasible with high accuracy using iodine maps from SDCT.

SST09-09 Quantifying Liver Iron Content Using Photon-Counting Detector Based Computed Tomography

Friday, Nov. 30 11:50AM - 12:00PM Room: E264

Participants
Kishore Rajendran, PhD, Rochester, MN (*Presenter*) Nothing to Disclose
Shengzhen Tao, Rochester, MN (*Abstract Co-Author*) Nothing to Disclose
Gregory J. Michalak, PhD, Rochester, MN (*Abstract Co-Author*) Nothing to Disclose
Shuai Leng, PHD, Rochester, MN (*Abstract Co-Author*) License agreement, Bayer AG
Cynthia H. McCollough, PhD, Rochester, MN (*Abstract Co-Author*) Research Grant, Siemens AG

PURPOSE

In a phantom. to quantify liver iron content using multi-energy photon-counting detector (PCD) CT and an image-based material decomposition technique.

METHOD AND MATERIALS

A wet liver analog was synthesized using dry liver extract (1:7 dilution of dry liver in water) to yield a base CT number enhancement of 50 HU at 140 kV, similar as that of normal human liver. Iron concentrations (iron III nitrate) were prepared at 1.8, 2.8 and 5.6 mg/mL with either wet liver or water as a solvent. Cylindrical vials containing approximately 10 mL of pure liver, iron-liver and iron-water solutions were placed inside a 20 cm multi-energy CT phantom (Gammex, Sun Nuclear, WI), and scanned using a whole-body PCD-CT system (Siemens CounT, Forchheim, Germany) at 120 kV, 178 mAs (CTDIvol = 13 mGy) and energy thresholds of 25, 63 keV. Multi-energy PCD-CT images were reconstructed at [25, 120] keV, [63, 120] keV and [25, 63] keV energy ranges using a quantitative smooth kernel (D30). Quantitative iron maps were obtained using an in-house material decomposition

technique with the [25, 120] keV and [63-120] keV images assuming 3 base materials: liver, water and iron. The image domain material decomposition (MD) algorithm is based on spectral prior image constrained compressed sensing (MD-SPICCS) which combines material decomposition and denoising into a unified framework. The mean density (mg/mL) of iron content was estimated from the iron maps generated using MD-SPICCS. A linear regression analysis was performed to compare measured iron concentrations in liver background with known true concentrations.

RESULTS

MD-SPICCS was able to successfully detect and quantify iron from liver background in the phantom images. Liver background from the iron-liver mixtures was assigned to the liver map, while water background from the iron-water mixtures was assigned to water map. Linear regression showed excellent correlation between measured and true iron concentrations in the iron-liver mixtures (slope = 1.1, R2 = 0.9997, RMSE =0.6 mg/mL).

CONCLUSION

We have demonstrated accurate iron quantification in a liver phantom scanned using the PCD-CT system and an image-based material decomposition technique. Measured iron concentrations showed excellent correlation with the ground truth.

CLINICAL RELEVANCE/APPLICATION

Diagnosing hemochromatosis characterized by liver iron overload using imaging methods requires accurate iron quantification to facilitate and monitor therapy.
